   2. "I need to read newspapers, watch news broadcasts, and search the Internet for information related to health."
   3. "I will join nursing committees at the hospital after I have completed orientation and better understand the issues affecting nursing."
   4. "Nurses do not have very much voice in legislation in Washington, DC, because of the nursing shortage."
   5. "I will go back to school as soon as I finish orientation."

15. You are floated to work on a nursing unit where you are given an assignment that is beyond your capability. Which is the best nursing action to take first?
   1. Call the nursing supervisor to discuss the situation
   2. Discuss the problem with a colleague
   3. Leave the nursing unit and go home
   4. Say nothing and begin your work

Answers: 1. 2, 3, 4, 5; **2.** 2, 3, 4; **3.** 4; **4.** 2, 5; **5.** 4; **6.** 2; **7.** 3; **8.** 1, 4; **9.** 3; **10.** 1, 5; **11.** 4; **12.** 4; **13.** 3; **14.** 1, 2, 3; **15.** 1.

Communication

OBJECTIVES

- Identify ways to apply critical thinking to the communication process.
- Use the five levels of communication with patients.
- Describe features of the circular transactional communication process.
- Incorporate features of a helping relationship when interacting with patients.
- Identify a nurse's communication approaches within the four phases of a nurse-patient helping relationship.
- Identify desired outcomes of nurse–health care team member relationships.
- Demonstrate qualities, behaviors, and communication techniques of professional communication while interacting with patients.
- Identify opportunities to improve communication with patients while giving care.
- Engage in effective communication techniques for older patients.
- Offer alternative communication devices when appropriate to promote communication with patients who have impaired communication.
- Implement nursing care measures for patients with special communication needs.

COMMUNICATION AND NURSING PRACTICE

Communication is a lifelong learning process. Nurses make the intimate journey with patients and their families from the miracle of birth to the mystery of death. As a nurse you communicate with patients and families to develop meaningful relationships. Within those relationships you collect relevant assessment data, provide education, and interact during nursing interventions. The use of therapeutic communication promotes personal growth and attainment of patients' health-related goals. Despite the complexity of technology and the multiple demands on nurses' time, it is the intimate moment of connection that makes all the difference in the quality of care and meaning for a patient and a nurse. Communication is the key to nurse-patient relationships and the ability to deliver patient-centered care.

Patient safety also requires effective communication among members of the health care team as patients move from one caregiver to another or from one care setting to another. Good communication skills help to reduce the risk of errors. These skills promote improved patient outcomes and increased patient satisfaction (Lang, 2012). Effective team communication and collaboration skills are essential to ensure patient safety and optimum patient care (Lazure et al., 2014). Competency in communication maintains effective relationships within the entire sphere of professional practice and meets legal, ethical, and clinical standards of care.

The qualities, behaviors, and therapeutic communication techniques described in this chapter characterize professionalism in caring relationships. Although the term *patient* is often used, the same principles apply when communicating with any person in any nursing situation.

Communication and Interpersonal Relationships

Caring relationships formed among a nurse and those affected by the nurse's practice are at the core of nursing (see Chapter 7). Communication establishes these caring healing relationships. All behavior communicates, and all communication influences behavior. For these reasons communication is essential to the nurse-patient relationship. Nurses with expertise in communication express caring by (Ryan, 2005; Watson, 1985):

- Becoming sensitive to self and others.
- Promoting and accepting the expression of positive and negative feelings.
- Developing caring relationships.
- Instilling faith and hope.
- Promoting interpersonal teaching and learning.
- Providing a supportive environment.
- Assisting with gratification of human needs.
- Allowing for spiritual expression.

A nurse's ability to relate to others is important for interpersonal communication. This includes the ability to take initiative in establishing and maintaining communication, to be authentic (one's self), and to respond appropriately to the other person. Effective interpersonal communication also requires a sense of mutuality (i.e., a belief that the nurse-patient relationship is a partnership and that both are equal participants). Nurses honor the fact that people are very complex and ambiguous. Often more is communicated than first meets the eye, and patient responses are not always what you expect. Each patient is a unique individual, with specific communication needs. Most nurses embrace the view that the profession has of the wholistic nature of people and their need for effective, supportive communication and human interaction. When patients and nurses work together, much can be accomplished. The Joint Commission (TJC) recognized the need to promote effective communication for patient- and family-centered care, cultural competence, and improved patient safety. TJC initiated a set of standards for hospitals that promote these improvements in communication, and they became part of the TJC requirements (TJC, 2011).

Therapeutic communication occurs within a healing relationship between a nurse and patient (Arnold and Boggs, 2011). Like any powerful therapeutic agent, a nurse's communication can result in both harm and good. Every nuance of posture, every small expression and gesture, every word chosen, every attitude held—all have the potential to hurt or heal, affecting others through the transmission of human energy. Knowing that intention and behavior directly influence health gives nurses the ethical responsibility to do no harm to those entrusted to their care. Respect the potential power of communication and do not misuse communication carelessly to hurt, manipulate, or coerce others. Skilled communication empowers others to express what they believe and make their own choices; these are essential aspects of the individualized healing process. Nurses have wonderful opportunities to bring about good things for themselves, their patients, and their colleagues through therapeutic communication.

Developing Communication Skills

Gaining expertise in communication requires both an understanding of the communication process and reflection about one's communication experiences as a nurse. Nurses who develop critical thinking skills make the best communicators. They form therapeutic relationships to gather relevant and comprehensive information about their patients. Then they draw on theoretical knowledge about communication and integrate this knowledge with knowledge previously learned through personal clinical experience. They interpret messages received from others to obtain new information, correct misinformation, promote patient understanding, and assist with planning patient-centered care (Arnold and Boggs, 2011).

Critical thinking attitudes and ethical standards of care promote effective communication. When you consider a patient's problems, it is important to apply critical thinking and critical reasoning skills to improve communication in assessment and care of the patient (Arnold and Boggs, 2011). For example, curiosity motivates a nurse to communicate and know more about a person. Patients are more likely to communicate with nurses who express an interest in them. Perseverance and creativity are also attitudes conducive to communication because they motivate a nurse to communicate and identify innovative solutions. A self-confident attitude is important because a nurse who conveys confidence and comfort while communicating more readily establishes an interpersonal caring relationship. In addition, an independent attitude encourages a nurse to communicate with colleagues and share ideas about nursing interventions. Integrity allows nurses to recognize when their opinions conflict with those of their patients, review positions, and decide how to communicate to reach mutually beneficial decisions. It is also very important for a nurse to communicate responsibly and ask for help if uncertain or uncomfortable about an aspect of patient care. An attitude of humility is necessary to recognize when you need to better communicate and intervene with patients, especially related to their cultural needs (Issacson, 2014).

It is challenging to understand human communication within interpersonal relationships. Each individual bases his or her perceptions about information received through the five senses of sight, hearing, taste, touch, and smell (Arnold and Boggs, 2011). An individual's culture and education also influence perception. Critical thinking helps nurses overcome **perceptual biases** or **stereotypes** that interfere with accurately perceiving and interpreting messages from others. People often incorrectly assume that they understand an individual's culture. They tend to distort or ignore information that goes against their expectations, preconceptions, or stereotypes (Issacson, 2014). By thinking critically about personal communication habits, you learn to control these tendencies and become more effective in interpersonal relationships.

You become more competent in the nursing process as your communication skills develop. You learn to integrate communication skills throughout the nursing process as you collaborate with patients and health care team members to achieve goals (Box 24-1). Use communication skills to gather, analyze, and transmit information and accomplish the work of each step of the process. Assessment, diagnosis, planning, implementation, and evaluation all depend on effective communication among nurse, patient, family, and others on the health care team. Although the nursing process is a reliable framework for patient care, it does not work well unless you master the art of effective interpersonal communication.

Patients often experience high levels of anxiety when they are ill or receiving treatment. **Emotional intelligence** (EI) is an assessment and communication technique that allows nurses to better understand and perceive the emotions of themselves and others. EI enables a nurse to use self-awareness, motivation, empathy, and social skills to build therapeutic relationships with patients (Marquis and Huston, 2015). Patients' emotions can negatively impact their self-care behaviors. If a nurse understands a patient's perceptions and motivations, he or she can help the patient make healthy behavior changes. Patients feel more comfortable addressing their poor health habits when this approach is used. This can lead to enhanced self-care behaviors and improved patient outcomes (Fox, 2013; Shanta and Connolly, 2013).

The nature of the communication process requires you to constantly decide what, when, where, why, and how to convey a message.

BOX 24-1   Communication Throughout the Nursing Process

Assessment
- Verbal interviewing and history taking
- Visual and intuitive observation of nonverbal behavior
- Visual, tactile, and auditory data gathering during physical examination
- Written medical records, diagnostic tests, and literature review

Nursing Diagnosis
- Intrapersonal analysis of assessment findings
- Validation of health care needs and priorities via verbal discussion with patient
- Documentation of nursing diagnosis

Planning
- Interpersonal or small-group health care team planning sessions
- Interpersonal collaboration with patient and family to determine implementation methods
- Written documentation of expected outcomes
- Written or verbal referral to health care team members

Implementation
- Delegation and verbal discussion with health care team
- Verbal, visual, auditory, and tactile health teaching activities
- Provision of support via therapeutic communication techniques
- Contact with other health resources
- Written documentation of patient's progress in medical record

Evaluation
- Acquisition of verbal and nonverbal feedback
- Comparison of actual and expected outcomes
- Identification of factors affecting outcomes
- Modification and update of care plan
- Verbal and/or written explanation of care plan revisions to patient

---

BOX 24-2   Challenging Communication Situations

- People who are silent, withdrawn, and have difficulty expressing feelings or needs
- People who are sad and depressed
- People who require assistance with visual or speech disabilities (special needs)
- People who are angry or confrontational and cannot listen to explanations
- People who are uncooperative and resent being asked to help others
- People who are talkative or lonely and want someone to be with them all the time
- People who are demanding and expect others to meet their requests
- People who are frightened, anxious, and having difficulty coping
- People who are confused and disoriented
- People who speak and/or understand little English
- People who are flirtatious or sexually inappropriate

A nurse's decision making is always contextual (i.e., the unique features of any situation influence the nature of the decisions made). For example, the explanation of the importance of following a prescribed diet to a patient with a newly diagnosed medical condition differs from the explanation to a patient who has repeatedly chosen not to follow diet restrictions. Effective communication techniques are easy to learn, but their application is difficult. Deciding which techniques best fit each unique nursing situation is challenging. Communication with patients and families about illness such as cancer or advance care planning can be stressful. Nurses may experience grief and fatigue related to emotional exhaustion when discussing these topics, especially when they have developed a bond with patients or families. However, discussion of these important and sensitive topics is linked to an increased quality of life for the patients and or family members (Moore and Reynolds, 2013).

Throughout this chapter brief clinical examples will guide you in the use of effective communication techniques. Situations that challenge a nurse's decision-making skills and call for careful use of therapeutic techniques often involve a variety of human behaviors described in Box 24-2. Because the best way to acquire skill is through practice, it is useful for you to discuss and role-play these scenarios before experiencing them in the clinical setting.

Levels of Communication

Nurses use different levels of communication in their professional role. A competent nurse uses a variety of techniques in each level.

Intrapersonal communication is a powerful form of communication that you use as a professional nurse. This level of communication is also called *self-talk*. People's thoughts and inner communications strongly influence perceptions, feelings, behavior, and self-esteem. Always be aware of the nature and content of your own thinking. Positive self-talk provides a mental rehearsal for difficult tasks or situations so individuals deal with them more effectively and with increased confidence (Arnold and Boggs, 2011). Nurses use intrapersonal communication to develop self-awareness and a positive self-esteem that enhances appropriate self-expression. Positive self-talk can help you diminish cognitive distortions that lead to a decrease in self-esteem and impact your ability to work with patients. Transforming statements from "I'm scared to work with this type of patient" into "This is my opportunity to learn about this patient and I can ask for help when it's needed" is an example of positive self-talk.

Interpersonal communication is one-on-one interaction between a nurse and another person that often occurs face to face. It is the level most frequently used in nursing situations and lies at the heart of nursing practice. It takes place within a social context and includes all the symbols and cues used to give and receive meaning. Because meaning resides in people and not in words, messages received are sometimes different from intended messages. Nurses work with people who have different opinions, experiences, values, and belief systems; thus it is important to validate meaning or mutually negotiate it between participants. For example, use interaction to assess understanding and clarify misinterpretations when teaching a patient about a health concern. Meaningful interpersonal communication results in an exchange of ideas, problem solving, expression of feelings, decision making, goal accomplishment, team building, and personal growth.

Small-group communication is the interaction that occurs when a small number of people meet. This type of communication is usually goal directed and requires an understanding of group dynamics. When nurses work on committees with nurses or other disciplines and participate in patient care conferences, they use a small-group communication process. Communication in these situations should be organized, concise, and complete. All participating disciplines are encouraged to contribute and provide feedback. Good communication skills help each participant better meet a patient's needs and promote a safer care environment.

Public communication is interaction with an audience. Nurses often speak with groups of consumers about health-related topics, present scholarly work to colleagues at conferences, or lead classroom

discussions with peers or students. Public communication requires special adaptations in eye contact, gestures, voice inflection, and use of media materials to communicate messages effectively. Effective public communication increases audience knowledge about health-related topics, health issues, and other issues important to the nursing profession.

Electronic communication is the use of technology to create ongoing relationships with patients and their health care team. Secure messaging provides an opportunity for frequent and timely communication with a patient's physician or nurse via a patient portal. An electronic portal enables patients to stay engaged and informed and build a therapeutic relationship with the health care team (Facchiano and Snyder, 2011; Rodriguez, 2010).

ELEMENTS OF THE COMMUNICATION PROCESS

Communication is an ongoing and continuously changing process. You are changing, the people with whom you are communicating are changing, and your environment is also continually changing. Figure 24-1 shows an example of a **circular transactional communication process** model. The model shows the situational contextual inputs, channels of communication, interpersonal contextual concepts, and factors affecting the sender and receiver. Nursing situations have many unique aspects that influence the nature of communication and interpersonal relationships. As a professional you will use critical thinking to focus on each aspect of communication so your interactions are purposeful and effective.

Circular Transactional Model

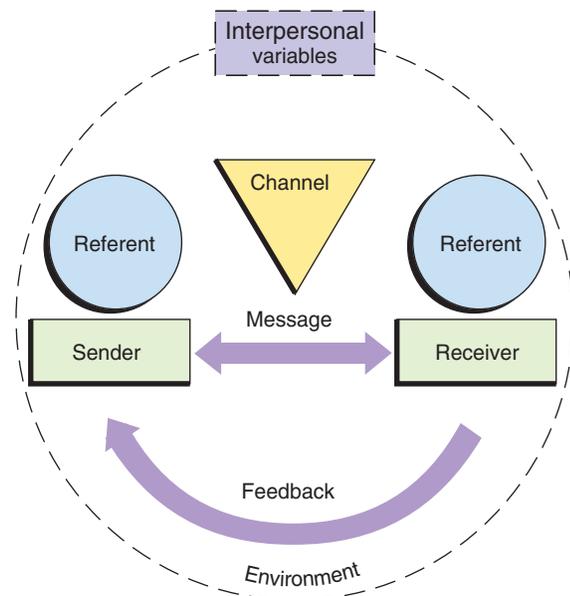
The **circular transactional model** includes several elements: the referent, sender and receiver, message, channels, context or environment in which the communication process occurs, feedback, and interpersonal variables (see Figure 24-1). In this model each person in the communication interaction is both a speaker and a listener and can be simultaneously sending and receiving messages. Both parties view the perceptions, attitudes, and potential reactions to a sent message. Communication becomes a continuous and interactive activity. Feedback from the receiver or environment enables the communicators to correct or validate the communication. This model also


FIGURE 24-1 Circular transactional model of communication.

describes the role relationship of the communicators as **complementary** and **symmetrical**. Complementary role relationships function with one person holding an elevated position over the other person. Symmetrical relationships are more equal. For example, a nurse provides education to a patient about a new medication. This would be a complementary role. A group of patients discussing their plans after discharge would be a symmetrical role relationship (Arnold and Boggs, 2011).

Referent. The **referent** motivates one person to communicate with another. In a health care setting sights, sounds, sensations, perceptions, and ideas are examples of cues that initiate the communication process. Knowing a stimulus or referent that initiates communication allows you to develop and organize messages more efficiently. For example, a patient request for help prompted by his difficulty breathing causes a different response than a patient request resulting from hunger.

Sender and Receiver. The **sender** is the person who encodes and delivers a message, and the **receiver** is the person who receives and decodes the message. The sender puts the message into verbal and nonverbal symbols that the receiver can understand (Arnold and Boggs, 2011). The sender's message acts as a referent for the receiver. Transactional communication involves the role of sender and receiver switching back and forth between nurse and patient. A decoding process includes the receiver interpreting the meaning of the word symbols. Active listening is important to accurately decode and understand a message. The more the sender and receiver have in common and the closer the relationship, the more likely they will accurately perceive one another's meaning and respond accordingly (Arnold and Boggs, 2011). Establishing a rapport with a patient ensures more effective communication.

Message. The **message** is the content of the communication. It contains verbal and nonverbal expressions of thoughts and feelings. Effective messages are clear, direct, and in understandable language. Individuals with communication barriers may need assistance via clarification devices such as hearing aids, interpreters, or pictures to ensure that messages sent and received are understandable. Personal perceptions may also distort the receiver's interpretation of a message. As a nurse you send effective messages by expressing clearly, directly, and in a manner familiar to a patient. You determine the need for clarification by watching the patient listen for nonverbal cues that suggest confusion or misunderstanding. Communication is difficult when participants have different levels of education and experience. For example, statements such as "Your incision is well approximated without purulent drainage" means the same as "Your wound edges are close together, and there are no signs of infection"; but the latter is easier to understand. You can also send messages in writing, but make sure that patients are able to read.

Channels. Communication **channels** are means of sending and receiving messages through visual, auditory, and tactile senses. Facial expressions send visual messages; spoken words travel through auditory channels. Touch uses tactile channels. Individuals usually understand a message more clearly when the sender uses more channels to send it.

Feedback. **Feedback** is the message a receiver receives from the sender. It indicates whether the receiver understood the meaning of the sender's message. Feedback occurs continuously between a sender and receiver. A sender seeks verbal and nonverbal feedback to evaluate

the receiver's response and effectiveness of a communicated message. The type of feedback a sender or receiver gives depends on factors such as their background, prior experiences, attitudes, cultural beliefs, and self-esteem. A sender and receiver need to be sensitive and open to one another's messages, to clarify the messages, and to modify behavior accordingly for successful communication.

Interpersonal Variables. **Interpersonal variables** are factors within both the sender and receiver that influence communication. Perception provides a uniquely personal view of reality formed by an individual's culture, expectations, and experiences. Each person senses, interprets, and understands events differently. A nurse says, "You haven't been talking very much since your family left. Is there something on your mind?" One patient may perceive the nurse's question as caring and concerned; another perceives the nurse as invading privacy and is less willing to talk. Cultural sensitivity enables you to explore the interpersonal variables such as educational and developmental level, sociocultural background, values and beliefs, emotions, gender, physical health status, and roles and relationships that affect how a patient communicates. Interpersonal variables associated with illness such as pain, anxiety, and medication effects also affect nurse-patient communication.

Environment. The **environment** is the setting for sender-receiver interaction. An effective communication setting provides participants with physical and emotional comfort and safety. Noise, temperature extremes, distractions, and lack of privacy or space create confusion, tension, and discomfort. Environmental distractions are common in health care settings and interfere with messages sent between people. You control the environment as much as possible to create favorable conditions for effective communication.

FORMS OF COMMUNICATION

Messages are conveyed verbally and nonverbally, concretely and symbolically. As people communicate, they express themselves through words, movements, voice inflection, facial expressions, and use of space. These elements work in harmony to enhance a message or conflict with one another to contradict and confuse it.

Verbal Communication

Verbal communication uses spoken or written words. Verbal language is a code that conveys specific meaning through a combination of words. The most important aspects of verbal communication are presented in the following paragraphs.

Vocabulary. Communication is unsuccessful if senders and receivers cannot translate one another's words and phrases. When you care for a patient who speaks another language, a professional interpreter is necessary. Even those who speak the same language use subcultural variations of certain words (e.g., *dinner* means a noon meal to one person and the last meal of the day to another). Medical jargon (technical terminology used by health care providers) sounds like a foreign language to patients unfamiliar with the health care setting. Limiting use of medical jargon to conversations with other health care team members improves communication. Children have a more limited vocabulary than adults and often use special words to describe bodily functions or a favorite blanket or toy. Teenagers often use words in unique ways that are unfamiliar to adults.

Denotative and Connotative Meaning. Some words have several meanings. Individuals who use a common language share the

denotative meaning: *baseball* has the same meaning for everyone who speaks English, but *code* denotes cardiac arrest primarily to health care providers. The connotative meaning is the shade or interpretation of the meaning of a word influenced by the thoughts, feelings, or ideas that people have about the word. For example, health care providers tell a family that a loved one is in serious condition and they believe that death is near; but to nurses *serious* simply describes the nature of the illness. You need to select words carefully, avoiding easily misinterpreted words, especially when explaining a patient's medical condition or therapy. Even a much-used phrase such as "I'm going to take your vital signs" may be unfamiliar to an adult or frightening to a child. "I'm going to check your blood pressure, heart rate, and temperature" may be more appropriate.

Pacing. Conversation is more successful at an appropriate speed or pace. Speak slowly and enunciate clearly. Talking rapidly, using awkward pauses, or speaking slowly and deliberately conveys an unintended message. Long pauses and rapid shifts to another subject give the impression that you are hiding the truth. Think before speaking and develop an awareness of the rhythm of your speech to improve pacing.

Intonation. Tone of voice dramatically affects the meaning of a message. Depending on intonation, even a simple question or statement expresses enthusiasm, anger, concern, or indifference. Be aware of voice tone to avoid sending unintended messages. If a patient interprets a nurse's patronizing tone of voice as condescending, this will inhibit further communication. A patient's tone of voice provides information about his or her emotional state or energy level.

Clarity and Brevity. Effective communication is simple, brief, and direct. For certain populations such as the elderly, fewer words result in less confusion. Speak slowly, enunciate clearly, and use examples to make explanations easier to understand. Repeating important parts of a message also clarifies communication. Phrases such as "you know" or "OK?" at the end of every sentence detract from clarity. Use sentences and words that express an idea simply and directly. "Where is your pain?" is much better than "I would like you to describe for me the location of your discomfort."

Timing and Relevance. Timing is critical in communication. Even though a message is clear, poor timing prevents it from being effective. For example, you do not begin routine teaching when a patient is in severe pain or emotional distress. Often the best time for interaction is when a patient expresses an interest in communicating. If messages are relevant or important to the situation at hand, they are more effective. When a patient is facing emergency surgery, discussing the risks of smoking is less relevant than explaining presurgical procedures. Communication while performing assessments, administering medications, and performing procedures are excellent opportunities to talk with patients and provide support or education. Patients report improved satisfaction, understanding, and perception of safety with registered nurses (RNs) who provided a bedside hand-off and communicate information about the plan of care (Ford et al., 2014).

Nonverbal Communication

Nonverbal communication includes the five senses and everything that does not involve the spoken or written word. Nonverbal aspects of communication such as voice tone, eye contact, and body positioning are often as important as verbal messages (Dossey and Keegan, 2013). Thus nonverbal communication is unconsciously motivated and more accurately indicates a person's intended meaning than

spoken words (Stuart, 2013). When there is incongruity between verbal and nonverbal communication, the receiver usually "hears" the nonverbal message as the true message.

All kinds of nonverbal communication are important, but interpreting them is often problematic. Sociocultural background is a major influence on the meaning of nonverbal behavior. In the United States, with its diverse cultural communities, nonverbal messages between people of different cultures are easily misinterpreted. Because the meaning attached to nonverbal behavior is so subjective, it is imperative that you verify it (Dossey and Keegan, 2013; Stuart, 2013). Assessing nonverbal messages is an important nursing skill.

Personal Appearance. Personal appearance includes physical characteristics, facial expression, and manner of dress and grooming. These factors communicate physical well-being, personality, social status, occupation, religion, culture, and self-concept. In the health care setting research has shown that patients prefer nurses to have their hair back and off their shoulders and to not have long fingernails (Johnson et al., 2008). Many health care agencies have restrictions in the form of a dress code that requires a certain color and type of uniform, limitations on jewelry to wear, and whether tattoos need to be covered. Remember, first impressions are largely based on appearance. Nurses learn to develop a general impression of patient health and emotional status through appearance, and patients develop a general impression of the nurse's professionalism and caring in the same way.

Posture and Gait. Posture and gait (manner or pattern of walking) are forms of self-expression. The way people sit, stand, and move reflects attitudes, emotions, self-concept, and health status. For example, an erect posture and a quick, purposeful gait communicate a sense of well-being and confidence. Leaning forward conveys attention. A slumped posture and slow shuffling gait indicates depression, illness, or fatigue.

Facial Expression. The face is the most expressive part of the body. Facial expressions convey emotions such as surprise, fear, anger, happiness, and sadness. Some people have an expressionless face, or flat affect, which reveals little about what they are thinking or feeling. An inappropriate affect is a facial expression that does not match the content of a verbal message (e.g., smiling when describing a sad situation). People are sometimes unaware of the messages their expressions convey. For example, a nurse frowns in concentration while doing a procedure, and the patient interprets this as anger or disapproval. Patients closely observe nurses. Consider the impact a nurse's facial expression has on a person who asks, "Am I going to die?" The slightest change in the eyes, lips, or facial muscles reveals the nurse's feelings. Although it is hard to control all facial expressions, try to avoid showing shock, disgust, dismay, or other distressing reactions in a patient's presence.

Eye Contact. People signal readiness to communicate through eye contact. Maintaining eye contact during conversation shows respect and willingness to listen. Eye contact also allows people to closely observe one another. Lack of eye contact may indicate anxiety, defensiveness, discomfort, or lack of confidence in communicating. However, people from some cultures consider eye contact intrusive, threatening, or harmful and minimize or avoid its use (see Chapter 9). Always consider a person's culture when interpreting the meaning of eye contact. Eye movements communicate feelings and emotions. Looking down on a person establishes authority, whereas interacting at the same eye level indicates equality in the relationship. Rising to the same eye level as an angry person helps establish autonomy.

Gestures. Gestures emphasize, punctuate, and clarify the spoken word. Gestures alone carry specific meanings, or they create messages with other communication cues. A finger pointed toward a person communicates several meanings; but, when accompanied by a frown and stern voice, the gesture becomes an accusation or threat. Pointing to an area of pain is sometimes more accurate than describing its location.

Sounds. Sounds such as sighs, moans, groans, or sobs also communicate feelings and thoughts. Combined with other nonverbal communication, sounds help to send clear messages. They have several interpretations: moaning conveys pleasure or suffering; and crying communicates happiness, sadness, or anger. Validate nonverbal messages with patients to interpret them accurately.

Territoriality and Personal Space. Territoriality is the need to gain, maintain, and defend one's right to space. Territory is important because it provides people with a sense of privacy, identity, security, and control. It is sometimes separated and made visible to others such as a fence around a yard or a curtain around a bed in a hospital room. Personal space is invisible, individual, and travels with a person. During interpersonal interaction people maintain varying distances between one another, depending on their culture, the nature of their relationship, and the situation. When personal space becomes threatened, people respond defensively and communicate less effectively. Situations dictate whether the interpersonal distance between nurse and patient is appropriate. Box 24-3 provides examples of nursing actions within communication zones (Stuart, 2013). Nurses frequently move into patients' territory and personal space because of the nature of caregiving. You need to convey confidence, gentleness, and respect for privacy, especially when your actions require intimate contact or involve a patient's vulnerable zone.

Metacommunication

Metacommunication is a broad term that refers to all factors that influence communication. Awareness of influencing factors helps people better understand what is communicated (Arnold and Boggs, 2011). For example, a nurse observes a young patient holding his body rigidly, and his voice is sharp as he says, "Going to surgery is no big deal." The nurse replies, "You say having surgery doesn't bother you, but you look and sound tense. I'd like to hear more about how you're feeling." Awareness of the tone of the verbal response and the nonverbal behavior results in further exploration of the patient's feelings and concerns.

PROFESSIONAL NURSING RELATIONSHIPS

A nurse's application of knowledge, understanding of human behavior and communication, and commitment to ethical behavior create professional relationships. Having a philosophy based on caring and respect for others helps you be more successful in establishing relationships of this nature.

Nurse-Patient Caring Relationships

Caring relationships are the foundation of clinical nursing practice. In such relationships you assume the role of a professional who cares about each patient and his or her unique health needs, human responses, and patterns of living. Therapeutic relationships promote a psychological climate that facilitates positive change and growth. Therapeutic communication between you and your patients allows the attainment of health-related goals (Arnold and Boggs, 2011). The goals of a therapeutic relationship focus on a patient achieving optimal

BOX 24-3 Zones of Personal Space

Zones of Personal Space
Intimate Zone (0-8 inches)
- Holding a crying infant
- Performing physical assessment
- Bathing, grooming, dressing, feeding, and toileting a patient
- Changing a patient's surgical dressing

Personal Zone (18 inches-4 feet)
- Sitting at a patient's bedside
- Taking a patient's nursing history
- Teaching an individual patient

Socio-Consultative Zone (9-12 feet)
- Giving directions to visitors in the hallway
- Asking if families need assistance from the patient doorway
- Giving verbal report to a group of nurses

Public Zone (12 feet and more)
- Speaking at a community forum
- Lecturing to a class of students
- Testifying at a legislative hearing

Special Zones of Touch
Social Zone (Permission Not Needed)
Hands, arms, shoulders, back

Consent Zone (Permission Needed)
Mouth, wrists, feet

Vulnerable Zone (Special Care Needed)
Face, neck, front of body

Intimate Zone (Permission and Great Sensitivity Needed)
Genitalia, rectum

BOX 24-4 Phases of the Helping Relationship

Preinteraction Phase
Before meeting a patient:
- Review available data, including the medical and nursing history.
- Talk to other caregivers who have information about the patient.
- Anticipate health concerns or issues that arise.
- Identify a location and setting that fosters comfortable, private interaction.
- Plan enough time for the initial interaction.

Orientation Phase
When the nurse and patient meet and get to know one another:
- Set the tone for the relationship by adopting a warm, empathetic, caring manner.
- Recognize that the initial relationship is often superficial, uncertain, and tentative.
- Expect the patient to test your competence and commitment.
- Closely observe the patient and expect to be closely observed by the patient.
- Begin to make inferences and form judgments about patient messages and behaviors.
- Assess the patient's health status.
- Prioritize the patient's problems and identify his or her goals.
- Clarify the patient's and your roles.
- Form contracts with the patient that specify who will do what.
- Let the patient know when to expect the relationship to be terminated.

Working Phase
When the nurse and patient work together to solve problems and accomplish goals:
- Encourage and help the patient express feelings about his or her health.
- Encourage and help the patient with self-exploration.
- Provide information needed to understand and change behavior.
- Encourage and help the patient set goals.
- Take action to meet the goals set with the patient.
- Use therapeutic communication skills to facilitate successful interactions.
- Use appropriate self-disclosure and confrontation.

Termination Phase
During the ending of the relationship:
- Remind the patient that termination is near.
- Evaluate goal achievement with the patient.
- Reminisce about the relationship with the patient.
- Separate from the patient by relinquishing responsibility for his or her care.
- Achieve a smooth transition for the patient to other caregivers as needed.

personal growth related to personal identity, ability to form relationships, and ability to satisfy needs and achieve personal goals (Stuart, 2013). There is an explicit time frame, a goal-directed approach, and a high expectation that what you discuss together is kept confidential among only members of the health care team involved in the patient's care. A nurse establishes, directs, and takes responsibility for the interaction; and a patient's needs take priority over a nurse's needs. Your nonjudgmental acceptance of a patient is an important characteristic of the relationship. Acceptance conveys a willingness to hear a message or acknowledge feelings. It does not mean that you always agree with the other person or approve of the patient's decisions or actions. A caring relationship between you and a patient does not just happen: you create it with skill and trust.

There is a natural progression of four goal-directed phases that characterize the nurse-patient relationship (Box 24-4). The relationship often begins before you meet a patient and continues until the caregiving relationship ends. Even a brief interaction uses an abbreviated version of preinteraction, orientation, working, and termination (Stuart, 2013). For example, a nursing student gathers patient information to prepare in advance for caregiving, meets the patient and establishes trust, accomplishes health-related goals through use of the nursing process, and says goodbye at the end of the day.

Socializing is an important initial component of interpersonal communication. It helps people get to know one another and relax. It is easy, superficial, and not deeply personal; whereas therapeutic interactions are often more intense, difficult, and uncomfortable. A nurse often uses social conversation to lay a foundation for a closer relationship: "Hi, Mr. Simpson, I hear it's your birthday today. How old are you?" A friendly, informal, and warm communication style establishes trust, but you have to move beyond social conversation to talk about issues or concerns affecting the patient's health. During social conversation some patients ask personal questions such as those about your family or place of residence. Students often wonder whether it is appropriate to reveal such information. The skillful nurse uses judgment about what to share and provides minimal information or

deflects such questions with gentle humor and refocuses conversation back to the patient.

In a therapeutic relationship it may be helpful to encourage patients to share personal stories. Sharing stories is called *narrative interaction*. Through listening to stories you begin to understand the context of others' lives and learn what is meaningful for them from their perspective. For example, a nurse listens to a patient's perception of what it means to refuse medication treatment for breast cancer and is then better able to articulate the patient's wishes (Gidman, 2013). Listen to patients' stories to better understand their concerns, experiences, and challenges. This information is not usually revealed with a standard history form that elicits short answers.

As a nurse you can also tell stories to enhance patient education. Telling good stories frames important messages you wish to send and makes messages memorable for your patients. Purposeful storytelling brings across factual information along with a human interest perspective that draws on an individual's emotions such as a patient's desire to get well or feel a sense of hope. Emotions play a significant role in helping adults learn the ability to grasp new ideas.

Motivational Interviewing

Motivational interviewing (MI) is a technique that holds promise for encouraging patients to share their thoughts, beliefs, fears, and concerns with the aim of changing their behavior. MI provides a way of working with patients who may not seem ready to make behavior changes that are considered necessary by their health practitioners. It can potentially be used to evoke change talk, which links to improved patient outcomes (Copeland et al., 2015). For example, an interviewer uses information about a patient's personal goals and values to promote the patient's adherence to a new medication or exercise plan. The interviewing is delivered in a nonjudgmental, guided communication approach. When using MI, a nurse tries to understand a patient's motivations and values using an empathic and active listening approach. The nurse identifies differences between the patient's current health goals and behaviors and his or her current health status. The patient is supported even though a phase of resistance and ambivalence often occurs. Communication then focuses on recognizing the patient's strengths and supporting those strengths in an effort to make positive changes. This can result in dramatic improvements in health outcomes and patient satisfaction (Stawnychy et al., 2014; Stuart, 2013).

Nurse-Family Relationships

Many nursing situations, especially those in community and home care settings, require you to form caring relationships with entire families. The same principles that guide one-on-one helping relationships also apply when the patient is a family unit, although communication within families requires additional understanding of the complexities of family dynamics, needs, and relationships (see Chapter 10).

Nurse–Health Care Team Relationships

Communication with other members of the health care team affects patient safety and the work environment. Breakdown in communication, lack of patient education, and poor health care provider accountability is a frequent cause of serious injuries in health care settings (TJC Resources, 2012). When patients move from one nursing unit to another or from one provider to another, there is a risk for miscommunication. To address this risk health care providers provide detailed hand-off reports at end of shifts or when patients transfer off care units to ensure that patients have a safe and smooth transition in care. TJC Resources recommends that the entire health care team collaborate and coordinate during patient transition. Standardized discharge or transfer procedures and forms reduce the risk of errors during patient

BOX 24-5 EVIDENCE-BASED PRACTICE

Safe and Effective Interprofessional Communication

PICO Question: Does the SBAR communication technique compared with standard end-of-shift narrative report among hospital health care team members improve patient outcomes?

Evidence Summary

Nurses are taught to be detailed and descriptive in their conversations but not to ''medically'' diagnose a problem or situation. Physicians express themselves in brief statements, providing only the specific facts (Haig et al., 2006). Disconnect in communication styles leads to dysfunctional physician-nurse communication and a significant increase in errors in patient care. Mutual respect and trust enable clarification and clear communication. Practitioners need an understanding and appreciation of interprofessional collaboration to promote effective team functioning necessary for optimum patient care (Lazure et al., 2014). Use of communication techniques such as SBAR (*S*ituation, *B*ackground, *A*ssessment, and *R*ecommendation) provides a framework for structure and accurate communication among health care providers that fosters patient safety. In a study involving 16 hospital units, nurses were trained to use SBAR to communicate with physicians in cases of deteriorating patient status. As a result, nurses had an increased perception of effective communication and collaboration between nurses and physicians (De Meester et al., 2013). Most important, the study found a decrease in unexpected deaths. Effective communication practices using SBAR and the Communication During Patient Handover (CDPH) approach minimize risk and improve hand-off communication between health care providers (Adams and Osborne-McKenzie, 2012).

Application to Nursing Practice

- Work in interprofessional teams to develop understanding and respect for other disciplines.
- Use a standardized approach (e.g., SBAR, CDPH, or a D-BANQ format) for report when patients are transferred to other units or facilities (Adams and Osborne-McKenzie, 2012).
- SBAR is not a document but rather a verbal technique that requires education for nurses and physicians (Compton et al., 2012).
- Provide the opportunity for questions and confirmation of understanding of communication.

---

transitions. Timely follow-up after discharge or transfer is also encouraged (TJC Resources, 2012).

Use of a common language such as the SBAR technique for communicating critical information improves perception of communication and information about patients between health care providers (De Meester et al., 2013). The SBAR technique is a popular communication tool that standardizes communication. SBAR is the acronym for *S*ituation, *B*ackground, *A*ssessment, and *R*ecommendation (see Chapter 26). The use of this easy-to-remember, orderly technique is to relay relevant information in a structured and timely manner (Marquis and Huston, 2015). Evidence identifies nursing actions that increase effectiveness of nurse-to-nurse interaction and interprofessional communication (Box 24-5).

Some organizations have added an introduction step (ISBAR) into the SBAR process. The introduction step is used when health care providers do not actively know one another. They start with an introduction, a description of their location, and their role in caring for the patient (Marquis and Huston, 2015).

Lateral Violence. Professional nursing care requires nurses to interact with members of the nursing team and interprofessional

health care providers. Communication focuses on team building, facilitating group processes, collaborating, consulting, delegating, supervising, leading, and managing (see Chapter 21). Social, informational, and therapeutic interactions help team members build morale, accomplish goals, and strengthen working relationships. **Lateral violence** or workplace bullying between colleagues sometimes occurs and includes behaviors such as withholding information, backbiting, making snide remarks or put downs, and nonverbal expressions of disapproval such as raising eyebrows or making faces. Lateral violence adversely effects the work environment, leading to job dissatisfaction, a decreased sense of value, poor teamwork, poor retention of qualified nurses, and nurses leaving the profession. New nurses are especially prone to bullying behavior (Frederick, 2014). Lateral violence can be a symptom of compassion fatigue, wherein health care workers perceive a threat during interactions with colleagues and react emotionally rather than communicating intentionally in a professional manner.

Lateral violence interferes with effective health care team communication and jeopardizes patient safety (Marquis and Huston, 2015). Intimidation decreases the likelihood that a nurse will report a near-miss, question an order, or take action to improve the quality of patient care. There must be zero tolerance of lateral violence. Develop skills in conflict management and assertive communication to stop the spread of lateral violence in the workplace. Requesting a mentor can help the new nurse learn skills to address the perpetrators of bullying. The mentor can also be a personal support for the nurse and serve as a role model for the department (Frederick, 2014). The nurse experiencing lateral violence can also use additional techniques such as the following:

- Address the behavior when it occurs in a calm manner.
- Describe how the behavior affects your functioning.
- Ask for the abuse to stop.
- Notify the manager to get support for the situation.
- Make a plan for taking action in the future.
- Document the incidences in detail.

Nurse-Community Relationships

Many nurses form relationships with community groups by participating in local organizations, volunteering for community service, or becoming politically active. As a nurse, learn to establish relationships with your community to be an effective change agent. Providing clear and accurate information to members of the public is the best way to prevent errors, reduce resistance, and promote change. Communication within the community occurs through channels such as neighborhood newsletters, health fairs, public bulletin boards, newspapers, radio, television, and electronic information sites. Use these forms of communication to share information and discuss issues important to community health (see Chapter 3).

ELEMENTS OF PROFESSIONAL COMMUNICATION

Professional appearance, demeanor, and behavior are important in establishing trustworthiness and competence. A professional is expected to be clean, neat, well groomed, conservatively dressed, and odor free. Visible tattoos and piercings may not be considered acceptable in some professional settings. Professional behavior reflects warmth, friendliness, confidence, and competence. Professionals speak in a clear, well-modulated voice; use good grammar; listen to others; help and support colleagues; and communicate effectively. Being on time, organized, well prepared, and equipped for the responsibilities of the nursing role also communicate professionalism.

Courtesy

Common courtesy is part of professional communication. To practice courtesy, say hello and goodbye to patients and knock on doors before entering. State your purpose, address people by name, and say "please" and "thank you" to team members. Introduce yourself and state your title. When a nurse is discourteous, others perceive him or her as rude or insensitive. It sets up barriers to forming helping relationships between nurse and patient and causes friction among team members.

Use of Names

Always introduce yourself. Failure to give your name and status (e.g., nursing student, RN, or licensed practical nurse) or acknowledge a patient creates uncertainty about an interaction and conveys an impersonal lack of commitment or caring. Making eye contact and smiling recognize others. Addressing people by name conveys respect for human dignity and uniqueness. Because using last names is respectful in most cultures, nurses usually use a patient's last name in an initial interaction and then use the first name if the patient requests it. Ask how your patients and co-workers prefer to be addressed and honor their personal preferences. Using first names is appropriate for infants, young children, patients who are confused or unconscious, and close team members. Avoid terms of endearment such as "honey," "dear," "grandma," or "sweetheart." Even the closest nurse-patient relationships rarely progress to identities outside of first names. Avoid referring to patients by diagnosis, room number, or other attribute, which is demeaning and sends the message that you do not care enough to know the person as an individual.

Trustworthiness

Trust is relying on someone without doubt or question. Being trustworthy means helping others without hesitation. To foster trust, communicate warmth and demonstrate consistency, reliability, honesty, competence, and respect. Sometimes it isn't easy for a patient to ask for help. Trusting another person involves risk and vulnerability; but it also fosters open, therapeutic communication and enhances the expression of feelings, thoughts, and needs. Without trust a nurse-patient relationship rarely progresses beyond social interaction and superficial care. Avoid dishonesty at all costs. Withholding key information, lying, or distorting the truth violates both legal and ethical standards of practice. Sharing personal information or gossiping about others sends the message that you cannot be trusted and damages interpersonal relationships.

Autonomy and Responsibility

Autonomy is being self-directed and independent in accomplishing goals and advocating for others. Professional nurses make choices and accept responsibility for the outcomes of their actions (Townsend, 2012). They take initiative in problem solving and communicate in a way that reflects the importance and purpose of a therapeutic

conversation (Arnold and Boggs, 2011). Professional nurses also recognize their patients' autonomy.

Assertiveness

Assertiveness allows you to express feelings and ideas without judging or hurting others. Assertive behavior includes intermittent eye contact; nonverbal communication that reflects interest, honesty, and active listening; spontaneous verbal responses with a confident voice; and culturally sensitive use of touch and space. An assertive nurse communicates self-assurance; communicates feelings; takes responsibility for choices; and is respectful of others' feelings, ideas, and choices (Stuart, 2013; Townsend, 2012). Assertive behavior increases self-esteem and self-confidence, increases the ability to develop satisfying interpersonal relationships, and increases goal attainment. Assertive individuals make decisions and control their lives more effectively than nonassertive individuals. They deal with criticism and manipulation by others and learn to say no, set limits, and resist intentionally imposed guilt. Assertive responses contain "I" messages such as "I want," "I need," "I think," or "I feel" (Townsend, 2012). Nurses may experience ethical issues that make it difficult to use their assertiveness skills for fear of retaliation (e.g., identifying an error made by another health care provider). In such a situation the individual would need to take steps to resolve this ethical dilemma (see Chapter 22).

AIDET® is a technique developed by the Studer Group to enable health care workers to provide accurate and timely communication to patients and families while focusing on excellent patient service. It is a technique commonly used in hospitals today. The acronym stands for *Acknowledge, Introduce, Duration, Explain,* and *Thank you.* When using AIDET, a health care worker first acknowledges the person standing in front of him or her with a positive attitude and makes the person feel comfortable. The worker introduces himself or herself and lets the person know what his or her role is in the department and the person's care. It is important to always wear a name badge when working in a health care setting. When possible, the worker gives the patient or family an idea of how long a procedure may take. This keeps the patient informed of any delays that may occur. It is also helpful to let a patient know how long it will take to get results if they are related to testing. When explaining procedures, describe what the patient will experience with the treatment, procedure, or test. Inform him or her of any safety precautions. The worker using AIDET thanks the patient for coming to this organization for care and lets the patient know how much he or she enjoyed working with him or her (Rubin, 2014).

❖ NURSING PROCESS

The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. It guides care for patients who need special assistance with communication. Use therapeutic communication techniques as an intervention in an interpersonal nursing situation.

◆ Assessment

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. Patient-centered care requires careful assessment of a patient's values; preferences; and cultural, ethnic, and social backgrounds (Harvey and Ahmann, 2014). During assessment a nurse also explores any personal biases and experiences that might affect his or her ability to form a therapeutic relationship. If the nurse cannot resolve his or her bias related to a patient, care

---

BOX 24-6 Assessment: Factors Influencing Communication

Psychophysiological Context (Internal Factors Affecting Communication)
- Physiological status (e.g., pain, hunger, nausea, weakness, dyspnea)
- Emotional status (e.g., anxiety, anger, hopelessness, euphoria)
- Growth and development status (e.g., age, developmental tasks)
- Unmet needs (e.g., safety/security, love/belonging)
- Attitudes, values, and beliefs (e.g., meaning of illness experience)
- Perceptions and personality (e.g., optimist/pessimist, introvert/extrovert)
- Self-concept and self-esteem (e.g., positive or negative)

Relational Context (Nature of the Relationship Among Participants)
- Social, helping, or working relationship
- Level of trust among participants
- Level of caring expressed
- Level of self-disclosure among participants
- Shared history of participants
- Balance of power and control

Situational Context (Reason for Communication)
- Information exchange
- Goal achievement
- Problem resolution
- Expression of feelings

Environmental Context (Physical Surroundings in Which Communication Occurs)
- Privacy level
- Noise level
- Comfort and safety level
- Distraction level

Cultural Context (Sociocultural Elements That Affect an Interaction)
- Educational level of participants
- Language and self-expression patterns
- Customs and expectations

---

should be transferred to another individual. Internal and external factors also affect a patient's ability to communicate (Box 24-6). Assessing these factors keeps a focus on the patient and helps you make patient-centered decisions during the communication process.

Physical and Emotional Factors. It is especially important to assess the psychophysiological factors that influence communication. Many altered health states and human responses limit communication. People with hearing or visual impairments often have difficulty receiving messages (see Chapter 49). Facial trauma, laryngeal cancer, or endotracheal intubation often prevents movement of air past vocal cords or mobility of the tongue, resulting in inability to articulate words. An extremely breathless person needs to use oxygen to breathe rather than speak. People with aphasia after a stroke or in late-stage Alzheimer's disease cannot understand or form words. Some mental illnesses such as psychoses or depression cause patients to jump from one topic to another, constantly verbalizing the same words or phrases or exhibiting a slowed speech pattern. People with high anxiety are sometimes unable to perceive environmental stimuli or hear explanations. Finally patients who are unresponsive or heavily sedated cannot send or respond to verbal messages.

Review of a patient's medical record provides relevant information about his or her ability to communicate. The medical history and physical examination document physical barriers to speech, neurological deficits, and pathophysiology affecting hearing or vision. Reviewing a patient's medication record is also important. For example, opiates, antidepressants, neuroleptics, hypnotics, or sedatives may cause a patient to slur words or use incomplete sentences. The nursing progress notes in the electronic health record (EHR) sometimes reveal other factors that contribute to communication difficulties such as the absence of family members to provide more information about a confused patient.

Assessment includes communicating directly with patients to determine their ability to attend to, interpret, and respond to stimuli. If patients have difficulty communicating, it is important to assess the effect of the problem. Patients who are unable to speak are at risk for injury unless nurses identify an alternate communication method. If barriers exist that make it difficult to communicate directly with patients, family or friends become important sources concerning the patients' communication patterns and abilities.

Developmental Factors. Aspects of a patient's growth and development also influence nurse-patient interaction. For example, an infant's self-expression is limited to crying, body movement, and facial expression; whereas older children express their needs more directly. Adapt communication techniques to the special needs of infants and children and their parents. Depending on a child's age, include the parents, child, or both as sources of information about the child's health. Giving a young child toys or other distractions allows parents to give you their full attention. Children are especially responsive to nonverbal messages; sudden movements, loud noises, or threatening gestures are frightening. They prefer to make the first move in interpersonal contacts and do not like adults to stare or look down at them. A child who has received little environmental stimulation possibly is behind in language development, thus making communication more challenging.

Age alone does not determine an adult's capacity for communication. Hearing loss and visual impairments are changes that may occur during aging that contribute to communication barriers (NIH, 2014). Communicate with older adults on an adult level and avoid patronizing or speaking in a condescending manner. Simple measures facilitate communication with older individuals who have hearing loss (Box 24-7).

Sociocultural Factors. Culture influences thinking, feeling, behaving, and communicating. Be aware of the typical patterns of interaction that characterize various ethnic groups, but do not allow this information to bias your response. Know each patient individually (e.g., does he or she feel comfortable with eye contact or in sharing information with others). You will approach a patient very differently if he or she is open and willing to discuss private family matters versus others who are reluctant to reveal personal or family information to strangers.

Foreign-born people do not always speak or understand English. Those who speak English as a second language often experience difficulty with self-expression or language comprehension. To practice cultural sensitivity in communication, understand that people of different ethnic origins use different degrees of eye contact, personal space, gestures, loud voice, pace of speech, touch, silence, and meaning of language. Make a conscious effort not to interpret messages through your cultural perspective, but consider the communication within the context of the other individual's background. Avoid stereotyping, patronizing, or making fun of other cultures. Language and cultural barriers are not only frustrating but also dangerous, causing delay in care (Box 24-8).

Gender. Gender influences how we think, act, feel, and communicate. Men tend to use less verbal communication but are more likely to initiate communication and address issues more directly. They are also more likely to talk about issues. Women tend to disclose more personal information and use more active listening, answering with responses that encourage the other person to continue the conversation. It is important for you to recognize a patient's gender communication pattern. Being insensitive blocks therapeutic nurse-patient relationships. Assess communication patterns of each individual and

---

BOX 24-7   FOCUS ON OLDER ADULTS

Tips for Improved Communication with Older Adults Who Have Hearing Loss (Arnold and Boggs, 2011)

- Make sure the patient knows that you are talking.
- Face the patient, be sure that your face/mouth is visible to him or her, and do not chew gum or talk while chewing.
- Speak clearly but do not exaggerate lip movement or shout.
- Speak a little more slowly but not excessively slow.
- Check if patient uses hearing aids, glasses, or other adaptive equipment.
- Choose a quiet, well-lit environment with minimal distractions.
- Allow time for the patient to respond. Do not assume that patient is being uncooperative if he or she does not reply or takes a long time to reply.
- Give the patient a chance to ask questions.
- Keep communication short and to the point. Ask one question at a time.

⊕ BOX 24-8   CULTURAL ASPECTS OF CARE

Communication with Non–English-Speaking Patients

Patients who speak little or no English present challenges for nurse-patient communication. Federal and state laws require that hospitals that receive federal funding, including Medicare, Medicaid, and SCHIP, are required to provide language access services for their patients. For hospitals unable to provide onsite interpreters, telephone interpretation services must be available (Marcus, 2014). Use of family members, friends, or bilingual staff members to interpret for patients is strongly discouraged. Sometimes communication with patients is needed in sudden crucial interactions. Use family members or friends cautiously when there is a delay in acquiring interpretive services. Use of family members, children, or auxiliary personnel poses legal liabilities. Language is not the only barrier. Cultural differences also lead to misunderstanding. Developing cultural competence increases understanding (Dossey and Keegan, 2013; Weldon et al., 2014).

Implications for Patient-Centered Care
- Understand your own cultural values and biases.
- Assess the patient's primary language and level of fluency in English.
- Provide a professional interpreter for the patient and health care providers to communicate with one another. Do not use a family member as an interpreter.
- Speak directly to the patient even if an interpreter is present.
- Nodding or statements such as "OK" do not necessarily mean that the patient understands.
- Provide written information in English and primary language.
- Learn about other cultures, especially those commonly encountered in your work area.
- Incorporate the patient's communication methods or need into plan of care.

do not make assumptions simply on the basis of gender, race, sexuality, or cultural differences.

◆ Nursing Diagnosis

Most individuals experience difficulty with some aspect of communication. Patients sometimes lack skills in attending, listening, responding, and self-expression as a result of illness, treatment effects, or cultural or language barriers. The primary nursing diagnostic label used to describe a patient with limited or no ability to communicate verbally is *Impaired Verbal Communication*. This is the state in which an individual experiences a decreased, delayed, or absent ability to receive, process, transmit, and use symbols for a variety of reasons. The defining characteristics for this diagnosis include the inability to articulate words, inappropriate verbalization, difficulty forming words, and difficulty comprehending, which you cluster together to form the diagnosis (Sparks and Taylor, 2014). This diagnosis is useful for a wide variety of patients with special problems and needs related to communication such as impaired perception, reception, and articulation. Although a patient's primary problem is *Impaired Verbal Communication*, the associated difficulty in self-expression or altered communication patterns may also contribute to other nursing diagnoses such as:

- *Anxiety*
- *Social Isolation*
- *Ineffective Coping*
- *Compromised Family Coping*
- *Powerlessness*
- *Impaired Social Interaction*

The related factors for *Impaired Verbal Communication* focus on the causes of a communication disorder. In the case of *Impaired Verbal Communication*, these are physiological, mechanical, anatomical, psychological, cultural, or developmental in nature. Accuracy in identifying related factors is necessary so you select interventions that effectively resolve the diagnostic problem. For example, you manage the diagnosis of *Impaired Verbal Communication related to cultural difference (Hispanic heritage)* very differently than the diagnosis of *Impaired Verbal Communication related to hearing loss.*

◆ Planning

Once you have identified the nature of a patient's communication issues, consider several factors when designing the care plan. Motivation is a factor in improving communication, and patients often require encouragement to try different approaches that involve significant change. It is especially important to involve the patient and family in decisions about the plan of care to determine whether suggested methods are acceptable. Consider ways to meet basic comfort and safety needs before introducing new communication methods and techniques. Allow adequate time for practice. Participants need to be patient with themselves and one another to achieve effective communication. When the focus is on practicing communication, arrange for a quiet, private place that is free of distractions such as television or visitors.

Goals and Outcomes. Once a diagnosis has been identified, select a goal that is relevant and achievable for the patient such as being able to express needs or achieving understanding of physical condition. Next select expected outcomes that are very specific and measurable. Outcomes identify ways to determine if a broader goal is met. For example, outcomes for the patient possibly include the following:

- Patient initiates conversation about diagnosis or health care problem.
- Patient is able to attend to appropriate stimuli.
- Patient conveys clear and understandable messages with health care team.

- Patient expresses increased satisfaction with the communication process.

At times you care for patients whose difficulty in sending, receiving, and interpreting messages interferes with healthy interpersonal relationships. In this case impaired communication is a contributing factor to other nursing diagnoses such as *Impaired Social Interaction* or *Ineffective Coping*. Plan interventions to help these patients improve their communication skills. Expected outcomes for a patient in this situation possibly include demonstrating the ability to appropriately express needs, feelings, and concerns; communicating thoughts and feelings more clearly; engaging in appropriate social conversation with peers and staff; and increasing feelings of autonomy and assertiveness.

Setting Priorities. It is essential to always maintain an open line of communication so a patient is able to express emergent needs or problems. This sometimes involves an intervention as simple as keeping a call light in reach for a patient restricted to bed or providing communication augmentative devices (e.g., message board or Braille computer). When you plan to have lengthy interactions with a patient, it is important to address physical care priorities first so the discussion is not interrupted. Make the patient comfortable by ensuring that any symptoms are under control and elimination needs have been met.

Teamwork and Collaboration. To ensure an effective plan of care, you sometimes need to collaborate with other health care team members who have expertise in communication strategies. Speech language pathologists help patients with aphasia, professional interpreters are necessary for patients who speak a foreign language, and mental health nurse specialists help angry or highly anxious patients to communicate more effectively.

◆ Implementation

In carrying out any plan of care, use communication techniques that are appropriate for a patient's individual needs. Before learning how to adapt communication methods to help patients with serious communication impairments, it is necessary to learn the communication techniques that serve as the foundation for professional communication. It is also important to understand communication techniques that create barriers to effective interaction.

Therapeutic Communication Techniques. Therapeutic communication techniques are specific responses that encourage the expression of feelings and ideas and convey acceptance and respect. These techniques apply in a variety of different situations. Although some of the techniques seem artificial at first, skill and comfort increase with practice. Tremendous satisfaction results from developing therapeutic relationships that achieve desired patient outcomes.

Active Listening. Active listening means being attentive to what a patient is saying both verbally and nonverbally. It facilitates patient communication. Inexperienced nurses sometimes feel the need to talk to prove that they know what they are doing or to decrease anxiety (Stuart, 2013). It is often difficult at first to be quiet and really listen. Active listening enhances trust because you communicate acceptance and respect for a patient. Several nonverbal skills facilitate attentive listening, using the acronym SOLER (Townsend, 2012):

S—Sit facing the patient. This posture conveys the message that you are there to listen and are interested in what the patient is saying.

O—Open position (i.e., keep arms and legs uncrossed). This position suggests that you are "open" to what the patient says. A "closed" position such as crossing arms conveys a defensive attitude, possibly provoking a similar response in the patient.

L—*L*ean toward the patient. This position conveys that you are involved and interested in the interaction.

E—*E*ye contact—Establish and maintain intermittent eye contact to convey your involvement in and willingness to listen to what the patient is saying. Absence of eye contact or shifting the eyes gives the message that you are not interested in what the patient is saying.

R—*R*elax. It is important to communicate a sense of being relaxed and comfortable with the patient. Restlessness communicates a lack of interest and a feeling of discomfort to the patient.

Sharing Observations. Nurses make observations by commenting on how the other person looks, sounds, or acts. Stating observations often helps a patient communicate without the need for extensive questioning, focusing, or clarification. This technique helps start a conversation with quiet or withdrawn persons. Do not state observations that will embarrass or anger a patient such as telling someone, "You look a mess!" Even if you make such an observation with humor, the patient can become resentful.

Sharing observations differs from making assumptions, which means drawing unnecessary conclusions about the other person without validating them. Making assumptions puts a patient in the position of having to contradict you. Examples include interpreting a patient's fatigue as depression or assuming that untouched food indicates lack of interest in meeting nutritional goals. Making observations is a gentler and safer technique: "You look tired …," "You seem different today …," or "I see you haven't eaten anything."

Sharing Empathy. **Empathy** is the ability to understand and accept another person's reality, accurately perceive feelings, and communicate this understanding to the other. This is a therapeutic communication technique that enables you to understand a patient's situation, feelings, and concerns (Dinkins, 2011). To express empathy you reflect that you understand and feel the importance of the other person's communication. Empathetic understanding requires you to be sensitive and imaginative, especially if you have not had similar experiences. Strive to be empathetic in every situation because it is a key to unlocking concern and communicating support for others. Statements reflecting empathy are highly effective because they tell a person that you heard both the emotional and the factual content of the communication. Empathetic statements are neutral and nonjudgmental and help establish trust in difficult situations. For example, a nurse says to an angry patient who has low mobility after a stroke, "It must be very frustrating to not be able to do what you want."

Sharing Hope. Nurses recognize that hope is essential for healing and learn to communicate a "sense of possibility" to others. Appropriate encouragement and positive feedback are important in fostering hope and self-confidence and for helping people achieve their potential and reach their goals. You give hope by commenting on the positive aspects of the other person's behavior, performance, or response. Sharing a vision of the future and reminding others of their resources and strengths also strengthen hope. Reassure patients that there are many kinds of hope and that meaning and personal growth can come from illness experiences. For example, a nurse says to a patient discouraged about a poor prognosis, "I believe that you'll find a way to face your situation because I've seen your courage and creativity."

Sharing Humor. Humor is an important but often underused resource in nursing interactions. It is a coping strategy that can reduce anxiety and promote positive feelings (Rose et al., 2013). It is a perception and attitude in which a person can experience joy even when facing difficult times. It provides emotional support to patients and professional colleagues and humanizes the illness experience. It enhances teamwork, relieves tension, and helps nurses develop a bond between people who laugh together. Patients use humor to release tension, cope with fear related to pain and suffering, communicate a fear or need, or cope with an uncomfortable or embarrassing situation (Dossey and Keegan, 2013). The goals of using humor as a health care provider are to bring hope and joy to a situation and enhance a patient's well-being and the therapeutic relationship. It makes you seem more warm and approachable (Feagai, 2011). Use humor during the orientation phase to establish a therapeutic relationship and during the working phase as you help a patient cope with a situation.

Today it is common to care for patients from different cultural backgrounds. When you interact with patients be sensitive and realize that they may misunderstand or misinterpret jokes and statements meant to be humorous. For example, a person who is homosexual might not appreciate a joke with sexual orientation, or a person from a lower socioeconomic group is not likely to enjoy a joke that disparages a minority.

Health care professionals sometimes use a kind of dark, negative humor after difficult or traumatic situations as a way to deal with unbearable tension and stress. This coping humor has a high potential for misinterpretation as uncaring by people not involved in the situation. For example, nursing students are sometimes offended and wonder how staff are able to laugh and joke after unsuccessful resuscitation efforts. When nurses use coping humor within earshot of patients or their loved ones, great emotional distress results.

Sharing Feelings. Emotions are subjective feelings that result from one's thoughts and perceptions. Feelings are not right, wrong, good, or bad, although they are pleasant or unpleasant. If individuals do not express feelings, stress and illness may worsen. Help patients express emotions by making observations, acknowledging feelings, encouraging communication, giving permission to express "negative" feelings, and modeling healthy emotional self-expression. At times patients will direct their anger or frustration prompted by their illness toward you. Do not take such expressions personally. Acknowledging patients' feelings communicates that you listened to and understood the emotional aspects of their illness situation.

When you care for patients, be aware of your own emotions because feelings are difficult to hide. Students sometimes wonder whether it is helpful to share feelings with patients. Sharing emotion makes nurses seem more human and brings people closer. It is appropriate to share feelings of caring or even cry with others, as long as you are in control of the expression of these feelings and express them in a way that does not burden the patient or break confidentiality. Patients are perceptive and sense your emotions. It is usually inappropriate to discuss negative personal emotions such as anger or sadness with patients. A social support system of colleagues is helpful; and employee assistance programs, peer group meetings, and the use of interprofessional teams such as social work and pastoral care provide other means for nurses to safely express feelings away from patients.

Using Touch. Because of modern fast-paced technical environments in health care, nurses face major challenges in bringing the sense of caring and human connection to their patients (see Chapter 7). Touch is one of the most potent and personal forms of communication. It expresses concern or caring to establish a feeling of connection and promote healing (Stuart, 2013). Touch conveys many messages such as affection, emotional support, encouragement, tenderness, and personal attention. Comfort touch such as holding a hand is especially important for vulnerable patients who are experiencing severe illness with its accompanying physical and emotional losses (Figure 24-2).

Students initially may find giving intimate care to be stressful, especially when caring for patients of the opposite gender. They learn to cope with intimate contact by changing their perception of the

FIGURE 24-2 The nurse uses touch to communicate.

situation. Since much of what nurses do involves touching, you need to learn to be sensitive to others' reactions to touch and use it wisely. It should be as gentle or as firm as needed and delivered in a comforting, nonthreatening manner. Sometimes you withhold touch for highly suspicious or angry persons who respond negatively or even violently to you.

Nurses need to be aware of patients' nonverbal cues and ask permission before touching them to ensure that touch is an acceptable way to provide comfort. Some individuals may be sensitive to physical closeness and uncomfortable with touch. When this is the case, share the information with other nurses who will care for the patient. Nurses should be aware of a patient's concern and act accordingly. A nod, gesture, body position, or eye contact can also convey interest and acceptance of touch, which promotes a bonding moment with a patient (Stuart, 2013).

Using Silence. It takes time and experience to become comfortable with silence. Most people have a natural tendency to fill empty spaces with words, but sometimes these spaces really allow time for a nurse and patient to observe one another, sort out feelings, think about how to say things, and consider what has been communicated. Silence prompts some people to talk. It allows a patient to think and gain insight (Stuart, 2013). In general, allow a patient to break the silence, particularly when he or she has initiated it.

Silence is particularly useful when people are confronted with decisions that require much thought. For example, it helps a patient gain the necessary confidence to share the decision to refuse medical treatment. It also allows the nurse to pay particular attention to nonverbal messages such as worried expressions or loss of eye contact. Remaining silent demonstrates patience and a willingness to wait for a response when the other person is unable to reply quickly. Silence is especially therapeutic during times of profound sadness or grief.

Providing Information. Providing relevant information tells other people what they need or want to know so they are able to make decisions, experience less anxiety, and feel safe and secure. It is also an integral aspect of health teaching (see Chapter 25). It usually is not helpful to hide information from patients, particularly when they seek it. If a health care provider withholds information, the nurse clarifies the reason with him or her. Patients have a right to know about their health status and what is happening in their environment. Information of a distressing nature needs to be communicated with sensitivity, at a pace appropriate to a patient's ability to absorb it, and in general terms at first: "John, your heart sounds have changed from earlier today, and so has your blood pressure. I'll let your doctor know." A nurse provides information that enables others to understand what is happening and what to expect: "Mrs. Evans, John is getting an echocardiogram right now. This test uses painless sound waves to create a moving picture of his heart structures and valves and should tell us what's causing his murmur."

Clarifying. To check whether you understand a message accurately, restate an unclear or ambiguous message to clarify the sender's meaning. In addition, ask the other person to rephrase it, explain further, or give an example of what the person means. Without clarification you may make invalid assumptions and miss valuable information. Despite efforts at paraphrasing, sometimes you do not understand a patient's message. Let the patient know if this is the case: "I'm not sure I understand what you mean by 'sicker than usual.' What is different now?"

Focusing. Focusing involves centering a conversation on key elements or concepts of a message. If conversation is vague or rambling or patients begin to repeat themselves, focusing is a useful technique. Do not use focusing if it interrupts patients while they are discussing important issues. Rather use it to guide the direction of conversation to important areas: "We've talked a lot about your medications; now let's look more closely at the trouble you're having in taking them on time."

Paraphrasing. Paraphrasing is restating another's message more briefly using one's own words. Through paraphrasing you send feedback that lets a patient know that he or she is actively involved in the search for understanding. Accurate paraphrasing requires practice. If the meaning of a message is changed or distorted through paraphrasing, communication becomes ineffective. For example, a patient says, "I've been overweight all my life and never had any problems. I can't understand why I need to be on a diet." Paraphrasing this statement by saying, "You don't care if you're overweight," is incorrect. It is more accurate to say, "You're not convinced that you need a diet because you've stayed healthy."

Validation. This is a technique that nurses use to recognize and acknowledge a patient's thoughts, feelings, and needs. Patients and families know they are being heard and taken seriously when the caregiver addresses their issues (Harvey and Ahmann, 2014). For example, a nurse validates the patient's stated comments by asking, "Tell me if I understand your concerns regarding your surgery. You're worried that you will not be able to return to your usual way of life." This type of statement enables a nurse to convey empathy and interest in the patient's thoughts, feelings, and perceptions.

Asking Relevant Questions. Nurses ask relevant questions to seek information needed for decision making. Ask only one question at a time and fully explore one topic before moving to another area. During patient assessment questions follow a logical sequence and usually proceed from general to more specific. Open-ended questions allow patients to take the conversational lead and introduce pertinent information about a topic. For example, "What's your biggest problem at the moment?" Use focused questions when more specific information is needed in an area: "How has your pain affected your life at home?" Allow patients to respond fully to open-ended questions before asking more-focused questions. Closed-ended questions elicit a yes, no, or one-word response: "How many times a day are you taking pain medication?" Although they are helpful during assessment, they are generally less useful during therapeutic exchanges.

Asking too many questions is sometimes dehumanizing. Seeking factual information does not allow a nurse or patient to establish a meaningful relationship or deal with important emotional issues. It is a way for a nurse to ignore uncomfortable areas in favor of more comfortable, neutral topics. A useful exercise is to try conversing without asking the other person a single question. By using techniques such as giving general leads ("tell me about it …"), making observations, paraphrasing, focusing, and providing information, you discover

important information that would have remained hidden if you limited the communication process to questions alone.

Summarizing. Summarizing is a concise review of key aspects of an interaction. It brings a sense of satisfaction and closure to an individual conversation and is especially helpful during the termination phase of a nurse-patient relationship. By reviewing a conversation, participants focus on key issues and add relevant information as needed. Beginning a new interaction by summarizing a previous one helps a patient recall topics discussed and shows him or her that you analyzed their communication. Summarizing also clarifies expectations, as in this example of a nurse manager who has been working with an unsatisfied employee, "You've told me a lot of things about why you don't like this job and how unhappy you've been. We've also come up with some possible ways to make things better, and you've agreed to try some of them and let me know if any help."

Self-Disclosure. Self-disclosures are subjectively true personal experiences about the self that are intentionally revealed to another person. This is not therapy for a nurse; rather it shows a patient that the nurse understands his experiences and that they are not unique. You choose to share experiences or feelings that are similar to those of the patient and emphasize both the similarities and differences. This kind of self-disclosure is indicative of the closeness of the nurse-patient relationship and involves a particular kind of respect for the patient. You offer it as an expression of sincerity and honesty, and it is an aspect of empathy (Stuart, 2013). Self-disclosures need to be relevant and appropriate and made to benefit the patient rather than yourself. Use them sparingly so the patient is the focus of the interaction.

Confrontation. When you confront someone in a therapeutic way, you help the other person become more aware of inconsistencies in his or her feelings, attitudes, beliefs, and behaviors (Stuart, 2013). This technique improves patient self-awareness and helps him or her recognize growth and deal with important issues. Use confrontation only after you have established trust, and do it gently with sensitivity: "You say you've already decided what to do; yet you're still talking a lot about your options."

Nontherapeutic Communication Techniques. Certain communication techniques hinder or damage professional relationships. These specific techniques are referred to as *nontherapeutic* or *blocking* and often cause recipients to activate defenses to avoid being hurt or negatively affected. Nontherapeutic techniques discourage further expression of feelings and ideas and engender negative responses or behaviors in others.

Asking Personal Questions. "Why don't you and John get married?" Asking personal questions that are not relevant to a situation simply to satisfy your curiosity is not appropriate professional communication. Such questions are nosy, invasive, and unnecessary. If patients wish to share private information, they will. To learn more about a patient's interpersonal roles and relationships, ask questions such as: "How would you describe your relationship with John?"

Giving Personal Opinions. "If I were you, I'd put your mother in a nursing home." When a nurse gives a personal opinion, it takes decision making away from the other person. It inhibits spontaneity, stalls problem solving, and creates doubt. Personal opinions differ from professional advice. At times people need suggestions and help to make choices. Suggestions that you present are options; the other person makes the final decision. Remember that the problem and its solution belong to the other person and not to you. A much better response is, "Let's talk about which options are available for your mother's care." The nurse also should not make promises to a patient about situations that require collaboration. For example, "I can't recommend that you stop taking the medications because of your side effects, but I would be happy to inform your primary care provider and ask if a change in medication is appropriate."

Changing the Subject. "Let's not talk about your problems with the insurance company. It's time for your walk." Changing the subject when another person is trying to communicate his or her story is rude and shows a lack of empathy. It blocks further communication, and the sender then withholds important messages or fails to openly express feelings. In some instances changing the subject serves as a face-saving maneuver. If this happens, reassure the patient that you will return to his or her concerns, "After your walk let's talk some more about what's going on with your insurance company."

Automatic Responses. "Older adults are always confused." "Administration doesn't care about the staff." Stereotypes are generalized beliefs held about people. Making stereotyped remarks about others reflects poor nursing judgment and threatens nurse-patient or team relationships. A cliché is a stereotyped comment such as "You can't win them all" that tends to belittle the other person's feelings and minimize the importance of his or her message. These automatic phrases communicate that you are not taking concerns seriously or responding thoughtfully. Another kind of automatic response is parroting (i.e., repeating what the other person has said word for word). Parroting is easily overused and is not as effective as paraphrasing. A simple "oh?" gives you time to think if the other person says something that takes you by surprise.

A nurse who is task oriented automatically makes the task or procedure the entire focus of interaction with patients, missing opportunities to communicate with them as individuals and meet their needs. Task-oriented nurses are often perceived as cold, uncaring, and unapproachable. When students first perform technical skills, it is difficult to integrate therapeutic communication because of the need to focus on the procedure. In time you learn to integrate communication with high-visibility tasks and accomplish several goals simultaneously.

False Reassurance. "Don't worry, everything will be all right." When a patient is seriously ill or distressed, you may be tempted to offer hope to him or her with statements such as "You'll be fine" or "There's nothing to worry about." When a patient is reaching for understanding, false reassurance discourages open communication. Offering reassurance not supported by facts or based in reality does more harm than good. Although you are trying to be kind, it has the secondary effect of helping you avoid the other person's distress, and it tends to block conversation and discourage further expression of feelings. A more facilitative response is, "It must be difficult not to know what the surgeon will find. What can I do to help?"

Sympathy. "I'm so sorry about your mastectomy; you probably feel devastated." Sympathy is concern, sorrow, or pity felt for another person. A nurse often takes on a patient's problems as if they were his or her own. Sympathy is a subjective look at another person's world that prevents a clear perspective of the issues confronting that person. If a nurse over-identifies with a patient, objectivity is lost, and the nurse is not able to help the patient work through the situation (Townsend, 2012). Although sympathy is a compassionate response to another's situation, it is not as therapeutic as empathy. A nurse's own emotional issues sometimes prevent effective problem solving and impair good judgment. A more empathetic approach is: "The loss of a breast is a major change. Do you feel comfortable talking about how it will affect your life?"

Asking for Explanations. "Why are you so anxious?" Some nurses are tempted to ask patients why they believe, feel, or act in a certain way. Patients frequently interpret "why" questions as accusations or think nurses know the reasons and are simply testing them. Regardless of a patient's perception of your motivation, asking "why" questions

causes resentment, insecurity, and mistrust. If you need additional information, it is best to phrase a question to avoid using the word "why." For example, "You seem upset. What's on your mind?" is more likely to help an anxious patient communicate.

Approval or Disapproval. "You shouldn't even think about assisted suicide; it's not right." Do not impose your own attitudes, values, beliefs, and moral standards on others while in the professional helping role. Other people have the right to be themselves and make their own decisions. Judgmental responses often contain terms such as *should, ought, good, bad, right,* or *wrong.* Agreeing or disagreeing sends the subtle message that you have the right to make value judgments about patient decisions. Approving implies that the behavior being praised is the only acceptable one. Often a patient shares a decision with you, not in an effort to seek approval but to provide a means to discuss feelings. Disapproval implies that the patient needs to meet your expectations or standards. Instead help patients explore their own beliefs and decisions. The response, "I'm surprised you're considering assisted suicide. Tell me more about it," gives the patient a chance to express ideas or feelings without fear of being judged.

Defensive Responses. "No one here would intentionally lie to you." Becoming defensive in the face of criticism implies that the other person has no right to an opinion. The sender's concerns are ignored when the nurse focuses on the need for self-defense, defense of the health care team, or defense of others. When patients express criticism, listen to what they have to say. Listening does not imply agreement. Listen nonjudgmentally to discover reasons for a patient's anger or dissatisfaction. By avoiding a defensive attitude you are able to defuse anger and uncover deeper concerns, "You believe that people are dishonest with you. It must be hard to trust anyone."

Passive or Aggressive Responses. "Things are bad, and there's nothing I can do about it." "Things are bad, and it's all your fault." Passive responses serve to avoid conflict or sidestep issues. They reflect feelings of sadness, depression, anxiety, powerlessness, and hopelessness. Aggressive responses provoke confrontation at the other person's expense. They reflect feelings of anger, frustration, resentment, and stress. Nurses who lack assertive skills also use triangulation (i.e., complaining to a third party rather than confronting the problem or expressing concerns directly to the source). This lowers team morale and draws others into the conflict situation. Assertive communication is a far more professional approach for a nurse to take.

Arguing. "How can you say you didn't sleep a wink when I heard you snoring all night long?" Challenging or arguing against perceptions denies that they are real and valid. A skillful nurse gives information or presents reality in a way that avoids argument, "You feel like you didn't get any rest at all last night, even though I thought you slept well since I heard you snoring."

Adapting Communication Techniques for the Patient with Special Needs.
With our aging population more patients have difficulty communicating. Hearing loss increases with age. Approximately one in three people between the ages 65 and 74 has hearing loss. Vision loss affects communication and presents a challenge for many individuals, particularly over the age of 65. This trend continues to increase. Rates of vision loss are predicted to double by the year 2030 as the population ages (Special Report on Aging, 2013).

Interacting with people who have conditions that impair communication requires special thought and sensitivity. For example, patients who have had a stroke or laryngectomy may require communication aids such as a writing or picture board or a special call system. Such patients benefit greatly when you adapt communication techniques to their unique circumstances, developmental level, or cognitive and sensory deficits. For example, a nurse caring for a patient with *Impaired*

Verbal Communication related to cognitive impairment can use several techniques to enable the patient to understand the caregiver. The nurse can use pictures, drawings, or demonstration such as eating behavior to help the patient understand the verbal direction (NIH, 2014).

A nurse directs actions toward meeting the goals and expected outcomes identified in the plan of care, addressing both the communication impairment and its contributing factors. Box 24-9 lists methods available to encourage, enhance, restore, or substitute for verbal communication. Be sure that a patient is physically able to use the chosen method and that it does not cause frustration by being too complicated or difficult. Non-English speaking patients and families need assistance with communication. Interpretation services can be used to better facilitate communication, which improves patient safety and patient outcomes (Weldon et al., 2014).

Because nursing care of the older adult ideally is delivered through an interprofessional model, the primary goal is to establish a reliable communication system that all health care team members can understand easily. Effective communication involves adapting special needs resulting from sensory, motor, or cognitive impairments. Encouraging older adults to share life stories and reminisce about the past has a therapeutic effect and increases their sense of well-being. Avoid sudden shifts from subject to subject. It is helpful to include a patient's family and friends and become familiar with a patient's favorite topics for conversation.

◆ Evaluation

Evaluate the effectiveness of your own communication by videotaping practice sessions with peers or by making process recordings—written records of your verbal and nonverbal interactions with patients. Process recording analysis reveals how to improve personal communication techniques to make them more effective. Box 24-10 contains a sample communication analysis of such a record. Analysis of a process recording enables you to evaluate the following:

- Determine whether you encouraged openness and allowed the patient to "tell his story," expressing both thoughts and feelings.
- Identify any missed verbal or nonverbal cues or conversational themes.
- Examine whether nursing responses facilitated or blocked the patient's efforts to communicate.
- Determine whether nursing responses were positive and supportive or superficial and judgmental.
- Examine the type and number of questions asked.
- Determine the type and number of therapeutic communication techniques used.
- Discover any missed opportunities to use humor, silence, or touch.

Through the Patient's Eyes. You and your patient determine the success of the plan of care by evaluating patient communication outcomes together. You determine which strategies or interventions were effective and which patient changes (behaviors or perceptions) resulted because of the interventions. Ask the patient if you and other members of the interprofessional health care team met his or her expectations. For example, does the patient believe that nurses responded in a timely way when the call light was turned on? Does the patient feel able to express his needs clearly? Is the patient satisfied with the information that has been provided about his condition or hospitalization? Successful nursing care related to patients' communication needs results in clear and effective communication between patients and all members of the health care team and can favorably impact patient satisfaction and the delivery of safe care.

BOX 24-9 Communicating with Patients Who Have Special Needs

Patients Who Cannot Speak Clearly (Aphasia, Dysarthria, Muteness)
- Listen attentively, be patient, and do not interrupt.
- Ask simple questions that require "yes" or "no" answers.
- Allow time for understanding and response.
- Use visual cues (e.g., words, pictures, and objects) when possible.
- Allow only one person to speak at a time.
- Encourage patient to converse.
- Let patient know if you have not understood him or her.
- Collaborate with speech therapist as needed.
- Use communication aids: letter boards, flash cards, computer-generated speech program),

Patients Who Are Cognitively Impaired
- Use simple sentences and avoid long explanations.
- Ask one question at a time.
- Allow time for patient to respond.
- Be an attentive listener.
- Include family and friends in conversations, especially in subjects known to patient.
- Use picture or gestures that mimic the action desired.

Patients Who Are Hearing Impaired
- Check for hearing aids and glasses.
- Reduce environmental noise.
- Get patient's attention before speaking.
- Face patient with mouth visible.
- Do not chew gum.
- Speak at normal volume—do not shout.
- Rephrase rather than repeat if misunderstood.
- Provide a sign-language interpreter if indicated.

Patients Who Are Visually Impaired
- Check for use of glasses or contact lenses.
- Identify yourself when you enter room and notify patient when you leave room.
- Speak in a normal tone of voice.
- Do not rely on gestures or nonverbal communication.
- Use indirect lighting, avoiding glare.
- Use at least 14-point print.

Patients Who Are Unresponsive
- Call patient by name during interactions.
- Communicate both verbally and by touch.
- Speak to patient as though he or she can hear.
- Explain all procedures and sensations.
- Provide orientation to person, place, and time.
- Avoid talking about patient to others in his or her presence.

Patients Who Do Not Speak English
- Speak to patient in normal tone of voice.
- Establish method for patient to ask for assistance (call light or bell).
- Provide a professional interpreter as needed.
- Avoid using family members, especially children, as interpreters.
- Use communication board, pictures, or cards.
- Translate words from native language into English list for patient to make basic requests.
- Have dictionary (e.g., English/Spanish) available if patient can read.

BOX 24-10 Sample Communication Analysis

Nurse: Good morning, Mr. Simpson."
(Smiles, approaches bed holding clipboard)
Acknowledged by name, social greeting to begin conversation
Patient: "What's good about it?"
(Arms crossed over chest, frowning, direct stare)
Nonverbal signs of anger
Nurse: "You sound unhappy."
(Pulls up chair and sits at bedside)
Sharing observation, nonverbal communication of availability
Patient: "You'd be unhappy, too, if nobody would answer your questions. That girl wouldn't tell me my blood sugar."
(Angry voice tone, challenging expression)
Further expression of feelings facilitated by nurse making accurate observation
Nurse: "This hospital has a fine staff, Mr. Simpson. I'm sure no one would intentionally keep information from you."
Feeling threatened and being defensive, a nontherapeutic technique
Nurse: "I'm going to test your glucose in a minute, and I'll tell you the results."
(Does test) "Your blood sugar was 350."
Providing information, demonstrating trustworthiness
Patient: "I'm so afraid complications will set in since my blood sugar is high."
(Stares out window)
Feels free to express deeper concerns, but they are hard to face
Nurse: "What kinds of things are you worried about?"
Open-ended question to seek information
Patient: "I could lose a leg, like my mother did, or go blind or have to live hooked up to a kidney machine for the rest of my life.
Nurse: "You've been thinking about all kinds of things that could go wrong, and it adds to your worry not to be told what your blood sugar is."
Summarizing to let patient "hear" what he has communicated
Patient: "I always think the worst."
(Shakes head in exasperation)
Expressing insight into his "inner dialogue"
Nurse: "I'll pass along to the technician that it's OK to tell you your glucose levels. And later this afternoon I'd like us to talk more about some things you can do to help avoid these complications and set some goals for controlling your glucose."
Providing information, encouraging collaboration and goal setting

Patient Outcomes. If expected outcomes for the patient's plan of care are not met or if progress is not satisfactory, you determine which factors influenced the outcomes and modify the plan of care. If your evaluation data indicate that a patient perceives difficulty in communicating, you explore contributing factors so they can be addressed. For example, if using a pen and paper is frustrating for a nonverbal patient whose handwriting is shaky, you revise the care plan to include use of a picture board instead. Possible questions you ask when a patient does not meet expected outcomes include:

- You seem to be having difficulty communicating right now. What do you think is contributing to this?
- You're telling me that you don't feel anxious right now, but your face appears tense. Help me better understand how you're feeling right now.
- You seem frustrated with the use of pencil and paper to communicate. Would you like to try a letter board or a picture board and see if either of these is easier for you to use?

Evaluation of the communication process helps nurses gain confidence and competence in interpersonal skills. Becoming an effective communicator greatly increases your professional satisfaction and success. There is no skill more basic, no tool more powerful.

KEY POINTS

- Communication is a powerful therapeutic tool and an essential nursing skill that influences others and achieves positive health outcomes.
- Effective interprofessional communication is essential to provide safe transitions in care.
- Effective team communication and collaboration skills are necessary to ensure safe patient care.
- Critical thinking and critical reasoning skills promote more effective communication and patient assessment.
- Communication is most effective when the receiver and sender accurately perceive the meaning of one another's messages via feedback loops and validation.
- The sender and receiver's physical and developmental status, perceptions, values, emotions, knowledge, sociocultural background, roles, and environment all influence message transmission.
- Effective verbal communication requires appropriate intonation, clear and concise phrasing, proper pacing of statements, and proper timing and relevance of a message.
- Effective nonverbal communication complements and strengthens the message conveyed by verbal communication.
- Nurses use intrapersonal, interpersonal, small-group, electronic communication and public interaction to achieve positive change and health goals.
- Nurses strengthen caring relationships by establishing trust, empathy, autonomy, confidentiality, and professional competence.
- Effective communication techniques are facilitative and tend to encourage the other person to openly express ideas, feelings, or concerns.
- Ineffective communication techniques are inhibiting and tend to block the other person's willingness to openly express ideas, feelings, or concerns.
- Blend social and informational interactions with therapeutic communication techniques to help your patients explore feelings and manage health issues.
- Older adults with sensory, motor, or cognitive impairments require the adaptation of communication techniques to compensate for their loss of function and special needs.
- Lateral violence can be a symptom of compassion fatigue, leading to nurse dissatisfaction and decreased sense of value. This interferes with team communication and jeopardizes patient safety.
- Assessment and communication techniques such as MI and EI assessment enable a nurse to better understand and motivate patients toward more positive health practices.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mr. Simpson is a 78-year-old patient whose wife died last year. He has been living alone. He has limited cooking skills; thus he eats out a lot. Since his wife died, his blood sugar has been poorly controlled. To help Mr. Simpson gain better blood sugar control, the dietitian came to see him. After she left, Mr. Simpson was angry and stated his desire to leave the hospital right now. He stated, "That diet person came to see me, and she doesn't know anything."

1. How would you approach Mr. Simpson? Which communication techniques would you use and which would you avoid?
2. You talk with the dietitian and learn that she gave the patient information about his diet and recipes that he could try. As you talk further with Mr. Simpson, you learn that the physician told him he might not be able to live alone anymore. You realize that he doesn't know how to cook. Knowing this, how would you respond to him?
3. After talking with Mr. Simpson, you determine that he is able to care for himself at home but will need some assistance. He is willing to consider various options for meal preparation. You call the physician to discuss this. Your hospital has established SBAR (Situation-Background-Assessment-Recommendation) as a standard communication tool. How do you effectively communicate your concerns and the patient's need to the physician using SBAR?

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. When working with an older adult who is hearing-impaired, the use of which techniques would improve communication? (Select all that apply.)
   1. Check for needed adaptive equipment.
   2. Exaggerate lip movements to help the patient lip read.
   3. Give the patient time to respond to questions.
   4. Keep communication short and to the point.
   5. Communicate only through written information.
2. Nurses must communicate effectively with the health care team for which of the following reasons? (Select all that apply.)
   1. Improve the nurse's status with the health team members
   2. Reduce the risk of errors to the patient
   3. Provide optimum level of patient care
   4. Improve patient outcomes
   5. Prevent issues that need to be reported to outside agencies
3. A new nurse complains to her preceptor that she has no time for therapeutic communication with her patients. Which of the following is the best strategy to help the nurse find more time for this communication?
   1. Include communication while performing tasks such as changing dressings and checking vital signs.
   2. Ask the patient if you can talk during the last few minutes of visiting hours.
   3. Ask Pastoral care to come back a little later in the day.
   4. Remind the nurse to complete all her tasks and then set up remaining time for communication.
4. Motivational interviewing (MI) is a technique that applies understanding a patient's values and goals in helping the patient make behavior changes. What are other benefits of using MI techniques? (Select all that apply.)
   1. Gaining an understanding of patient's motivations
   2. Focusing on opportunities to avoid poor health choices
   3. Recognizing patient's strengths and supporting their efforts
   4. Providing assessment data that can be shared with families to promote change
   5. Identifying differences in patient's health goals and current behaviors
5. A nurse is talking with a young-adult patient about the purpose of a new medication. The nurse says, "I want to be clear. Can you tell me in your words the purpose of this medicine?" This exchange

is an example of which element of the transactional communication process?
   1. Message
   2. Obtaining feedback
   3. Channel
   4. Referent

6. A patient who is Spanish-speaking does not appear to understand the nurse's information on wound care. Which action should the nurse take?
   1. Arrange for a Spanish-speaking social worker to explain the procedure
   2. Ask a fellow Spanish-speaking patient to help explain the procedure
   3. Use a professional interpreter to provide wound care education in Spanish
   4. Ask the patient to write down questions that he or she has for the nurse

7. A nurse prepares to contact a patient's physician about a change in the patient's condition. Put the following statements in the correct order using SBAR (Situation, Background, Assessment, and Recommendation) communication.
   1. "She is a 53-year-old female who was admitted 2 days ago with pneumonia and was started on Levaquin at 5 PM yesterday. She complains of a poor appetite."
   2. "The patient reported feeling very nauseated after her dose of Levaquin an hour ago."
   3. "Would you like to make a change in antibiotics, or could we give her a nutritional supplement before her medication?"
   4. "The patient started complaining of nausea yesterday evening and has vomited several times during the night."

8. A nurse is assigned to care for a patient for the first time and states, "I don't know a lot about your culture and want to learn how to better meet your health care needs." Which therapeutic communication technique did the nurse use in this situation?
   1. Validation
   2. Empathy
   3. Sarcasm
   4. Humility

9. A new nurse is experiencing lateral violence at work. Which steps could the nurse take to address this problem?
   1. Challenge the nurses in a public forum to embarrass them and change their behavior
   2. Talk with the department secretary and ask if this has been a problem for other nurses
   3. Talk with the preceptor or manager and ask for assistance in handling this issue
   4. Say nothing and hope things get better

10. A nurse has been gathering physical assessment data on a patient and is now listening to the patient's concerns. The nurse sets a goal of care that incorporates the patient's desire to make treatment decisions. This is an example of the nurse engaged in which phase of the nurse-patient relationship?
    1. Working phase
    2. Preinteraction phase

    3. Termination phase
    4. Orientation phase

11. A patient is evaluated in the emergency department after causing an automobile accident while being under the influence of alcohol. While assessing the patient, which statement would be the most therapeutic?
    1. "Why did you drive after you had been drinking?"
    2. "We have multiple patients to see tonight as a result of this accident."
    3. "Tell me what happened before, during, and after the automobile accident tonight."
    4. "It will be okay. No one was seriously hurt in the accident."

12. A nursing student is reviewing a process recording with the instructor. The student engaged the patient in a discussion about availability of family members to provide support at home once the patient is discharged. The student reviews with the instructor whether the comments used encouraged openness and allowed the patient to "tell his story." This is an example of which step of the nursing process?
    1. Planning
    2. Assessment
    3. Intervention
    4. Evaluation

13. Which strategies should a nurse use to facilitate a safe transition of care during a patient's transfer from the hospital to a skilled nursing facility? (Select all that apply.)
    1. Collaboration between staff members from sending and receiving departments
    2. Requiring that the patient visit the facility before a transfer is arranged
    3. Using a standardized transfer policy and transfer tool
    4. Arranging all patient transfers during the same time each day
    5. Relying on family members to share information with the new facility

14. A nurse is explaining to a patient how to follow infection control practices at home. During the discussion the nurse touches the patient on the shoulder. Explain which zone of touch the nurse should be practicing and what problems the action might cause.

15. The nurse uses silence as a therapeutic communication technique. What is the purpose of the nurse's silence? (Select all that apply.)
    1. Prevent the nurse from saying the wrong thing
    2. Prompt the patient to talk when he or she is ready
    3. Allow the patient time to think and gain insight
    4. Allow time for the patient to drift off to sleep
    5. Determine if the patient would prefer to talk with another staff member

Answers: 1. 1, 3, 4; 2. 2, 3, 4; 3. 1; 4. 1, 3; 5. 2; 6. 3; 7. 4S, 1B, 2A, 3R; 8. 4; 9. 3; 10. 1; 11. 3; 12. 4; 13. 1, 3; 14. See Evolve; 15. 2, 3.

Patient Education

OBJECTIVES

- Identify the appropriate topics that address a patient's health education needs.
- Describe the similarities and differences between teaching and learning.
- Identify the role of the nurse in patient education.
- Identify the purposes of patient education.
- Describe appropriate communication principles when providing patient education.
- Describe the domains of learning.

- Identify basic learning principles.
- Discuss how to integrate education into patient-centered care.
- Differentiate factors that determine readiness to learn from those that determine ability to learn.
- Compare and contrast the nursing and teaching process.
- Write learning objectives for a teaching plan.
- Establish an environment that promotes learning.
- Include patient teaching while performing routine nursing care.
- Use appropriate methods to evaluate learning.

- Content Updates

Patient education is one of the most important nursing interventions in any health care setting. Shorter hospital stays, increased demands on nurses' time, increase in the number of chronically ill patients, and the need to give acutely ill patients meaningful information quickly emphasize the importance of quality patient education. As nurses try to find the best way to educate patients, the general public has become more assertive in seeking knowledge, understanding health, and finding resources available within the health care system. Nurses provide patients with information needed for self-management of acute and chronic conditions to ensure continuity of care from the hospital to the home (Lorig et al., 2013; Falvo, 2011). Part of the patient education process is designing patient-centered action plans, which are an essential component of chronic disease self-management and are associated with improved health outcomes (Lorig et al., 2014a; 2014b).

Patients have the right to know and be informed about their diagnoses, prognoses, and available treatments to help them make intelligent, informed decisions about their health and lifestyle. Part of patient-centered care is to integrate educational approaches that acknowledge patients' understanding of their own health. The goals of a well-designed, comprehensive teaching plan include providing a good fit with each patient's unique learning needs, reducing health care costs, improving quality of care, and ultimately changing behaviors to improve patient outcomes. In due course this helps patients make

informed decisions about their care and become healthier and more independent (Edelman et al., 2014; Friedman et al., 2011).

STANDARDS FOR PATIENT EDUCATION

Patient education has long been a standard for professional nursing practice. All state Nurse Practice Acts recognize that patient teaching falls within the scope of nursing practice (Bastable, 2014). In addition, various accrediting agencies set guidelines for providing patient education in health care institutions. For example, The Joint Commission (TJC, 2015a) sets standards for patient and family education. These standards require nurses and all health care providers to assess patients' learning needs and provide education on a variety of topics, including medications, nutrition, use of medical equipment, pain management, and the patient's plan of care. Successful fulfillment of the standards requires collaboration among health care professionals and enhances patient safety. Ensure that your educational efforts are patient centered by taking into consideration your patients' own education and experience; their desire to actively participate in the educational process; and their psychosocial, spiritual, and cultural values. It is important to document patient education interventions and a patient's response to teaching in the medical record. Standards such as these help to direct patient education and ensure best possible outcomes.

PURPOSES OF PATIENT EDUCATION

The goal of educating others about their health is to help individuals, families, or communities achieve optimal levels of health (Edelman et al., 2014). Patient education is an essential component of providing safe, patient-centered care (QSEN, 2014). In addition, providing education about preventive health care helps reduce health care costs and hardships on individuals and those surrounding them. Patients now know more about health and want to be actively involved in their health maintenance. Comprehensive patient education includes three important purposes, each involving a separate phase of health care: health promotion and illness prevention, health restoration, and coping.

Maintenance and Promotion of Health and Illness Prevention

As a nurse you are a visible, competent resource for patients who want to improve their physical and psychological well-being. In the school, home, clinic, or workplace you provide information and skills to help patients adopt healthier behaviors. For example, in childbearing classes you teach expectant parents about physical and psychological changes in a woman. After learning about normal childbearing, the mother who applies new knowledge is more likely to eat healthy foods, engage in physical exercise, and avoid substances that can harm the fetus. Promoting healthy behavior through education allows patients to assume more responsibility for their own health (Thom et al., 2013). Greater knowledge results in better health maintenance habits. In addition, when patients become more health conscious, they are more likely to seek early diagnosis of health problems (Hawkins et al., 2011).

Restoration of Health

Injured or ill patients need information and skills to help them regain or maintain their levels of health. Patients recovering from and adapting to changes resulting from illness or injury often seek information about their conditions. However, some patients find it difficult to adapt to illness and become passive and disinterested in learning. As the nurse you learn to identify patients' willingness to learn and motivate interest in learning (Bastable, 2014). The family often is a vital part of a patient's return to health. Family caregivers usually require as much education as the patient, including information on how to perform skills within the home. If you exclude a family from a teaching plan, conflicts can occur. However, do not assume that a family should be involved; assess the patient-family relationship before providing education for family caregivers.

Coping with Impaired Functions

Not all patients fully recover from illness or injury. In addition, patients with preexisting mental illness are also challenged during recovery (Lorig et al., 2014b). Many have to learn to cope with permanent health alterations. New knowledge and skills are often necessary for patients to continue activities of daily living. For example, a patient loses the ability to speak after larynx surgery and has to learn new ways of communicating. Changes in function are physical or psychosocial. In the case of serious disability such as following a stroke or a spinal cord injury, the patient's family needs to understand and accept many changes in his or her physical capabilities. The family's ability to provide support results in part from education, which begins as soon as you identify the patient's needs and the family displays a willingness to help. Teach family members to help the patient with health care management (e.g., giving medications through gastric tubes and doing passive range-of-motion exercises). Families of patients with alterations such as alcoholism, mental retardation, or drug dependence learn

to adapt to the emotional effects of these chronic conditions and provide psychosocial support to facilitate the patient's health. Comparing the desired level of health with the actual state of health enables you to plan effective teaching programs.

TEACHING AND LEARNING

It is impossible to separate teaching from learning. **Teaching** is the concept of imparting knowledge through a series of directed activities. It consists of a conscious, deliberate set of actions that help individuals gain new knowledge, change attitudes, adopt new behaviors, or perform new skills (Billings and Halstead, 2012). An educator needs to be knowledgeable about the subject matter and patient teaching principles in order to provide individuals with guidance, appropriately set the learning pace, and creatively introduce concepts to successfully achieve the desired learning objectives.

Learning is the purposeful acquisition of new knowledge, attitudes, behaviors, and skills through an experience or external stimulus (Bastable, 2014). It is a process of both understanding and applying newly acquired concepts. A new mother exhibits learning when she demonstrates how to bathe her newborn. The mother shows transfer of learning when she uses the principles she learned about bathing a newborn when she bathes her older child. Teaching and learning generally begin when a person identifies a need for knowing or acquiring an ability to do something. Teaching is most effective when it responds to the learner's needs. An educator assesses these needs by asking questions and determining a learner's interests. Interpersonal communication is essential for successful teaching to occur (see Chapter 24).

Role of the Nurse in Teaching and Learning

Nurses have an ethical responsibility to teach their patients (Heiskell, 2010). In The Patient Care Partnership, the American Hospital Association (2003) indicates that patients have the right to make informed decisions about their care. The information required to make informed decisions must be accurate, complete, and relevant to patients' needs, language, and literacy.

The Joint Commission's Speak Up Initiatives helps patients understand their rights when receiving medical care (TJC, 2015b). The assumption is that patients who ask questions and are aware of their rights have a greater chance of getting the care they need when they need it. The program offers the following Speak Up tips to help patients become more involved in their treatment:

- **S**peak up if you have questions or concerns. If you still do not understand, ask again. It is your body, and you have a right to know.
- **P**ay attention to the care you get. Always make sure that you are getting the right treatments and medicines by the right health care professionals. Do not assume anything.
- **E**ducate yourself about your illness. Learn about the medical tests that are prescribed and your treatment plan.
- **A**sk a trusted family member or friend to be your advocate (advisor or supporter).
- **K**now which medicines you take and why you take them. Medication errors are the most common health care mistakes.
- **U**se a hospital, clinic, surgery center, or other type of health care organization that has been checked out carefully. For example, TJC visits hospitals to see if they are meeting TJC quality standards.
- **P**articipate in all decisions about your treatment. You are the center of the health care team.

In addition, patients are advised that they have a right to be informed about the care they will receive, obtain information about care in their

preferred language, know the names of their caregivers, receive treatment for pain, receive an up-to-date list of current medications, and expect that they will be heard and treated with respect.

Teach information that patients and their families need. You frequently clarify information provided by health care providers and are the primary source of information that patients need to adjust to health problems (Bastable, 2014). However, it is also important to understand patients' preferences for what they wish to learn. For example, a patient requests information about a new medication, or family members question the reason for their mother's pain. Identifying the need for teaching is easy when patients request information. However, a patient's need for teaching is often less obvious. To be an effective educator, the nurse has to do more than just pass on facts. Carefully determine what patients need to know and find the time to educate them when they are ready to learn. When you value and provide education, patients are better prepared to assume health care responsibilities. Nursing research about patient education supports the positive impact of patient education on patient outcomes (Box 25-1).

Teaching as Communication

The teaching process closely parallels the communication process (see Chapter 24). Effective teaching depends in part on effective interpersonal communication. An educator applies each element of the communication process while providing information to learners. Thus the educator and learner become involved together in a teaching process that increases the learner's knowledge and skills.

The steps of the teaching process are similar to those of the communication process. You use patient requests for information or perceive a need for information because of a patient's health restrictions or the recent diagnosis of an illness. Then you identify specific **learning objectives** to describe the behaviors the learner will exhibit as a result of successful instruction (Bastable, 2014).

The nurse is the sender who conveys a message to the patient. Many intrapersonal variables influence your style and approach. Attitudes, values, emotions, cultural perspective, and knowledge influence the way information is delivered. Past experiences with teaching are also helpful for choosing the best way to present necessary content.

The receiver in the teaching-learning process is the learner. A number of intrapersonal variables affect motivation and ability to learn. Patients are ready to learn when they express a desire to do so and are more likely to receive your message when they understand the content. Attitudes, anxiety, and values influence the ability to understand a message. The ability to learn depends on factors such as emotional and physical health, education, cultural perspective, patients' values about their health, the stage of development, and previous knowledge.

Effective communication involves feedback. An effective educator provides a mechanism for evaluating the success of a teaching plan and then provides positive reinforcement (Bastable, 2014). This type of response reinforces health behavior and promotes continued self-management. You need to provide feedback both during and at the completion of each instructional encounter. Feedback needs to demonstrate the success of the learner in achieving objectives (i.e., the learner verbalizes information or provides a return demonstration of skills learned). Feedback you receive from the learner is equally important because it indicates the effectiveness of instruction and whether or not you need to modify your approach.

DOMAINS OF LEARNING

Learning occurs in three domains: cognitive (understanding), affective (attitudes), and psychomotor (motor skills) (Bastable, 2014). Health

BOX 25-1   EVIDENCE-BASED PRACTICE

The Effectiveness of Individualized Patient Education in Self-Management of Diabetes

PICO Question: In patients with poorly controlled diabetes, does individualized patient education result in better glucose control compared with patients who participate in group education and those who receive no assigned education?

Evidence Summary

As of 2012, 29.1 million people in the world have diabetes (CDC, 2014). The majority of these people do not receive any formal diabetes education. Diabetes self-management education (DSME) is an essential element of care for people with diabetes to gain the knowledge necessary to manage the disease and prevent many of its potential complications (Haas et al., 2013). Although there are many approaches to diabetes education, little literature is available that supports one model over another, and systematic reviews on DSME have rated its quality as moderate to poor. Research that compared individual education (IE) to group education (GE) and usual care (no assigned education) found that participants who received IE resulted in better glucose control outcomes and more improved psychosocial and behavioral outcomes than did those assigned to group education or usual care (Sperl-Hillen et al., 2011). Quality DSME curricula contain the following seven components: physical activity, healthy eating, taking medications, monitoring blood glucose, problem solving, risk reduction, and healthy coping. However, to be successful it is necessary that content be tailored to match the specific needs of an individual and modified on the basis of the patient's medical history, age, cultural background, literacy level, support system, and financial status. Nurses who account for these variables when creating a new educational program will deliver content that is more relevant and engaging and can lead to improved patient outcomes (Haas et al., 2013; Sperl-Hillen et al., 2011).

Application to Nursing Practice

- Individuals with poorly controlled diabetes who receive IE often experience better patient outcomes, including improved overall blood glucose control, improved physical activity and nutrition scores, and greater patient satisfaction.
- The process of DSME needs to be patient centered and address the entire range of each participant's personal profile and medical history.
- Work with your patients to create a personalized agenda and select discussion topics that align with individual goals and values.
- You need to ensure that all information and educational materials are delivered at an appropriate literacy level and make use of interpreters when necessary.

---

topics involve one or all domains or any combination of the three. You often work with patients who need to learn in each domain. For example, patients diagnosed with diabetes need to learn how diabetes affects the body and how to control blood glucose levels for healthier lifestyles (cognitive domain). In addition, patients begin to accept the chronic nature of diabetes by learning positive coping mechanisms (affective domain). Finally many patients living with diabetes learn to test their blood glucose levels at home. This requires learning how to use a glucose meter (psychomotor domain). The characteristics of learning within each domain influence your teaching and evaluation methods. Understanding each learning domain prepares you to select proper teaching techniques and apply the basic principles of learning (Box 25-2).

Cognitive Learning

Cognitive learning requires thinking and encompasses the acquisition of knowledge and intellectual skills (Billings and Halstead, 2012; Krau, 2011). The revised taxonomy of six cognitive behaviors is hierarchical and increases in complexity as in the following list:
- Remembering: Learning new facts or information and being able to recall them
- Understanding: Ability to understand the meaning of learned material
- Applying: Using abstract, newly learned ideas in an actual situation
- Analyzing: Breaking down information into organized parts
- Evaluating: Ability to judge the value of something for a given purpose
- Creating: Ability to apply knowledge and skills to create something new

Affective Learning

Affective learning deals with expression of feelings and development of values, attitudes, and beliefs (Billings and Halstead, 2012; Krau, 2011). Values clarification (see Chapter 22) is an example of affective learning. The simplest behavior in the hierarchy is receiving, and the most complex is characterizing. Affective learning includes the following:
- Receiving: Learner is passive and needs only to pay attention and receive information
- Responding: Requires active participation through listening and reacting verbally and nonverbally
- Valuing: Attaching worth and value to the acquired knowledge as demonstrated by the learner's behavior
- Organizing: Developing a value system by identifying and organizing values according to their worth
- Characterizing: Acting and responding with a consistent value system; requires introspection and self-examination of one's own values in relation to an ethical issue or particular experience

Psychomotor Learning

Psychomotor learning involves acquiring motor skills that require coordination and the integration of mental and physical movements such as the ability to walk or use an eating utensil (McDonald, 2014). The simplest behavior in the hierarchy is perception, whereas the most complex is origination. Psychomotor learning includes the following:
- Perception: Being aware of objects or qualities through the use of sensory stimulation
- Set: Readiness to take a particular action; there are three sets: mental, physical, and emotional
- Guided response: Early stages of learning a particular skill under the guidance of an instructor that involves imitation and practice of a demonstrated act
- Mechanism: Higher level of behavior in which a person gains confidence and proficiency in performing a skill that is more complex or involves several more steps than a guided response
- Complex overt response: Smoothly and accurately performing a motor skill that requires complex movement patterns
- Adaptation: Motor skills are well developed and movements can be modified when unexpected problems occur
- Origination: Using existing psychomotor skills to create new movement patterns and perform them as needed in response to a particular situation or problem

BASIC LEARNING PRINCIPLES

To teach effectively and efficiently, you must first be aware of the factors that influence how a person learns (Bastable, 2014). Achievement of the desired learning outcomes depends on a number of factors, including an individual's motivation and ability to learn and the context and environment where learning will take place. Motivation underlies a

person's desire or willingness to learn. Previous knowledge, experience, attitudes, and sociocultural factors all influence a person's motivation. The ability to learn depends on physical and cognitive attributes, developmental level, physical wellness, and intellectual thought processes. Both a patient's willingness and ability to become involved in learning influence your teaching approach.

A person's learning style affects his or her preferences for learning. People process information in a number of ways: through seeing and hearing, reflecting and acting, reasoning logically and intuitively, and analyzing and visualizing. Effective teaching plans incorporate a combination of activities that target a variety of learning styles (Billings and Halstead, 2012). When you tailor your teaching approach to meet your patient's needs and learning style, you will optimize the learning experience at the individual level.

Motivation to Learn

Attentional Set. An attentional set is the mental state that allows the learner to focus on and comprehend a learning activity. Before learning anything, patients must give attention to, or concentrate on, the information to be learned. Physical discomfort, anxiety, and environmental distractions influence the ability to focus. Therefore determine a patient's level of comfort before beginning a teaching plan and ensure that the patient is able to focus on the information.

As anxiety increases, a patient's ability to pay attention often decreases. Anxiety is uneasiness or worry resulting from anticipating a threat or danger. When faced with change or the need to act differently, a person often feels anxious. A mild level of anxiety motivates learning. However, a high level of anxiety prevents learning from occurring. It incapacitates a person, creating an inability to focus on anything other than relieving the anxiety. Assess for and moderate the patient's anxiety (see Chapter 38) before educating to improve his or her comprehension and understanding of the information given (Bastable, 2014).

Motivation.   **Motivation** is a force that acts on or within a person (e.g., an idea, emotion, or a physical need) to cause the person to behave in a particular way (Miller and Stoeckel, 2015). If a person does not want to learn, it is unlikely that learning will occur. You assess a patient's motivation to learn and what the patient needs to know to promote adherence to his or her prescribed therapy. Unfortunately not all people are interested in maintaining health. Many do not adopt new health behaviors or change unhealthy behaviors unless they perceive a disease as a threat, overcome barriers to changing health practices, and see the benefits of adopting a healthy behavior. For example, some patients with lung disease continue to smoke. No therapy has an effect unless a person believes that health is important and that the therapy will improve health.

Use of Theory to Enhance Motivation and Learning. Health education often involves changing attitudes and values that are not easy to change simply through transfer of information. Therefore it is important for you to use various theory-based interventions when developing patient education plans. Learning theories focus on how individuals learn and can facilitate the teaching-learning process by creating the desired climate and guiding the selection of instructional strategies. Because of the complexity of patient education, different theories and models are available to guide patient education. Using a theory that matches a patient's needs and personal learning preferences allows the patient to become an active participant, leading to effective instruction. Social learning theory provides one of the most useful approaches to patient education because it considers the personal characteristics of the learner, behavior patterns, and the environment and guides the educator in developing effective teaching interventions

that result in improved motivation and enhanced learning (Bastable, 2014; Sanderson et al., 2012).

According to social learning theory, a person's state of mind and intrinsic motivational factors (i.e., sense of accomplishment, pride, or confidence) reinforce behaviors and influence learning (Burkhart et al., 2012). This type of internal reward system allows a person to attain desired outcomes and avoid undesired outcomes, resulting in improved motivation. **Self-efficacy**, a concept included in social learning theory, refers to a person's perceived ability to successfully complete a task. When people believe that they are able to execute a particular behavior, they are more likely to perform the behavior consistently and correctly.

Self-efficacy beliefs come from four sources: enactive mastery experiences, vicarious experiences, verbal persuasion, and physiological and affective states (Bandura, 1997). Understanding the four sources of self-efficacy allows you to develop interventions to help patients adopt healthy behaviors. For example, a nurse who is wishing to teach a child recently diagnosed with asthma how to correctly use an inhaler expresses personal belief in the child's ability to use the inhaler (verbal persuasion). Then the nurse demonstrates how to use the inhaler (vicarious experience). Once the demonstration is complete, the child uses the inhaler (enactive mastery experience). As the child's wheezing and anxiety decrease after the correct use of the inhaler, he or she experiences positive feedback, further enhancing his or her confidence to use it (physiological and affective states). Interventions such as these enhance perceived self-efficacy, which in turn improves the achievement of desired outcomes.

Self-efficacy is a concept included in many health promotion theories because it often is a strong predictor of healthy behaviors and because many interventions improve self-efficacy, resulting in improved lifestyle choices (Bandura, 1997). Because of its use in theories and research studies, many evidence-based teaching interventions include a focus on self-efficacy. When nurses implement interventions to enhance self-efficacy, their patients frequently experience positive outcomes. For example, researchers associated interventions that included self-efficacy with effective management of diabetes and glycemic control (Tan et al., 2011), self-management of asthma in school-age children (Burkhart et al., 2012), and improved functioning along with a reduction in symptoms related to anxiety and depression (Brown et al., 2014).

Psychosocial Adaptation to Illness. A temporary or permanent loss of health is often difficult for patients to accept. They need to grieve, and the process of grieving gives them time to adapt psychologically to the emotional and physical implications of their illnesses. The stages of grieving (see Chapter 37) include a series of responses that patients experience during a loss such as illness. They experience these stages at different rates and sequences, depending on their self-concept before illness, the severity of the illness, and the changes in lifestyle that the illness creates. Effective, supportive care guides the patient through the grieving process.

Readiness to learn is related to the stage of grieving (Table 25-1). Patients cannot learn when they are unwilling or unable to accept the reality of illness. However, properly timed teaching facilitates adjustment to illness or disability. Identify a patient's stage of grieving on the basis of his or her behaviors. When a patient enters the stage of acceptance, the stage compatible with learning, introduce a teaching plan. Continuous assessment of a patient's behaviors determines the stages of grieving. Teaching continues as long as the patient remains in a stage conducive to learning.

Active Participation. Learning occurs when a patient is actively involved in an educational session (Edelman et al., 2014). A patient's

TABLE 25-1 Relationship Between Psychosocial Adaptation to Illness, Grief, and Learning

Stage	Patient's Behavior	Learning Implications for Nurse and Family Caregiver	Rationale
Denial or disbelief	Patient avoids discussion of illness ("I'm fine; there's nothing wrong with me"), withdraws from others, and disregards physical restrictions. Patient suppresses and distorts information that has not been presented clearly.	Provide support, empathy, and careful explanations of all procedures while they are being done. Let patient know that you are available for discussion. Explain situation to family or significant other if appropriate. Teach in present tense (e.g., explain current therapy).	Patient is not prepared to deal with problem. Any attempt to convince or tell patient about illness results in further anger or withdrawal. Provide only information patient pursues or absolutely requires.
Anger	Patient blames and complains and often directs anger toward nurse or others.	Do not argue with patient but listen to concerns. Teach in present tense. Reassure family and significant others that patient's anger is normal.	Patient needs opportunity to express feelings and anger; he or she is still not prepared to face future.
Bargaining	Patient offers to live better life in exchange for promise of better health. ("If God lets me live, I promise to quit smoking.")	Continue to introduce only reality. Teach only in present tense.	Patient is still unwilling to accept limitations.
Resolution	Patient begins to express emotions openly, realizes that illness has created changes, and begins to ask questions.	Encourage expression of feelings. Begin to share information needed for future and set aside formal times for discussion.	Patient begins to perceive need for assistance and is ready to accept responsibility for learning.
Acceptance	Patient recognizes reality of condition, actively pursues information, and strives for independence.	Focus teaching on future skills and knowledge required. Continue to teach about present occurrences. Involve family/significant other in teaching information for discharge.	Patient is more easily motivated to learn. Acceptance of illness reflects willingness to deal with its implications.

involvement in learning implies an eagerness to acquire knowledge or skills. It also improves the opportunity for the patient to make decisions during teaching sessions. For example, when teaching car-seat safety during a parenting class, hold a teaching session in the parking lot where the participants park their cars. Encourage active participation by providing the learners with several different car seats for them to place in their cars. At the completion of this session, the parents are able to determine which type of car seat fits best in their cars and which is the easiest to use. This provides participants with the information needed to purchase the appropriate car seat.

Ability to Learn

Developmental Capability. Cognitive development influences a patient's ability to learn. You can be a competent educator, but if you do not consider a patient's intellectual abilities, teaching is unsuccessful. Learning, like developmental growth, is an evolving process. You need to know a patient's level of knowledge and intellectual skills before beginning a teaching plan. Learning occurs more readily when new information complements existing knowledge. For example, measuring liquid or solid food portions requires the ability to perform mathematical calculations. Reading a medication label or discharge instructions requires reading and comprehension skills. Learning to regulate insulin dosages requires problem-solving skills.

Learning in Children. The capability for learning and the type of behaviors that children are able to learn depend on the child's maturation. Without proper physiological, motor, language, and social development, many types of learning cannot take place. However, learning occurs in children of all ages. Intellectual growth moves from the concrete to the abstract as the child matures. Therefore information presented to children needs to be understandable, and the expected outcomes must be realistic based on the child's developmental stage (Box 25-3). Use teaching aids that are developmentally appropriate

(Figure 25-1). Learning occurs when behavior changes as a result of experience or growth (Hockenberry and Wilson, 2015).

Adult Learning. Teaching adults differs from teaching children. Adults are able to reflect on their current situation critically but sometimes need help to see their problems and change their perspectives. Because adults become independent and self-directed as they mature, they are often able to identify their own learning needs (Billings and Halstead, 2012). Learning needs come from problems or tasks that result from real-life situations. Although adults tend to be self-directed learners, they often become dependent in new learning situations. The amount of information you provide and the amount of time you spend with an adult patient varies, depending on the patient's personal situation and readiness to learn. An adult's readiness to learn is often associated with his or her developmental stage and other events that are occurring in his or her life. Resolve any needs or issues that a patient perceives as extremely important so learning can occur.

Adults have a wide variety of personal and life experiences. Therefore patient learning will be enhanced if they perceive the information to be relevant and are asked to use past experiences to solve real-life problems (Billings and Halstead, 2012). Furthermore, you make education patient centered by developing educational topics and goals in collaboration with the adult patient. Adult patients ultimately are responsible for changing their own behavior. Assessing what an adult patient currently knows, teaching what the patient wants to know, and setting mutual goals improve the outcomes of patient education (Bastable, 2014).

Physical Capability. The ability to learn often depends on a patient's level of physical development and overall physical health. To learn psychomotor skills a patient needs to possess a certain level of strength, coordination, and sensory acuity. For example, it is useless to teach a patient to transfer from a bed to a wheelchair if he or she has

FIGURE 25-1 The nurse uses developmentally appropriate food models to teach healthy eating behaviors to the school-age child.

Any condition (e.g., pain or fatigue) that depletes a person's energy also impairs the ability to learn. For example, a patient who spends a morning having rigorous diagnostic studies is unlikely to be able to learn later in the day because of fatigue. Postpone teaching when an illness becomes aggravated by complications such as a high fever or respiratory difficulty. As you work with a patient, assess energy level by noting the patient's willingness to communicate, the amount of activity initiated, and responses to questions. Temporarily stop teaching if the patient needs rest. You achieve greater teaching success when patients are physically able to actively participate in learning.

Learning Environment

Factors in the physical environment where teaching takes place make learning either a pleasant or a difficult experience (Bastable, 2014). The ideal setting helps a patient focus on the learning task. The number of people included in the teaching session; the need for privacy; the room temperature; and the lighting, noise, ventilation, and furniture in the room are important factors when choosing the setting. The ideal environment for learning is well lit and has good ventilation, appropriate furniture, and a comfortable temperature. A darkened room interferes with a patient's ability to watch your actions, especially when demonstrating a skill or using visual aids such as posters or pamphlets. A room that is cold, hot, or stuffy makes a patient too uncomfortable to focus on the information being presented.

It is also important to choose a quiet setting. A quiet setting offers privacy; infrequent interruptions are best. Provide privacy even in a busy hospital by closing cubicle curtains or taking the patient to a quiet spot. Family caregivers often need to share in discussions in the home. However, patients who are reluctant to discuss the nature of the illness when others are in the room benefit from receiving education in a room separate from household activities such as a bedroom.

Teaching a group of patients requires a room that allows everyone to be seated comfortably and within hearing distance of the educator. Make sure that the size of the room does not overwhelm the group. Arranging the group to allow participants to observe one another further enhances learning. More effective communication occurs as learners observe others' verbal and nonverbal interactions.

❖ NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. There are distinct similarities between the nursing process

insufficient upper body strength. An older patient with poor eyesight or the inability to grasp objects tightly cannot learn to apply an elastic bandage. Therefore do not overestimate the patient's physical development or status. The following physical characteristics are necessary to learn psychomotor skills:

- Size (patient's height and weight should match the task to be performed or the equipment being used)
- Strength (ability of the patient to follow a strenuous exercise program)
- Coordination (dexterity needed for complicated motor skills such as using utensils or changing a bandage)
- Sensory acuity (visual, auditory, tactile, gustatory, and olfactory; sensory resources needed to receive and respond to messages taught)

TABLE 25-2 Comparison of the Nursing and Teaching Processes

Basic Steps	Nursing Process	Teaching Process
Assessment	Collect data about patient's physical, psychological, social, cultural, developmental, and spiritual needs from patient, family, diagnostic tests, medical record, nursing history, and literature.	Gather data about patient's learning needs, motivation, ability to learn, health literacy, and teaching resources from patient, family, learning environment, medical record, nursing history, and literature.
Nursing diagnosis	Identify appropriate nursing diagnoses on basis of assessment findings.	Identify patient's learning needs on basis of three domains of learning. Identify conditions that may interfere with learning.
Planning	Develop an individualized care plan. Set diagnosis priorities on basis of patient's immediate needs, expected outcomes, and patient-centered goals. Collaborate with patient on care plan.	Establish learning objectives stated in behavioral terms. Identify priorities regarding learning needs. Collaborate with patient about teaching plan. Identify type of teaching method to use.
Implementation	Perform nursing care therapies. Include patient as active participant in care. Involve family/significant other in care as appropriate.	Implement teaching methods. Actively involve patient in learning activities. Include family caregiver as appropriate.
Evaluation	Identify success in meeting desired outcomes and goals of nursing care. Alter interventions as indicated when goals are not met.	Determine outcomes of teaching-learning process. Measure patient's achievement of learning objectives. Reinforce information as needed.

and the teaching process. During the assessment phase of the nursing process, determine a patient's health care needs (see Unit 3). During this phase a patient's need for health care information sometimes emerges. When education becomes a part of the care plan, the teaching process begins. Like the nursing process, the teaching process requires assessment—in this case analyzing a patient's learning needs, motivation, and ability to learn. A diagnostic statement specifies the information or skills that a patient requires or identifies factors interfering with learning. Develop specific learning objectives, implement appropriate patient-centered teaching strategies, and use learning principles to ensure that your patient acquires the necessary knowledge and skills. Finally the teaching process requires an evaluation of learning based on learning objectives.

The nursing and teaching processes differ when the nursing process requires assessment of all sources of data to determine a patient's total health care needs. The teaching process focuses on a patient's learning needs and willingness and capability to learn. Table 25-2 compares the teaching and nursing processes.

◆ **Assessment**

Through the Patient's Eyes. When providing patient education, it is important to partner with the patient to ensure safe, compassionate, and coordinated care (QSEN, 2014). During the assessment process thoroughly assess a patient and critically analyze your findings to ensure that you make patient-centered clinical decisions required for safe nursing care. To be successful in teaching a patient, you need to assess all factors that will influence the choice of relevant teaching topics and your approach. This includes the patient's learning needs, motivation to learn, and ability to learn; the teaching environment; the resources available; and any health literacy and learning disabilities. By seeing health care situations "through the patient's eyes," you gain a better appreciation of your patient's knowledge, expectations, and preferences for learning.

Learning Needs. Learning needs, identified by both you and the patient, determine the choice of teaching content. An effective assessment provides the basis for individualized patient teaching (Olsen, 2010). Box 25-4 summarizes examples of specific assessment questions to use in determining a patient's unique learning needs.

Sometimes nurses use formal educational assessment tools to determine their patients' perceived learning needs. Other times they simply identify their patients' expectations during routine assessments. Patients often identify their own learning needs on the basis of the

BOX 25-4 **Nursing Assessment Questions**

Previous Learning and Identification of Learning Needs and Preferences
- What do you want to know about _____?
- What do you know about your illness and your treatment plan?
- Which experiences have you had in the past that are similar to those you are experiencing now?
- Together we can choose the best way for you to learn about your disease. How can I best help you?
- When you learn new information, do you prefer to have it given to you in pictures or written down in words?
- When you give someone directions to your house, do you tell the person how to get there, write out the instructions, or draw a map?

Self-Management
- How does (or will) your illness affect your current lifestyle?
- Which barriers currently exist that prevent you from managing your illness the way you would like to manage it?
- What role do you believe your health care providers should take in helping you manage your illness or maintain health?
- How involved do you want a family member to be in the management of your illness? Who is that family member?

Cultural and Spiritual Influences
- Which cultural or spiritual beliefs do you have regarding your illness and the prescribed treatment?

For Family Caregivers
- When are you available to help, and how do you plan to help your loved one?
- Your spouse needs some help. How do you feel about learning how to assist him or her?
- Tell me how you feel about performing the care activities that your family member requires.

implications of living with their illness. To meet these learning needs, assess what patients view as important information to know. When a patient has a need to know something, he or she is likely to be receptive to information presented. For example, many parents need to know how to care for their new baby. Therefore they are often very receptive to information about infant care (e.g., how to feed the infant and make sure that he or she gets enough sleep).

Determine information that is critical for patients to learn. Learning needs change, depending on a patient's current health status. Because health status is dynamic, assessment is an ongoing activity. Assess the following:

- Information or skills needed by a patient to perform self-care and to understand the implications of a health problem: Health care team members anticipate learning needs related to specific health problems. For example, you teach a young man who has just entered high school how to prevent sexually transmitted infections (STIs).
- Patient experiences (e.g., new or recurring problem, past hospitalization) that influence the need to learn.
- Information that family caregivers require to support the patient's needs: The amount of information needed depends on the extent of a family member's role in helping the patient.

Motivation to Learn. Ask questions to identify and define the patient's motivation. These questions help to determine if a patient is prepared and willing to learn. Assess the following motivational factors:

- Behavior (e.g., attention span, tendency to ask questions, memory, and ability to concentrate during the teaching session)
- Health beliefs and sociocultural background: Norms, values, experiences, and traditions all influence a patient's beliefs and values about health and various therapies, communication patterns, and perceptions of time (see Chapter 9).
- Perception of the severity and susceptibility of a health problem and the benefits and barriers to treatment
- Perceived ability to perform needed health behaviors
- Desire to learn
- Attitudes about health care providers (e.g., role of patient and nurse in making decisions)
- Learning style preference: As the nurse, any educational effort will be more effective if the chosen method of instruction aligns with your patient's preferred learning style (Billings and Halstead, 2012). Patients who are visual-spatial learners enjoy learning through pictures, visual charts, or any exercise that allows them to visualize concepts. The verbal/linguistic learner demonstrates strength in the language arts and therefore prefers learning by listening or reading information. Kinesthetic learners process knowledge by moving and participating in hands-on activities. Role-play and return demonstrations are popular activities for the kinesthetic learner. Patients who learn through logical-mathematical reasoning think in terms of cause and effect and respond best when required to predict logical outcomes. Specific teaching strategies could include open-ended questioning or problem-solving exercises. Assess and inquire about your patient's learning preferences when planning your instruction.

Ability to Learn. Determine a patient's physical and cognitive ability to learn. Health care providers often underestimate patients' cognitive deficits. Many factors impair the ability to learn, including preexisting physical or mental illness, fatigue, body temperature, electrolyte imbalance, oxygenation status, and blood glucose level. In any health care setting several of these factors often influence a patient at the same time. Assess the following factors related to the ability to learn:

- Physical strength, endurance, movement, dexterity, and coordination: Determine the extent to which a patient can perform skills by having him or her practice with equipment that will be used in self-care at home.

- Sensory deficits (see Chapter 49) that affect a patient's ability to understand or follow instruction
- Patient's reading level: This is often difficult to assess because patients who are functionally illiterate are often able to conceal it by using excuses such as not having the time or not being able to see. One way to assess a patient's reading level and level of understanding is to ask the patient to read instructions from an educational handout and then explain their meaning (see the discussion of health literacy below).
- Patient's developmental level: This influences the selection of teaching approaches (see Box 25-3).
- Patient's cognitive function, including memory, knowledge, association, and judgment
- Pain, fatigue, depression, anxiety, or other physical or psychological symptoms that interfere with the ability to maintain attention and participate: In acute care settings a patient's physical condition can easily prevent a patient from learning.

Teaching Environment. The environment for a teaching session needs to be conducive to learning. Assess the following environmental factors:

- Distractions or persistent noise: A quiet area is essential for focusing on the topic and effective learning.
- Comfort of the room, including ventilation, temperature, lighting, furniture, and size
- Room facilities and available equipment

Resources for Learning. A patient frequently requires the support of family members or significant others. If this support is necessary, assess the readiness and ability of family caregivers to learn the information necessary for the care of the patient. Also review resources within the home environment. Assess the following:

- Patient's willingness to have family caregivers involved in the teaching plan and provide health care: Information about a patient's health care is confidential unless the patient chooses to share it. Sometimes it is difficult for a patient to accept the help of family caregivers, especially when bodily functions are involved.
- Family caregiver's perceptions and understanding of a patient's illness and its implications: Family caregivers' perceptions should match those of the patient; otherwise conflicts occur in the teaching plan.
- Family caregiver's willingness and ability to participate in care: If a patient chooses to share information about his or her health status with family members, they need to be responsible, willing, and physically and cognitively able to assist in care activities such as bathing or administering medications. Not all family members meet these requirements.
- Resources: These include financial or material resources such as having the ability to obtain health care equipment.
- Teaching tools, including brochures, audiovisual materials, or posters: Printed material needs to present current information that is written clearly and logically and matches the patient's reading level.

Health Literacy and Learning Disabilities. Research shows that health literacy is a strong predictor of a person's health status (Osborn et al., 2011). The World Health Organization (WHO, 2015) defines **health literacy** as the cognitive and social skills that determine the motivation and ability of individuals to gain access to, understand, and use information in ways that promote and maintain good health. Health literacy pertains not only to a patient's ability to read and

comprehend health-related information, but to having the skills to problem solve, articulate, and make appropriate health care decisions as well (Ingram, 2011). People most likely to be at risk for low health literacy include the elderly (age 65 years and older), minority populations, immigrant populations, people of low income, and people with chronic mental and/or physical health conditions. For example, approximately half of Medicare/Medicaid recipients read below the fifth-grade level (National Network of Libraries of Medicine, 2014).

Functional illiteracy, the inability to read above a fifth-grade level, is a major problem in America today. The National Assessment of Adult Literacy Survey (NAALS), conducted in 2003 by the National Center for Education Statistics, assessed the extent of literacy skills in Americans over the age of 16 (Kutner et al., 2006). Results from a 2015 survey by the U.S. Department of Education, National Institute of Literacy (U.S. Department of Education, 2015) found that 32 million American adults had below-basic levels of health literacy. Older adults, men, people who did not speak English before entering school, people living below poverty level, and people without a high school education tended to have lower health literacy scores.

To compound the problem, the readability of printed health education material is often above the patient's reading level, which can lead to misinterpretation and prevent patients from asking for help (Gargoum and O'Keeffe, 2014; Protheroe et al., 2015). This discrepancy results in unsafe care. Health literacy is one of the most important predictors of health outcomes. Studies have shown that patients with low literacy levels are 1.5 to 3 times more likely to experience adverse health outcomes and an increased risk for hospitalization than those with higher literacy levels (Kasabwala et al., 2012). To ensure patient safety, all health care providers need to ensure that information is presented clearly and in a culturally sensitive manner (TJC, 2015a). Both the American Medical Association (AMA) and National Institutes of Health (NIH) recommend that patient education materials be written at the sixth-grade level or lower (Kasabwala et al., 2012).

Because health literacy influences how you deliver teaching strategies, it is critical for you to assess a patient's health literacy before providing instruction. Assessing health literacy is challenging, especially in busy clinical settings where often there is little time to conduct a thorough health literacy assessment. However, all health care providers need to identify problems and provide appropriate education to people who have special health literacy needs (TJC, 2015a). Research shows that many Americans read and understand information that is 3 to 5 years below their last year of formal education.

To assess health literacy, ask patients to perform simple literacy skills. For example, can a patient read a medication label back to you correctly? After you give a simple 1-minute explanation of a diet or exercise program, can the patient explain it back to you? Can a patient correctly describe in his or her own words the information in a written handout? Most people with low health literacy say they are good readers even if they cannot read (Lee et al., 2010). A variety of screening tools are available to test literacy. The Wide Range Achievement Test (WRAT 3) is a word-recognition screening test that evaluates reading, spelling, and arithmetic skills for patients from 5 to 74 years of age. The Rapid Estimate of Adult Literacy in Medicine (REALM) uses pronunciation of health care terms to determine a patient's ability to read medical vocabulary. The Cloze test, used to assess comprehension of health education materials, asks patients to fill in the blanks that are in a written paragraph.

In addition to illiteracy, assess patients for learning disabilities. For example, many self-care behaviors require an understanding of mathematics, including computation and fractions. If a learning disability impairs a patient's ability to effectively use mathematics skills, teaching

BOX 25-5 Nursing Diagnostic Process

Deficient Knowledge (Psychomotor) Regarding Use of Crutches Related to Lack of Experience

Assessment Activities	Defining Characteristics
Have patient describe how to walk with crutches.	Patient states that he or she has not received information about use of crutches. Patient asks questions about how to use crutches.
Have patient demonstrate three-point crutch walking on level surfaces and up stairs.	Patient uses crutches inappropriately. Patient cannot go up or down stairs on crutches.

is challenging, especially when trying to teach him or her about complex medication dosages and frequencies. Although not considered a learning disability, attention-deficit hyperactivity disorder (ADHD) also affects a patient's ability to learn. Patients with ADHD frequently experience inattention, hyperactivity, and impulsivity, which makes it difficult for them to stay focused during educational sessions, making learning challenging (Learning Disabilities Association of America, 2015).

Patients who have low health literacy or learning disabilities may be ashamed of not being able to understand you and often try to mask their inability to comprehend information. Therefore make sure that you are sensitive and maintain a therapeutic relationship with your patients while assessing their ability to learn. Appreciating the unique qualities of your patients helps to ensure safe and effective patient care (QSEN, 2014).

◆ Nursing Diagnosis

After assessing information related to the patient's ability and need to learn, interpret data and cluster-defining characteristics to form diagnoses that reflect his or her specific learning needs or factors affecting the ability to learn (Box 25-5). This ensures that teaching will be goal directed and individualized. If a patient has several learning needs, the nursing diagnoses guide priority setting. When the nursing diagnosis is *Deficient Knowledge,* the diagnostic statement describes the specific type of learning need and its cause (e.g., *Deficient Knowledge* regarding a surgical procedure related to lack of recall and exposure to information). Patients often require education to support resolution of their various health problems. Examples of nursing diagnoses that indicate a need for education include the following:

- *Decisional Conflict*
- *Deficient Knowledge (Affective, Cognitive, Psychomotor)*
- *Ineffective Health Maintenance*
- *Noncompliance*
- *Readiness for Enhanced Health Management*
- *Self-Neglect*

When you can manage or eliminate health care problems through education, the related factor of a diagnostic statement is *Deficient Knowledge.* For example, an older adult is having difficulty managing a medication regimen that involves a number of newly prescribed medications that she has to take at different times of the day. The nursing diagnosis is *Ineffective Health Maintenance related to deficient knowledge regarding scheduling of medications*. In this case educating the patient about her medications and the correct dosage schedules improves her ability to schedule and take them as directed. When you identify conditions that cause barriers to effective learning (e.g.,

nursing diagnosis of *Acute Pain* or *Activity Intolerance),* teaching is inappropriate. In these cases delay teaching until the nursing diagnosis is resolved or the health problem controlled.

◆ Planning

After determining the nursing diagnoses that identify a patient's learning needs, develop a teaching plan, determine goals and expected outcomes, and involve the patient in selecting learning experiences (see the Nursing Care Plan). Expected outcomes of an education plan are learning objectives. They guide the choice of teaching strategies and approaches with a patient. Patient participation ensures a more relevant, meaningful plan.

Goals and Outcomes. Goals of patient education identify what a patient needs to achieve to gain a better understanding of the information provided and better manage his or her illness (e.g., "achieves ostomy self-care"). Outcomes describe behaviors that identify a patient's ability to do something on completion of teaching such as empties colostomy bag or administers an injection. When developing outcomes, conditions or time frames need to be realistic and meet the patient's needs (e.g., "will identify the side effects of aspirin by discharge"). Consider conditions under which the patient or family will typically perform the behavior (e.g., "will walk from bedroom to bathroom using crutches"). If possible, include the patient when establishing learning goals and outcomes and serve as a resource in setting the minimum criteria for success.

In some health care settings nurses develop written teaching plans. The teaching plan includes topics for instruction, resources (e.g., equipment, teaching booklets, and referrals to special educational programs), recommendations for involving family, and objectives of the teaching plan. Some plans are very detailed, whereas others are in outline form. Detailed chronic disease self-management plans (CDSMP), such as those used with patients who have type 2 diabetes, have been shown to result in significant improvements in health indicators and behaviors (Lorig et al., 2013). Use the plan to provide continuity of instruction. The more specific the plan, the easier it is to follow.

The setting influences the complexity of any teaching plan. In an acute care setting plans are concise and focused on the primary learning needs of the patient because there is limited time for teaching. Home care and outpatient clinic teaching plans are usually more comprehensive in scope because you often have more time to instruct patients and patients are often less anxious in outpatient settings.

Setting Priorities. Include the patient when determining priorities for patient education. Base priorities on a patient's immediate needs, nursing diagnoses, and the goals and outcomes established for him or her. Priorities also depend on what a patient perceives to be most important, his or her anxiety level, and the amount of time available to teach. A patient's learning needs are set in order of priority. For example, a patient recently diagnosed with coronary artery disease has *Deficient Knowledge related to the illness and its implications.* The patient benefits most by first learning about the correct way to take nitroglycerin and how long to wait before calling for help when chest pain occurs. Once you assist in meeting patient needs related to basic survival, you can discuss other topics such as exercise and nutritional changes.

Timing. When is the right time to teach? Before a patient enters a hospital? When a patient first enters a clinic? At discharge? At home? Each is appropriate because patients continue to have learning needs as long as they stay in the health care system. Plan teaching activities for a time when a patient is most attentive, receptive, and alert and

organize the patient's activities to provide time for rest and teaching-learning interactions.

Timing is sometimes difficult because the emphasis is often on a patient's discharge from a hospital. For example, it takes several days after surgery for a patient to be alert and comfortable enough to learn. By the time a patient feels ready to learn, discharge is already scheduled. Therefore, to improve patient outcomes, anticipate patients' educational needs before they occur and involve family if possible.

Although prolonged sessions cause concentration and attentiveness to decrease, make sure that teaching sessions are not too brief. A patient needs time to comprehend the information and give feedback. It is easier for patients to tolerate and retain interest in the material during frequent sessions lasting 10 to 15 minutes. However, factors such as shorter hospital stays and lack of insurance reimbursement for outpatient education sessions often necessitate longer teaching sessions.

The frequency of sessions depends on a learner's abilities and the complexity of the material. For example, a child newly diagnosed with diabetes requires more visits to an outpatient center than the older adult who has had diabetes for 15 years and lives at home. Make sure that intervals between teaching sessions are not so long that the patient forgets information. Home care nurses frequently reinforce learning during home visits when patients are discharged from the hospital.

Organizing Teaching Material. An effective educator carefully considers the order of information to present. When a nurse has an ongoing relationship with a patient, as in the case of home health or case management, an outline of content helps organize information into a logical sequence. Material needs to progress from simple to complex because a person must learn the simple facts and concepts before learning how to make associations or complex interpretations of ideas. Staff nurses in an acute care setting often focus on the simpler, more essential concepts, whereas home health nurses can better address complex issues. For example, to teach a woman how to feed her husband who has a gastric tube, the nurse first teaches the wife how to measure the tube feeding and manipulate the equipment. Once the wife has accomplished this, the process of administering the feeding occurs.

Begin instruction with essential content because patients are more likely to remember information that you teach early in the teaching session. For example, immediately after surgical removal of a malignant breast tumor, a patient has many learning needs. To ensure that all essential material is covered, start with content considered to be high priority such as how to monitor the incision site for signs of infection; deal with the emotional aspects of a cancer diagnosis and complete the teaching session with informative but less critical content. Repetition reinforces learning. A concise summary of key content helps the learner remember the most important information (Bastable, 2014).

Teamwork and Collaboration. During planning choose appropriate teaching methods, encourage the patient to offer suggestions, and make referrals to other health care professionals (e.g., dietitians and physical, speech, or occupational therapists) when appropriate. As a nurse you are the member of the health care team primarily responsible for ensuring that all patient educational needs are met. However, sometimes patient needs are highly complex. In these cases identify appropriate health education resources within the health care system or the community during planning. Examples of resources for patient education include diabetes education clinics, cardiac rehabilitation programs, prenatal classes, and support groups. When patients receive education and support from these types of resources, the nurse obtains a referral order if necessary, encourages patients to attend educational sessions, and reinforces information taught. Resources that specialize in a particular health need (e.g., wound care or ostomy specialists) are integral to successful patient education.

◎ NURSING CARE PLAN

Deficient Knowledge: Surgical Procedure

ASSESSMENT

Connie, a nurse in a surgeon's office, is preparing Mr. Holland for a colon resection, which is scheduled in 1 week. Mr. Holland is 75 years old and was recently diagnosed with colorectal cancer. Connie's assessment focuses on Mr. Holland's readiness to learn and factors that affect his ability to understand the procedure and related postoperative care.

*Assessment Activities**	*Findings/Defining Characteristics*
Assess Mr. Holland's readiness to learn and ask what his primary doctor has already told him about the surgery.	Mr. Holland responds, "**I can't remember what the doctor told me when I saw him last week,** but I need to know how to take care of myself. My surgery is scheduled for next week."
Ask Mr. Holland to explain what he knows about postoperative care, including performing a return demonstration of deep breathing and coughing.	**Mr. Holland is unable to describe postoperative care or provide a return demonstration of deep breathing and coughing.**
Observe Mr. Holland's behavior during the office visit.	Mr. Holland states he is anxious but asks appropriate questions. He maintains good contact with the nurse.
Ask patient how he prefers to learn.	Mr. Holland says, "I am a visual learner."

*****Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Deficient Knowledge: surgical procedure related to lack of recall and exposure to information

PLANNING

Goals	*Expected Outcomes (NOC)*†
	Knowledge: Treatment Procedure
Mr. Holland will describe preoperative and postoperative care activities before surgery.	Mr. Holland verbalizes understanding of the surgical procedure, postoperative monitoring, and activity planned on the day of surgery.
Mr. Holland will participate in postoperative care during hospitalization.	Mr. Holland demonstrates deep breathing and coughing.
	Mr. Holland advances his level of physical activity after his surgery.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 5, St Louis, 2013, Mosby.

INTERVENTIONS (NIC)‡

Learning Readiness Enhancement

Provide a nonthreatening environment in the consultation area. Sit with the patient and encourage any questions during instruction.

Learning Facilitation

Offer Mr. Holland teaching modalities that match his learning preference (e.g., brochures and DVDs describing preoperative and postoperative care) while explaining preoperative and postoperative care.

Explain postoperative care activities, including frequent monitoring; demonstrate deep breathing and coughing; and have Mr. Holland perform return demonstration.

RATIONALE

The adult patient's learning is enhanced when the patient is ready to learn and when he or she perceives the information to be important (Bastable, 2014).

Providing patients with educational methods that use multiple senses is effective in educating older adults. Older adults prefer written handouts in large fonts (Meiner, 2014).

Improving self-efficacy by using role modeling and having the patient perform behaviors enhance the successful adoption of healthy behaviors (Bandura, 1997).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 6, St Louis, 2013, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Mr. Holland to describe what will happen before and after surgery.	Mr. Holland is able to state understanding of preoperative and postoperative care activities.	Mr. Holland's anxiety level has decreased, and he reports that he is ready for surgery.
Observe patient as he demonstrates deep breathing and coughing and advances his activity after surgery.	Mr. Holland is able to deep breathe and cough after surgery, but he is hesitant to advance his activity level.	Patient has not totally achieved outcome of advancing activity after surgery. Manage barriers inhibiting attainment of this outcome (e.g., pain) and continue to encourage and educate patient.

◆ Implementation

The implementation of patient education depends on your ability to critically analyze assessment data to form diagnoses that identify patient learning needs. On the basis of the diagnoses, you develop a teaching plan (see Care Plan). Carefully evaluate the learning objectives and determine which teaching and learning principles most effectively and efficiently help the patient meet expected goals and outcomes. Implementation involves believing that each interaction with a patient is an opportunity to teach. Use evidence-based interventions to create an effective learning environment.

Maintaining Learning Attention and Participation. Active participation is key to learning. People learn better when more than one of the senses is stimulated. Audiovisual aids and role play are good teaching strategies. By actively experiencing a learning event, a person is more likely to retain knowledge. An educator's actions also increase learner attention and interest. When conducting a discussion with a learner, an educator stays active by changing the tone and intensity of his or her voice, making eye contact, and using gestures that accentuate key points of discussion. An effective educator engages learners and talks and moves among a group rather than remaining stationary

behind a lectern or table. A learner remains interested in an educator who is actively enthusiastic about the subject under discussion.

Building on Existing Knowledge. A patient learns best on the basis of preexisting cognitive abilities and knowledge. Thus an educator is more effective when he or she presents information that builds on a learner's existing knowledge. A patient quickly loses interest if a nurse begins with familiar information. For example, a patient who has lived with multiple sclerosis for several years is beginning a new medication that is given subcutaneously. Before teaching the patient how to prepare the medication and give the injection, the nurse asks him or her about previous experience with injections. On assessment the nurse learns that the patient's father had diabetes and the patient administered the insulin injections. The nurse individualizes the teaching plan by building on the patient's previous knowledge and experience with insulin injections.

Teaching Approaches. A nurse's approach in teaching is different from teaching methods. Some situations require an educator to be directive. Others require a nondirective approach. An effective educator concentrates on the task and uses teaching approaches according to the learner's needs. A learner's needs and motives frequently change over time. Thus the effective educator is always aware of the need to modify teaching approaches.

Telling. Use the telling approach when teaching limited information (e.g., preparing a patient for an emergent diagnostic procedure). If a patient is highly anxious but it is vital for information to be given, telling is effective. When using telling, the nurse outlines the task that a patient will perform and gives explicit instructions. There is no opportunity for feedback with this method.

Participating. In the participating approach a nurse and patient set objectives and become involved in the learning process together. The patient helps decide content, and the nurse guides and counsels the patient with pertinent information. In this method there is opportunity for discussion, feedback, mutual goal setting, and revision of the teaching plan. For example, a parent caring for a child with leukemia learns how to care for the child at home and recognize problems that need to be reported immediately. The parent and nurse collaborate on developing an appropriate teaching plan. After each teaching session is completed, the parent and nurse review the objectives together, determine if the objectives were met, and plan what will be covered in the next session.

Entrusting. The entrusting approach provides a patient the opportunity to manage self-care. The patient accepts responsibilities and performs tasks correctly and consistently. The nurse observes the patient's progress and remains available to assist without introducing more new information. For example, a patient has been managing type 2 diabetes well for 10 years with oral medications, diet, and exercise. However, 1 year ago his diabetes changed, and it was difficult to control his glucose level. As a result, the oral medications were discontinued and insulin was added to his self-management plan.

Because of arthritis in his hips, the patient now needs to walk instead of jog during exercise. The patient understands how to adjust insulin when exercising to prevent hypoglycemia. The nurse instructs the patient about the newly prescribed exercise therapy and allows him or her to adjust insulin dosages independently.

Reinforcing. **Reinforcement** requires the use of a stimulus to increase the probability of a desired response. A learner who receives reinforcement before or after a desired learning behavior is more likely to repeat that behavior. Reinforcers can be positive or negative. Positive reinforcement such as a smile or verbal praise promotes desired behaviors. Although negative reinforcement such as frowning or criticizing can decrease an undesired response, it may also discourage participation and cause the learner to withdraw (Bastable, 2014). The effects of negative reinforcement are less predictable and often undesirable.

Reinforcers come in the form of social acknowledgments (e.g., nods, smiles, words of encouragement), pleasurable activities (e.g., walks or play time), and tangible rewards (e.g., toys or food). Choosing an appropriate reinforcer to alter behavior requires careful observation of an individual's response to specific stimuli. When a nurse works with a patient, most reinforcers are social; however, material reinforcers may work well with young children. In adults reinforcement is more effective when the nurse has established a therapeutic relationship with the patient. Whatever the form, it is important that reinforcement closely follow the desired behavior. Timing is essential so that a clear correlation between the desired behavior and reward is established (Bastable, 2014).

Incorporating Teaching with Nursing Care. Many nurses find that they are able to teach more effectively while delivering nursing care. This becomes easier as you gain confidence in your clinical skills. For example, while hanging blood you explain to the patient why the blood is necessary and the symptoms of a transfusion reaction that need to be reported immediately. Another example is explaining the side effects of a medication while administering it. An informal, unstructured style relies on the positive therapeutic relationship between nurse and patient, which fosters spontaneity in the teaching-learning process. Teaching during routine care is efficient and cost-effective (Figure 25-2).

Instructional Methods. Choose instructional methods that match a patient's learning needs, the time available for teaching, the setting, the resources available, and your comfort level with teaching. Skilled educators are flexible in altering teaching methods according to a learner's responses. An experienced educator uses a variety of techniques and teaching aids. Do not expect to be an expert educator

FIGURE 25-2 Teaching postoperative care while walking with the patient uses time efficiently.

when first entering nursing practice. Learning to become an effective educator takes time and practice.

When first starting to teach patients, it helps to remember that patients perceive you as an expert. However, this does not mean that they expect you to have all of the answers. It simply means that they expect that you will keep them appropriately informed. Effective nurses keep the teaching plan simple and focused on patients' needs.

One-on-One Discussion. Perhaps the most common method of instruction is one-on-one discussion. When teaching a patient at the bedside, in a health care provider's office, or in the home, the nurse shares information directly. You usually give information in an informal manner, allowing the patient to ask questions or share concerns. Use various teaching aids such as models or diagrams during the discussion, depending on the patient's learning needs. Use unstructured and informal discussions when helping patients understand the implications of illness and ways to cope with health stressors.

Group Instruction. You may choose to teach patients in groups because of the advantages associated with group teaching. Groups are an economical way to teach a number of patients at one time, and patients are able to interact with one another and learn from the experiences of others. Learning in a group of six or less is most effective and avoids distracting behaviors. Group-based instruction also results in improvement in patient satisfaction and self-management skills (Steinsbekk et al., 2012). Group instruction often involves both lecture and discussion. Lectures are highly structured and efficient in helping groups of patients learn standard content about a subject. A lecture does not ensure that learners are actively thinking about the material presented; thus discussion and practice sessions are essential. After a lecture, learners need the opportunity to share ideas and seek clarification. Group discussions allow patients and families to learn from one another as they review common experiences. A productive group discussion helps participants solve problems and arrive at solutions toward improving each member's health. To be an effective group leader, you guide participation. Acknowledging a look of interest, asking questions, and summarizing key points foster group involvement. However, not all patients benefit from group discussions; sometimes the physical or emotional level of wellness makes participation difficult or impossible.

Preparatory Instruction. Patients frequently face unfamiliar tests or procedures that create significant anxiety about the procedure and outcome. Providing information about procedures often decreases anxiety because this gives patients a better idea of what to expect during their procedures, which provides them a sense of control. The known is less threatening than the unknown. Use the following guidelines for giving preparatory explanations:

- Describe physical sensations during a procedure. For example, when drawing a blood specimen, explain that the patient will feel a sticking sensation as the needle punctures the skin.
- Describe the cause of the sensation, preventing misinterpretation of the experience. For example, explain that a needlestick burns because the alcohol used to clean the skin enters the puncture site.
- Prepare patients only for aspects of the experience that others have commonly noticed. For example, explain that it is normal for a tight tourniquet to cause a person's hand to tingle and feel numb.
- Be sure the patients know when the results will be available and who will give them the results of their tests and/or procedures.

Demonstrations. Use demonstrations when teaching psychomotor skills such as preparing a syringe, bathing an infant, crutch walking, or taking a pulse. Demonstrations are most effective when learners first observe the educator and during a **return demonstration** have the

chance to practice the skill. Combine a demonstration with discussion to clarify concepts and feelings. An effective demonstration requires advanced planning:

1. Be sure that the learner can see each step of the demonstration easily. Position the learner to provide a clear view of the skill being performed.
2. Assemble and organize the equipment. Make sure that all equipment works.
3. Perform each step slowly and accurately in sequence while analyzing the knowledge and skills involved and allow the patient to handle the equipment.
4. Review the rationale and steps of the procedure.
5. Encourage the patient to ask questions so he or she understands each step.
6. Judge proper speed and timing of the demonstration on the basis of the patient's cognitive abilities and anxiety level.
7. To demonstrate mastery of the skill, have the patient perform a return demonstration under the same conditions that will be experienced at home or in the place where the skill is to be performed. For example, when a patient needs to learn to walk with crutches, stimulate the home environment. If the patient's home has stairs, the patient practices going up and down a staircase in the hospital.

Analogies. Learning occurs when an educator translates complex language or ideas into words or concepts that a patient understands. **Analogies** supplement verbal instruction with familiar images that make complex information more real and understandable. For example, when explaining arterial blood pressure, use an analogy of the flow of water through a hose. Follow these general principles when using analogies:

- Be familiar with the concept.
- Know the patient's background, experience, and culture.
- Keep the analogy simple and clear.

Role Play. During role play people are asked to play themselves or someone else. Patients learn required skills and feel more confident in being able to perform them independently. The technique involves rehearsing a desired behavior. For example, a nurse who is teaching a parent how to respond to a child's behavior pretends to be a child who is having a temper tantrum. The parent responds to the nurse who is pretending to be the child. Afterward the nurse evaluates the parent's response and determines whether an alternative approach would have been more appropriate.

Simulation. Simulation is a useful technique for teaching problem solving, application, and independent thinking. During individual or group discussion you pose a pertinent problem or situation for patients to solve. For example, patients with heart disease plan a meal that is low in cholesterol and fat. The patients in the group decide which foods are appropriate. You ask the group members to present their diet, providing an opportunity to identify mistakes and reinforce correct information.

Illiteracy and Other Disabilities. Implications of low health literacy, illiteracy, and learning disabilities include an impaired ability to analyze instructions or synthesize information. In addition, many of these patients have not acquired or are unable to acquire the problem-solving skills of drawing conclusions and inferences from experience, and they do not ask questions to obtain or clarify information that has been presented. Using strategies to promote health literacy creates a more patient-centered approach to health education and can have a significant impact on patient outcomes (Edelman et al., 2014). You can promote health literacy by creating a safe, shame-free environment, using clear and purposeful communication techniques, using visual

BOX 25-6   PATIENT TEACHING

Teaching a Patient with Literacy or Learning Disability Problems

Objective
- Patient will perform desired behaviors accurately.

Teaching Strategies
- Establish trust with patient before beginning the teaching-learning session.
- Speak slowly and encourage questions.
- Use simple terminology and avoid medical jargon. If necessary, explain medical terms using basic one- or two-syllable words.
- Keep teaching sessions short and to the point and minimize distractions. Include the most important information at the beginning of the session.
- Teach in increments and organize information into sections.
- Provide teaching materials that reflect reading level of patient, with attention given to short words and sentences, large type, and simple format (generally information written on a fifth-grade reading level is recommended for adult learners).
- Relate practical information to personal experiences or real-life situations.
- Use visual aids when appropriate and simple analogies or stories to personalize messages.
- Model appropriate behavior and use role-play to help patient learn how to ask questions and ask for help effectively.
- Frequently ask patient for feedback to determine if he or she comprehends information.
- Ask for return demonstrations, use the Teach Back method, and clarify instructions when needed.
- Keep motivation high and recognize progress with positive reinforcement.
- Reinforce the most important information at the end of the session.
- Schedule teaching sessions at frequent intervals.

Evaluation
- Observe and evaluate patient's ability to perform desired behaviors.
- Use **Teach Back:** To determine patient's and family's understanding about a topic or ability to demonstrate a procedure. Teach Back determines patient's and family caregiver's level of understanding of instructional topic. Always revise your instruction or develop a plan for revised patient teaching if patient is not able to teach back correctly.

Data from Bastable S: *Nurse as educator: principles of teaching and learning for nursing practice,* ed 4, Burlington, 2014, Jones & Bartlett.

⊕ BOX 25-7   CULTURAL ASPECTS OF CARE

Patient Education

Patient education needs to be patient centered and culturally sensitive for learning to occur. Sociocultural norms, values, and traditions often determine the importance of different health education topics and the preference of one learning approach over another. Educational efforts are especially challenging when patients and educators do not speak the same language or when written materials are not culturally sensitive and are written above patients' reading abilities.

Implications for Patient-Centered Care
- Develop a cultural awareness to establish and maintain respectful relationships with culturally diverse patients to encourage trust and communication (Ingram, 2011) (see Chapter 9).
- Sociocultural factors influence a patient's perception of health and illness and how patients seek health care information (Campinha-Bacote, 2011).
- Carefully assess a patient's cultural needs and preferences for instructional methods to enhance learning and compliance.
- Nurses need to have access to a variety of culturally diverse health care resources and select teaching strategies that are relevant to the individual patient.
- When you and the patient do not speak the same language, professional translators are necessary.

presence to patients with visual impairments before approaching them. If the patient has partial vision, use colors and a print font size (14-point font or greater) that the patient is able to see. Be sure to use proper lighting. Other helpful interventions include audio recording teaching sessions and providing structured, well-organized instructions (Bastable, 2014).

QSEN **QSEN: BUILDING COMPETENCY IN PATIENT-CENTERED CARE.** You are doing a home visit with Bob, a 47-year-old patient with hyperlipidemia and hypothyroidism. Bob was recently diagnosed with type 2 diabetes and is having difficulty following a complicated medication schedule at home. He needs to take three different medications to control his hyperlipidemia and hypothyroidism. Now he has been prescribed two new oral medications to control his blood glucose. During your assessment you find that he has difficulty understanding printed teaching sheets. He admits, "I had to drop out of school when I was in eighth grade, and my vision is not as good as it used to be." When you ask Bob where he keeps his medications, he shows you the prescription bottles in a kitchen cabinet. Which additional assessment questions and teaching strategies, approaches, and tools do you use to enhance Bob's learning and ability to take his medications as ordered?

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

---

aids to reinforce spoken material, and taking special care to evaluate patient understanding of the content. Face a patient when speaking and sit at his or her level to maintain eye contact. Because medical jargon can be confusing, it is important to use words that a patient is able to understand. Printed information, including hospital forms, legal documents, and patient education materials, must be written using plain language in a clear and concise manner. Encourage questions and verify understanding of content following any teaching intervention. Box 25-6 summarizes interventions to use when caring for patients who have literacy or learning disability problems.

Sometimes patients have sensory deficits that affect how you present information (see Chapter 49). For example, patients who are deaf may require a sign language interpreter. Not all people who are deaf read lips. Therefore it is very important to provide clear written materials that match the patients' reading level. Visual impairments also affect the teaching strategy you use. Many people who are blind have acute listening skills. Avoid shouting and announce your

Cultural Diversity. You should appreciate the patient's cultural background and belief system and gauge his or her ability to understand instructions in a language that may be different from his or her native language (see Chapter 9 and Box 25-7). Assess and determine a patient's personal beliefs, values, and customs as they relate to health (Campinha-Bacote, 2011; Ingram, 2011). However, be careful not to generalize or stereotype patients solely on the basis of their culture. Collaborate with other nurses and educators to develop appropriate teaching approaches and ask people from their cultural group to help by sharing their values and beliefs. Ethnic nurses are excellent resources who are able to provide input through their experiences to improve

the care provided to members of their own community (Bastable, 2014). When patients cannot understand English, use trained and certified health care interpreters to provide health care information.

In addition, be aware of intergenerational conflict of values. This occurs when immigrant parents uphold their traditional values and their children, who are exposed to American values in social encounters, develop beliefs similar to those of their American peers. Consider this conflict in values when providing information to families or groups who have members from different generations. To enhance patient education in culturally diverse populations, know when and how to provide education while respecting cultural values. Modify teaching to accommodate for cultural differences. Effective educational strategies require you to use culturally tailored, interactive instructional methods that involve the family and community in the learning process (Chin et al., 2012).

Using Teaching Tools. Many teaching tools are available for patient education. Selection of the right tool depends on the instructional method, a patient's learning needs, and the ability to learn (Table 25-3). For example, a printed pamphlet is not the best tool to use for a patient with poor reading comprehension, but an audio recording is a good choice for a patient with visual impairment. Health care facilities often provide clinicians with access to a variety of teaching resources. Be knowledgeable about what is available in your facility to better serve your patients.

Special Needs of Children and Older Adults. Children, adults, and older adults learn differently. You adapt teaching strategies to each learner. Children pass through several developmental stages (see Unit 2). In each developmental stage children acquire new cognitive and psychomotor abilities that respond to different types of teaching methods (Figure 25-3). Incorporate parental input in planning health education for children.

Older adults experience numerous physical and psychological changes as they age (see Chapter 14). These changes not only increase their educational needs but also create barriers to learning unless adjustments are made in nursing interventions. Sensory changes such

FIGURE 25-3 The preschool child learns not to be afraid of medical equipment by being allowed to handle the stethoscope and imitating its use.

as visual and hearing changes require adaptation of teaching methods to enhance functioning. Older adults learn and remember effectively if you pace the learning properly and if the material is relevant to the learner's needs and abilities. Although many older adults have slower cognitive function and reduced short-term memory, you facilitate learning in several ways to support behaviors that maximize the individual's capacity for self-care (Box 25-8).

Establish short-term goals when teaching older patients. Include family members who assume care for the patient. However, be sensitive to a patient's desire for assistance because offering unwanted support often results in negative outcomes and perceptions of nagging and interference. Furthermore, not all relationships between older adults and other family members are therapeutic. Because of the high incidence of abuse and neglect of older adults, assess family dynamics before including family members in educational sessions.

◆ Evaluation

Through the Patient's Eyes. Patient education is not complete until you evaluate outcomes of the teaching-learning process (see Care Plan). Engage patients in the evaluation process to determine if they have learned essential material. It is also important to determine if patients believe that they have the information necessary to continue self-care activities within the home. This is why it is important to evaluate through the patient's eyes, respecting the type of situations to which patients return after receiving care. Evaluation reinforces correct behavior, helps learners realize how to change incorrect behavior, and helps the educator determine adequacy of teaching.

Patient Outcomes. The nurse is legally responsible for providing accurate, timely patient information that promotes continuity of care; therefore it is essential to document the outcomes of teaching. Documentation of patient teaching also supports quality improvement efforts, meets TJC standards, and promotes third-party reimbursement. Teaching flow sheets and written plans of care (e.g., CareMaps) are excellent records that document the plan, implementation, and evaluation of learning.

You evaluate success by observing a patient's performance of each expected behavior. Success depends on a patient's ability to meet the established goals and outcomes. Questions should be phrased carefully to ensure that the learner understands them and that objectives are truly measured. Examples of questions to ask when evaluating patient education include the following:

- Were the patient's goals or outcomes realistic and observable?
- Is the patient able to perform the behavior or skill in the natural setting (e.g., home)?
- How well is the patient able to answer questions about the topic?
- Does the patient continue to have problems understanding the information or performing a skill? If so, how can you change the interventions to enhance knowledge or skill performance?

Teach Back. The ability of the patient to recall and comprehend information that has been taught is a predictor of patient adherence to health and disease management (Xu, 2012). One way to evaluate patient understanding is with the Teach Back method. Teach Back is a closed-loop communication technique that assesses patient retention of the information imparted during a teaching session. To perform Teach Back, ask the patient to explain material that was discussed, such as the role of diet and exercise in managing blood glucose levels, or to demonstrate a skill, such as self-monitoring blood glucose. The response allows you to determine the degree to which the patient remembers and understands what was taught or demonstrated. If the patient has difficulty recalling the material or demonstrating a skill,

TABLE 25-3 Teaching Tools for Instruction

Description	Learning Implications
Written Materials	
Printed Material and Online Materials	
Written teaching tools available in print or online as pamphlets, booklets, brochures	Material needs to be easy to read. Information needs to be accurate and current. Method is ideal for understanding complex concepts and relationships.
Programmed Instruction	
Written sequential presentation of learning steps requiring that learners answer questions and educators tell them whether they are right or wrong	Instruction is primarily verbal, but the educator sometimes uses pictures or diagrams. Method requires active learning, giving immediate feedback, correcting wrong answers, and reinforcing right answers. Learner works at own pace.
Computer Instruction	
Use of programmed instruction format in which computers store response patterns for learners and select further lessons on basis of these patterns (programs can be individualized)	Method requires reading comprehension, psychomotor skills, and familiarity with computer.
Nonprint Materials	
Diagrams	
Illustrations that show interrelationships by means of lines and symbols	Method demonstrates key ideas, summarizes, and clarifies key concept.
Graphs (Bar, Circle, or Line)	
Visual presentations of numerical data	Graphs help learner grasp information quickly about single concept.
Charts	
Highly condensed visual summary of ideas and facts that highlights series of ideas, steps, or events	Charts demonstrate relationship of several ideas or concepts. Method helps learners know what to do.
Pictures	
Photographs or drawings used to teach concepts in which the third dimension of shape and space is not important	Photographs are more desirable than diagrams because they more accurately portray the details of the real item.
Physical Objects	
Use of actual equipment, objects, or models to teach concepts or skills	Models are useful when real objects are too small, large, or complicated or are unavailable. Allows learners to manipulate objects that they will use later in skill.
Other Audiovisual Materials	
Slides, audiotapes, television, and videotapes used with printed material or discussion	Materials are useful for patients with reading comprehension problems and visual deficits.

BOX 25-8 FOCUS ON OLDER ADULTS

Providing Patient Education

Facilitate learning by using the following teaching strategies when providing patient education to older adults:

- Promote concentration and learner readiness by scheduling teaching sessions when the patient is comfortable and well rested. Provide medication for pain relief when necessary.
- Create a casual and relaxed learning environment.
- Establish personalized, realistic short-term learning goals.
- Provide sufficient lighting with low glare.
- If using visual aids or written materials to supplement instruction, assess the patient's reading ability and make sure that information is printed in a large font size and color that contrasts the background (e.g., black 14-point print on matte white paper). Avoid blues and greens because these colors can become more difficult to distinguish with age.
- To accommodate for hearing loss, present information slowly, in a clear, low tone of voice. Eliminate any extraneous noises and directly face the learner when speaking.
- Encourage the use of prosthesis (i.e., glasses, hearing aid) and ensure proper fit and working condition.
- Allow sufficient time to process and comprehend new information.
- Build on existing knowledge and present content in a way that relates to relevant past life experiences.
- Make information meaningful by using concrete examples that apply to current situations.
- Only present the most significant information to avoid overwhelming the learner. Use repetition to reinforce content.
- When giving instructions or teaching a new skill, give concise, step-by-step directions. Assess understanding of each step before moving ahead.
- Provide regular positive reinforcement.
- Keep teaching sessions short and allow for frequent breaks. Schedule follow-up sessions as needed to ensure learning.
- Conclude with a brief summary and allow sufficient time for questions and feedback.

Data from Touhy TA, Jett KF: *Ebersole and Hess' toward healthy aging,* ed 8, St Louis, 2012, Mosby; Edelman CL, et al: *Health promotion throughout the lifespan*, ed 8, St Louis, 2014, Mosby.

modify and repeat the content and reassess his or her retention. Patient understanding is confirmed when the patient can accurately restate the information in his or her own words (Tamura-Lis, 2013).

KEY POINTS

- The nurse ensures that patients, families, and communities receive information needed to promote, restore, and maintain optimal health.
- Teaching is most effective when it is responsive to a learner's needs.
- Teaching is a form of interpersonal communication, with the educator and learner actively involved in a process that increases the learner's knowledge and skills.
- The ability to learn depends on a person's physical and cognitive attributes.
- The ability to attend to the learning process depends on physical comfort, anxiety levels, and the presence of environmental distraction.
- A person's health beliefs influence the willingness to gain knowledge and skills necessary to maintain health.
- Use of a theory (e.g., social learning theory) or theoretical concepts (e.g., self-efficacy) enhances learning.
- Time teaching so it occurs when a patient is ready to learn.
- Patients of different age-groups require different teaching strategies because of developmental capabilities.
- Involve patients actively in all aspects of teaching plans.
- Use learning objectives to set learning priorities.
- A combination of teaching methods improves the learner's attentiveness and involvement.
- An educator is more effective when presenting information that builds on a learner's existing knowledge.
- Effective educators use positive reinforcement.
- Older adults learn most effectively when information is slower paced and presented in small amounts.
- Evaluate a patient's learning by observing performance of expected learning behaviors under desired conditions.
- Effective documentation describes the entire process of patient education, promotes continuity of care, and demonstrates that educational standards have been met.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

While Connie is providing preoperative teaching, she provides Mr. Holland with several teaching brochures that explain what colorectal cancer is and what to expect before, during, and after the surgery. Mr. Holland reads through the brochures and nods his head as if he understands the material.

1. To evaluate Mr. Holland's learning, Connie states, "I want to be sure you understand the brochure. Can you tell me in your own words what you read in the brochure?" He has trouble describing it. Connie asks him questions about information in the brochures and discovers that he misunderstood much of the information. What do the assessment data suggest about Mr. Holland's health literacy? Which special considerations does Connie need to implement at this time?

2. The surgeon comes to see Mr. Holland after surgery. A new nurse, John, is in the hospital room at this time. The surgeon tells Mr. Holland that his cancer is aggressive and that he will probably need to have chemotherapy once the incision is healed. The surgeon leaves the room. John sits in a chair to talk with Mr. Holland. Mr.

Holland states, "I'm sure the doctor is wrong. After all, he's a surgeon, not an oncologist." How is Mr. Holland accepting this diagnosis? What approach should John take in planning education for him?

3. Mr. Holland is discharged. In planning discharge teaching, John reviews the medications that Mr. Holland will be taking at home. He notices that his physician prescribed three new medications. When John asks Mr. Holland what he understands about them, Mr. Holland states, "I've never heard of these medications." When John asks him to explain when he should take the medications, Mr. Holland is unable to do so correctly. What is the nursing diagnosis for this situation?

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A patient needs to learn to use a walker. Which domain is required for learning this skill?
   1. Affective domain
   2. Cognitive domain
   3. Attentional domain
   4. Psychomotor domain

2. The nurse is planning to teach a patient about the importance of exercise. When is the best time for teaching to occur? (Select all that apply.)
   1. When there are visitors in the room
   2. When the patient states that he or she is pain free
   3. Just before lunch, when the patient is most awake and alert
   4. When the patient is talking about current stressors in his or her life
   5. When the patient is being transported for a procedure

3. A patient newly diagnosed with cervical cancer is going home. The patient is avoiding discussion of her illness and postoperative orders. What is the nurse's best plan in teaching this patient?
   1. Teach the patient's spouse
   2. Focus on knowledge the patient will need in a few weeks
   3. Provide only the information that the patient needs to go home
   4. Convince the patient that learning about her health is necessary

4. The _____ is a closed-loop communication technique used to evaluate patient understanding and retention of material.

5. When planning for instruction on cardiac diets to a patient with heart failure, which of the following instructional methods would be the most appropriate for someone identified as a visual/spatial learner?
   1. Printed pamphlets on cardiovascular disease and dietary recommendations from the American Heart Association
   2. A role-play activity requiring the patient to select proper foods from a wide selection
   3. Colored visual diagrams that categorize foods according to fat and sodium content
   4. A lecture-style discussion on heart healthy diet options

6. A patient with chest pain is having an emergency cardiac catheterization. Which teaching approach does the nurse use in this situation?
   1. Telling approach
   2. Selling approach

3. Entrusting approach

4. Participating approach

7. The nurse is organizing a disease prevention program for a specific cultural group. To effectively meet the needs of this group the nurse will: (Select all that apply.)

1. Assess the needs of the community in general.

2. Involve those affected by the problem in the planning process.

3. Develop generalized goals and objectives for the program.

4. Use educational materials that are simplistic and have many pictures.

5. Assess commonly held health beliefs among the cultural group.

6. Educate the specific cultural group about Western concepts of health and illness.

7. Include cultural practices that are relevant to the specific community.

8. An older adult is being started on a new antihypertensive medication. In teaching the patient about the medication, the nurse:

1. Speaks loudly.

2. Presents the information once.

3. Expects the patient to understand the information quickly.

4. Allows the patient time to express himself or herself and ask questions.

9. A patient needs to learn how to administer a subcutaneous injection. Which of the following reflects that the patient is ready to learn?

1. Describing difficulties a family member has had in taking insulin

2. Expressing the importance of learning the skill correctly

3. Being able to see and understand the markings on the syringe

4. Having the dexterity needed to prepare and inject the medication

10. A patient who is hospitalized has just been diagnosed with diabetes. He is going to need to learn how to give himself injections. Which teaching method does the nurse use?

1. Simulation

2. Demonstration

3. Group instruction

4. One-on-one discussion

11. When a nurse is teaching a patient about how to administer an epinephrine injection in case of a severe allergic reaction, the nurse tells the patient to hold the injection like a dart. Which of the following instructional methods did the nurse use?

1. Telling

2. Analogy

3. Demonstration

4. Simulation

12. A nurse needs to teach a young woman newly diagnosed with asthma how to manage her disease. Which of the following topics does the nurse teach first?

1. How to use an inhaler during an asthma attack

2. The need to avoid people who smoke to prevent asthma attacks

3. Where to purchase a medical alert bracelet that says she has asthma

4. The importance of maintaining a healthy diet and exercising regularly

13. A nurse is teaching a group of young college-age women the importance of using sunscreen when going out in the sun. Which type of content is the nurse providing?

1. Simulation

2. Restoring health

3. Coping with impaired function

4. Health promotion and illness prevention

14. A nurse is planning a teaching session about healthy nutrition with a group of children who are in first grade. The nurse determines that after the teaching session the children will be able to name three examples of foods that are fruits. This is an example of:

1. A teaching plan.

2. A learning objective.

3. Reinforcement of content.

4. Enhancing the children's self-efficacy.

15. A nurse is teaching a 27-year-old gentleman how to adjust his insulin dosages on the basis of his blood sugar results. This type of activity addresses learning in the cognitive domain at the level of _____.

Answers: 1. 4; **2.** 2, 3; **3.** 4. Teach Back method; **5.** 3; **6.** 1; **7.** 2, 5, 7; **8.** 4; **9.** 2; **10.** 2; **11.** 2; **12.** 1; **13.** 4; **14.** 2; **15.** Application.

Documentation and Informatics

ⓔ MEDIA RESOURCES

Documentation is a nursing action that produces a written account of pertinent patient data, nursing clinical decisions and interventions, and patient responses in a health record (O'Toole, 2013). Documentation in a patient's medical record is a vital aspect of nursing practice. Nursing documentation needs to be accurate and comprehensive. Nursing documentation systems need to be flexible enough to retrieve clinical data, facilitate continuity of care, track patient outcomes, and reflect current standards of nursing practice. Information in a patient's record provides a detailed account of the level of quality of care delivered. Effective documentation helps ensure continuity of care, saves time, and minimizes the risk of errors. The quality of care, the standards of regulatory agencies and nursing practice, the reimbursement structure in the health care system, and legal guidelines make documentation and reporting an extremely important nursing responsibility.

PURPOSES OF THE MEDICAL RECORD

A patient's medical record is a valuable source of data for all members of the health care team. Data entered into the medical record facilitate interdisciplinary communication; provide a legal record of care provided; justify financial billing/reimbursement; and allow for auditing, monitoring, and evaluation of care provided. Medical records also serve as sources of research data and as learning resources for nursing and health care education.

Communication

A patient's medical record is one way that members of the health care team communicate about patients' needs and responses to care, clinical decision making, individual therapies, content of consultations, patient education, and discharge planning. The record is the most current and

accurate continuous source of information about a patient's health care status; the plan of care needs to be clear to anyone who accesses the record (see Unit 3). Information communicated in a patient's record allows health care providers to know a patient thoroughly, facilitating safe, effective, timely, and patient-centered clinical decision making. To enhance communication and promote safe patient care, document assessment findings and patient information as soon as possible after you provide care (e.g., immediately after providing a nursing intervention or completing a patient assessment).

Legal Documentation

Accurate documentation is one of the best defenses for legal claims associated with nursing care (see Chapter 23). You need to document in a timely manner. Documentation needs to indicate clearly that a patient received individualized, goal-directed nursing care on the basis of your nursing assessment. When documenting, describe exactly what happened to a patient and follow agency standards. Documenting the nursing process is a critical nursing responsibility that limits nursing liability by providing evidence that you maintained nursing practice standards while providing patient care (Lewis et al., 2014).

Mistakes in documentation that commonly result in malpractice include (1) failing to record pertinent health or drug information, (2) failing to record nursing actions, (3) failing to record medication administration, (4) failing to record drug reactions or changes in patients' conditions, (5) incomplete or illegible records, and (6) failing to document discontinued medications. Table 26-1 provides guidelines for legally sound documentation.

Reimbursement

Documentation by all members of the health care team is used to determine the severity of illness, the intensity of services received, and the quality of care provided during an episode of care. Insurance companies use this information to determine payment or reimbursement for health care services (ANA, 2010). **Diagnosis-related groups (DRGs)** are classifications based on a patient's primary and secondary medical diagnoses that are used as the basis for establishing Medicare reimbursement for patient care (O'Toole, 2013). Hospitals are reimbursed a predetermined dollar amount by Medicare for each DRG. Detailed recording establishes diagnoses for determining a DRG. A medical record audit reviews financial charges accrued throughout an episode of patient care. Private insurance carriers and auditors from federal agencies review records to determine the reimbursement that a patient or a health care agency receives. Accurate nursing documentation of services provided and supplies and equipment used in a patient's care clarifies the type of treatment a patient received and supports accurate and timely reimbursement to a health care agency and/or patient.

Auditing and Monitoring

Hospitals establish quality improvement programs for conducting objective, ongoing reviews of patient care and to keep nurses informed of standards of nursing practice to maintain excellence in nursing care. Accrediting agencies such as The Joint Commission (TJC, 2015) require quality improvement programs and set standards for the information needed in patient records, including evidence of an individualized plan of care developed with a patient's input, discharge planning, and patient education. Nurses periodically audit records to determine the degree to which standards of care are met and identify areas needing improvement and staff development. Health care agencies use these reports to make institutional changes to positively affect patient care. TJC requires self-regulation and quality improvement actions; one example is that nurses are required to review nursing outcomes

(see Chapter 5). Nurses share deficiencies and successes identified during monitoring with all members of the nursing staff to make changes in policy or practice.

Research

After securing appropriate agency and institutional review board (IRB) approval, researchers use patient records to gather statistical data on the incidence and prevalence of health problems, complications, use and effectiveness of specific medical and nursing interventions, outcomes in recovery from illness, and deaths. Data analysis contributes to evidence-based nursing practice and quality health care (see Chapter 5). For example, a nurse researcher wants to compare use of a new method of pain control with use of a standard pain control protocol in two separate groups of patients. The investigator plans to collect data from patient health records that describe the types and doses of analgesic medications administered, objective assessment data, and patients' subjective reports of pain relief. The researcher compares findings from both groups to determine if the new method of pain control is more effective than the standard pain-control protocol.

Education

One way to learn the nature of an illness and an individual's response to it is to read a patient care record. A patient's record contains a variety of information, including diagnoses, signs and symptoms of disease, successful and unsuccessful therapies, diagnostic findings, and patient behaviors. No two patients have identical records, but in the course of clinical training nursing and other health care students review records of patients who have similar health problems to identify patterns of information and anticipate the type of care required for a patient.

The Shift to Electronic Documentation

Traditionally health care professionals documented on paper medical records. Paper records are episode oriented, with a separate record for each patient visit to a health care agency. Key information such as patient allergies, current medications, and complications from treatment are sometimes lost from one episode of care (e.g., hospitalization or clinic visit) to the next, jeopardizing a patient's safety (Hebda and Czar, 2013).

To enhance communication among health care providers and thus patient safety, the American Recovery and Reinvestment Act (ARRA) of 2009 set a goal that all medical records will be kept electronically as of 2014. Since 2011 the Health Information Technology for Economic and Clinical Health Act (HITECH), enacted under Title XIII of ARRA, has been a major driver in the adoption and use of the electronic health record across the United States. HITECH established provisions to promote the meaningful use of health information technology (HIT) to improve the quality and value of health care. These included the appropriation of a total of $2 billion in discretionary funding and incentive payments under the Medicare and Medicaid programs that reward providers for the adoption and meaningful use of certified EHR technology (Dacey and Bholat, 2012).

The CMS Medicare and Medicaid EHR incentive programs evolved into three stages of the implementation of meaningful use. Stage 1 began in 2011 and set the basic functionalities of EHRs; requirements focused on the capture of patient data and the ability of providers to share that data with patients and other health care professionals. Stage 2 began in 2014; requirements focused on the exchange of health information among providers and the promotion of patient engagement through secure online access to personal health information. Stage 3, which includes recommendations for the expansion of the meaningful use objective to improve health care outcomes, is scheduled to begin in 2016 (HITECH Answers, 2015).

TABLE 26-1 Legal Guidelines for Documentation

Guidelines for Electronic and Written Documentation	Rationale	Correct Action
Do not document retaliatory or critical comments about a patient or care provided by another health care professional. Do not enter personal opinions.	Statements can be used as evidence for nonprofessional behavior or poor quality of care.	Enter only objective and factual observations of a patient's behavior or the actions of another health care professional. Quote all patient statements.
Correct all errors promptly.	Errors in recording can lead to errors in treatment or may imply an attempt to mislead or hide evidence.	Avoid rushing to complete documentation; be sure that information is accurate and complete.
Record all facts.	Record must be accurate, factual, and objective.	Be certain that each entry is factual and thorough. A person reading your documentation needs to be able to determine that a patient received adequate care.
Document discussions with providers that you initiate to seek clarification regarding an order that is questioned.	If you carry out an order that is written incorrectly, you are just as liable for prosecution as the health care provider.	Do not record "physician made error." Instead document that "Dr. Smith was called to clarify order for analgesic." Include the date and time of the phone call, with whom you spoke, and the outcome.
Document only for yourself.	You are accountable for information that you enter into a patient's record.	Never enter documentation for someone else (exception: if caregiver has left unit for the day and calls with information that needs to be documented; include date and time of entry and reference specific date and time to which you are referring and name of source of information in entry; include that information was provided via telephone).
Avoid using generalized, empty phrases such as "status unchanged" or "had good day."	This type of documentation is subjective and does not reflect patient assessment.	Use complete, concise descriptions of assessments and care provided so documentation is objective and factual.
Begin each entry with date and time and end with your signature and credentials.	Ensures that the correct sequence of events is recorded; signature documents who is accountable for care delivered.	Do not wait until the end of shift to record important changes that occurred several hours earlier; sign each entry according to agency policy (e.g., M. Marcus, RN).
Protect the security of your password for computer documentation.	Maintains security and confidentiality of patient medical records.	Once logged into a computer, do not leave computer screen unattended. Log out when you leave the computer. Make sure that a computer screen is not accessible for public viewing.

Guidelines Specific to Written Documentation	Rationale	Correct Action
Do not erase, apply correction fluid, or scratch out errors made while recording.	Charting becomes illegible: it appears as if you were attempting to hide information or deface a written record.	Draw single line through error, write word error above it, and sign your name or initials and date it. Then record note correctly.
Do not leave blank spaces or lines in a written nurses' progress note.	Allows another person to add incorrect information in open space.	Chart consecutively, line by line; if space is left, draw a line horizontally through it and place your signature and credentials at the end.
Record all written entries legibly and in black ink. Do not use felt-tip pens or erasable ink.	Illegible entries are easily misinterpreted, causing errors and lawsuits; ink from felt-tip pen can smudge or run when wet and may destroy documentation; erasures are not permitted in clinical documentation; black ink is more legible when records are photocopied or scanned.	Never use pencil to document in a written clinical record. Never erase entries, use correction fluid, or use pencil. To indicate an error in written documentation, place a single line through the inaccurate information and write your signature with credentials at the end of the text that has been crossed out.

Although ARRA's goal to keep all medical records electronically by 2014 was not realized, EHR adoption has accelerated rapidly since the passage of HITECH. As of May 2013 more than 293,000 eligible medical providers and over 3900 eligible hospitals received incentive payments from the Medicare and Medicaid EHR incentive programs, and more than 220,000 of the nation's eligible professionals and over 3000 of the nation's eligible hospitals achieved the requirements for stage I meaningful use of electronic patient data. These numbers represent nearly 80% of eligible hospitals and over half of physicians and other eligible professionals (Mostashari, 2013).

As of now evidence that the EHR will be an effective, if not essential, element to improving health care quality is not conclusive (Fontenot, 2013; Kelley et al., 2011). Englebright et al. (2014) reported a first step in using computerized nursing documentation to capture meaningful data at a 170-bed community hospital in the central United States. These authors describe the development of a definition of basic nursing

care that includes ten activities classified under "assess and monitor," "perform or provide," "teach," and "manage" that are provided to all hospitalized adult patients. The list of activities was coded using the Clinical Care Classification (CCC) taxonomy system and built into the nursing information system of the hospital. Many other professional organizations and accrediting body initiatives also support initiation of the **electronic health record (EHR)**. Ultimately experts believe that implementing EHRs across the health care delivery system will decrease costs and improve the quality of patient care.

Although the terms *EHR* and **electronic medical record (EMR)** frequently are used interchangeably in practice, there are differences between them. An EHR is a digital version of patient data that is found in traditional paper records. The term *EHR* is used increasingly to refer to a longitudinal (lifetime) record of all health care encounters for an individual patient (Hebda and Czar, 2013). An EMR is the legal record that describes a single encounter or visit created in hospitals and outpatient health care settings that is the source of data for the EHR (Hebda and Czar, 2013).

To meet agreed-on standards, EHRs are expected to have the following attributes or components (Hebda and Czar, 2013):
- Provide a longitudinal or lifetime patient record by linking all patient data from previous health care encounters
- Include a problem list indicating current clinical problems for each health care encounter, the number of occurrences associated with all past and current problems, and the current status of each problem
- Require the use of accepted, standardized measures to evaluate and record health status and functional levels
- Provide a method for documenting the clinical reasoning or rationale for diagnoses and conclusions that allows clinical decision making to be tracked by all providers who access the record
- Support confidentiality, privacy, and audit trails
- Provide continuous access to authorized users at any time
- Allow multiple health care providers access to customized views of patient data at the same time
- Support links to local or remote information resources such as databases using the Internet or intranet resources based within an organization
- Support the use of decision analysis tools
- Support direct entry of patient data by physicians
- Include mechanisms for measuring the cost and quality of care
- Support existing and evolving clinical needs by being flexible and expandable

The promise of the EHR is twofold: (1) making a positive impact on the quality of patient care through interprofessional collaboration with improved data availability and information synthesis, and (2) improving patient safety through the use of clinical decision support (Saleem et al., 2013). The EHR provides access to a patient's health record information at the time and place that clinicians need it. A unique feature of an EHR is its ability to integrate all patient information into one record, regardless of the number of times a patient enters a health care system. An EHR also includes results of diagnostic studies that may include diagnostic images (e.g., x-ray film or ultrasound images) and decision support software programs. Because an unlimited number of patient records potentially can be stored within an EHR system, health care providers can access clinical data to identify quality issues, link interventions with positive outcomes, and make evidence-based decisions. Here is an example of how an EHR works: A patient with a complex medical history sees multiple specialists to manage his or her health such as an endocrinologist to address diabetes, a pulmonologist to manage emphysema, and a cardiologist to manage heart failure and atrial fibrillation. Each of these providers is able to access patient data from the EMR at the same time.

The development of an EHR for all patients has the potential to benefit every member of the health care team. As of 2013 approximately 80% of all eligible hospitals and critical-access hospitals and more than half of physicians and other eligible professionals in the United States received an incentive payment for adopting, implementing, upgrading, or meaningfully using an EHR (USDHHS, 2013).

Accurate documentation within an EHR facilitates interprofessional communication; helps to meet professional, regulatory, and legal requirements; and aids in quality improvement efforts and health care research (Blair and Smith, 2012). Members of the health care team use EHRs to improve continuity of health care from one episode of illness to another. A clinician accesses relevant and timely information about a patient and focuses on the priority problems to make timely, well-informed clinical decisions. An EHR includes tools to guide and critique medication administration (see Chapter 32) and basic decision-support tools such as physician order sets and interdisciplinary treatment plans. The key advantages of an EHR for nursing include a means for nurses to compare current clinical data about a patient with data from previous health care encounters and to maintain an ongoing record of health education provided to a patient and the patient's response to that information.

INTERPROFESSIONAL COMMUNICATION WITHIN THE MEDICAL RECORD

The quality of patient care depends on your ability to communicate with other members of the health care team. Regardless of whether documentation is entered electronically or on paper, each member of the health care team needs to document patient information in an accurate, timely, concise, and effective manner to develop and maintain an effective, organized, and comprehensive plan of care. When a plan is not communicated to all members of the health care team, care becomes fragmented, tasks are repeated, and delays or omissions in care often occur.

The health care environment creates many challenges for accurately documenting and reporting the care delivered to patients. Whether the transfer of patient information occurs through verbal reports, electronic records, or written documents, you need to follow some basic principles.

CONFIDENTIALITY

Nurses are legally and ethically obligated to keep information about patients confidential. Only members of the health care team who are directly involved in a patient's care have legitimate access to the medical record. Thus you only discuss a patient's diagnosis, treatment, assessment, and/or any personal conversations with members of the health care team who are involved in a patient's care. Do not share information with other patients or health care team members who are not caring for a patient. Patients have the right to request copies of their medical records and read the information. Each institution has policies that describe how medical records are shared with patients or other people who request them. In most situations patients are required to give written permission for release of medical information.

The Health Insurance Portability and Accountability Act (HIPAA) of 1996 was the first federal legislation providing protection for patient records; it governs all areas of patient information and management of that information. To eliminate barriers that possibly delay access to care, HIPAA requires providers to notify patients of privacy policies

and obtain written acknowledgment from patients indicating that they received this information. Under HIPAA the Privacy Rule requires that disclosure or requests regarding health information be limited to the specific information required for a particular purpose (Hebda and Czar, 2013). For example, if you need a patient's home telephone number to reschedule an appointment, access to the medical records is limited solely to telephone information. Of equal importance under HIPAA is the Security Rule, which specifies administrative, physical, and technical safeguards for 18 defined elements of protected health information (PHI) in electronic form (Administrative Committee of the Federal Registrar, 2014).

Sometimes nurses use health care records for data gathering, research, or continuing education. As long as a nurse uses a record as specified and permission is granted, this is permitted. When you are a student in a clinical setting, confidentiality and compliance with HIPAA are part of professional practice. You can review your patients' medical records only for information needed to provide safe and effective patient care. For example, when you are assigned to care for a patient, you need to review the patient's medical record and plan of care. You do not share this information with classmates (except for clinical conferences) and do not access the medical records of other patients on the unit. Access to EHRs is traceable through user log-in information. Not only is it unethical to view medical records of other patients, but breaches of confidentiality lead to disciplinary action by employers and dismissal from work or nursing school. To protect patient confidentiality, ensure that written or electronic materials used in your student clinical practice do not include patient identifiers (e.g., room number, date of birth, demographic information) and never print material from an EHR for personal use.

Privacy, Confidentiality, and Security Mechanisms

Electronic documentation has legal risks. It is possible for anyone to access a computer station within a health care agency and gain information about almost any patient. Therefore protection of information and computer systems is a top priority. Under HIPAA ensuring appropriate access to and confidentiality of PHI is the responsibility of all people working in health care. PHI includes individually identifiable health information such as demographic data; facts that relate to an individual's past, present, or future physical or mental health condition; provision of care; and payment for the provision of care that identifies the individual (Hebda and Czar, 2013).

Most security mechanisms for computerized information systems use a combination of logical and physical restrictions to protect information. For example, an automatic sign-off is a safety mechanism that logs a user off a computer system after a specified period of inactivity (Hebda and Czar, 2013). Other security measures include firewalls and the installation of antivirus and spyware-detection software. A **firewall** is a combination of hardware and software that protects private network resources (e.g., the information system of the hospital) from outside hackers, network damage, and theft or misuse of information.

Physical security measures include placing computers or file servers in restricted areas or using privacy filters for computer screens visible to visitors or others without access. This form of security has limited benefit, especially if an organization uses mobile wireless devices such as notebooks, tablets, personal computers (PCs), and personal digital assistants (PDAs). These devices are easily misplaced or lost, falling into the wrong hands. Some organizations use motion detectors or alarms with these devices to help prevent theft.

Access or log-in codes along with passwords are frequently used for authenticating authorized access to electronic records. A password is a collection of alphanumeric characters that a user types into a computer before accessing a program after the entry and acceptance of an access code or user name. Strong passwords use combinations of letters, numbers, and symbols that are difficult to guess. When using a health care agency computer system, it is essential that you do not share your computer password with anyone under any circumstances. A good system requires frequent, random changes in personal passwords to prevent unauthorized people from tampering with records. A password does not appear on the computer screen when it is typed, nor should it be known to anyone but the user and information system administrators (Hebda and Czar, 2013). In addition, most health care personnel are only given access to patients in their work area. Some staff (e.g., administrators or risk managers) have authority to access all patient records. To protect patient privacy, health care agencies track who accesses patient records and when they access them. Disciplinary action, including loss of employment, occurs when nurses or other health care personnel inappropriately access patient information.

Handling and Disposing of Information

Maintaining the confidentiality of medical records is an essential responsibility of all members of the health care team. It is equally important to safeguard any information that is printed from the record or extracted for report purposes. For example, you print a copy of a nursing-activities work list to use as a day planner while providing patient care. You refer to information on the list and write notes to enter later into the computer. Information on the list is PHI; you do not leave it out for view by unauthorized people. Destroy (e.g., shred) anything that is printed when the information is no longer needed. Nursing students must write down patient data needed for clinical paperwork directly from a patient's medical record on the computer screen or the physical chart. You need to de-identify all patient data when you write it onto forms or include it in papers written for nursing courses. Do not remove patient information that is printed out from a clinical agency. If you need to remove printed information from a clinical setting, de-identify all PHI, keep the documents secure, and destroy documents by shredding or disposing of them in a locked receptacle as soon as possible.

Historically the primary sources for inadvertent, unauthorized disclosure of PHI occurred when information was printed from a patient record and/or faxed to other health care providers. Thus you destroy all papers containing PHI (e.g., Social Security number, date of birth or age, patient's name or address) immediately after you use or fax them. Most agencies have shredders or locked receptacles for shredding and incineration. Some nurses work in settings where they are responsible for erasing files from a computer hard drive that contain calendars, surgery or diagnostic procedure schedules, or other daily records that contain PHI (Hebda and Czar, 2013). Know and follow the disposal policies for records in the institution where you work.

Health care facilities and departments have policies for the use of fax machines, which specify the types of information that can be faxed, allowable recipients of the information, where information is sent, and the process used to verify that information was sent to and received by the appropriate person(s). Only fax the amount of information that is requested or required for immediate clinical needs. The following are some steps to take to enhance fax security (Hebda and Czar, 2013):

- Confirm that fax numbers are correct before sending to be sure that you direct information properly.
- Use a cover sheet to eliminate the need for the recipient to read the information to determine who gets it. This is especially important if a fax machine serves a number of different users.
- Authenticate at both ends before data transmission to verify that source and destination are correct. Use the cover sheet to list intended recipient(s), the sender, and the phone and fax

numbers. Verify the fax number on the transmittal confirmation sheet.
- Use programmed speed-dial keys to eliminate the chance of a dialing error and misdirected information.
- Use the encryption feature on the fax machine. Encoding transmissions makes it impossible to read confidential information without the encryption key.
- Place fax machines in a secure area and limit machine access to designated individuals.
- Log fax transmissions. This feature is often available electronically on the machine.

QSEN QSEN: BUILDING COMPETENCY IN INFORMATICS.
Nurses and nursing students are responsible for maintaining the confidentiality of patient records. A group of nurses working at a physician's office where an EHR is being implemented are having a discussion about how electronic records are kept confidential.
- If you were part of this group, which suggestions would you add to the discussion?
- Which specific measures need to be taken to safeguard patient data from being viewed electronically?
- Which additional measures are needed when you print data from an EHR?

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

STANDARDS

Each health care organization has standards that govern the type of information you document and for which you are accountable. Institutional standards or policies often dictate the frequency of documentation such as how often you record a nursing assessment or a patient's level of pain. Know the standards of your health care organization to ensure complete and accurate documentation. Nurses are expected to meet the standard of care for every nursing task they perform. A court of law uses patient records to demonstrate whether nursing standards of practice were or were not met (ANA, 2010).

In addition, your documentation needs to conform to the standards of the National Committee for Quality Assurance (NCQA) and accrediting bodies such as TJC to maintain institutional **accreditation** and minimize liability. Usually an organization incorporates accreditation standards into its policies and revises documentation forms to suit these standards. Current documentation standards require that all patients admitted to a health care facility have an assessment of physical, psychosocial, environmental, self-care, knowledge level, and discharge planning needs. According to current standards your documentation needs to demonstrate application of the nursing process and include evidence of patient and family teaching and discharge planning (TJC, 2015). Other standards such as HIPAA include those that are directed by state and federal regulatory agencies and are enforced through the Department of Justice and the Centers for Medicare and Medicaid Services (ANA, 2010).

Patient care requires effective communication among members of the health care team. The medical record is an important means of communication because it is a confidential, permanent, legal documentation of information relevant to a patient's health care. The record is a continuing account of a patient's health care status and is available to all members of the health care team. All medical records contain the following information:
- Patient identification and demographic data
- Existence of "Living Will" or "Durable Power of Attorney for Healthcare" documents
- Informed consent for treatment and procedures
- Admission data
- Nursing diagnoses or problems and the nursing or interdisciplinary care plan
- Record of nursing care treatment and evaluation
- Medical history
- Medical diagnoses
- Therapeutic orders, including code status (i.e., provider order for "Do Not Resuscitate")
- Medical and interdisciplinary progress notes
- Physical assessment findings
- Diagnostic study results
- Patient education
- Summary of operative procedures
- Discharge summary and plan

GUIDELINES FOR QUALITY DOCUMENTATION

High-quality documentation is necessary to enhance efficient, individualized patient care. Quality documentation has five important characteristics: it is factual, accurate, complete, current, and organized. It is easier to maintain these characteristics if you continually seek to express ideas clearly and succinctly by (Beach and Oates, 2014):
- Sticking to the facts.
- Writing in short sentences.
- Using simple, short words.
- Avoiding the use of jargon or abbreviations.

Factual

A factual record contains descriptive, objective information about what a nurse observes, hears, palpates, and smells. Avoid vague terms such as appears, seems, or apparently. These words suggest that you are stating an opinion; they do not communicate facts accurately and do not inform another caregiver of the details regarding the behaviors exhibited by a patient. Objective data are obtained through direct observation and measurement (e.g., "B/P 80/50, patient diaphoretic, heart rate 102 and regular"). Objective documentation includes the description of a patient's behaviors. The only subjective data that you include in the record is what a patient says. When recording subjective data, you document the patient's exact words within quotation marks whenever possible. Include objective data to support subjective data so your charting is as descriptive as possible. For example, instead of documenting "the patient seems anxious," provide objective signs of anxiety and document the patient's statement about the feeling(s) experienced (e.g., "the patient's pulse rate is 110 beats/min, respiratory rate is slightly labored at 22 breaths/min, and the patient states 'I feel very nervous'").

Accurate

The use of exact measurements establishes accuracy and helps you determine if a patient's condition has changed in a positive or negative way. For example, a description such as "intake, 360 mL of water" is more accurate than "Patient drank an adequate amount of fluid." Charting that an abdominal incision is "approximated, 5 cm in length without redness, drainage, or edema" is more descriptive than "large abdominal incision healing well." Documentation of concise data is clear and easy to understand. It is essential to avoid the use of unnecessary words and irrelevant detail. For example, the fact that the patient is watching television is only necessary when this activity is significant to the patient's status and plan of care.

To ensure patient safety use abbreviations carefully to avoid misinterpretation. TJC's "do not use" list of abbreviations (see Chapter 32)

TABLE 26-2	Examples of Criteria for Documentation and Reporting
Topic	**Criteria to Report or Record**
Subjective assessment data	Patient's description of episode in quotation marks (e.g., *"I feel like an elephant is sitting on my chest, and I can't catch my breath."*) Describe in patient's own words the onset, location, description of condition (severity, duration, frequency, precipitating, aggravating, and relieving factors) (e.g., *"The pain in my left knee started last week after I knelt on the ground. Every time I bend my knee, I have a shooting pain on the inside of the knee."*).
Objective assessment data (e.g., rash, tenderness, breath sounds, or descriptions of patient behavior [e.g., anxiety, confusion, hostility])	Onset, location, description of condition (e.g., 11:00: 2-cm raised pale, red area noted on back of left hand). Onset, precipitating factors, behaviors exhibited (e.g., pacing in room, avoiding eye contact with nurse), patient statements (e.g., repeatedly stating, *"I have to go home now."*)
Nursing interventions, treatments, and evaluation (e.g., enema, bath, dressing change)	Time administered, equipment used, patient's response (subjective and objective response) compared to previous treatment (e.g., denied incisional pain during abdominal dressing change, ambulated 300 feet in hallway without assistance)
Medication administration	At time of administration when using a computerized bar-code medication administration program (or immediately after administration), document: time medication given, medication name, dose, route, preliminary assessment (e.g., pain level, vital signs), patient response, or effect of medication (e.g., 1500: Reports *"throbbing headache all over my head."* Rates pain at 6 (scale 0 to 10). Tylenol 650 mg given PO. 1530: Patient reports pain level 2 (scale 0 to 10) and states, *"the throbbing has stopped."*
Patient and/or family teaching	Information presented; method of instruction (e.g., discussion, demonstration, videotape, booklet); and patient response, including questions and evidence of understanding such as Teach Back, return demonstration, or change in behavior
Discharge planning	Measurable patient goals or expected outcomes, progress toward goals, need for referrals.

is used by all health care providers to promote patient safety. In addition, TJC (2015) requires that health care institutions develop a list of standard abbreviations, symbols, and acronyms to be used by all members of the health care team when documenting or communicating patient care and treatment. To minimize errors, spell out abbreviations in their entirety when they become confusing.

Correct spelling demonstrates a level of competency and attention to detail. Many terms are easily misinterpreted (e.g., dysphagia or dysphasia and dram or gram). Some spelling errors result in serious treatment errors (e.g., the names of certain look alike–sound alike medications such as Lamictal and Lamisil or hydromorphone and hydrocodone are similar). Transcribe medication names carefully to ensure that patients receive the correct medications.

You need to date and time all entries in medical records, and there needs to be a method to identify the authors of all entries (TJC, 2015). Each entry in a patient's record ends with the caregiver's full name or initials and credentials/title/role such as "Jane Woods, RN." If initials are used in a signature, the full name and credentials/title/role of the individual need to be documented at least once in the medical record to allow others to readily identify the individual. As a nursing student enter your full name and nursing student (NS) abbreviation such as "David Jones, NS. The abbreviation for nursing student varies between NS for nursing student or SN for student nurse. Include your educational institution when required by agency policy.

Complete

You need to ensure that the information within a recorded entry or a report is complete, containing appropriate and essential information. Follow established criteria and standards for thorough communication within the medical record or when reporting certain health problems or nursing activities (Table 26-2). Your written entries in a patient's medical record describe the nursing care you administer and a patient's response. An example of a thorough nurse's note follows:

19:15 Verbalizes sharp, throbbing pain localized along lateral side of right ankle, which began approximately 15 minutes ago after twisting his foot on the stairs. Rates pain as 8 on a scale of 0 to 10. Pain increases with movement, is slightly relieved with elevation and rest. Pedal pulses equal bilaterally. Right ankle circumference 1 cm larger than left. Bilateral lower extremities warm, pale pink, skin intact, responds to tactile stimulation, capillary refill less than 3 seconds. Ice applied to right ankle. Percocet 2 tabs (PO) given for pain. Dr. M. Smith notified. Lee Turno, RN

19:45 States pain was somewhat relieved with ice and now rates pain as a 3 on a scale of 0 to 10. States, "The pain medication really helped." Lee Turno, RN

You frequently use flow sheets or graphic records to document routine activities such as daily hygiene care, vital signs, and pain assessments. Describe these data in greater detail when they are relevant such as when a change in functional ability or status occurs. For example, if your patient's blood pressure, pulse, and respirations are elevated above expected values following a walk down the hall, document additional description about the patient's status and response to the walk in the appropriate place in the medical record (e.g., nurse's notes).

Current

Timely entries are essential in a patient's ongoing care. Delays in documentation lead to unsafe patient care. To increase accuracy and decrease unnecessary duplication, many health care agencies keep records or computers near a patient's bedside to facilitate immediate documentation of information as it is collected. Document the following activities or findings at the time of occurrence:

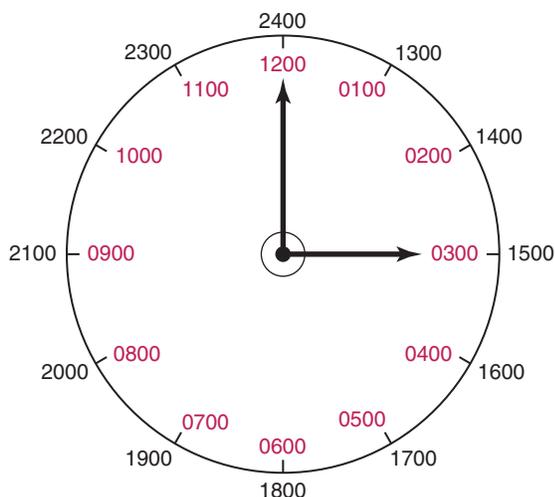
- Vital signs
- Pain assessment
- Administration of medications and treatments


FIGURE 26-1 Comparison of 24 hours of military time with the hourly positions for civilian time on the clock face.

- Preparation for diagnostic tests or surgery, including preoperative checklist
- Change in patient status and who was notified (e.g., physician, manager, patient's family)
- Admission, transfer, discharge, or death of a patient
- Treatment for sudden change in patient status
- Patient's response to treatment or intervention

Most health care agencies use military time, a 24-hour system that avoids misinterpretation of AM and PM times (Figure 26-1). Instead of two 12-hour cycles in standard time, the military clock is one 24-hour time cycle. The military clock ends with midnight at 2400 and begins at one minute after midnight as 0001. For example, 10:22 AM is 10:22 military time; 3:00 PM is 15:00 military time.

Organized

Information entered into a medical record facilitates communication when it is documented in a logical order. Documentation is also more effective when notes are concise, clear, and to the point. To document notes about complex situations in an organized fashion, think about the situation and make a list of what you need to include before beginning to enter data in the medical record. Applying your critical thinking skills and the nursing process gives logic and order to nursing documentation. For example, an organized entry describes a patient's pain, your assessment and interventions, and the patient's response.

METHODS OF DOCUMENTATION

There are several documentation methods for recording patient assessment data and progress notes (Box 26-1). Regardless of whether documentation is entered electronically or on paper, each health care agency selects a documentation system that reflects its philosophy of nursing. The same system is used throughout a specific agency and is sometimes used throughout a health care system as well.

Narrative Documentation

Narrative documentation is the method traditionally used to record patient assessment and nursing care provided. It is simply the use of a storylike format to document information. In an electronic nursing information system, this is accomplished through use of free text entry or menu selections (Hebda and Czar, 2013). Narrative documentation tends to be time consuming and repetitious. It requires the reader to

---

BOX 26-1 Examples of a Nursing Progress Note Written in Different Formats

Narrative Note
Patient stated, "I'm worried about the surgery. Last time I had a lot of pain when I got out of bed." Discussed importance of postoperative ambulation and demonstrated turning, coughing, deep-breathing (TCDB) exercises. Patient set postoperative pain-rating goal at 4 on scale of 0 to 10. Discussed analgesic plan of care and reassured that analgesics will be offered around the clock as ordered. Encouraged to tell nursing staff as soon as possible if pain is not relieved. Provided with teaching booklet on postoperative care. Stated, "I feel less anxious about my pain now." Verbalized understanding of the importance of postoperative ambulation and confidence in the plan of care.

SOAP (Subjective—Objective—Assessment—Plan) Note
S: "I'm worried about the surgery. Last time I had a lot of pain when I got out of bed."
O: Asking multiple questions about how postoperative pain will be addressed.
A: *Anxiety related to perceived threat of postoperative pain* as evidenced by statement of prior experience with uncontrolled postoperative pain.
P: Explain routine postoperative analgesic plan of care. Encourage to inform nursing staff as soon as possible if pain is not relieved. Explain rationale for early postoperative ambulation and demonstrate TCDB exercises. Provide teaching booklet on postoperative nursing care.

PIE (Problem—Intervention—Evaluation) Note
P: *Anxiety related to perceived threat of postoperative pain* as evidenced by statement of prior experience with uncontrolled postoperative pain.
I: Explained importance of postoperative ambulation and demonstrated TCDB exercises. Described analgesic plan of care. Encouraged to inform nursing staff as soon as possible if pain is not relieved. Provided teaching booklet on postoperative nursing care.
E: Stated, "I feel less anxious about postoperative pain now" and performed return demonstration of TCDB exercises correctly. Needs review of postoperative nursing care.

Focus Charting (Data—Action—Response) Note
D: Patient stated, "I'm worried about the surgery. Last time I had a lot of pain when I got out of bed." Asking frequent questions about postoperative pain management.
A: Discussed importance of postoperative ambulation and demonstrated TCDB exercises. Described postoperative analgesic plan of care that is in place. Provided teaching booklet on postoperative nursing care.
R: Demonstrated TCDB exercises correctly. Needs review of postoperative nursing care. States, "I feel better knowing how my pain will be treated."

---

sort through a lot of information to locate desired data. However, some nurses believe that in certain situations use of this method provides better detail of individual patient assessment findings and/or complex patient situations (Kerr, 2013). Physicians and other health care providers review nursing documentation for details about changes in a patient's condition (Penoyer et al., 2014). One of the limitations of electronic documentation is the limited use of narrative documentation. Some areas of the EMR are designed to use multiple checkboxes or drop-down lists, which some believe may not adequately convey the details of significant events that result in a change in patient condition (Kerr, 2013; Penoyer et al., 2014). EMRs that incorporate options for narrative descriptions in a format that is easily retrieved and reviewed may enhance clinician communication and interdisciplinary understanding for patient care.

Problem-Oriented Medical Record

The **problem-oriented medical record (POMR)** is a system of organizing documentation to place the primary focus on patients' individual problems. Data are organized by problem or diagnosis. Ideally each member of the health care team contributes to a single list of identified patient problems, which coordinates a common plan of care. The POMR has the following major sections: database, problem list, care plan, and progress notes.

Database. The database section contains all available assessment information pertaining to a patient (e.g., history and physical examination, nursing admission history and ongoing assessment, physical therapy assessment, laboratory reports, and radiological test results). The database provides the foundation for identifying patient problems and planning care. As new data become available, the database is revised. It accompanies patients through successive hospitalizations or clinic visits.

Problem List. After analyzing data, health care team members identify problems and make a single problem list. The problem list includes a patient's physiological, psychological, social, cultural, spiritual, developmental, and environmental needs. Team members list the problems in chronological order and file the list in the patient's record to serve as an organizing guide for patient care. Team members add and date new problems as they arise. When a problem is resolved, the text of that problem is highlighted, or lined out, and the date is recorded.

Care Plan. Disciplines involved in a patient's care develop a care plan or plan of care for each problem (see Chapter 18). Nurses document the plan of care in a variety of formats; generally all of these formats include nursing diagnoses, expected outcomes, and interventions.

Progress Notes. Health care team members monitor and record the progress made toward resolving a patient's problems in progress notes. Health care providers write progress notes in one of several formats or structured notes within a POMR (see Box 26-1).

One method is the SOAP note. The acronym **SOAP** stands for: *S:* Subjective data (verbalizations of the patient), *O:* Objective data (that which is measured and observed), *A:* Assessment (diagnosis based on the data), and *P:* Plan (what the caregiver plans to do). An "I" and an "E" are added (i.e., **SOAPIE**) in some institutions. The *I* stands for intervention, and the *E* represents evaluation. The logic of the SOAPIE note format is similar to that of the nursing process. You collect data about a patient's problems, draw conclusions, develop a plan of care, and then evaluate the outcome(s). Each SOAP note is numbered and titled according to the problem on the list that it addresses.

A second progress note used in the POMR is the **PIE** format. It is similar to SOAP charting in its problem-oriented nature. However, a PIE note differs from a SOAP note in that it has a nursing origin. *P:* Identifies a nursing diagnosis, *I:* Describes the interventions that will be used to address the problem, and *E:* Is the evaluation. The format simplifies documentation by unifying the care plan and progress notes. PIE notes also differ from SOAP notes because the narrative does not include assessment information. A nurse's daily assessment data appear on flow sheets, preventing duplication of data. PIE notes are also numbered or labeled according to the patient's problems. Problems that are resolved are dropped from daily documentation after a nurse's review. Nurses document about continuing problems daily with a PIE note for each problem.

The third format used for notes within a POMR is **focus charting**. It involves the use of **DAR** notes, which include *D:* Data (both subjective and objective), *A:* Action or nursing intervention, and *R:* Response of the patient (i.e., evaluation of effectiveness). A DAR note addresses patient concerns: a sign or symptom, condition, nursing diagnosis, behavior, significant event, or change in a patient's condition (see Box 26-1). Documentation in this format also follows the nursing process. This format allows nurses to broaden their thinking to include any patient concerns, not just problem areas. Focus charting incorporates all aspects of the nursing process, highlights a patient's concerns, and can be integrated into any clinical setting.

Charting by Exception

The philosophy behind **charting by exception (CBE)** is that a patient meets all standards unless otherwise documented. The method was introduced in the early 1980s; and, although the philosophy behind the method has consistently raised professional concern (Kerr, 2013), many computerized nursing documentation systems use a CBE design. Exception-based documentation systems incorporate standards of care, evidence-based interventions, and clearly defined criteria for nursing assessment and documentation of "normal" findings. The predefined statements used to document nursing assessment of body systems are called *within defined limits (WDL)* or *within normal limits (WNL)* definitions. They consist of written criteria for a "normal" assessment for each body system. Automated documentation within a computerized documentation system allows nurses to select a WDL statement or to choose other statements from a drop-down menu that allow description of any assessment findings that deviate from the WDL definition or that are unexpected (Hebda and Czar, 2013). You only write a progress note when a patient's assessment does not meet the standardized criteria for "normal" in one or more body systems. When changes in a patient's condition develop, you need to include a thorough and precise description of the effects of the change(s) on the patient and the actions taken to address the change(s) in the progress note.

Case Management and Use of Critical Pathways

The **case management** model of delivering care (see Chapter 2) incorporates an interprofessional approach to documenting patient care. **Critical pathways** (also known as clinical pathways, practice guidelines, critical pathways, or CareMap® tools) are interprofessional care plans that identify patient problems, key interventions, and expected outcomes within an established time frame (American Health Consultants, 2015). The document facilitates the integration of care because all health care team members use the same critical pathway to monitor a patient's progress during each shift or, in the case of home care, every visit (Chan and Webster, 2013). Many organizations summarize the standardized plan of care into critical pathways for a specific disease or condition. For example, in cancer care some pathways focus on malignancies that have a higher incidence such as breast, colon, prostate, and lung cancers and certain types of blood cancers (DeMartino and Larsen, 2012). Evidence-based critical pathways improve patient outcomes. For example, one critical pathway to manage pain caused by vascular-occlusive crisis in patients with sickle cell disease significantly improved the time interval between patient triage and administration of first analgesic dose and the likelihood of ketorolac administration in a pediatric emergency department (Ender et al., 2014).

A critical pathway eliminates nurses' notes, flow sheets, and nursing care plans because the document integrates all relevant information. Unexpected outcomes, unmet goals, and interventions not specified within the critical pathway are called **variances**. A variance occurs

You are using a critical pathway for "Routine Postoperative Care" for a 56-year-old man who had abdominal surgery yesterday. One of the expected outcomes for postoperative day 1 on the critical pathway document is "Afebrile with lungs clear bilaterally." This patient has an elevated temperature, his breath sounds are decreased bilaterally in the bases of both lobes of the lungs, and he is slightly confused.

The following is an example of how you document this variance on the pathway:

"Breath sounds diminished bilaterally at the bases. T-100.4; P-92; R-28/min; pulse oximetry 84% on room air. Daughter states he is "confused" and did not recognize her when she arrived a few minutes ago. Oxygen 2 L nasal cannula started per standing orders. Oxygen saturation improved to 92% after 5 minutes. Dr. Lopez notified of change in status. Daughter remains at bedside."

when the activities on the critical pathway are not completed as predicted or a patient does not meet the expected outcomes. A positive variance occurs when a patient progresses more rapidly than expected (e.g., use of a Foley catheter is discontinued a day early). An example of a negative variance is when a patient develops pulmonary complications after surgery, requiring oxygen therapy and monitoring with pulse oximetry. You document all variances on the critical pathway (Box 26-2). Analysis of variances identifies trends and provides data to develop an effective action plan to respond to identified patient problems. Variances sometimes result from changes in a patient's health or because of other health complications not associated with the primary reason for which a patient requires care. Once you identify a variance, you modify the patient's care to meet the needs associated with the variance. Over time health care teams revise critical pathways when similar variances recur.

COMMON RECORD-KEEPING FORMS

Nurses use a variety of electronic or paper forms for the type of information routinely documented. The categories or data fields within a form are usually derived from institutional standards of practice or guidelines established by accrediting agencies.

Admission Nursing History Form

A nurse completes a nursing history form when a patient is admitted to a nursing unit. The fields in the form guide you through a comprehensive assessment to identify relevant nursing diagnoses or problems (see Chapters 16 and 17). Completion of this form provides baseline data that you use for comparison when a patient's condition changes.

Flow Sheets and Graphic Records

Acute and critical care nurses commonly use **flow sheets** and graphic records to document physiological data and routine care. Within a computerized documentation system these forms allow you to quickly and easily enter assessment data about a patient such as vital signs, admission and or daily weights, and percentage of meals eaten. They also facilitate the documentation of the provision of routine, repetitive care such as hygiene measures, ambulation, and safety and restraint checks. These documents provide current patient information accessible to all members of the health care team and help team members quickly see patient trends over time. You explain any occurrence on a flow sheet that is unusual or represents a significant change in a patient's condition in detail in a progress note. For example, if a patient's blood pressure becomes dangerously high, you first complete

and record a focused assessment and then document the action taken in a progress note.

Patient Care Summary

Many computerized documentation systems have the ability to generate a patient care summary document that you review and sometimes print for each patient at the beginning and/or end of each shift. The document automatically updates and provides the most current information that has been entered into the EHR and usually includes the following information:

- Basic demographic data (e.g., age, religion)
- Health care provider's name
- Primary medical diagnosis
- Medical and surgical history
- Current orders from health care provider (e.g., dressing changes, ambulation, glucose monitoring)
- Nursing care plan
- Nursing orders (e.g., education needed, symptom relief measures, counseling)
- Scheduled tests and procedures
- Safety precautions used in the patient's care
- Factors that affect patient independence with activities of daily living
- Nearest relative/guardian or person to contact in an emergency
- Emergency code status (e.g., indication of "do not resuscitate" order)
- Allergies

Standardized Care Plans

Many computerized documentation systems include **standardized care plans** or **clinical practice guidelines (CPGs)** to facilitate the creation and documentation of a nursing and or interprofessional plan of care. Each CPG facilitates safe and consistent care for an identified problem by describing or listing institutional standards and evidence-based guidelines that are easily accessed and included in a patient's EHR. After completing a nursing assessment, the nurse identifies the CPGs that are appropriate for the patient and selects each one to be included in an individualized plan of care within the EHR. Most computer documentation systems allow CPGs to be modified, allowing you to individualize interventions, goals, and/or outcomes for each patient.

Standardized care plans or CPGs are useful when conducting quality improvement audits. They also improve continuity of care among professional nurses. When they are used, the nurse remains responsible for providing individualized care to each patient. Standardized care plans or CPGs cannot replace a nurse's professional judgment and decision making. Update care plans or CPGs on a regular basis to ensure that the documents are appropriate and evidence based.

Discharge Summary Forms

Nurses help ensure cost-effective care and appropriate reimbursement by preparing patients for an effective, timely discharge from a health care institution. The development of a comprehensive plan for safe discharge relies on interprofessional discharge planning. This process includes identification of key clinical outcomes and appropriate timelines for reaching them, the appropriate level of care for discharge, and all necessary resources.

Ideally discharge planning begins at admission. By identifying discharge needs early, nursing and other health care professionals begin planning for discharge to the appropriate level of care, which sometimes includes support services such as home care and equipment

needs. Involve the patient and family in the discharge planning process so they have the necessary information and resources to return home. Discharge documentation includes medications, diet, community resources, follow-up care, and who to contact in case of an emergency or for questions. All of this information is included in a discharge summary that is printed out and given to the patient on discharge but remains in the EHR as a record of the discharge teaching that was provided (Box 26-3).

ACUITY RATING SYSTEMS

Nurses use **acuity ratings** to determine the hours of care and number of staff required for a given group of patients every shift or every 24 hours. A patient's acuity level, usually determined by assessment data entered into a computer program by a registered nurse, is based on the type and number of nursing interventions (e.g., intravenous [IV] therapy, wound care, or ambulation assistance) required by a patient over a 24-hour period. Although acuity ratings are not part of a patient's medical record, nursing documentation within the medical record provides evidence to support the assessment of an acuity rating for an individual patient.

The acuity level is a classification used to compare one or more patients to another group of patients. For example, an acuity system classifies bathing patients from 1 (independent in all but one or two aspects of care; almost ready for discharge) to 5 (totally dependent in all aspects of care; requiring intensive care). Using this system, a patient returning from surgery requiring frequent monitoring and extensive care has an acuity level of 3 compared with another patient awaiting discharge after a successful recovery from surgery who has an acuity level of 1. Accurate acuity ratings justify the number and qualifications of staff needed to safely care for patients. The patient-to-staff ratios established for a unit depend on a composite gathering of 24-hour acuity data for all patients receiving care.

DOCUMENTATION IN THE HOME HEALTH CARE SETTING

Documentation in the home care setting is different from other areas of nursing. Medicare has specific guidelines to establish eligibility for home care reimbursement. Information used for reimbursement is gathered from documentation of care provided in the home care setting. Documentation is both the quality control and the justification for reimbursement from Medicare, Medicaid, or private insurance

companies. Information in the home care medical record includes patient assessment, referral and intake forms, interprofessional plan of care, a list of medications, and reports to third-party payers. Nurses must document all of their services for payment (e.g., direct skilled care, patient teaching, skilled observation, and evaluation visits) (TJC, 2015).

The use of laptop and tablet computers makes it possible for home health care records to be available in multiple locations (the patient's home and the home care agency), improving accessibility to information and facilitating interprofessional collaboration.

Nurses use two different data sets to document the clinical assessments and care provided in the home care setting: the Outcome and Assessment Information Set (OASIS) and the Omaha System (Monsen et al., 2012). The Centers for Medicare and Medicaid Services (CMS) mandates the use of OASIS for collecting and reporting patient assessments and outcomes in the home care setting. OASIS includes a comprehensive admission assessment and calculates clinical, functional, and service scores to provide justification for reimbursement of services (Allender et al., 2014). The Omaha System consists of three components: Problem Classification Scheme, Intervention Scheme, and Problem Rating Scale for Outcomes (Monsen et al., 2012). It provides a useful model for the comprehensive evaluation of nursing care and evaluates the quality of nursing care provided in the home care setting (Allender et al., 2014).

DOCUMENTATION IN THE LONG-TERM HEALTH CARE SETTING

The long-term health care setting includes skilled nursing facilities (SNFs) in which patients receive 24-hour-a-day care, which includes housing, meals, specialized (skilled) nursing care, and treatment services, and long-term care facilities in which patients with chronic conditions receive 24–hour-a-day care, which includes housing, meals, personal care, and basic nursing care. Individual state regulations, TJC, and The CMS govern documentation requirements in these facilities. The Resident Assessment Instrument (RAI), which includes the Minimum Data Set (MDS) and the Care Area Assessment (CAA), is the data set that is federally mandated for use in long-term care facilities by CMS. MDS assessment forms are completed on admission and then periodically, within specific guidelines and time frames for all residents in certified nursing homes (American Health Information Management Association, 2010).

The MDS also determines the reimbursement level under the prospective payment system for Medicare Part A residents in an SNF. On the basis of the MDS scoring, a resource utilization group (RUG) is assigned, which determines the per-diem payment (American Health Information Management Association, 2010). Communication among nurses; social workers; dietitians; and recreational, speech, physical, and occupational therapists is essential. Documentation in the long-term care setting supports an interprofessional approach to the assessment and planning process for all patients. Compliance with state and federal requirements and reimbursement for care provided in a long-term care facility depend on accurate completion of the required documentation to justify the care provided (Hebda and Czar, 2013).

DOCUMENTATNG COMMUNICATION WITH PROVIDERS AND UNIQUE EVENTS

Telephone Calls Made to a Provider

Document every phone call you make to a health care provider. Your documentation includes when the call was made, who made it (if you

BOX 26-4 Guidelines for Telephone and Verbal Orders

- Clearly determine the patient's name, room number, and diagnosis.
- Use clarification questions to avoid misunderstandings.
- Write TO (telephone order) or VO (verbal order), including date and time, name of patient, the complete order; sign the name of the physician or health care provider and nurse.
- Read back any prescribed orders to the physician or health care provider.
- Follow agency policies; some institutions require telephone (and verbal) orders to be reviewed and signed by two nurses.

did not make the call), who was called, to whom information was given, what information was given, and what information was received. An example follows: "*10/16/2015 (20:30): Called Dr. Morgan's office. Spoke with S. Thomas, RN, who will inform Dr. Morgan that Mr. Wade's potassium level drawn at 21:00 was 5.9 mEq/dL. Informed that Dr. Morgan will call back after he is finished seeing his current patient. D. Markle, RN.*"

Telephone and Verbal Orders

Telephone orders (TOs) occur when a health care provider gives therapeutic orders over the phone to a registered nurse. Verbal orders (VOs) occur when a health care provider gives therapeutic orders to a registered nurse while they are standing in proximity to one another. TOs and VOs usually occur at night or during emergencies; they should be used only when absolutely necessary and not for the sake of convenience. In some situations it is prudent to have a second person listen to TOs. Check agency policy. Box 26-4 provides guidelines that promote accuracy when receiving TOs or VOs.

The nurse receiving a TO or VO enters the complete order into the computer using the **computerized provider order entry (CPOE)** software or writes it out on a physician's order sheet for entry in the computer as soon as possible. After you have taken the order, read it back using the "read-back" process and document that you did this to provide evidence that the information received (such as call-back instructions and/or therapeutic orders) was verified with the provider. An example follows: "*10/16/2015 (08:15), Change IV fluid to Lactated Ringers with potassium 20 mEq per liter to run at 125 mL / hour. TO: Dr. Knight/J. Woods, RN, read back.*" The health care provider later verifies the TO or VO legally by signing it within a set time (e.g., 24 hours) as set by hospital policy.

Incident or Occurrence Reports

An incident or occurrence is any event that is not consistent with the routine, expected care of a patient or the standard procedures in place on a health care unit. Examples include patient falls, needlestick injuries, a visitor losing consciousness, medication administration errors, accidental omission of ordered therapies, and any circumstances that lead to injury or pose a risk for patient injury. You complete **incident (or occurrence) reports** whenever an incident occurs. They are an important part of the quality improvement program of a unit (see Chapter 2). A "near miss" is an incident in which no property was damaged and no patient or personnel were injured; but, given a slight shift in time or position, damage or injury could have occurred easily (OSHA, n.d.). When an incident occurs, document an objective description of what happened; what you observed; and the follow-up actions taken, including notification of the patient's health care provider in the patient's medical record. Remember to evaluate and document the patient's response to the incident.

Incident reports contain confidential information; distribution of the report is limited to those responsible for reviewing the forms. Follow agency policy when making an incident report and file the report with the risk-management department of your agency. Analysis of incident reports helps identify trends in an organization that provide justification for changes in policies and procedures or for in-service programs. Do not include any reference to an incident in the medical record. A notation about an incident report in a patient's medical record makes it easier for a lawyer to argue that the reference makes the incident report part of the medical record and therefore subject to attorney review.

INFORMATICS AND INFORMATION MANAGEMENT IN HEALTH CARE

Information technology (IT) refers to the management and processing of information, generally with the assistance of computers. **Health informatics** is the "application of computer and information science in all basic and biomedical sciences to facilitate the acquisition, processing, interpretation, optimal use, and communication of health-related data. The focus is the patient and the process of care, and the goal is to enhance the quality and efficiency of care provided" (Hebda and Czar, 2013, p. 6). A health care information system (HIS) is a group of systems used within a health care organization to support and enhance health care. A HIS consists of two major types of information systems: clinical information systems and administrative information systems. Together the two systems operate to make the entry and communication of data and information more efficient. You will find that any single health care agency uses one or several of these systems.

Nursing competence in health care informatics is becoming a priority as health care providers and facilities across the United States implement electronic documentation. You need informatics competencies to deliver safer and more efficient care, to add to the nursing professional knowledge base, and to facilitate the growth of evidence-based practice. Professional organizations such as the Institute of Medicine, The Robert Wood Johnson Foundation, and the National League for Nursing recommend that all nurses acquire a minimal level of awareness and competence in informatics and use of IT. The American Association of Colleges of Nursing established a framework that outlines curricular goals and outcomes in informatics for baccalaureate, masters, and doctoral programs of nursing (Hebda and Czar, 2013).

The Technology Informatics Guiding Education Reform (TIGER) Initiative began as a grassroots program in 2006 and was supported by over 70 contributing organizations, two grants from the Robert Wood Johnson Foundation, and one personal endowment. TIGER is focused on better preparing the clinical workforce to use technology and informatics to improve the delivery of patient care. On September 22, 2014, TIGER transitioned to the Healthcare Information and Management Systems Society (HIMSS). Under the direction of HIMSS, the momentum of the grass roots initiative will benefit from the robust volunteer structure that HIMSS can provide so strategies for the recruitment, retention, and training of current and future workforces for informatics education, practice, and research can be advanced (Healthcare Information and Management Systems Society, 2015).

Competence in informatics is not the same as computer competency. To become competent in informatics you need to be able to use evolving methods of discovering, retrieving, and using information in practice (Hebda and Czar, 2013). This means that you learn to recognize when information is needed and have the skills to find, evaluate, and use that information effectively. As a nurse you also need to know

how to use clinical databases within your institution and apply the information so you can deliver high-quality, appropriate patient care.

Nursing Informatics

Nursing informatics is broadly defined as the "use of information and computer technology to support all aspects of nursing practice, including direct delivery of care, administration, education, and research," (Hebda and Czar, 2013, p. 6). All nurses deal with data, information, and knowledge. It is important that you know how to record, interpret, and report data and critically think and apply that knowledge when providing patient care. Data include numbers, characters, or facts that you collect according to a perceived need for analysis and possible action. You gain knowledge from gathering and using information from several sources. An example is a nurse's review of several, consecutive assessments of a wound documented within the EHR. Reviewing changes in the descriptions of the edges of the wound, color of drainage, and measurements over several days allows the nurse to evaluate and identify a pattern that indicates that the wound is not healing (information). On the basis of evidence available in the scientific literature, the nurse applies knowledge of wound care principles and intervenes to manage the patient's wound to promote healing.

Nursing informatics is also recognized as a specialty area of nursing practice. Informatics nurses have advanced preparation in information management and demonstrate proficiency with informatics to support all areas of nursing practice, including quality improvement, research, project management, and system design (Hebda and Czar, 2013). Through the application of nursing informatics, technology is put to practical use to enhance bedside care and education. The application of nursing informatics results in an efficient and effective nursing information system that facilitates the integration of data, information, and knowledge to support patients, nurses, and other providers in decision making in all roles and settings.

Clinical Information Systems

All members of the interprofessional health care team, including nurses, physicians, pharmacists, social workers, and therapists, use programs available on a **clinical information system (CIS)**. These programs include monitoring systems; order entry systems; and laboratory, radiology, and pharmacy systems. A monitoring system includes devices that automatically monitor and record biometric measurements (e.g., vital signs, oxygen saturation, cardiac index, and stroke volume) in acute care, critical care, and specialty areas. The devices electronically send measurements directly to the nursing documentation system.

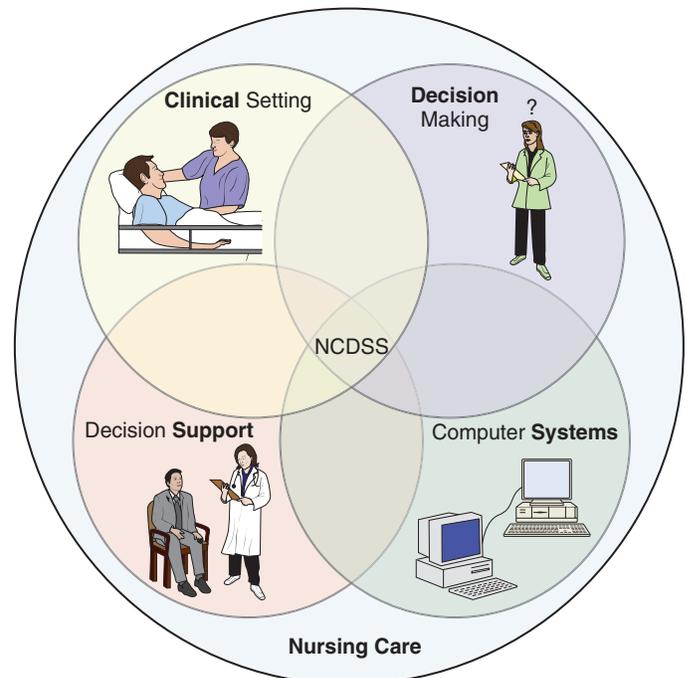
Order-entry systems allow nurses to order supplies and services from another department. An example is a computer program that provides the ability to order sterile supplies from the central supply department. This eliminates the use of written order forms and expedites the delivery of needed supplies to a nursing unit. Computerized provider order entry (CPOE) systems allow health care providers to directly enter orders for patient care into hospital information system. In advanced systems CPOE has built-in reminders and alerts that help a health care provider select the most appropriate medication or diagnostic test. The direct entry of orders eliminates issues related to illegible handwriting and transcription errors. In addition, a CPOE system potentially speeds the implementation of ordered diagnostic tests and treatments, which improves staff productivity and saves money because the unit secretary no longer transcribes a written order onto a nursing order form (Hebda and Czar, 2013). Orders made through CPOE are integrated within the record and sent to the appropriate departments (e.g., pharmacy or radiology).


FIGURE 26-2 Model of a nursing clinical decision support system (CDSS).

Clinical decision support systems (CDSSs) are computerized programs used within the health care setting to aid and support clinical decision making. When used to support nursing decisions it is called a nursing CDSS (Figure 26-2). The knowledge base within a CDSS contains rules and logic statements that link information required for clinical decisions to generate tailored recommendations for individual patients, which are presented to nurses as alerts, warnings, or other information for consideration (Lee, 2013). For example, an effective CDSS notifies health care providers of patient allergies before ordering a medication, which enhances patient safety during the medication ordering process. CDSSs also improve nursing care. When patient assessment data are combined with patient care guidelines, nurses are better able to implement evidence-based nursing care, resulting in improved patient outcomes (Box 26-5).

Nursing Clinical Information Systems

A well-designed **nursing clinical information system (NCIS)** incorporates the principles of nursing informatics to support the work that nurses do by facilitating documentation of nursing process activities and offering resources for managing nursing care delivery. As a nurse you need to access a computer program easily, review a patient's medical history and health care provider orders, and then go to the patient's bedside to conduct a comprehensive assessment. Once you complete an assessment, enter data into the computer terminal at the patient's bedside and develop a plan of care from the information gathered. This allows you to quickly share the plan of care with your patient. Periodically return to the computer to check on laboratory test results and document the care you deliver. The computer screens and optional pop-up windows make it easy to locate information, enter and compare data, and make changes.

NCISs have two designs. The nursing process design is the most traditional. It organizes documentation within well-established formats such as admission and postoperative assessment problem lists,

BOX 26-5 EVIDENCE-BASED PRACTICE

Effect of Clinical Decision Support Systems on Patient Outcomes

PICO Question: Do nurses who work at health care agencies that use clinical decision support systems (CDSSs) provide safer and more effective patient care when compared with nurses who work at agencies that do not use CDSSs?

Evidence Summary

Nurses who provide evidence-based care at the bedside provide safe and effective care. However, one barrier to implementing evidence-based practice is getting information to nurses at the bedside when they need it. Several studies investigated the effect of the CDSS on patient outcomes. Harrison et al. (2013) examined the impact of a nursing CDSS integrated with the electronic heart record developed to facilitate adherence to guidelines for the management of hypoglycemia. Data were collected and reviewed 6 months before implementation, 6 months following implementation, and 7 to 12 months after implementation of the CDSS. The findings of this study demonstrated a statistically significant improvement in adherence to use of the clinical guideline. The study also showed that the protocol was almost 3 times as likely to be followed 7 to 12 months after implementation of the CDSS. Current evidence also shows that use of CDSS improves adherence to implementation of evidence-based sepsis care in intensive care units (Giuliano et al., 2011) and completion of screening for osteoporosis in primary care settings (DeJesus et al., 2012). These studies show that CDSSs that provide automatic decision support at the time and place nurses need it enhance the quality and safety of patient care. CDSSs also help nurses initiate evidence-based care faster and with more accuracy, improving patient outcomes.

Application to Nursing Practice

- CDSSs enhance the implementation of evidence-based practice into nursing care because they remind nurses which interventions need to be implemented for specific patients at the time the care is needed.
- Nurses need to be involved in the design and selection of CDSSs to ensure that they provide clinical decision support effectively and efficiently.
- Nurses need to evaluate patient outcomes when CDSSs are used. They also need to be involved in developing solutions to improve the effectiveness of CDSSs when opportunities for improvement are identified.

---

care plans, intervention lists or notes, and discharge planning instructions. The nursing process design facilitates the following:

- Generation of a nursing work list that outlines routine scheduled activities related to the care of each patient
- Documentation of routine aspects of patient care such as hygiene, positioning, fluid intake and output, wound care measures, and blood glucose measurements
- Progress note entries using narrative notes, charting by exception, and/or flow-sheets
- Documentation of medication administration (see Chapter 32)

More advanced systems incorporate standardized nursing languages such as the North American Nursing Diagnosis Association–International (NANDA-I) nursing diagnoses, the Nursing Interventions Classification (NIC), and the Nursing Outcomes Classification (NOC) into the software.

The other model for an NCIS is the protocol or critical pathway design (Hebda and Czar, 2013). This design facilitates interdisciplinary management of information because all health care providers use evidenced-based protocols or critical pathways to document the care they provide. The information system allows a user to select one or more appropriate protocols for a patient. An advanced system merges multiple protocols, using a master protocol or path to direct patient care activities. Standard health care provider order sets are included in the protocols and automatically processed. The system integrates appropriate information into the medication delivery process to enhance patient safety. In addition, the system identifies variances of the anticipated outcomes on the protocols as documentation is entered. This provides all caregivers the ability to analyze variances and offer an accurate clinical picture of a patient's progress.

Advantages of a Nursing Clinical Information System. Anecdotal reports and descriptive studies suggest that NCISs offer important advantages to nurses in practice. According to Hebda and Czar (2013), some specific advantages include:

- Better access to information.
- Enhanced quality of documentation through prompts.
- Reduced errors of omission.
- Reduced hospital costs.
- Increased nurse job satisfaction.
- Compliance with requirements of accrediting agencies (e.g., TJC).
- Development of a common clinical database.
- Enhanced ability to track records.

Many NCIS's include content-importing technologies that allow the use of templates, macros, automated data points, and the ability to copy forward either parts of or entire nursing shift assessments that enable nurses to quickly document their assessment or the care they provided. These features have benefits and risks associated with their use. When allergy and current medication lists are automatically imported into nursing admission documentation from a previous hospital encounter, you need to meticulously review this information for accuracy and update it as needed to avoid documentation errors and patient safety concerns. When nursing shift assessment data is copied forward from a previous shift or day, it must be updated so it accurately reflects a patient's current clinical status (Weis and Levy, 2014).

QSEN QSEN: BUILDING COMPETENCY IN INFORMATICS.
You are using the bar-code medication administration (BCMA) system at the hospital where you work to document administration of a dose of warfarin (Coumadin) 7.5 mg PO to one of your patients. When you scan the dose of medication, an alert pops up on the computer screen in the patient's room, which requires you to enter the patient's current international normalized ratio (INR) result before you can give the patient the medication and complete the documentation of the administration of the medication.

At your hospital the normal range for INR is 0.8 to 1.1, and the therapeutic range for INR for patient's taking Warfarin (Coumadin) is 2.5 to 3.0. Your patient's INR result for today is 4.2 (much higher than the therapeutic range desired). What will you do in response to the alert that popped up on the computer screen?

Answers to QSEN Activities can be found on the Evolve website.

KEY POINTS

- The electronic (or paper-based) medical record is a legal document that contains information describing the care delivered to a patient.
- The medical record is also a financial record that serves as the basis for reimbursement.
- All information contained in the medical record is confidential; access to patient records is limited to individuals involved in the care of the patient.

- Interdisciplinary communication among members of the health care team is essential, and the medical record is one tool that supports and facilitates that communication.
- Accurate record keeping requires an objective interpretation of data with precise measurements, correct spelling, and proper use of abbreviations.
- To keep medical records accurate, any change in a patient's condition warrants immediate documentation about the event and the action that was taken to address the change.
- A nurse's electronic or handwritten signature on an entry in a record designates accountability for the contents of that entry.
- Protection of the confidentiality of patients' health information and the security of computer systems are top priorities that include log-in processes, audit trails, firewalls, data-recovery processes, and policies about handling and disposing of data to protect patient information.
- POMRs are organized by the patient's health care problems.
- SOAP, SOAPIE, PIE, or DAR charting formats organize entries in the progress notes according to the nursing process.
- Medicare guidelines establish the requirements for documentation by nurses working in the home care setting that supports and justifies reimbursement for care delivered.
- Long-term care documentation is interdisciplinary and closely linked with fiscal requirements of outside agencies.
- Always verify patient care information communicated to providers through telephone orders by using and documenting use of the "read-back" process.
- A hospital information system consists of two major types of information systems: CIS and administrative information systems.
- Computerized information systems provide information about patients in an organized and easily accessible fashion.
- Nursing informatics facilitates the integration of data, information, and knowledge to support clinical decision making of nurses and other providers in all roles and settings.

■ CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

David Page, an 80-year-old man, is admitted to the hospital with a diagnosis of possible pneumonia. He states that he is not feeling well and has a frequent cough, which produces thick, light tan sputum. Vital signs are: blood pressure, 150/90 mm Hg; pulse rate, 92 beats/min; respirations, 22 breaths/min. During your initial assessment he coughs violently for 40 to 45 seconds. His lungs have wheezes and rhonchi in both bases but are otherwise clear. He states, "My chest hurts when I cough, and the pain radiates into my shoulders."

1. Which data do you document as objective?
2. Which data are subjective?
3. This assessment information was documented electronically in narrative format. Discuss the benefits and negatives associated with this format of documentation.

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

■ REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A manager is reviewing the nursing documentation entered by a staff nurse in a patient's electronic medical record and finds the following entry, "Patient is difficult to care for, refuses suggestion for improving appetite." Which of the following statements is most appropriate for the manager to make to the staff nurse who entered this information?
   1. "Avoid rushing when documenting an entry in the medical record."
   2. "Use correction fluid to remove the entry."
   3. "Draw a single line through the statement and initial it."
   4. Enter only objective and factual information about a patient in the medical record.

2. A preceptor observes a new graduate nurse discussing changes in a patient's condition with a physician over the phone. The new graduate nurse accepts telephone orders for a new medication and for some laboratory tests from the physician at the end of the conversation. During the conversation the new graduate writes the orders down on a piece of paper to enter them into the electronic medical record when a computer terminal is available. At this hospital new medication orders entered into the electronic medical record can be viewed immediately by hospital pharmacists, and hospital policy states that all new medications must be reviewed by a pharmacist before being administered to patients. Which of the following actions requires the preceptor to intervene? The new nurse:
   1. Reads the orders back to the health care provider to verify accuracy of transcribing the orders after receiving them over the phone.
   2. Documents the date and time of the phone conversation, the name of the physician, and the topics discussed in the electronic record.
   3. Gives a newly ordered medication before entering the order in the patient's medical record.
   4. Asks the preceptor to listen in on the phone conversation.

3. As the nurse enters a patient's room, the nurse notices that the patient is anxious. The patient quickly states, "I don't know what's going on; I can't get an explanation from my doctor about my test results. I want something done about this." Which of the following is the most appropriate way for the nurse to document this observation of the patient?
   1. "The patient has a defiant attitude and is demanding test results."
   2. "The patient appears to be upset with the nurse because he wants his test results immediately."
   3. "The patient is demanding and is complaining about the doctor."
   4. "The patient stated feelings of frustration from the lack of information received regarding test results."

4. The nurse is reviewing the Health Insurance Portability and Accountability Act (HIPAA) regulations with the patient during the admission process. The patient states, "I'm not familiar with these HIPAA regulations. How will they affect my care?" Which of the following is the best response?
   1. HIPAA allows all hospital staff access to your medical record.
   2. HIPAA limits the information that is documented in your medical record.
   3. HIPAA provides you with greater protection of your personal health information.
   4. HIPAA enables health care institutions to release all of your personal information to improve continuity of care.

5. A patient states, "I would like to see what is written in my medical record." What is the nurse's best response?
   1. "Only your family can read your medical record."
   2. "You have the right to read your record."
   3. "Patients are not allowed to read their records."
   4. "Only health care workers have access to patient records."

6. Which of the following documentation entries is most accurate?
   1. "Patient walked up and down hallway with assistance, tolerated well."
   2. "Patient up, out of bed, walked down hallway and back to room, tolerated well."
   3. "Patient up, walked 50 feet and back down hallway with assistance from nurse. Spouse also accompanied patient during the walk."
   4. "Patient walked 50 feet and back down hallway with assistance from nurse; HR 88 and regular before exercise, HR 94 and regular following exercise."

7. Label each line of documentation with the appropriate SOAP category (Subjective [S], Objective [O], Assessment [A], Plan [P]).
   1. _____ Repositioned patient on right side. Encouraged patient to use patient-controlled analgesia (PCA) device.
   2. _____ "The pain increases every time I try to turn on my left side."
   3. _____ *Acute pain related to tissue injury from surgical incision.*
   4. _____ Left lower abdominal surgical incision, 3 inches in length, closed, sutures intact, no drainage. Pain noted on mild palpation.

8. **Fill in the Blank.** While working on a unit within a hospital, the nurse was able to access a patient's medical record and review the education that other nurses provided during an initial hospitalization and three subsequent clinic visits that occurred in different provider's offices over the past 6 months. This type of feature is most common in a(n) _____.

9. The nurse is transferring a patient to a long-term, skilled care facility and has just given a telephone report to a registered nurse (RN) who works at that facility and who will be receiving the patient. In documenting this call, the nurse begins by writing the date and time the report was given and the name of the RN taking the report. Which of the following pieces of information does the nurse include in the documentation of this telephone call? (Select all that apply.)
   1. The patient's name, age, and admitting diagnoses
   2. The discussion of any allergies to food and medications that the patient has
   3. That the nurse receiving the report was advised that the patient is "needy" and "on the call light all the time"
   4. That the patient's pain rating went from 8 to 2 on a scale of 1 to 10 after receiving 650 mg of Tylenol
   5. Description of any unresolved problems and current interventions in place

10. The nurse is supervising a beginning nursing student and allowing the student to complete documentation of care under direct observation. Which of the following actions are not appropriate and would require intervention? The nursing student: (Select all that apply.)
    1. Documents a medication given by another nursing student.
    2. Includes the date and time of the entry into the medical record.
    3. Enters assessment data into the electronic medical record using the computer mounted on the wall in the patient's room.
    4. Leaves a slip of paper with her user name and password in the patient's room.
    5. Starts to enter "Docusate sodium 100 mg ordered at 08:00 held. Patient declined to take dose stating, "I had several loose stools yesterday, and I'm afraid if I take this dose the problem will get worse," as a narrative comment.

11. A group of nurses is discussing the advantages of using computerized provider order entry (CPOE). Which of the following statements indicates that the nurses understand the major advantage of using CPOE?
    1. "CPOE reduces transcription errors."
    2. "CPOE reduces the time needed for health care providers to write orders."
    3. "CPOE eliminates verbal and telephone orders from health care providers."
    4. "CPOE reduces the time nurses use to communicate with health care providers."

12. The nurse is working the evening shift at a hospital that uses military time for documentation. The nurse administered morphine 2 mg intravenously (IV) for pain at 3:45 PM, changed the dressing over the patient's abdominal incision at 5:34 PM, and administered Ancef 1 g IV at 8:00 PM. Using correct military time, label the documentation for each task with the time that it was completed.
    1. _____ Morphine 2 mg IV given for pain rating of 8/10
    2. _____ Dressing changed over midline abdominal incision using aseptic technique
    3. _____ Ancef 1 g given IVPB over 30 minutes.

13. The nurse is caring for a patient with a nasogastric feeding tube who is receiving a continuous tube feeding at a rate of 45 mL per hour. The nurse enters the patient assessment data and information that the head of the patient's bed is elevated to 20 degrees. An alert appears on the computer screen warning that this patient is at a high risk for aspiration because the head of the bed is not elevated enough. This warning is known as which type of system?
    1. Electronic health record
    2. Clinical documentation
    3. Clinical decision support system
    4. Computerized physician order entry

14. While reviewing the pulmonary assessment entered by a nurse in a patient's electronic medical record (EMR), a physician notices that the only information documented in that section is "WDL" (within defined limits). The physician also is not able to find a narrative description of the patient's respiratory status in the nurse's progress notes. What is the most likely reason for this?
    1. The nurse caring for the patient forgot to document on the pulmonary system.
    2. The EMR uses a charting-by-exception format.
    3. The computer shut down unexpectedly when the nurse was documenting the assessment.
    4. Because of HIPAA regulations, physicians are not authorized to view the nursing assessment.

15. What is the appropriate way for a nurse to dispose of information printed out from a patient's electronic health record?
    1. Rip the papers up into small pieces and place the pieces into a standard trash can
    2. Place all papers in the flip-top binder designated for that patient that is located in the nurse's station on the patient care unit
    3. Place papers with patient information in a secure canister marked for shredding
    4. Burn documents with patient information in the steel sink located within the dirty supply room on the patient care unit

Answers: 1. 4; **2.** 3; **3.** 4; **4.** 3; **5.** 2; **6.** 4; **7.** 1=P, 2=S, 3=A, 4=O; **8.** Electronic health record; **9.** 1, 2, 4, 5; **10.** 1, 4; **11.** 1; **12.** 1=15:45, 2=17:34, 3=20:00; **13.** 3; **14.** 2; **15.** 3.

Patient Safety and Quality

Safety, often defined as freedom from psychological and physical injury, is a basic human need. Health care provided in a safe manner and a safe community environment is essential for a patient's survival and well-being. A safe environment reduces the risk for illness and injury and helps to contain the cost of health care by preventing extended lengths of treatment and/or hospitalization, improving or maintaining a patient's functional status, and increasing a patient's sense of well-being. The Institute of Medicine's report *To Err Is Human: Building a Safer Health System* (IOM, 2000) was a pivotal publication that brought patient safety to the forefront of health care in the United States. This report indicated that 44,000 to 98,000 people die each year as a result of preventable medical errors. In an effort to improve patient safety, many organizations became devoted to developing and monitoring key health care safety initiatives and providing information to health care organizations and the public. Health care organizations foster a patient-centered safety culture by continually focusing on performance-improvement endeavors, risk-management findings, and safety reports; providing current reliable technology; integrating evidence-based practice into procedures; designing a safe work environment and atmosphere; and providing continuing education and access to appropriate resources for staff (Box 27-1).

As part of the health care team, nurses are professionally responsible for engaging in activities that support a patient-centered safety culture. The IOM defined patient-centered care as health care that establishes a partnership among practitioners, patients, and their families (when appropriate) to ensure that decisions respect patients' wants, needs, and preferences and that patients have the education and support they need to make decisions and participate in their own care (IOM, 2001). Considerable emphasis is placed on improving the education of nursing students so they become competent in promoting safe health care practices.

The Quality and Safety Education for Nurses (QSEN) project was developed to meet the challenge of preparing future nurses who will have the knowledge, skills, and attitudes necessary to continuously improve the quality and safety of the health care systems within which they work (QSEN, 2014). The QSEN safety competency for a nurse is defined as "Minimizes risk of harm to patients and providers through both system effectiveness and individual performance." As a nurse you are responsible for incorporating critical thinking skills when using the nursing process, assessing each patient and his or her environment for hazards that threaten safety, and planning and intervening appropriately to maintain a safe environment. By doing this you become a

provider of safe acute, restorative, and continuing care and an active participant in health promotion.

SCIENTIFIC KNOWLEDGE BASE

Environmental Safety

A patient's environment includes physical and psychosocial factors that influence or affect the life and survival of that patient. This broad definition of environment crosses the continuum of care for settings in which the nurse and patient interact such as the hospital, long-term care facility, clinic, community center, school, and home. A safe environment protects the staff as well, allowing them to function optimally. Vulnerable groups who often require help in achieving a safe environment include infants, children, older adults, the ill, the physically and mentally disabled, the illiterate, and the poor. A safe environment includes meeting basic needs, reducing physical hazards and the transmission of pathogens, and controlling pollution.

Basic Needs. Physiological needs, including the need for sufficient oxygen, nutrition, and optimum temperature, influence a person's safety. According to Maslow's hierarchy of needs, these basic needs must be met before physical and psychological safety and security can be addressed (see Chapter 6).

Oxygen. Supplemental oxygen is sometimes required to meet a person's oxygenation needs. Oxygen is not flammable, but it is combustible. This means that fire needs oxygen to start and to keep burning. When more oxygen is in the air, a fire burns hotter and faster. Strict codes regulate the use and storage of medical oxygen in health care facilities. This is not necessarily true in the home environment. Hospital emergency departments see approximately 1190 thermal burns per year caused by ignitions associated with home medical oxygen (NFPA, 2008). Smoking is the leading cause of burns, reported fires, deaths, and injuries involving home medical oxygen.

Be aware of factors in a patient's environment that decrease the amount of available oxygen. A common environmental hazard in the home is an improperly functioning heating system. A furnace, stove, or fireplace that is not properly vented introduces carbon monoxide into the environment (NFPA, 2014a). Carbon monoxide affects a person's oxygenation by binding with hemoglobin, preventing the formation of oxyhemoglobin and thus reducing the supply of oxygen delivered to tissues (see Chapter 41). Low concentrations cause nausea, dizziness, headache, and fatigue. Very high concentrations cause death after 1 to 3 minutes of exposure (Mayo Clinic, 2014).

Nutrition. Meeting nutritional needs adequately and safely requires environmental controls and knowledge (see Chapter 45). Health care facilities and restaurants are required to meet State Board of Health regulations. To protect consumers, commercially processed and packaged foods are subject to **Food and Drug Administration (FDA)** regulations. The FDA is a federal agency responsible for the enforcement of federal regulations regarding the manufacture, processing, and distribution of foods, drugs, and cosmetics to protect consumers against the sale of impure or dangerous substances. Although food supply in the United States is one of the safest in the world, about 48 million illnesses occur annually, more than 128,000 people are hospitalized, and 3000 die from foodborne illness (CDC, 2014a). Groups at the highest risk are children, pregnant women, older adults, and people with compromised immune systems. Foods that are inadequately prepared or stored or subject to unsanitary conditions increase a patient's risk for infections and food poisoning.

Temperature. A person's comfort zone is usually between 18.3° and 23.9° C (65° and 75° F). Temperature extremes that frequently occur during the winter and summer affect comfort, productivity, and safety. Exposure to severe cold for prolonged periods causes frostbite and accidental hypothermia. Older adults, the young, patients with cardiovascular conditions, patients who have ingested drugs or alcohol in excess, and people who are homeless are at high risk for hypothermia. Exposure to extreme heat changes the electrolyte balance of the body and raises the core body temperature, resulting in heatstroke or heat exhaustion. Chronically ill patients, older adults, and infants are at greatest risk for injury from extreme heat. These patients need to avoid extremely hot, humid environments (see Chapter 30).

Physical Hazards. On average 33.5 million injuries take place each year (CDC, 2010). Physical hazards in the environment threaten a person's safety and often result in physical or psychological injury or death. Unintentional injuries are the fifth leading cause of death for Americans of all ages (National Center for Injury Prevention and Control, 2010a, 2010b). Motor vehicle accidents are the leading cause, followed by poisonings and falls. Additional hazards consist of fire and disasters. Nurses play a role in educating patients about common safety hazards and how to prevent injury while placing emphasis on hazards to which patients are more vulnerable.

Motor Vehicle Accidents. Vehicle design and equipment such as seat belts, air bags, and laminated windshields (remain in one piece when impacted) have improved safety for vehicle occupants. State-specific laws relating to young driver licensing, safety belt use, child restraint use, and motorcycle helmets exist for protection. Child safety seats and booster seats appropriate for a child's age and weight and the type of car need to be used. The American Academy of Pediatrics (AAP, 2011a) recommends that all infants and toddlers ride in the back seat with a rear-facing-only seat and rear-facing convertible seat until they are 2 years of age or they reach the highest weight or height allowed by the manufacturer of the car safety seat. Toddlers and preschoolers or any child who has outgrown the rear-facing weight or height limit for his convertible car seat should use a forward-facing car seat. The website of the AAP, Healthy Children, http://www.healthychildren.org/English/safety-prevention/on-the-go/Pages/Car-Safety-Seats-Information-for-Families.aspx, has information for children of all ages and the type of safety seat to use. The back seat of a car is the safest part of the vehicle in the event of a crash and prevents injury from deployment of passenger and side air bags.

According to the CDC (2014b), the risk of motor vehicle accidents is higher among 16- to 19-year-old drivers than any other age-group. Teens are more likely to underestimate dangerous situations or not be able to recognize hazardous situations, speed and allow shorter headways, ride with intoxicated drivers, and drive after using alcohol and drugs. Teens also have the lowest rate of seat belt use. Older drivers are keeping their licenses longer and driving more miles than in the past. Per mile traveled, fatal crash rates increase starting at age 75 and

increase markedly after age 80 (Insurance Institute for Highway Safety, 2015). An older adult is not always able to quickly observe situations in which an accident is likely to occur. Decreased hearing acuity alters the ability to hear emergency vehicle sirens or vehicle horns. A decreased nervous system response prevents older adults from being able to react as quickly as they once could to avoid an accident. A decline in these skills accounts for the most common types of accidents, including right-of-way and turning accidents.

Poison. A **poison** is any substance that impairs health or destroys life when ingested, inhaled, or absorbed by the body. Almost any substance is poisonous if too much is taken. Sources in a person's home include drugs, medicines, other solid and liquid substances, and gases and vapors. Poisons often impair the function of every major organ system. Health care providers are at risk from chemicals such as toxic cleaning agents. In the home accidental poisoning is a greater risk for toddlers, preschoolers, and young school-age children, who often ingest household cleaning solutions, medications, or personal hygiene products. Emergency treatment is necessary when a person ingests a poisonous substance or comes in contact with a chemical that is absorbed through the skin. In 2014 more than 2000 people a day were seen in emergency departments after a poison incident (CDC, 2014c). A poison control center is the best resource for patients and parents needing information about the treatment of an accidental poisoning.

Although lead has not been used in house paint or plumbing materials since the U.S. Consumer Product Safety Commission banned it in 1978, older homes in poorer communities continue to contain high lead levels. Soil and water systems are sometimes contaminated. Poisoning occurs from swallowing or inhaling lead. Fetuses, infants, and children are more vulnerable to lead poisoning than adults because their bodies absorb lead more easily and small children are more sensitive to the damaging effects of lead. Exposure to excessive levels of lead affects a child's growth or causes learning and behavioral problems and brain and kidney damage (Agency for Toxic Substances and Disease Registry, 2014).

Falls. Falls are a major public health problem. Among adults 65 years and older, falls are the leading cause of both fatal and nonfatal injuries (CDC, 2015a). Numerous factors increase the risk of falls, including a history of falling, being age 65 or over, reduced vision, orthostatic hypotension, lower-extremity weakness, gait and balance problems, urinary incontinence, improper use of walking aids, and the effects of various medications (e.g., anticonvulsants, diuretics, hypnotics, sedatives, certain analgesics) (Deandrea et al., 2010). Common physical hazards that lead to falls in the home include inadequate lighting, barriers along normal walking paths and stairways, loose rugs and carpeting, and a lack of safety devices in the home. Falls are also a common problem in health care settings (Spoelstra et al., 2011). Hospitals throughout the country carefully monitor the incidence of falls and fall-related injuries as part of their ongoing performance improvement work. Falls are often a combination of individual and transient risk factors, the physical environment (e.g., poor lighting, high bed position, improper equipment), and the riskiness of a person's behavior (unwilling to call for assistance when getting up) (Spoelstra et al., 2011). Falls often lead to serious injuries such as fractures or internal bleeding. Patients most at risk for injury are those with bleeding tendencies resulting from disease or medical treatments and osteoporosis.

Fire. A total of 487,500 structure fires were reported in the United States in 2013, resulting in 2855 deaths and 14,075 injuries (NFPA, 2014b). The leading cause of fire-related death is careless smoking, especially when people smoke in bed at home. However, the U.S. Consumer Product Safety Commission estimates that more than

25,000 residential fires every year are associated with the use of space heaters, resulting in more than 300 deaths (Energy.gov, 2014). The improper use of cooking equipment and appliances, particularly stoves, is a main source for in-home fires and fire injuries. Smoke detectors and carbon monoxide detectors need to be placed strategically throughout a home. Multipurpose fire extinguishers need to be near the kitchen and any workshop areas. Advise families to only purchase newer-model space heaters that have all of the current safety features.

Disasters. Natural disasters such as floods, tsunamis, hurricanes, tornadoes, and wildfires are a major cause of death and injury. These types of disasters result in death and leave many people homeless. Every year millions of Americans face disaster and its terrifying consequences. Bioterrorism is another cause of disaster. Threats of this type come in the form of biological, chemical, and radiological attacks. Bioterrorism, or the use of biological agents such as anthrax, smallpox, and botulism to create fear or threat, is the most likely form of a terrorist attack to occur (CDC, 2014d).

Transmission of Pathogens. Pathogens and parasites pose a threat to patient safety (see Chapter 29). A **pathogen** is any microorganism capable of producing an illness. The most common means of transmission of pathogens is by the hands. For example, if an individual infected with hepatitis A does not wash his or her hands thoroughly after having a bowel movement, the risk for transmitting the disease during food preparation is great. One of the most effective methods for limiting the transmission of pathogens is the medically aseptic practice of hand hygiene (see Chapter 29). It is important to educate your patients and their family caregivers about the importance of hand hygiene. Hand hygiene is used in all aspects of life, not just in food preparation practices or when caring for a sick family member. Teach all family members to wash their hands after activities such as play, coming home from work, working in the garden, and car maintenance. Hand hygiene is a simple and effective measure to reduce the transmission of pathogens and the risk of subsequent illness.

The human immunodeficiency virus (HIV), the pathogen that causes acquired immunodeficiency syndrome (AIDS), and the hepatitis B virus are transmitted through blood and other select body fluids. High-risk behaviors such as sexual contact and drug use are common risk factors for HIV. People who abuse drugs often share syringes and needles, which increases the risk of acquiring these viruses. Some states and many nonprofit organizations fund syringe-exchange programs as a means to slow down the spread of infectious diseases obtained through needle sharing (Coalition for Safe Community Needle Disposal, 2015).

Immunization reduces, and in some cases prevents, the transmission of disease from person to person. Great progress has been made in the United States over the last 50 years in the use of vaccines to prevent serious and infectious diseases. However, frequently issues about vaccine safety and the increasing complexity of immunization schedules have fostered doubts among parents about the necessity of vaccinations (Kennedy et al., 2011). You are responsible as a nurse to educate parents about the benefits of immunization. A survey conducted in 2010 found that over half of the parents expressed concerns that their child would have a serious reaction from the vaccine or that the vaccine might not be safe. The researchers found that these concerns were predictive of the parents delaying future immunizations for their children (Opel et al., 2013). However, a 2011 survey of over 300 parents found that the majority surveyed reported that they had either already vaccinated (83%) or planned to vaccinate (11%) their children with all recommended vaccines (Kennedy et al., 2011). Lack of immunization puts children and adults at risk.

Pollution.   A healthy environment is free of pollution. A **pollutant** is a harmful chemical or waste material discharged into the water, soil, or air. People commonly think of pollution only in terms of air, land, or water pollution; but excessive noise is also a form of pollution that presents health risks. Air pollution is the contamination of the atmosphere with a harmful chemical. Prolonged exposure to industrial waste and vehicle exhaust increases the risk of pulmonary disease. In the home, school, or workplace, cigarette smoke is the primary cause of air pollution. Improper disposal of radioactive and bioactive waste products (e.g., dioxin) can cause land pollution. Water pollution is the contamination of lakes, rivers, and streams, usually by industrial pollutants. If water becomes contaminated, the public needs to use bottled or boiled water for drinking and cooking. Flooding damages water-treatment stations and also requires the use of bottled or boiled water.

NURSING KNOWLEDGE BASE

Factors Influencing Patient Safety

In addition to being knowledgeable about the home and health care environment and the inherent safety risks, nurses need to know a patient's developmental level; mobility, sensory, and cognitive status; lifestyle choices; and knowledge of common safety precautions. They also need to be aware of the special risks to safety that are found in health care settings.

Risks at Developmental Stages.   A patient's developmental stage creates threats to safety as a result of lifestyle, cognitive and mobility status, sensory impairments, and safety awareness. With this information you tailor safety prevention programs to the needs, preferences, and life circumstances of particular age-groups. Unfortunately all age-groups are subject to abuse. Child abuse, domestic violence, and elder abuse are serious threats to safety (see Chapters 11 to 14).

Infant, Toddler, and Preschooler.   Injuries are the leading cause of death in children over age 1 and cause more death and disabilities than do all diseases combined (Hockenberry and Wilson, 2015). The nature of the injury sustained is closely related to normal growth and development. For example, the incidence of lead poisoning is highest in late infancy and toddlerhood. Children at this stage explore the environment and, because of their increased level of oral activity, put objects in their mouths. This increases risk for poisoning and choking. Fire often results from their curiosity in playing with matches. In addition, limited physical coordination contributes to falls from bicycles and playground equipment. Additional injuries at this age are related to riding unrestrained in a motor vehicle, drowning, and head trauma from objects. Accidents involving children are largely preventable, but parents need to be aware of specific dangers at each stage of growth and development. Thus accident prevention requires health education for parents and the removal of dangers whenever possible.

School-Age Child.   When a child enters school, the environment expands to include the school, transportation to and from school, school friends, and after-school activities. School-age children are learning how to perform more complicated motor activities and often are uncoordinated. Parents, teachers, and nurses need to instruct children in safe practices to follow at school or play, including what to do if approached by strangers. Teach school-age children involved in team and contact sports the rules for playing safely and how to use protective safety equipment such as helmets and other protective gear. Head injuries are a major cause of death, with bicycle accidents being one of the major causes of such injuries (Hockenberry and Wilson, 2015). Bikes need to be the proper size for the child, and helmets must be worn (Figure 27-1). Parents need to be reminded of the importance of

FIGURE 27-1 Proper bicycle safety equipment for school-age child.

a helmet for tricycles, scooters, and motorized toys. Additional injuries in this age-group are decreased by using seat belts and booster seats in motor vehicles properly and providing pedestrian safety education.

Adolescent.   Adolescents develop greater independence and begin to develop a sense of identity and their own values. The adolescent begins to separate emotionally from his or her family, and peers generally have a stronger influence. Wide variations that swing from childlike to mature behavior are characteristic of adolescent behavior (Hockenberry and Wilson, 2015). In an attempt to relieve the tensions associated with physical and psychosocial changes and peer pressures, some adolescents engage in risk-taking behaviors such as smoking, drinking alcohol, and using drugs. This increases the incidence of accidents such as drowning and motor vehicle accidents. When adolescents learn to drive, their environment expands, and so does their potential for injury. Teen motor vehicle crashes are preventable by avoiding distractions such as using cell phones, texting, eating, and drinking while driving.

To assess for possible substance abuse, have parents look for environmental and psychosocial clues from their children. Environmental clues include the presence of drug-oriented magazines, beer and liquor bottles, drug paraphernalia and blood spots on clothing, and the continual wearing of long-sleeved shirts in hot weather and dark glasses indoors. Psychosocial clues include failing grades, change in dress, increased absenteeism from school, isolation, increased aggressiveness, and changes in interpersonal relationships. Because adolescence is a time when mature sexual physical characteristics develop, some adolescents begin to have physical relationships with others that present the risk of sexually transmitted infections.

Adult.   The threats to an adult's safety are frequently related to lifestyle habits. For example, a person who uses alcohol excessively is at greater risk for motor vehicle accidents. People who smoke long-term have a greater risk of cardiovascular or pulmonary disease as a result of the inhalation of smoke and the effect of nicotine on the circulatory system. Likewise, the adult experiencing a high level of stress is more likely to have an accident or illness such as headaches, gastrointestinal (GI) disorders, and infections.

Older Adult.   The physiological changes associated with aging, effects of multiple medications, psychological and cognitive factors, and the effects of acute or chronic disease increase an older adult's risk for falls and other types of accidents. The risk of being seriously injured in a fall increases with age. Patients who wander have special safety challenges. Wandering is the meandering, aimless, or repetitive locomotion that exposes a person to harm and is often in conflict with boundaries (such as doors), limits, or obstacles (Herdman and

Kamitsuru, 2014). Individuals can walk away from home or off care units or enter restricted or closed areas without the knowledge of caregivers. This is a common problem in patients who are confused or disoriented. Interrupting a wandering patient can increase his or her distress.

Older patients are more likely to fall in the bedroom, bathroom, and kitchen in their homes. Environmental factors such as broken stairs, icy sidewalks, inadequate lighting, throw rugs, and exposed electrical cords cause many of the accidents. Inside falls most often occur while transferring from beds, chairs, and toilets; getting into or out of bathtubs; tripping over items such as cords covered by rugs or carpets, carpet edges, or doorway thresholds; slipping on wet surfaces; and descending stairs. Fear of falling is a concern of community-dwelling older adults, and many avoid activities because of their fear. Main risk factors for developing fear of falling are at least one fall, being female, and being older (Scheffer et al., 2008).

Multiple trials and systemic review provide clear evidence that falls in the community can be reduced through regular exercise (Sherrington et al., 2011). Falls can be decreased by group exercise, tai chi, and having cataract surgery. Decreasing hazards in the home that increase falls is also effective (Gillespie et al., 2012). Clinicians in hospital settings continue to struggle to find consistent and reliable approaches for fall reduction. Interventions shown to reduce hospital fall rates include developing a culture of safety, conducting fall risk assessments, and multifactorial interventions (e.g., equipment upgrades, removing hazards, identifying high-risk patients, low beds) (Spoelstra et al., 2011).

Individual Risk Factors. Other risk factors posing threats to safety include lifestyle, impaired mobility, sensory or communication impairment, and the lack of safety awareness. Know your patients' risks when you plan their nursing care.

Lifestyle. Some lifestyle choices increase safety risks. People who drive or operate machinery while under the influence of chemical substances (drugs or alcohol), work at inherently dangerous jobs, or are risk takers are at greater risk of injury. In addition, people experiencing stress, anxiety, fatigue, or alcohol or drug withdrawal or those taking prescribed medications are sometimes more accident prone. Because of these factors, some people are too preoccupied to notice the source of potential accidents such as cluttered stairs or a stop sign.

Impaired Mobility. A patient with impaired mobility has many kinds of safety risks. Muscle weakness, paralysis, and poor coordination or balance are major factors in falls. Immobilization predisposes patients to additional physiological and emotional hazards, which in turn further restrict mobility and independence. People who are physically challenged are at greater risk for injury when entering motor vehicles and buildings that are not handicap accessible.

Sensory or Communication Impairment. Cognitive impairments associated with delirium, dementia, and depression contribute to altered concentration and attention span, impaired memory, and orientation changes. Patients with these alterations become easily confused about their surroundings and are more likely to have falls and burns. Patients with visual, hearing, tactile, or communication impairment such as aphasia or a language barrier are not always able to perceive a potential danger or express their need for assistance (see Chapter 49).

Lack of Safety Awareness. Some patients are unaware of safety precautions such as keeping medicine or poisons away from children or reading the expiration date on food products. A nursing assessment that includes a home inspection helps you identify a patient's level of knowledge about home safety so you can correct deficiencies with an individualized nursing care plan.

BOX 27-2 The Joint Commission 2015 National Patient Safety Goals for Critical Access Hospitals

- Identify patients correctly.
- Improve staff communication.
- Use medicines safely.
- Use alarms safely.
- Prevent infection.
- Prevent mistakes in surgery.

Risks in the Health Care Agency. Patient safety continues to be one of the most pressing health care challenges in the nation. Medical errors happen when something that was planned as part of medical care doesn't work out or when the wrong plan was used. They occur in all health care settings. You must be aware of regulatory and organizational safety initiatives and individual patient risk factors. The Agency for Healthcare Research and Quality lists 20 tips to help prevent medical errors (AHRQ, 2014). You can view these tips at the AHRQ website, http://www.ahrq.gov/patients-consumers/care-planning/errors/20tips/.

The Joint Commission (TJC) and the Centers for Medicare and Medicaid Services (CMS) emphasize error prevention and patient safety. Their "Speak Up" campaign encourages patients to take a role in preventing health care errors by becoming active, involved, and informed participants on the health care team. For example, patients are encouraged to ask health care workers if they have washed their hands before providing care. The National Patient Safety Goals of TJC (2016) are specifically directed to reduce the risk of medical errors (Box 27-2). The goals highlight specific improvements in patient safety and ongoing problematic areas in health care. These evidence-based recommendations require health care facilities to focus their attention on a series of specific actions.

The mission of the National Quality Forum (NQF) (2011a) is improving the quality of health care in America by:
- Building consensus on national priorities and goals for performance improvement and working in partnership to achieve them;
- Endorsing national consensus standards for measuring and publicly reporting on performance; and
- Promoting the attainment of national goals through education and outreach programs.

Recently the NQF released its *National Voluntary Consensus Standards for Public Reporting of Patient Safety Events* (NQF, 2011b). The report provides a framework for publicly reporting patient safety information, including events, indicators, and measures, about health care organizations to consumers. It is important for nurses to understand the NQF standards and their intent since ultimately they influence the types of priorities that patient care organizations (e.g., hospitals, community health centers) set to improve the quality of care delivered to patients. Many of the NQF measures of patient safety (e.g., patient falls with injury, incidence of pressure ulcers, and central line bloodstream infection) are standards for judging the quality of care of health care organizations. The measures are also used by other organizations such as TJC and the CMS. Among the safety measures, the NQF endorsed a select list of serious reportable events (SREs), which was updated in 2006. The 28 events (Box 27-3) are a major focus of health care providers for patient safety initiatives. The CMS names select SREs as *Never Events* (i.e., adverse events that should never occur in a health care

BOX 27-3 The National Quality Forum List of Serious Reportable Events

Surgical Events
A. Surgery performed on the wrong body part
B. Surgery performed on the wrong patient
C. Wrong surgical procedure performed on a patient
D. Unintended retention of foreign object in a patient after surgery or procedure
E. Intraoperative or immediately postoperative death

Patient-Protection Events
A. Infant discharged to wrong person
B. Patient death or serious disability associated with patient elopement
C. Patient suicide or attempted suicide resulting in serious disability during care in a health care facility

Care-Management Events
A. Patient death or serious disability associated with medication error
B. Patient death or serious disability associated with hemolytic reaction as a result of administration of ABO/HLA–incompatible blood or blood products
C. Maternal death or serious disability associated with labor or delivery in a low-risk pregnancy during care in a health care facility
D. Patient death or serious disability associated with hypoglycemia, the onset of which occurs during care in a health care facility
E. Death or serious disability associated with failure to identify and treat hyperbilirubinemia in neonates
F. Stage III or IV pressure ulcers acquired after admission to a health care facility
G. Patient death or serious disability caused by spinal manipulative therapy
H. Artificial insemination with wrong donor sperm or wrong egg

Product or Device Events
A. Patient death or serious disability associated with use of contaminated drugs, devices, or biologicals provided by the health care facility
B. Patient death or serious disability associated with use or function of a device in patient care when the device is used for functions other than as intended
C. Patient death or serious disability associated with intravascular air embolism that occurs during care in a health care facility

Environmental Events
A. Patient death or serious disability associated with an electric shock during care in a health care facility
B. Any incident in which a line designated for oxygen or other gas to be delivered to a patient contains the wrong gas or is contaminated by toxic substances
C. Patient death or serious disability associated with burn incurred from any source during care in a health care facility
D. Patient death or serious disability associated with fall during care in a health care facility
E. Patient death or serious disability associated with use of restraints or bedrails during care in a health care facility

Criminal Events
A. Care provided by someone impersonating a health care provider
B. Abduction of patient of any age
C. Sexual assault on patient within or on the grounds of a health care facility
D. Death or significant injury resulting from a physical assault that occurs within or on the grounds of the facility

Copyright © 2015 National Quality Forum.

BOX 27-4 The 2014 Centers for Medicare and Medicaid Services Hospital-Acquired Conditions (Present-on-Admission Indicator)

- Foreign object retained after surgery
- Air embolism
- Blood incompatibility
- Pressure ulcer stages III and IV
- Falls and trauma (fracture, dislocation, intracranial injury, crushing injury, burn, electric shock)
- Catheter-associated urinary tract infections
- Vascular catheter-associated infections
- Manifestations of poor glycemic control (diabetic ketoacidosis, nonketotic hyperosmolar coma, hypoglycemic coma, secondary diabetes with ketoacidosis, secondary diabetes with hyperosmolarity)

- Surgical site infections following:
  - Mediastinitis following coronary artery bypass graft
  - Certain orthopedic procedures (spine, neck, shoulder, elbow)
  - Bariatric surgery for obesity (laparoscopic gastric bypass, gastroenterostomy, laparoscopic gastric restrictive surgery)
  - Cardiac implantable medical device
  - Deep-vein thrombosis (DVT)/pulmonary embolism (PE) following certain orthopedic procedures (total knee replacement, hip replacement)
  - Iatrogenic pneumothorax with venous catheterization

From Centers for Medicare and Medicaid Services (CMS): *Hospital-acquired conditions,* 2015, http://www.cms.gov/HospitalAcqCond/06_Hospital-Acquired_Conditions.asp. Accessed September 2015.

setting) (DHHS, 2008). The CMS (2015) denies hospitals higher payment for any hospital-acquired condition resulting from or complicated by the occurrence of certain Never Events (Box 27-4). Many of the hospital-acquired conditions (e.g., fall or stage III pressure ulcer) are nurse-sensitive indicators, meaning that a nurse directly affects their development. The NQF (2011c) also released 34 safe practices for better health care. Evidence supports the effectiveness of these practices in reducing the occurrence of adverse health care events.

Being aware of and engaged in activities focused on the prevention of these conditions not only enhances patient safety but also contributes to the overall success of the health care facility. The CMS believes that the Never Events will strengthen incentives by hospitals to develop safety practices and reduce health care costs in the long term. Health care facilities often conduct a failure mode and effect analysis (FMEA) to identify problems with processes and products before they occur.

When an actual or potential adverse event occurs, the nurse or health care provider involved completes an incident or occurrence report. An incident report is a confidential document that completely describes any patient accident occurring on the premises of a health

care agency (see Chapter 23). Reporting allows an organization to identify trends/patterns throughout the facility and areas to improve. Focusing on the root cause of an event instead of the individual involved promotes a "culture of safety" that helps in specifically identifying what contributed to an error. The probability of an accident occurring declines when health care providers adhere to evidence-based principles of safety (Taylor-Adams et al., 2009).

Nurses face specific environmental risks in health care facilities. An example is exposure to various forms of chemicals. Chemicals found in some medications (e.g., chemotherapy), anesthetic gases, cleaning solutions, and disinfectants are potentially toxic if ingested, absorbed into the skin, or inhaled. Material safety data sheets (MSDSs) are required resources available in any health care agency (OSHA, 2014). The MSDS provides detailed information about the chemical, health hazards imposed, first aid guidelines, and precautions for safe handling and use. MSDSs give information on the steps to take in case the material is released or spilled. Be aware of the location of the MSDSs and be knowledgeable about hazardous chemicals in your environment. Spread of pathogens also presents a risk to both nurses and other patients. Therefore always follow standard and transmission-based isolation precautions and use proper hand hygiene (see Chapter 29).

Specific risks to a patient's safety within the health care environment include falls, patient-inherent accidents, procedure-related accidents, and equipment-related accidents. The nurse assesses for these four potential problem areas and, considering the developmental level of the patient, takes steps to prevent or minimize accidents.

Falls. Falls result in minor-to-severe injuries such as bruises, hip fractures, or head trauma that result in reduced mobility and independence and increase the risk for premature death. Patients who have underlying disease states are more susceptible to fall-related injuries (Grundstrom et al., 2012). For example, a patient with a bleeding disorder is more likely to have an intracranial bleed; a patient with osteoporosis has a greater chance for fracture. The unfamiliar environment, effects of acute illness or surgery, impaired mobility, effects of medications and treatments, and placement of various tubes and catheters place patients of any age at risk of falling. Nurses can implement multifactorial interventions, including assessment and communication about patient risks, staff assignments in close proximity, signage, improved patient hand-offs, nurse toilet and comfort safety rounds, and involving the patient and family (Spoelstra et al., 2011). Injuries from falls often extend a patient's length of stay in the health care environment, placing them at an even greater risk for other complications.

Patient-Inherent Accidents. Patient-inherent accidents are accidents (other than falls) in which a patient is the primary reason for the accident. Examples include self-inflicted cuts, injuries, and burns; ingestion or injection of foreign substances; self-mutilation or fire setting; and pinching fingers in drawers or doors. One of the more common precipitating factors for a patient-inherent accident is a seizure.

Procedure-Related Accidents. Procedure-related accidents are caused by health care providers and include medication and fluid administration errors, improper application of external devices, and accidents related to improper performance of procedures such as dressing changes or urinary catheter insertion. Nurses are able to prevent many procedure-related accidents by adhering to organizational policy and procedures and standards of nursing practice. For example, proper preparation and administration of medications, use of patient and medication bar coding, and "smart" intravenous (IV) pumps reduce medication errors (see Chapters 32 and 42). All staff need to be aware that distractions and interruptions contribute to procedure-related accidents and need to be limited, especially during

high-risk procedures such as medication administration. The potential for infection is reduced when surgical asepsis is used for sterile dressing changes or any invasive procedure such as insertion of a urinary catheter. Finally, correct use of safe patient handling techniques and equipment reduces the risk of injuries when moving and lifting patients (see Chapter 39).

Equipment-Related Accidents. Accidents that are equipment related result from the malfunction, disrepair, or misuse of equipment or from an electrical hazard. To avoid rapid infusion of IV fluids, all general-use and patient-controlled analgesic pumps need to have free-flow protection devices. To avoid accidents, do not operate monitoring or therapy equipment without adequate instruction. If you find a piece of faulty equipment, place a tag on it to prevent it from being used on another patient and promptly report any malfunctions. Assess potential electrical hazards to reduce the risk of electrical fires, electrocution, or injury from faulty equipment. In health care settings the clinical engineering staff make regular safety checks of equipment. Facilities must report all suspected medical device–related deaths to both the FDA and the manufacturer of the product if known (USFDA, 2015). This is usually done in conjunction with the risk-management department after tagging and removing the piece of equipment.

> **QSEN** **QSEN: BUILDING COMPETENCY IN SAFETY.** A nurse is caring for a patient who is receiving chemotherapy. The patient becomes confused, pulls out her IV line, and the chemotherapy drug leaks into the bed linens and all over the floor. What risks are posed for this patient? What risks are posed for the nurse? How should the nurse handle the situation?
>
> ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

CRITICAL THINKING

Successful critical thinking requires a synthesis of knowledge, experience, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require nurses to anticipate necessary information, analyze the data, and make decisions regarding patient care. Critical thinking is an ongoing process. During assessment (Figure 27-2) consider all critical thinking elements and information about a specific patient to make appropriate nursing diagnoses.

In the case of safety, a nurse integrates knowledge from nursing and other scientific disciplines, previous experiences in caring for patients who were at risk for or had an injury, critical thinking attitudes such as responsibility and discipline, and any standards of practice that are applicable. For example, the American Nurses Association (ANA) standards for nursing practice address the nurse's responsibility in maintaining patient safety. TJC (2016) also provides standards for safety. Apply this information and your experience as you conduct a detailed assessment of a specific patient. For example, while assessing a patient's home environment, you consider typical locations within the home where dangers commonly exist. If a patient has a visual impairment, you apply previous experiences in caring for patients with visual changes to anticipate how to thoroughly assess his or her needs. Critical thinking directs you to anticipate what you need to assess and how to make conclusions about available data.

❖ NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of safe patient care.

Knowledge
- Basic human needs
- Potential risks to patient safety from physical hazards, lifestyle, risks associated with health care environment, environmental risks, and biohazards
- Influence of developmental stage on safety needs
- Influence of illness/medications on patient safety

Experience
- Caring for patients whose mobility, cognitive, or sensory impairments increase threats to safety
- Personal experience in caring for younger siblings or children

ASSESSMENT
- Identify patient's perceptions of safety needs and risks
- Identify actual and potential threats to the patient's safety
- Determine impact of the underlying illness on the patient's safety
- Identify the presence of risks for the patient's developmental stage and patient's environment
- Determine effect of environmental influence on the patient's safety

Standards
- Apply intellectual standards such as accuracy, significance, and completeness when assessing for threats to the patient's safety
- Apply ANA standards for nursing practice
- Apply agency practice standards (e.g., fall prevention or restraint protocols)
- Review and apply the most current TJC patient safety goals

Attitudes
- Demonstrate perseverance when necessary to identify all safety threats
- Be responsible for collecting unbiased, accurate data regarding threats to the patient's safety
- Show discipline in conducting a thorough review of the patient's home environment

FIGURE 27-2 Critical thinking model for safety assessment. *ANA,* American Nurses Association; *TJC,* The Joint Commission.

◆ **Assessment**

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe patient care.

Through the Patient's Eyes. Patients generally expect to be safe in health care settings and in their homes. However, sometimes a patient's view of what is safe does not agree with that of the nurse and the standards he or she hopes to enforce. For this reason your assessment needs to be patient centered and include the patient's own perceptions of his or her risk factors, concerns about being in a health care setting, knowledge of how to adapt to any safety risks, and previous experience with any accidents (Box 27-5). This is important if you need to make changes in the patient's environment. Patients usually do

BOX 27-5 Nursing Assessment Questions

Activity and Exercise
- Do you use any assistive devices such as a wheelchair, walker, or cane to help you move or get around? Did someone show you how to use them safely?
- Do you have any difficulty bathing? Dressing? Eating?
- Do you need assistance in using the bathroom? Getting out of bed or a chair?
- What type of exercise or physical activity do you get? How often?
- How do you handle meal preparation (e.g., use stove and appliances safely)?
- Do you do your own laundry? How do you do this, and where are these appliances located?
- Do you drive a car or motorcycle? When do you normally drive? How far?
- How often do you wear a safety belt when in the car or a helmet when on your bike?

Medication History
- Which medications (prescription, over-the-counter, herbal) do you take?
- Has your doctor or pharmacist reviewed your medicines with you?
- Do any medications make you dizzy or light-headed?

History of Falls
- Have you ever fallen or tripped over anything in your home? Have you had any near misses? (If so, describe)
- Have you ever suffered an injury from a fall? What was it and how did it happen?
- Did you have any symptoms right before you fell? What were they?
- Which activity were you performing before the fall?

Home Maintenance and Safety
- Who does your simple home maintenance or minor home repairs?
- Who shovels your snow? Mows your lawn?
- Do you feel safe in your home? Which things in your environment make you feel unsafe?
- Do you have someone to call in case of an emergency?
- How do you feel about modifying your home to make it safer? Do you need help finding resources to help you do this?

not purposefully put themselves in jeopardy. When they are uninformed or inexperienced, threats to their safety occur. You always need to consult patients or family members about ways to reduce hazards in their environment. To conduct a thorough patient assessment, consider possible threats to the patient's safety, including the immediate environment and any individual risk factors.

Nursing History. A nursing history (see Chapter 31) includes data about a patient's level of wellness to determine if any underlying conditions exist that pose threats to safety. For example, give special attention to assessing a patient's gait, lower-body muscle strength and coordination, and balance by having the patient walk in his or her room. Consider a review of the patient's developmental status as you analyze assessment information. Also review if the patient is taking any medications or undergoing any procedures that pose risks. For example, use of diuretics increases the frequency of voiding and results in the patient having to use toilet facilities more often. Falls often occur with patients who have to get out of bed quickly because of urinary urgency.

Health Care Environment. When caring for patients within a health care facility, determine if any hazards exist in the immediate care environment. Does the placement of equipment (e.g., drainage bags,

IV pumps) or furniture pose barriers when the patient tries to ambulate? Does positioning of the patient's bed allow him or her to reach items on a bedside table or stand easily? Does the patient need help with ambulation? Are there multiple tubes or IV lines? Is the call bell within reach? Contact the clinical engineering staff if there are questions as to whether equipment is functioning properly and in good condition.

Risk for Falls. Assessment of a patient's risk factors for falling is essential to determine specific needs and develop targeted interventions to prevent falls. Many different fall risk–assessment instruments are available; use the tool chosen by your health care agency. Most tools include categories on age, fall history, elimination habits, high-risk medications, mobility, and cognition. At a minimum the assessment needs to be completed on admission, following a change in a patient's condition, after a fall, and when transferred. If it is determined that a patient is at risk for falling, regular assessment always continues. In many cases family members are important resources in assessing a patient's fall risk. Families often are able to report on the patient's level of confusion and ability to ambulate. On the basis of the results of a fall risk assessment, you implement multiple evidence-based interventions. It is very important to inform a patient and family members about a patient's risks. Often younger patients are not aware of how medications and treatments cause dizziness, orthostatic hypotension, or changes in balance. When patients are unaware of their risks, they are less likely to ask for assistance. If family members are informed, they will often call for help (when they are visiting patients) to be sure that patients have appropriate assistance.

Risk for Medical Errors. Be alert to factors within your own work environment that create conditions in which medical errors are more likely to occur. Studies show that overwork and fatigue, particularly when working consecutive 12 hour-shifts, cause a significant decrease in alertness and concentration, leading to errors (Geiger-Brown et al., 2012). It is important for you to be aware of these factors and include checks and balances when working under stress. For example, to reduce chances for a medical error, it is essential that you check the patient's identification by using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy before beginning any procedure or administering a medication (see Chapter 32).

Disasters. Hospitals must be prepared to respond to and care for a sudden influx of patients at the time of a community disaster. Although the occurrence of a bioterrorist attack has been limited to the anthrax deaths following September 11, 2001, the threat is very real. Be prepared to make accurate and timely assessments in any type of setting. A bioterrorist attack will likely resemble a natural outbreak initially. Acutely ill patients representing the earliest cases after a covert attack seek care in emergency departments. Patients less ill at the onset of an illness possibly seek care in primary care settings. Rapid detection of a bioterrorism attack occurs through syndrome surveillance and specific clinical reporting of suspected cases. The early signs of a bioterrorism-related illness often include nonspecific symptoms (e.g., nausea, vomiting, diarrhea, skin rash, fever, confusion) that may persist for several days before the onset of more severe disease. Patients with prodromal illnesses seek outpatient care and are assigned nonspecific diagnoses such as "viral syndrome." Data on patients fitting various syndromic criteria are then transferred to a health department and tested. Be alert for these types of cases in your practice.

Patient's Home Environment. When caring for a patient in the home, a home hazard assessment is necessary. A thorough hazard assessment covers topics such as adequacy of lighting (inside and outdoors), presence of safety devices, placement of furniture or other items that can create barriers, condition of flooring, and safety in the kitchen and bathrooms. Know where medications and cleaning supplies are located. Walk through the home with the patient and discuss how he or she normally conducts daily activities and whether the environment poses problems. Assess for the presence of locks on doors and windows that make the home less susceptible to intruders. When assessing the adequacy of lighting, inspect the areas where the patient moves and works such as outside walkways, steps, interior halls, and doorways. Getting a sense of a patient's routines helps you recognize less obvious hazards.

Assessment for risk of food infection or poisoning includes assessing a patient's knowledge of food preparation and storage practices. For example, does a patient know to check expiration dates of prepared food and milk products? Does he or she keep foods in the refrigerator that are fresh and not spoiled? Does the patient clean fresh fruits and vegetables correctly before eating them? Assess for clinical signs of infection by conducting an examination of GI and central nervous system function, observing for a fever, and analyzing the results of cultures of feces and emesis. In the home inspect suspected food and water sources and assess the patient's handwashing practices. It is useful to ask patients when they routinely wash their hands. This then prompts a helpful discussion about the purpose and importance of handwashing.

Assessment of the environmental comfort of a patient's home includes a review of when the patient normally has heating and cooling systems serviced. Does the patient have a functional furnace or space heater? Does the home have air conditioning or fans? Inform patients who use space heaters of the risk for fires. Are smoke detectors and carbon monoxide detectors up-to-date and functional, and are fire extinguishers present and placed strategically throughout the home and checked routinely?

When patients live in older homes, encourage them to have inspections for the presence of lead in paint, dust, or soil. Because lead also comes from the solder or plumbing fixtures in a home, patients need to have water from each faucet tested. Local health offices will help homeowners locate a trained lead inspector who takes samples from various locations and has them analyzed at a laboratory for lead content.

It is important that your assessment help individuals focus on avoiding losses and reducing their risk for injury associated with disasters. The Federal Emergency Management Agency (http://www.fema.gov/) and the American Red Cross (http://www.redcross.org/) provide nationwide education to help community members prepare for disasters of all types.

◆ Nursing Diagnosis

Gather data from your nursing assessment and analyze clusters of defining characteristics or risk factors to identify relevant nursing diagnoses. Include specific related or contributing factors to individualize your nursing care (Box 27-6). For example, the nursing diagnosis *Risk for Falls* is associated with altered mobility or sensory alteration (e.g., visual) risk factors. Altered mobility leads you to select such nursing interventions as range-of-motion (ROM) exercises; more frequent supervised ambulation; or teaching the proper use of safety devices such as side rails, canes, or crutches. Also consult with a physician about a physical therapy referral. If visual impairment is the risk factor, select different interventions such as keeping the area well lit; orienting the patient to the surroundings; or keeping eye glasses clean, handy, and well protected. When you do not identify the correct risk factors for the diagnosis *Risk for Falls,* the use of inappropriate interventions may increase a patient's risk for falling. For example, not evaluating the home environment for hazards can result in sending a hospitalized

BOX 27-6 **Nursing Diagnostic Process**

Risk for Falls

Assessment Activities	Defining Characteristics
Observe patient's posture, range of motion, strength, balance, and body alignment.	Decrease in lower-extremity strength, difficulty with gait, impaired balance
Assess patient's visual acuity, ability to read, identify distant objects.	Reports difficulty seeing at night
	Vision blurred, unable to identify near objects
Complete a home hazard appraisal.	Poorly lighted home
	Rooms filled with small items
	Excessive amount of furniture for size of room
	Rugs not secure

patient home only to return with an additional injury. Examples of additional nursing diagnoses for patients with safety risk include the following:

- *Risk for Injury*
- *Impaired Home Maintenance*
- *Deficient Knowledge*
- *Risk for Poisoning*
- *Risk for Suffocation*
- *Risk for Trauma*

◆ **Planning**

Patients with actual or potential risks to safety require a nursing care plan with interventions that prevent and minimize threats to their safety. Design your interventions to help a patient feel safe to move about and interact freely within the environment. The total plan of care addresses all aspects of patient needs and uses resources of the health care team and the community when appropriate. Critically synthesize information from multiple sources (Figure 27-3). Critical thinking ensures that a patient's plan of care integrates all that you learned about the patient and the key critical thinking elements. For example, you reflect on knowledge regarding the services that other health professions (e.g., occupational therapy, case management) provide to help patients return to their home environments safely. Also reflect on previous experiences when patients benefited from safety interventions. Such experience helps you adapt approaches with each new patient. Applying critical thinking attitudes such as creativity helps you to collaborate with a patient in planning interventions that are relevant and most useful, particularly when making changes in the home environment.

Goals and Outcomes. You collaborate with a patient, family, and other members of the health care team when setting goals and expected outcomes during the planning process (see the Nursing Care Plan). The patient who actively participates in reducing threats to safety becomes more alert to potential hazards and is more likely to adhere to the plan. Make sure that goals and outcomes for each nursing diagnosis are measurable and realistic, with consideration of the resources available to the patient. For example, in the case of the nursing diagnosis of *Impaired Physical Mobility related to left-sided paralysis,* the goal is the patient "will remain free of injury throughout hospitalization." Examples of expected outcomes include:

- Patient uses tripod cane correctly within 24 hours.
- Patient describes approach to rise up from bed correctly with assistance by end of the teaching session today.

Knowledge
- Role of community resources in safety promotion
- Safety risks posed in use of home care therapies (e.g., home oxygenation, IV therapy)
- Safety interventions suited to patient's risks and condition
- Services available from other disciplines to promote safety

Experience
- Previous patient responses to planned nursing therapies to improve safety (e.g., what worked and what did not work)

PLANNING
- Involve patient as a partner in planning care
- Select nursing interventions to promote safety according to the patient's developmental and health care needs
- Consult with occupational and physical therapists for assistive devices
- Select interventions that will improve the safety of the patient's home environment

Standards
- Establish interventions individualized to the patient's safety needs
- Apply ANA and TJC standards of providing interventions in a safe and appropriate manner
- Apply ANA Code of Ethics to safeguard the patient from incompetent or unethical care

Attitudes
- Use creativity to design interventions suited to patient needs and available resources
- Take risks to implement interventions that explore new resources or use current resources in new ways

FIGURE 27-3 Critical thinking model for safety planning. *ANA,* American Nurses Association; *IV,* intravenous; *TJC,* The Joint Commission.

Setting Priorities. Prioritize a patient's nursing diagnoses and interventions to provide safe and efficient care. For example, the concept map (Figure 27-4) has several nursing diagnoses that apply to Ms. Cohen in the care plan. The patient's mobility problem is an obvious priority because of its influence on risk for falls and skin integrity. Plan individualized interventions on the basis of the severity of risk factors and the patient's developmental stage, level of health, lifestyle, and cultural needs (Box 27-7). Planning involves an understanding of the patient's need to maintain independence within physical and cognitive capabilities. Collaborate to establish ways of maintaining the patient's active involvement within the home and health care environment. Education of the patient and family is also an important intervention to plan for reducing safety risks over the long term.

Teamwork and Collaboration. Collaboration with the patient, family, and other health professions such as social work and occupational and physical therapy becomes an important part of a patient's plan of care. For example, a hospitalized patient may need to go to a rehabilitation facility to gain strength and endurance before being discharged home. Communication is essential. You communicate risk

◎ NURSING CARE PLAN

Risk for Falls

ASSESSMENT

Mr. Key, a home health nurse, is seeing Ms. Cohen, an 85-year-old woman, at her home. The patient is recovering from a mild stroke affecting her left side. Ms. Cohen lives alone but receives regular assistance from her daughter Peggy and son Michael, who both live within 10 miles. Mr. Key's assessment included a discussion of Ms. Cohen's health problem and how the stroke has affected her, a pertinent physical examination, and home hazard assessment.

Assessment Activities*	Findings/Defining Characteristics
Ask how the stroke has affected her mobility.	She responds, "**I bump into things,** and **I'm afraid I'm going to fall.**"
Conduct a home hazard assessment.	Cabinets in kitchen are **cluttered** and full of breakable items that could fall out. **Throw rugs are on floors;** bathroom **lighting is poor** (40-watt bulbs); bathtub **lacks safety strips** or grab bars; **home is cluttered** with furniture and small objects.
Observe gait and posture.	She has **kyphosis** and a **hesitant, uncoordinated gait;** frequently holds walls for support.
Assess muscle strength.	**Left arm and leg are weaker** than right.
Assess visual acuity with corrective lenses.	She has **trouble reading and seeing familiar objects at a distance** while wearing current glasses.

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Risk for falls

PLANNING

Goals	Expected Outcomes (NOC)†
	Risk Control
Ms. Cohen's family will modify the home to eliminate hazards within 1 month.	Family members will reduce modifiable hazards in kitchen and hallway within 1 week.
	Family members will modify bathroom in 1 month.
	Knowledge: Personal Safety
Ms. Cohen and family will be knowledgeable of potential hazards for Ms. Cohen's age-group within 1 week.	Ms. Cohen and daughter will identify risks for falls and prevention methods to avoid falls in home at conclusion of teaching session next week.
	Fall Prevention Behavior
Ms. Cohen will express greater sense of feeling safe from falling in 1 month.	Ms. Cohen will report improved vision with the aid of new eyeglasses in 2 weeks.
Ms. Cohen will be free of injury within 1 week.	Ms. Cohen will safely ambulate throughout the home within 1 week.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC)*, ed 5, St Louis, 2013, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Fall Prevention	
Review findings from home hazard assessment with Ms. Cohen and her children and collaborate on proposed changes.	Home hazard assessment highlights extrinsic factors that lead to falls and that can be changed.
Establish a list of priorities to modify and have Ms. Cohen's son help to install bathroom safety devices.	Implementing home modifications based on home assessment decreases falls (Chase et al., 2012).
Discuss with Ms. Cohen and daughter the normal changes of aging, effects of recent stroke, associated risks for injury, and how to reduce risks.	Education regarding hazards reduces fear of falling (Olsen and Bergland, 2014).
Encourage daughter to schedule vision testing for new prescription within 2 to 4 weeks.	Improved visual acuity reduces incidence of falls (Chase et al., 2012).
Refer to physical therapist to assess need for strengthening and endurance training and use of assistive devices for kyphosis, left-sided weakness, and gait.	Exercise is effective in reducing falls and needs to include a comprehensive program combining muscle strengthening, balance, and/or endurance training for a minimum of 12 weeks (Sherrington et al., 2011).

‡Intervention classification labels from Bulechek GM et al: *Nursing interventions classification (NIC)*, ed 6, St Louis, 2013, Mosby.

EVALUATION

Nursing Actions	Patient Response/Finding	Achievement of Outcome
Ask Ms. Cohen and family to identify fall risks.	Ms. Cohen and family are able to identify risks during a walk through the home and express a greater sense of safety as a result of changes made.	Ms. Cohen and family are more knowledgeable of potential hazards.
Observe environment for elimination of hazards.	Throw rugs were removed. Lighting was increased to 75 watts except in bathroom and bedroom.	Environmental hazards are partially reduced.
Reassess Ms. Cohen's visual acuity.	Ms. Cohen has new glasses and says she is able to read better and see distant objects more clearly.	Ms. Cohen's vision has improved, enabling her to ambulate more safely.
Observe Ms. Cohen's gait and posture.	Ms. Cohen's gait remains hesitant and uncoordinated; she reports that her daughter has limited time to take her to the physical therapist.	Outcome of safe ambulation is not totally achieved; help daughter develop a schedule that allows her time to take her mother to physical therapy appointments.

CONCEPT MAP

Nursing diagnosis: Risk for falls
- Cluttered home
- Difficulty seeing objects at a distance
- Uncoordinated gait

Interventions
- Identify and eliminate trip hazards in the home
- Encourage patient to see ophthalmologist for visual assessment
- Consult with physical therapist to help with strengthening exercises

Nursing diagnosis: Anxiety related to fear of falling
- States is worried about falling and health status
- Difficulty focusing during conversation
- Has difficulty understanding patient teaching about medications

Interventions
- Establish therapeutic relationship with patient
- Encourage use of effective coping skills previously used
- Help patient identify actions she can take to adapt to left-sided weakness

Primary health problem: Cerebrovascular accident with left-sided weakness and neglect
Priority assessments: Mobility, coping strategies, emotional effect of change in health status, home safety

Nursing diagnosis: Impaired physical mobility related to left-sided weakness
- Changes in gait
- Limited ability to perform fine and gross motor skills on left side

Interventions
- Teach patient how to perform range-of-motion and strengthening exercises on left side
- Educate on use of walker and cane around the home
- Consult with physical therapist

Nursing diagnosis: Unilateral neglect related to brain injury from cerebrovascular accident
- Fails to notice people approaching from left side
- Does not eat food on left side of plate
- Does not move head to the left side in response to loud noises on left side

Interventions
- Remind patient to scan entire environment when walking
- Encourage family to eat with patient, and remind her to eat food on left side of plate
- Teach patient to touch left side of body with right hand frequently

——— Link between medical diagnosis and nursing diagnosis   ----- Link between nursing diagnoses

FIGURE 27-4 Concept map for Ms. Cohen. *ADLs,* Activities of daily living; *CVA,* cerebrovascular accident.

factors and the plan of care with the patient, family, and other health care providers, including other disciplines and nurses on other shifts. Permanent dry-erase boards in the patient's room with patient information such as activity and level of assistance communicate information to all health care providers. A standard approach to

communication such as SBAR (*S*ituation, *B*ackground, *A*ssessment, *R*ecommendation) helps you obtain and organize information (see Chapter 26).

Patients need to be able to identify, select, and know how to use resources within their community (e.g., neighborhood block homes, local police departments, and neighbors willing to check on their well-being) that enhance safety. Make sure that the patient and family understand the need for these resources and are willing to make changes that promote their safety.

◆ Implementation

The QSEN project (2014) outlines recommended skills to ensure nurse competency in patient safety. Among these skills are those involving safe nursing practice during direct care:
- Demonstrate effective use of technology and standardized practices that support safety and quality.

⊕ BOX 27-7 CULTURAL ASPECTS OF CARE

A Patient-Centered Care Approach

Hospitalization places patients at risk for injury in an unfamiliar and confusing environment. The experience is usually at least minimally frightening. Normal life cues such as a bed without side rails and the direction one usually takes to the bathroom are absent. Thought processes and coping mechanisms are affected by illness and its accompanying emotions. Thus patients are more vulnerable to injury. This vulnerability is often intensified for patients of diverse backgrounds. It is a nurse's responsibility to diligently protect all patients, regardless of their socioeconomic status and cultural background. Most untoward events are related to failures of communication. It has been estimated that more than 300 languages are spoken in the United States and more than 90 million Americans have low health literacy, creating challenges during your assessment and efforts at implementing safe care measures (TJC, 2016). Screen all patients for health literacy. Ensure that you use an approach that recognizes a patient's cultural background so you ask appropriate questions to reveal health behaviors and risks. Also be aware of cultural beliefs about restraints when caring for patients who need restraints. Safety is enhanced when you consider patients in light of the whole person and value seeing each care situation through "the patient's eyes" and not just through your own perspective. Some specific patient-centered safety guidelines about the use of restraints follow.

Implications for Patient-Centered Care

- When restraints are needed, assess their meaning to the patient and the family. Some cultures may find restraints to be disrespectful. Similarly some survivors of war or persecution or those suffering from post-traumatic stress disorder may view restraints as imprisonment or punishment.
- Collaborate with family members in accommodating a patient's cultural perspectives about restraints. Removing the restraints when family members are present shows respect and caring for the patient.
- Define the protocol of the nursing unit on the use of restraints. Identify potential areas for negotiation with the patient's/family's preferences for using restraints, including having family members stay with the patient.

- Demonstrate effective use of strategies to reduce risk of harm to self or others.
- Use appropriate strategies to reduce reliance on memory (e.g., forcing functions, checklists).

Direct your nursing interventions toward maintaining a patient's safety in all types of settings. You implement health promotion and illness prevention measures in the community setting, whereas prevention is a priority in the acute care setting.

Health Promotion. To promote an individual's health, it is necessary for the individual to be in a safe environment and practice a lifestyle that minimizes risk of injury. Edelman and Mandle (2013) describe passive and active strategies aimed at health promotion. Passive strategies include public health and government legislative interventions (e.g., sanitation and clean water laws) (see Chapter 3). Active strategies are those in which an individual is actively involved through changes in lifestyle (e.g., engaging in better nutritional health or exercise programs, wearing seat belts) and participation in wellness programs.

Nurses promote individual and community health by supporting legislation, acting as positive role models, and working in community-based settings. Because environmental and community values have the greatest influence on health promotion, community and home health nurses are able to assess and recommend safety measures in the home, school, neighborhood, and workplace.

Developmental Interventions

Infant, Toddler, and Preschooler. Growing, curious children need adults to protect them from injury. Children are trusting of their environment and do not perceive themselves to be in danger. Educate parents or guardians about reducing risks of injuries to children and ways to promote safety in the home (Table 27-1). Nurses working in prenatal and postpartum settings easily incorporate safety into the care plans of childbearing families. Community health nurses assess the home and show parents how to promote safety. Educate parents about the importance of immunizations and how they protect a child from life-threatening disease.

TABLE 27-1 Interventions to Promote Safety for Children and Adolescents

Intervention	Rationale
Infants and Toddlers	
Have infants sleep on their back or side. Teach parents the mnemonic "back to sleep."	Placing infants on their back confers the lowest risk of sudden infant death syndrome (SIDS) and is the preferred position (AAP, 2011b).
Infants should be immunized.	Evidence suggests that immunization reduces the risk of SIDS by 50% (AAP, 2011b).
Do not fill cribs with pillows, bumper pads, large stuffed toys, or comforters. Use snug-fitting sheets.	Possibility exists for these items to cause potential risk of suffocation, strangulation, or entrapment.
Do not attach pacifiers to string or ribbon and place around a child's neck.	String or ribbon around the neck increases risk for choking.
Follow all instructions for preparing and storing formula.	Proper formula preparation and storage prevent contamination. Following product directions ensures proper concentration of formula. Undiluted formula causes fluid and electrolyte disturbances; much diluted formula does not provide sufficient nutrients.
Use large, soft toys without small parts such as buttons.	Small parts become dislodged, and choking and aspiration can occur.
Do not leave the mesh sides of playpens lowered; spaces between crib slats need to be less than 2⅜ inches (6 cm) apart.	Possibility exists for a child's head to become wedged in the lowered mesh side or between crib slats, and asphyxiation may occur.
Never leave crib sides down or babies unattended on changing tables or in infant seats, swings, strollers, or high chairs.	Infants and toddlers roll or move and fall from changing tables or out of accessories such as infant seats or swings.

Continued

TABLE 27-1	Interventions to Promote Safety for Children and Adolescents—cont'd
Intervention	**Rationale**
Discontinue using accessories such as infant seats and swings when the child becomes too active or physically too big and/or according to the manufacturer's directions.	When physically active or too big, the child can fall out of or tip over these accessories and suffer an injury.
Never leave a child alone in the bathroom, tub, or near any water source (e.g., pool).	Supervision reduces risk for accidental drowning.
Baby-proof the home; remove small or sharp objects and toxic or poisonous substances, including plants; install safety locks on floor-level cabinets.	Babies explore their world with their hands and mouth. Choking and poisoning can occur.
Remove plastic bags from the cleaners or grocery store from the home.	Removal reduces risk for suffocation from plastic bags.
Cover electrical outlets.	Covers reduce opportunity for crawling babies to insert objects into outlets and experience an electrical shock.
Place window guards on all windows.	Guards prevent children from falling out of windows.
Install keyless locks (e.g., deadbolts) on doors above a child's reach, even when they are standing on a chair.	Deadbolts prevent a toddler from leaving the house and wandering off. Keyless locks allow for rapid exit in case of fire.
Put children weighing less than 80 lbs or under 8 years of age in an age/weight–appropriate car seat that has been installed according to manufacturer's instructions. This includes car seats and booster seats. In cars with a passenger air bag, children under 12 need to be in the back seat. All passengers need to wear seat belts.	In case of a sudden stop or crash, an unrestrained child suffers severe head injuries and death.
Caregivers need to learn cardiopulmonary resuscitation (CPR) and the Heimlich maneuver.	Caregivers need to be prepared to intervene in acute emergencies such as choking.
Preschoolers	
Teach children to swim at an early age but always provide supervision near water.	Learning to swim is a useful skill that can someday save a child's life. However, all children need constant supervision.
Teach children how to cross streets and walk in parking lots. Instruct them to never run out after a ball or toy.	Pedestrian accidents involving young children are common.
Teach children not to talk to, go with, or accept any item from a stranger.	Avoiding strangers reduces the risk of injury and stranger abduction.
Teach children basic physical safety rules such as proper use of safety scissors, never running with an object in their mouth or hand, and never attempting to use the stove or oven unassisted.	Risk of injury is lower if children know basic safety procedures.
Teach children not to eat items found in the street or grass.	Avoiding these items reduces risk for possible poisoning.
Remove doors from unused refrigerators and freezers. Instruct children not to play or hide in a car trunk or unused appliances.	If a child cannot freely exit from appliances and car trunks, asphyxiation can occur.
School-Age Children	
Teach children the safe use of equipment for play and work.	The child needs to learn the safe, appropriate use of implements to avoid injury.
Teach children proper bicycle safety, including use of helmet and rules of the road.	Reduces injuries from falling off a bike or being hit by a car.
Teach children proper techniques for specific sports and the need to wear proper safety gear (e.g., helmets, eyewear, mouth guards).	Using proper techniques, correct equipment, and protective gear prevents injuries.
Teach children not to operate electrical equipment while unsupervised.	If an electrical mishap were to occur, no one would be available to help.
Do not allow children access to firearms or other weapons. Keep all firearms in locked cabinets.	Children are often fascinated by firearms and often try to play with them.
Adolescents	
Encourage enrollment in driver education classes.	Many injuries in this age-group are related to motor vehicle accidents.
Provide information about the effects of using alcohol and drugs.	Adolescents are prone to risk-taking behaviors and are subject to peer pressures.
Refer adolescents to community and school-sponsored activities.	The adolescent needs to socialize with peers, yet needs some supervision.
Encourage mentoring relationships between adults and adolescents.	Adolescents are in need of role models after whom they can pattern their behavior.
Teach them safe use of the Internet.	Avoids overuse and possible exposure to inappropriate websites.

Modified from Hockenberry M, Wilson D: *Wong's nursing care of infants and children,* ed 10th, St Louis, 2015, Mosby.

School-Age Child. School-age children increasingly explore their environment (see Chapter 12). They have friends outside their immediate neighborhood; and they become more active in school, church, and community activities. The school-age child needs specific teaching regarding safety in school and at play. See Table 27-1 for nursing interventions to help guide parents in providing for the safety of school-age children.

Adolescent. Risks to the safety of adolescents involve many factors outside the home because much of their time is spent away from home and with their peer group (see Chapter 12). Adults serve as role models for adolescents and, by providing examples, setting expectations, and providing education, help them minimize risks to their safety. This age-group has a high incidence of suicide because of feelings of decreased self-worth and hopelessness. Be aware of the risks posed at this time and be prepared to teach adolescents and their parents measures to prevent accidents and injury.

Adult. Risks to young and middle-age adults frequently result from lifestyle factors such as childrearing, high stress levels, inadequate nutrition, use of firearms, excessive alcohol intake, and substance abuse (see Chapter 13). In this fast-paced society there also appears to be more expression of anger, which can quickly precipitate accidents related to "road rage." Help adults understand their safety risks and guide them in making lifestyle modifications by referring them to resources such as classes to help quit smoking and for stress management, including employee-assistance programs. Also encourage adults to exercise regularly, maintain a healthy diet, practice relaxation techniques, and get adequate sleep.

Older Adult. Nursing interventions for older adults reduce patients' risks of falls and other accidents and compensate for the physiological changes of aging (Box 27-8). The American Geriatric Society (2015) developed an algorithm for fall prevention (Figure 27-5). Provide information about neighborhood resources to help an older adult maintain an independent lifestyle. Older adults frequently relocate to new neighborhoods and need to become acquainted with new resources such as modes of transportation, church schedules, and food resources (e.g., Meals on Wheels).

Educate older adults about safe driving tips (e.g., driving shorter distances or only in daylight, using side and rearview mirrors carefully, and looking behind them toward their "blind spot" before changing lanes). If hearing is a problem, encourage the patient to keep a window rolled down while driving or reduce the volume of the radio. Counseling is often necessary to help older patients make the decision of when to stop driving. At that time help locate resources in the community that provide transportation.

Burns and scalds are also more apt to occur with older people because they sometimes forget and leave hot water running or become confused when turning the dials on a stove or other heating appliance. Nursing measures for preventing burns minimize the risk from impaired vision. Hot-water faucets and dials are color coded to make it easier for an adult to know which is hot and which is cold. Reducing the temperature of the hot water heater is also very beneficial.

Many older adults love to walk. Reduce pedestrian accidents for older adults and all other age-groups by persuading people to wear reflectors on garments when walking at night; stand on the sidewalk and not in the street when waiting to cross a street; always cross at corners and not in the middle of the block (particularly if the street is a major one); cross with the traffic light and not against it; and look left, right, and left again before entering the street or crosswalk. Also encourage people to assess their walking route for hazards such as unequal or damaged walk ways, unrestrained dogs, and excessive toys; all of these increase the risk for falls.

BOX 27-8 FOCUS ON OLDER ADULTS

Physiological Changes of Aging and Their Effect on Patient Safety

As people age physiological changes occur. They experience visual and hearing alterations; slowed reaction time; and decreased range of motion, flexibility, and strength. In addition, reflexes are slowed, and the ability to respond to multiple stimuli is reduced. Memory can become impaired, and nocturia and incontinence are more frequent in older adults. The family plays a significant role in the care of older adults. Over 66 million unpaid caregivers for adults are mostly family members (i.e., nearly 40% of the U.S. adult population) (National Alliance for Caregiving, 2015). Encourage the family to allow the older adult to remain as independent as possible and provide help only for those things that are especially stressful or depleted.

The high prevalence of chronic conditions in older adults results in the use of a high number of prescription and over-the-counter medications. Coupled with age-related changes in pharmacokinetics, there is a greater risk of serious adverse effects. Medications typically prescribed for older adults include anticholinergics, diuretics, anxiolytic and hypnotic agents, antidepressants, antihypertensives, vasodilators, analgesics, and laxatives, all of which pose risks or interact to increase the risk for falls.

Implications for Practice
- Encourage annual vision and hearing examinations and frequent cleaning of glasses and hearing aids as a means of preventing falls and burns.
- Teach patients safety tips for avoiding automobile accidents. Sometimes driving needs to be restricted to daylight hours or temporarily or permanently suspended.
- Encourage supervised exercise classes for older adults and teach them to seek assistance with household tasks as needed. Safety features such as grab bars in the bathroom are often necessary.
- Be sure that adults know how to use assist devices (e.g., walkers and canes) correctly. Consult with a physical therapy staff member.
- Institute a regular toileting schedule for the patient. A recommended frequency is every 3 hours. Give diuretics in the morning. Provide assistance, along with adequate lighting, to patients who need to go to the bathroom at night.
- Encourage patients to use medication organizers, which can be purchased at any drugstore at a very reasonable cost. Fill these dispensers once a week with the proper medications to be taken at a specific time during the day.
- Review the patient's drug profile to ensure that these drugs are used cautiously and assess the patient regularly for any adverse effects that increase fall risk.

Environmental Interventions. Nursing interventions directed at eliminating environmental threats include those associated with a person's basic needs and general preventive measures.

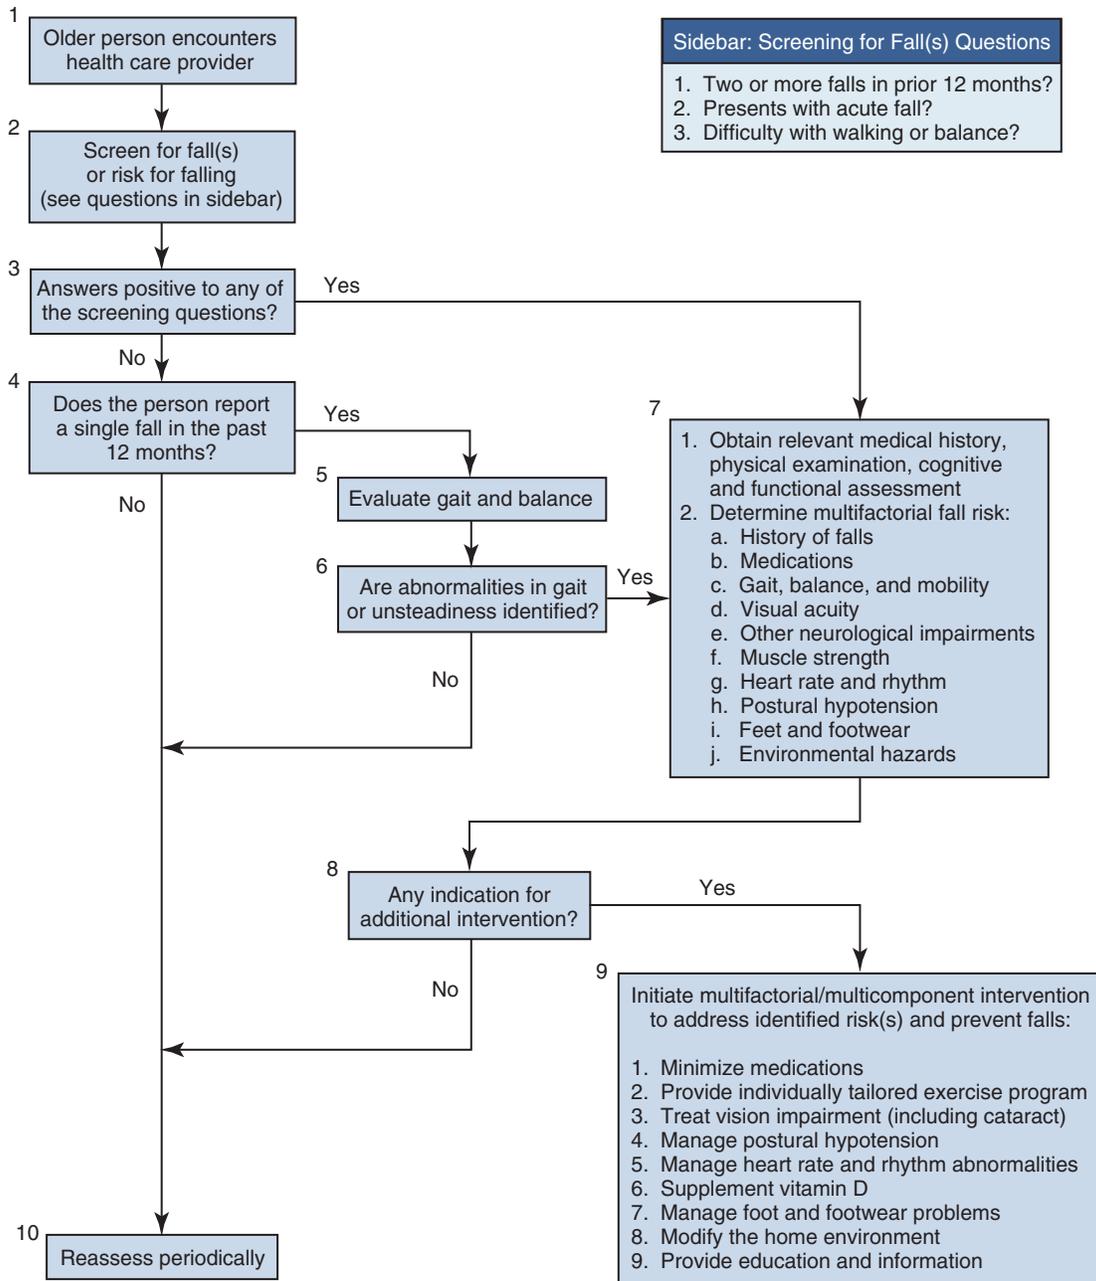
Basic Needs. Nurses contribute to a safer environment by helping patients meet basic needs related to oxygen, nutrition, and temperature. When oxygen is in use, take appropriate precautions to prevent fire. Contact with heat or a spark is required to trigger combustion; therefore certain precautions are necessary, regardless of the setting where oxygen is in use. Post "No Smoking" and "Oxygen in Use" signs in patient rooms. Do not use oxygen around electrical equipment or flammable products. Store oxygen tanks upright in carts or stands to prevent tipping or falling or place the tanks flat on the floor when not in use. Check tubing for kinks that affect the oxygen flow. Maintain oxygen at the prescribed liter flow and do not change without a health care provider's order. Additional precautions are indicated for liquid or pressurized oxygen and when traveling with home oxygen. Refer to


FIGURE 27-5 American Geriatrics Society Clinical Practice Guideline Fall Prevention Algorithm 2010. (From American Geriatrics Society/British Geriatrics Society: *Clinical practice guideline for prevention of falls in older persons,* 2010, http://www.medcats.com/FALLS/frameset.htm. Accessed August 14, 2015.)

the oxygen supplier. Recommend that the patient have annual inspections of heating systems, chimneys, and fuel-burning appliances in the home. Carbon monoxide detectors are available at a reasonable cost but are not a replacement for proper use and maintenance of fuel-burning appliances.

Teach basic techniques for food handling and preparation:
- Properly refrigerate, store, and prepare food to decrease the risk of foodborne illness. Store perishable foods in refrigerators to maintain freshness.
- Wash hands before and after preparing foods.
- Rinse fruits and vegetables thoroughly.
- Pay attention to prevent cross-contamination of one food with another during food preparation, especially with poultry. Use separate cutting boards.

- Use a separate cutting board for vegetables, meats, and poultry.
- Adequately cook foods to kill any residual organisms. Refrigerate leftovers promptly. Bacteria grow quickly at room temperature.
- Have family caregivers label the date when leftovers are saved.

General Preventive Measures. Adequate lighting and security measures in and around the home, including the use of night-lights, exterior lighting, and locks on windows and doors, enable patients to reduce the risk of injury from crime. The local police department and community organizations often have safety classes available for residents to learn how to take precautions to minimize the chance of becoming involved in a crime. For example, some useful tips include always parking the car near a bright light or busy public area, carrying a whistle attached to the car keys, keeping car doors locked while

BOX 27-9 PATIENT TEACHING

Prevention of Electrical Hazards

Objective
- Patient will recognize and eliminate electrical hazards in the home.

Teaching Strategies
- Discuss importance of checking for grounding of electrical appliances and other equipment.
- Provide examples of common hazards: frayed cords, damaged equipment, and overloaded outlets.
- Discuss guidelines to prevent electrical shocks:
  - Use extension cords only when necessary and use electrical tape to secure the cord to the floor, preferably against baseboards.
  - Do not run wires under carpeting.
  - Grasp the plug, not the cord, when unplugging items.
  - Keep electrical items away from water.
  - Do not operate unfamiliar equipment.
  - Disconnect items before cleaning.

Evaluation
- Have patient list electrical hazards existing in the home.
- Review steps the patient will take to eliminate these hazards.
- Observe the home environment after the patient has had an opportunity to eliminate hazards.

BOX 27-10 PATIENT TEACHING

Correct Use of a Fire Extinguisher in the Home

Objective
- Patient will use a fire extinguisher in the home correctly.

Teaching Strategies
- Discuss how to choose a correct location for an extinguisher. It is recommended that one be placed on each level of the home, near an exit, in clear view, away from stoves and heating appliances, and above the reach of small children. Keep a fire extinguisher in the kitchen, near the furnace, and in the garage.
- Make sure that patients read instructions after purchasing the extinguisher and how often to review the instructions.
- Describe the steps to take before using the extinguisher. Attempt to fight the fire only when all occupants have left the home, the fire department has been called, the fire is confined to a small area, there is an exit route readily available, the extinguisher is the right type for the fire (see discussion in text for a description of the types of extinguishers), and the patient knows how to use it.
- Instruct the patient to memorize the mnemonic PASS: *P*ull the pin to unlock handle, *A*im low at the base of the fire, *S*queeze the handles, and *S*weep the unit from side to side (see Figure 27-9).

Evaluation
- Patient is able to describe when it is appropriate to use a home fire extinguisher.
- Patient correctly lists the steps to take before attempting to use an extinguisher.
- Patient demonstrates correct use of the extinguisher while reciting the instructions with the mnemonic PASS.

driving, and always paying attention while driving to notice if anyone starts to follow the car.

Modifications in the environment easily reduce the risk of falls. To reduce the risk of injury in the home, remove all obstacles from halls and other heavily traveled areas. Necessary objects such as clocks, glasses, or tissues remain on bedside tables within reach of the patient but out of the reach of children. Take care to ensure that end tables are secure and have stable, straight legs. Place nonessential items in drawers to eliminate clutter. Patients who have problems stumbling or tripping should never have small area rugs in the home. If small area rugs are used, secure them with a nonslip pad or skid-resistant adhesive strips. Make sure that carpeting on the stairs is secured with carpet tacks. If patients have a history of falling and live alone, recommend that they wear an electronic safety alert device. When activated by the wearer, this device alerts a monitoring site to call emergency services for assistance.

Accidental home fires typically result from smoking in bed, placing cigarettes in trash cans, grease fires, improper use of candles or space heaters, or electrical fires resulting from faulty wiring or appliances. Teach patients and families how to reduce the risk of electrical injury in the home (Box 27-9) and how to use a home fire extinguisher (Box 27-10). To reduce the risk of fires in the home, instruct patients to quit smoking or smoke outside the home. Have them inspect the condition of cooking equipment and appliances, particularly irons and stoves. Have patients with visual deficits install dials with large numbers or symbols on temperature controls. Make sure that smoke detectors are in strategic positions throughout the home so the alarm will alert the occupants in a home in case of fire. All patients, even young children, need to know the phrase "stop, drop, and roll," which describes what to do when a person's clothing or skin is burning.

Help parents reduce the risk of accidental poisoning by teaching them to keep hazardous substances such as medications, cleaning fluids, and batteries out of the reach of children. Drug and other substance poisonings in adolescents and adults are commonly related to suicide attempts or drug experimentation. Teach parents that calling a poison control center for information before attempting home remedies will save their child's life. Guidelines for accepted interventions for accidental poisonings are available to teach a parent or guardian (Box 27-11). Older adults are also at risk for poisoning because diminished eyesight may cause an accidental ingestion of a toxic substance. In addition, the impaired memory of some older adults results in an accidental overdose of prescription medications. In health care settings it is important for you to know how to respond when exposure to a poisonous substance occurs. In addition, adhere to guidelines for intervening in accidental poisoning.

Be sure that a patient's home medications are kept in their original containers and labeled in large print. Recommend the use of medication organizers that are filled once a week by the patient and/or family caregiver. Have patients keep poisonous substances out of the bathroom and discard old or unused medications appropriately.

To prevent the transmission of pathogens, nurses teach aseptic practices. Medical asepsis, which includes hand hygiene and environmental cleanliness, reduces the transfer of organisms (see Chapter 29). Patients and family members need to learn how to perform thorough hand hygiene (handwashing or use of a hand rub) and when to use it (i.e., before and after caring for a family member, before food preparation, before preparing a medication for a family member, after using the bathroom, and after contacting any body fluids). Patients also need to know how to dispose of infected material such as wound dressings and used needles in the home setting. Heavy plastic containers such as hard, colored plastic liquid detergent bottles are excellent for needle disposal. The Environmental Protection Agency (EPA) encourages disposal of used needles by way of community drop-off programs,

BOX 27-11 Intervening in Accidental Poisoning

1. If the person is conscious and alert, call the local poison control center or the national toll-free poison control center number (1-800-222-1222) before trying any intervention. Be sure that this number is posted and easy to access in the home. Poison control centers have information needed to treat poisoned patients or offer referral to treat. *The administration of ipecac syrup or induction of vomiting is no longer recommended for routine home treatment of poisoning.*

2. Assess for signs or symptoms of ingestion of harmful substance such as nausea, vomiting, foaming at the mouth, drooling, difficulty breathing, sweating, and lethargy.

3. Stop exposure to the poison. Have the person empty his or her mouth of pills, plant parts, or other material.

4. If poisoning is caused by skin or eye contact, irrigate the skin or eye with copious amounts of cool tap water for 15 to 20 minutes. In the case of an inhalation exposure, safely remove the victim from the potentially dangerous environment.

5. Identify the type and amount of substance ingested to help determine the correct type and amount of antidote needed.

6. If the victim has collapsed or stopped breathing, call 911. Initiate CPR if indicated until emergency personnel arrive. Ambulance personnel can provide emergency measures if needed. In addition, a parent or guardian is sometimes too upset to drive safely.

7. Position the victim with head turned to side to reduce risk for aspiration.

8. Never induce vomiting if the victim has ingested the following poisonous substances: lye, household cleaners, hair care products, grease or petroleum products, furniture polish, paint thinner, or kerosene.

Modified from Hockenberry MJ, Wilson D: *Wong's essentials of pediatric nursing,* ed 10, St Louis, 2015, Mosby; American Academy of Pediatrics, Committee on Injury, Violence and Poison Prevention: Gastrointestinal decontamination of the poisoned patient, *Pediatr Emerg Care* 24(3):176, 2008.

BOX 27-12 EVIDENCE-BASED PRACTICE

Effects of Nursing Rounds on Patient Safety and Patient Satisfaction

PICO Question: In the hospitalized adult patient, will hourly rounding compared with standard practice decrease patient falls and improve patient's perception of nurse responsiveness?

Evidence Summary

Patient falls are considered a nurse-sensitive indicator. Nurses have the opportunity to reduce this adverse outcome on the basis of evidence-based nursing actions. Hospitalized patients often require assistance with basic activities of daily living such as toileting and mobility. Not meeting patient needs in a timely fashion decreases patient satisfaction and places patients at greater risk for injury when they attempt to move unassisted (Mitchell et al., 2014). Current evidence supports a patient-centered approach to nursing care by implementing purposeful hourly rounding (Ford, 2010). A recent systematic review looked at 16 studies and found moderately strong evidence to support that hourly rounding programs reduce patient falls and call-light use and increase their perception of nursing responsiveness. Most of the programs used every hour or every 2-hour rounds and used the 5 Ps: *p*ain, *p*otty, *p*osition, *p*ossessions, and *p*lan of care as the focus (Mitchell et al., 2014).

Application to Nursing Practice

- Implementation of purposeful, hourly nursing rounds with nurses visiting patients improves outcomes by reducing patient falls (Mitchell et al., 2014).
- Purposeful rounding includes specific nursing actions such as addressing toileting, assessing pain level, turning, and ensuring that possessions are within reach.
- Nurses and nursing assistive personnel often share rounding responsibilities (e.g., alternating every other hour).
- Nurse responsiveness to call lights is an important factor in a patient's hospital experience and leads to improved patient satisfaction.

household hazardous waste facilities, sharps mail-back programs, or home needle destruction devices (CDC, 2011)

Acute and Restorative Care. Within hospital and long-term care settings nurses take various measures to maintain patient safety, including fall-prevention strategies, prevention of injuries from use of restraints and side rails, and precautions to prevent fires and exposure to poisoning and electrical hazards. Special precautions are also necessary to prevent injury in patients susceptible to having seizures. Radiation injuries are also a specific safety concern in hospitals.

Nurses use standard precautions for all patients to protect themselves from contact with blood and other potentially infectious body fluids (see Chapter 29). Additional specific safety measures are applicable to patients in the acute care environment. Nurses are responsible for making a patient's bedside safe. Explain and demonstrate to patients how to use the call light or intercom system and always place the call device close to the patient at the conclusion of every nurse-patient interaction. Respond quickly to call lights and bed/chair alarms. Keep the environment free from clutter around the bedside.

Fall Prevention. TJC recommends that hospitals have formal fall-reduction programs (TJC, 2015). A fall-reduction program includes a fall risk assessment of every patient conducted on admission and routinely (see hospital policy) until a patient's discharge. Many health care organizations are implementing hourly rounding to reduce falls (Box 27-12). In addition, most organizations apply yellow color-coded

wristbands to patients' wrists to communicate to all health care providers that a patient is a fall risk. In 2008 the American Hospital Association issued an advisory recommending that hospitals standardize wristband colors: red for patient allergies, yellow for fall risk, and purple for do-not-resuscitate preferences (American Hospital Association, 2008). This recommendation came after a near-miss incident in which a nurse working in two different hospitals placed a wrong-colored band on a patient. Many state hospital associations and communities are now standardizing colors to reduce confusion both within and across the health care organizations.

Patient-centered care is important, with nurses making patients and families their partners in recognizing fall risks and taking preventive action. Most hospitals and long-term care facilities have fall-prevention protocols for those patients at risk for falling. A patient assessed as being at fall risk receives a fall risk identification bracelet (yellow in color), is given information about personal fall risks, and receives additional individualized nursing interventions (see Skill 27-1 on pp. 395-399). For example, if a patient has postural hypotension, a nurse chooses a low bed and the practice of dangling the patient for 5 minutes on the side of the bed before ambulating. Or a patient with a history of urinary urgency or incontinence benefits from a bedside commode instead of being expected to walk to the bathroom unassisted. Other interventions include established elimination schedules, placement of a fall pad on the floor along the bed, and use of bed safety alarms or motion detectors. A gait belt provides a secure way to steady or guide patients who need assistance with ambulation when

FIGURE 27-6 Safety bars around toilets and showers.

FIGURE 27-7 Wheelchair with safety locks and anti-tip bars.

transferring or walking. Use additional safety equipment as needed when moving patients (see Chapter 39).

When patients use assistive aids such as canes, crutches, or walkers, it is important to routinely check the condition of rubber tips and the integrity of the aid. Also be sure that patients use their devices correctly. Remove excess furniture and equipment and make sure that patients wear rubber-soled shoes or slippers for walking or transferring. Safety bars near toilets (Figure 27-6), locks on beds and wheelchairs (Figure 27-7), and call lights are additional safety features found in health care settings.

Another area of fall risk includes wheelchair-related falls involving older adults or patients with disabilities. Patients are at risk for falls during transfer tasks and reaching while seated in a wheelchair. An example of a wheelchair characteristic that increases risk for falls is having smaller and harder front wheels that cause a chair to tip when striking uneven terrain (such as uneven floor surface moving into an elevator). Tripping over the front foot or leg rest and leaning over the back of a wheelchair to engage or disengage the wheel lock are common causes of injury.

Restraints. Patients who are confused or disoriented and who wander or repeatedly fall or try to remove medical devices (e.g., oxygen equipment, IV lines, or dressings) often require the temporary use of restraints to keep them safe. *However, remember, the use of alternatives to restraints is preferred.* Current nursing home laws prohibit the unnecessary use of restraints; except in emergencies, nursing homes cannot use restraints without a resident's consent (CANHR, 2015).

Physical and chemical restraints restrict a patient's physical activity or normal access to the body and are not a usual part of treatment indicated by a patient's condition or symptoms. Thus restraints are not a solution to a patient problem but rather a temporary means to maintain patient safety. The CMS set the standard that restraints may be imposed only to ensure the immediate physical safety of a patient and must be discontinued at the earliest possible time (Department of Health and Human Services, Office of Inspector General, 2008).

A physical **restraint** is any manual method or physical or mechanical device (such as full set of side rails), material, or equipment that immobilizes or reduces the ability of a patient to move his or her arms, legs, body, or head freely (TJC, 2015). Chemical restraints are medications such as anxiolytics and sedatives used to manage a patient's behavior and are not a standard treatment or dosage for the patient's condition. A restraint does not include devices such as orthopedically prescribed devices, surgical dressings or bandages, protective helmets, or other methods that involve physically holding a patient to conduct routine physical examinations or tests, protecting the patient from falling out of bed, or permitting the patient to participate in activities without the risk of physical harm (TJC, 2015).

The use of restraints is associated with serious complications resulting from immobilization such as pressure ulcers, pneumonia, constipation, and incontinence. In some cases death has resulted because of restricted breathing and circulation. Patients have been strangled while trying to get out of bed while restrained in a jacket or vest restraint. As a result, many health care facilities have eliminated the use of the jacket (vest) restraint (Capezuti et al., 2008). Loss of self-esteem, humiliation, and agitation are also serious concerns. Legislation emphasizes reducing the use of restraints. Regulatory agencies such as TJC and the CMS enforce standards for the safe use of restraint devices. The optimal goal for all patients is a restraint-free environment.

Always consider and implement alternatives to restraints first. Individualize your approaches for each patient. Restraint alternatives include more frequent observations, social interaction such as involvement of family during visitation, frequent reorientation, regular exercise, and the introduction of familiar and meaningful stimuli (e.g., involve in hobbies such as knitting or crocheting or looking at family photos) within the environment. These interventions reduce behaviors such as wandering that often lead to restraint use. In nursing homes evidence shows that outcomes related to behavior issues, cognitive performance, falls, walking dependence, activities of daily living, pressure ulcers, and contractures are significantly worse when a restraint is used compared to no restraint (Castle, 2009). An interdisciplinary approach that includes individualized assessments and development of structured treatment plans reduces restraint use.

The use of restraints involves a psychological adjustment for the patient and family. If restraints are necessary, the nurse assists family members and patients by explaining their purpose, expected care while the patient is restrained, precautions taken to avoid injury, and that the restraint is temporary and protective. Informed consent from family members is required before using restraints in long-term care settings.

For legal purposes know agency-specific policy and procedures for appropriate use and monitoring of restraints. The use of a restraint must be clinically justified and a part of the patient's prescribed medical treatment and plan of care. A physician's order is required, based on a face-to-face assessment of the patient. The order must be current,

state the type and location of restraint, and specify the duration and circumstances under which it will be used. These orders need to be renewed within a specific time frame according to the policy of the agency. In hospital settings each original restraint order and renewal is limited to 8 hours for adults, 2 hours for ages 9 through 17, and 1 hour for children under age 9 (TJC, 2015). Restraints are not to be ordered prn (as needed). You must conduct ongoing assessment of patients who are restrained. Proper documentation, including the behaviors that necessitated the application of restraints, the procedure used in restraining, the condition of the body part restrained (e.g., circulation to hand), and the evaluation of the patient response, is essential. Restraints must be removed periodically, and the nurse assesses the patient to determine if they continue to be necessary. Skill 27-2 on pp. 399-403 includes guidelines for the proper use and application of restraints. Their use must meet one of the following objectives:

- Reduce the risk of patient injury from falls
- Prevent interruption of therapy such as traction, IV infusions, nasogastric (NG) tube feeding, or Foley catheterization
- Prevent patients who are confused or combative from removing life-support equipment
- Reduce the risk of injury to others by the patient

In keeping with current safety trends, electronic devices are alternatives to restraints. Weight and motion sensor mats placed on patients' beds or chairs emit silent or audible alarms when pressure is released off the mat. An alarm signals at the central nurses' station or sends a text message to a staff member's phone so staff is alerted quickly when a patient is moving and getting up and out of bed. Alarms on doors also alert staff or family members when a patient who is confused, disoriented, or prone to wandering opens a door.

A less-restrictive restraint is the Posey bed (Figure 27-8). It is a soft-sided, self-contained enclosed bed that is much less restrictive than chemical or physical restraints. It allows for freedom of movement and thus reduces the side effects such as pressure ulcers and loss of dignity caused by physical restraints. A vinyl top covers the padded upper frame of the bed, and the nylon-net canopy surrounds the mattress and completely encloses the patient in the bed. Zippers on the four sides of the enclosure provide access to the patient. The Posey bed enclosure works well for patients who are restless and unpredictable, cognitively impaired, and at risk for injury if they were to fall or get

FIGURE 27-8 Posey Bed All-Care Model. (Courtesy JT Posey Co, Arcadia, CA.)

out of bed such as patients on anticoagulant therapy at risk for intracranial bleed. The bed is also a safer alternative to side rails.

Side Rails. Side rails help to increase a patient's mobility and/or stability when repositioning or moving in bed or moving from bed to chair. They are the most commonly used physical restraint. However, many deaths and injuries related to entrapment and falls for both adult portable bedrail products and hospital bed rails have been reported to the U.S. Consumer Product Safety Commission (CPSC) and the U.S. Food and Drug Administration (FDA) (USFDA, 2014). The FDA recommends that all bedrails be used with caution, especially with older adults and people with altered cognition, physical limitations, and certain medical conditions.

There are a variety of beds with different side rail designs. Basically a patient needs to have a route to exit a bed safely and move freely within the bed; in this case side rails are not considered a restraint. For example, raising only the top two side rails of a four rail system gives a patient room to exit a bed safely. Side rails used to prevent a patient, such as one who is sedated, from falling out of bed are not considered a restraint. Always check agency policy about the use of side rails. Be sure that a bed is in the lowest position possible when side rails are raised. Always assess the risk of using side rails compared to not using them. Check their condition; bars between the bedrails need to be closely spaced to prevent entrapment, the space between bedrails and mattress and between headboard and mattress is filled to prevent patients from falling in between, and latches securing bedrails are stable.

The use of side rails alone for a patient who is disoriented usually causes more confusion and further injury. A patient who is determined to get out of bed attempts to climb over the side rail or climbs out at the foot of the bed. Either attempt usually results in a fall or injury. Nursing interventions to reduce a patient's confusion first focus on determining and eliminating the cause of the confusion such as a response to a new medication, dehydration, or pain. Frequently nurses mistake a patient's attempt to explore his or her environment or to self-toilet as confusion. Additional safety measures include the use of a low bed with a nonskid mat placed alongside the bed on the floor. A low bed reduces the distance between the bed and floor, facilitating a roll rather than a fall from the bed.

Fires. Although smoking is not allowed in most hospital and long-term care settings, smoking-related fires continue to pose a significant risk because of unauthorized smoking in the bed or bathroom. Institutional fires often result from an electrical fire. The best intervention is to prevent fires. Nursing measures include complying with the smoking policies and keeping combustible materials away from heat sources. Box 27-13 discusses additional fire-intervention

---

BOX 27-13 Fire Intervention Guidelines

- Keep the phone number for reporting fires visible on the telephone at all times.
- Know the fire drill and evacuation plan of the agency.
- Know the location of all fire alarms, exits, extinguishers, and oxygen shutoff in your work area.
- Use the mnemonic RACE to set priorities in case of fire:
  - *R*—Rescue and remove all patients in immediate danger.
  - *A*—Activate the alarm. Always do this before attempting to extinguish even a minor fire.
  - *C*—Confine the fire by closing doors and windows and turning off oxygen and electrical equipment.
  - *E*—Extinguish the fire with an appropriate extinguisher (see Figure 27-9).

guidelines in health care agencies. Regardless of where a fire occurs, it is important to have an evacuation plan in place. Know where fire extinguishers and gas shut-off valves are located and how to activate a fire alarm.

If a fire occurs in a health care agency, protect patients from immediate injury, report the exact location of the fire, contain it, and extinguish it if possible. Some agencies have fire doors that are held open by magnets and close automatically when a fire alarm sounds. It is important to keep equipment from blocking these doors. All personnel evacuate patients when appropriate. Patients who are close to a fire, regardless of its size, are at risk of injury and need to be moved to another area. If a patient is on life support, maintain his or her respiratory status manually with a bag-valve-mask device (e.g., Ambu-bag) (see Chapter 41) until he or she is moved away from the fire. Direct all ambulatory patients to walk by themselves to a safe area. In some cases they are able to help move patients in wheelchairs. Move bedridden patients from the scene of a fire by a stretcher, their bed, or a wheelchair. If none of these methods is appropriate, they need to be carried from the area. If you have to carry a patient, do so correctly (e.g., two-man carry). If you overextend your physical limits for lifting, injuring yourself results in further injury to the patient. If fire department personnel are on the scene, they help evacuate the patients.

After a fire is reported and patients are out of danger, health care personnel take measures to contain or extinguish it such as closing doors and windows, placing wet towels along the base of doors, turning off sources of oxygen and electrical equipment, and using a fire extinguisher. Fire extinguishers are categorized as type A, used for ordinary combustibles (e.g., wood, cloth, paper, and many plastic items); type B, used for flammable liquids (e.g., gasoline, grease, paint, and anesthetic gas); and type C, used for electrical equipment. Figure 27-9 demonstrates the process of using an extinguisher.

Electrical Hazards. Much of the equipment used in health care settings is electrical and must be well maintained. The clinical engineering departments of hospitals inspect biomedical equipment such as hospital beds, infusion pumps, or ventilators regularly. You know that a piece of equipment is safe to use when you see a safety inspection sticker with an expiration date. Decrease the risk for electrical injury and fire by using properly grounded and functional electrical equipment. The ground prong of an electrical outlet carries any stray electrical current back to the ground. Remove equipment that is not in proper working order or that sparks when plugged in for service and notify the appropriate hospital staff.

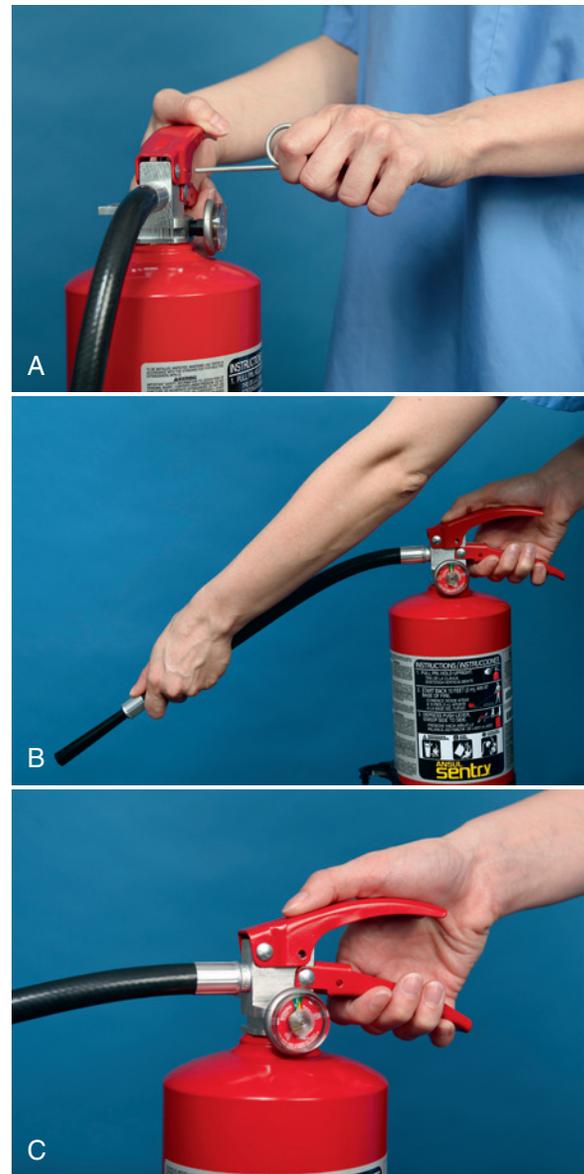
Seizures. Patients who have experienced some form of neurological injury or metabolic disturbance are at risk for a seizure. A **seizure** is hyperexcitation and disorderly discharge of neurons in the brain leading to a sudden, violent, involuntary series of muscle contractions that is paroxysmal and episodic, causing loss of consciousness, falling, tonicity (rigidity of muscles), and clonicity (jerking of muscles). A generalized tonic-clonic, or grand mal, seizure lasts approximately 2 minutes (no longer than 5) and is characterized by a cry and loss of consciousness with falling, tonicity, clonicity, and incontinence. During a fall or as a result of muscle jerking, musculoskeletal injuries can occur. Before a convulsive episode a few patients report an aura, which serves as a warning or sense that a seizure is about to occur. An **aura** is often a bright light, smell, or taste. During a seizure the patient often experiences shallow breathing, cyanosis, and loss of bladder and bowel control. A postictal phase follows the seizure, during which the patient has amnesia or confusion and falls into a deep sleep. A person in the community needs to be taken to a medical facility immediately if he or she has repeated seizures; if a single seizure lasts longer than 5 minutes without any sign of slowing down or is unusual in some way;


FIGURE 27-9 Correct use of a fire extinguisher. **A, *P*** ull pin. **B, *A*** im at base of fire. **C, *S*** queeze handles and ***S*** weep from side to side to coat area evenly.

if the person has trouble breathing afterwards or appears to be injured or in pain; or if recovery is different from usual (Epilepsy Foundation, 2014). Instruct family members in steps to take when a patient experiences a seizure. Assess a patient's home for environmental hazards in light of a seizure condition.

Prolonged or repeated seizures indicate **status epilepticus**, a medical emergency that requires intensive monitoring and treatment. It is important that you observe the patient carefully before, during, and after the seizure so you are able to document the episode accurately. **Seizure precautions** encompass all nursing interventions to protect a patient from traumatic injury, position for adequate ventilation and drainage of oral secretions, and provide privacy and support following the seizure (Box 27-14).

Radiation. Radiation and radioactive materials used in the diagnosis and treatment of patients is a health hazard in health care settings. Hospitals have strict guidelines for the care of patients who receive

BOX 27-14 Tips for Protecting Patients During a Seizure

1. When seizure begins, note time, stay with patient, and call for help. Track duration of seizure. Notify health care provider immediately.
2. Position patient safely. If standing or sitting, guide patient to floor and protect head by cradling in your lap or placing a pad under head.
3. Do not lift patient from floor to bed while seizure is in progress. Clear surrounding area of furniture. If patient is in bed, remove pillows and raise side rails.
4. If possible, turn patient onto one side, head tilted slightly forward.
5. Do not restrain patient; hold limbs loosely if they are flailing. Loosen clothing.
6. Never force apart a patient's clenched teeth. Do not place any objects into patient's mouth such as fingers, medicine, tongue depressor, or airway when teeth are clenched. **Insert a bite-block or oral airway in advance only if you recognize the possibility of a tonic-clonic seizure.**
7. Stay with patient, observing sequence and timing of seizure activity.
8. As patient regains consciousness reorient and reassure. Assist patient to position of comfort in bed with side rails up (one rail down for easy exit) and bed in lowest position.
9. Conduct a head-to-toe evaluation, including an inspection of oral cavity for breaks in mucous membranes from bites or broken teeth; look for bruising of skin or injury to bones and joints.

radiation and are exposed to radioactive materials. Be familiar with established agency protocols. To reduce your exposure to radiation, limit the time spent near the source, make the distance from the source as great as possible, and use shielding devices such as lead aprons. Staff who work regularly near radiation wear devices that track the accumulative exposure to radiation.

Disasters. As a nurse you need to be prepared to respond and care for a sudden influx of patients during a disaster. TJC (2016) requires hospitals to have an emergency-management plan that addresses identifying possible emergency situations and their probable impact, maintaining adequate amount of supplies, and a formal response plan that includes actions to be taken by staff and steps to restore essential services and resume normal operations following the emergency.

Infection control practices are critical in the event of a biological attack. Therefore you manage all patients with suspected or confirmed bioterrorism-related illnesses using standard precautions (see Chapter 29). For certain diseases such as smallpox or pneumonic plague, additional precautions such as airborne or contact isolation precautions are necessary. Most infections associated with biological agents are not transmissible from patient to patient. Transport and move patients only when it is essential for treatment and care. An important aspect of care for patients who have a bioterrorism-related illness is postexposure management.

◆ Evaluation

Through the Patient's Eyes. Patient-centered care involves a thorough evaluation of a patient's perspective related to safety and whether his or her expectations have been met. Ask the patient questions such as "Are you satisfied with the changes made to your home? Do you feel safer as a result of the changes? Have you had any falls or injury? Are you still afraid of falling?" Involve the family in your evaluation, especially if they live with the patient and provide assistance in the home.

Patient Outcomes. Evaluation involves monitoring the actual care delivered by the health care team on the basis of the expected

Knowledge
- Effect of new medication therapies on the patient's cognitive/motor functioning
- Characteristics of safe and unsafe patient behaviors
- Characteristics of a safe environment

Experience
- Previous patient responses to planned nursing therapies to improve the patient's safety (e.g., what worked and what did not work)

EVALUATION
- Evaluate if patient's expectations of care are met
- Reassess the patient for the presence of physical, social, environmental, or developmental risks
- Determine if changes in the patient's care resulted in increased threats to safety

Standards
- Use established expected outcomes to evaluate the patient's response to care (e.g., reduction in modifiable risk factors)

Attitudes
- Display humility when rethinking unsuccessful interventions designed to promote patient safety
- Demonstrate responsibility for accurately evaluating nursing interventions designed to promote the patient's safety

FIGURE 27-10 Critical thinking model for safety evaluation.

outcomes (Figure 27-10). For each nursing diagnosis measure whether the outcomes of care have been met. If your patient meets the goals, the diagnosis is resolved, and your nursing interventions were effective and appropriate. If not, determine whether new safety risks to the patient have developed or whether previous risks remain. For example, if the patient has a recurrent fall, reassess the conditions surrounding that fall and determine whether contributing factors can be removed or managed. The patient and family need to participate to find permanent ways to reduce risks to safety. When patient outcomes are not met, ask the following questions:

- What factors led to your fall/injury?
- Help me understand what makes you feel unsafe in your environment.
- What questions do you have about your safety?
- Do you need help locating community resources to help make your home safer?
- What changes have you recently experienced that you believe contribute to your risk for falling or lack of safety?

Continually reassess a patient's and family's need for additional support services such as home care, physical therapy, counseling, and further teaching. A safe environment is essential to promoting, maintaining, and restoring health. Overall your expected outcomes include a safe physical environment and a patient whose expectations have been met, who is knowledgeable about safety factors and precautions, and who is free of injury.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care:

- On the basis of your assessment and knowledge of physiological and behavioral factors, anticipate a patient's fall risks when choosing fall prevention strategies.

- Involve patients and families in selection of fall prevention strategies.
- Always try restraint alternatives before using a restraint. Involve family in your approach.
- Protect patients from injury. Follow assessment guidelines while patients are restrained to avoid injury from inappropriate placement.
- Protect patients from falling by implementing fall prevention protocols and providing patient and family education about fall prevention.

SKILL 27-1	FALL PREVENTION IN HEALTH CARE SETTINGS

DELEGATION AND COLLABORATION

The skill of assessing and communicating a patient's risk for falling cannot be delegated to nursing assistive personnel (NAP). Skills used to prevent falls can be delegated. The nurse instructs NAP to:

- Use fall prevention measures that match a patient's mobility limitations.
- Use specific environmental safety precautions (e.g., bed locked in low position, call light within reach).
- Report to the nurse any patient behaviors (e.g., disorientation, wandering) that are precursors to falls.

EQUIPMENT

- Fall risk assessment tool
- Hospital bed with side rails; *option*—low bed
- Call light/intercom system
- Gait belt
- Wheelchair (as needed)
- Additional safety devices (e.g., bed alarm pad, wedge cushion)

STEP	RATIONALE

ASSESSMENT

1. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).

2. Assess patient's fall risks using an agency fall risk assessment tool. Assess patient's age (over 65), number of co-morbidities, impaired memory and cognition, incontinence or urinary frequency/urgency, decreased hearing, decreased vision, orthostatic hypotension, impaired gait, weak lower extremities, poor balance, fatigue, need for transfer assistance, decreased peripheral sensation (Spoelstra, 2011; Viera et al., 2011).

A variety of physiological factors predispose patients to fall.

3. Determine if patient has a history of recent falls or other injuries within the home. Assess previous falls, using the acronym SPLATT (Touhy and Jett, 2014).
   - *S*ymptoms at time of fall
   - *P*revious fall
   - *L*ocation of fall
   - *A*ctivity at time of fall
   - *T*ime of fall
   - *Tr*auma after fall

Key symptoms are helpful in identifying cause for falls. Onset, location, and activity associated with a fall provide further details on causative factors and how to prevent future falls.

4. Review patient's medications (including over-the-counter [OTC] medications and herbal products) for use of antidepressants, anticonvulsants, antipsychotics, hypnotics (especially benzodiazepines), anxiolytics, diuretics, antihypertensives, antihistamines, anti-Parkinson drugs, hypoglycemics, muscle relaxants, analgesics, and laxatives. Also assess for polypharmacy (i.e., over six medications, duplicate medications, drugs inappropriate for condition) (Bushardt et al., 2008).

Effects of certain medications and use of multiple medications increase risk for falls and injury (Chang et al., 2011; Gribbin et al., 2010; Kojima et al., 2011).

CLINICAL DECISION: *If patient takes multiple medications, confer with health care provider on possibility of reducing or adjusting number of medications.*

5. Assess patient for fear of falling: those higher at risk are over 75 years of age, female, lower income, or single and have poor perceived general health or history of falling in last 3 months (Boyd and Stevens, 2009).

Fear of falling is interrelated with incidence of falls.

STEP	RATIONALE
6. Perform the "Timed Get-up and Go" (TUG) if patient is able to ambulate. At a minimum observe patient walk in room (with or without assistance). Steps for TUG dual assessment: • Give patient verbal instructions to stand up from a chair, walk 10 feet (3 meters) as quickly and safely as possible (cross a line marked on the floor), turn around, walk back, and sit down. • Have patient rise from straight back chair without using arms for support. • Begin counting. • Look for unsteadiness in patient's gait. • Have patient return to chair and sit down without using arms for support. Check time elapsed. For accuracy, a patient should have one practice trial that is not included in the score. Patient must use the same assistive device each time he or she is tested to be able to compare scores.	The Timed Get-up and Go (TUG) is a revision to the original Get-up and Go test (Podsiadlo and Richardson, 1991). It quantifies a patient's functional mobility. Observing a patient walk allows you to determine if gait and posture are normal. The TUG is a measure of physical and cognitive performance. A patient's ability to follow simple instructions measures cognitive function. An older adult who takes 12 seconds or longer to complete the TUG is at high risk for falling (CDC, 2015b). Balance function is scored on a five-point scale: 1 = Normal; 2 = Very slightly abnormal; 3 = Mildly abnormal; 4 = Moderately abnormal; 5 = Severely abnormal (Mathias et al., 1986). A score of 3 or more on the balance scale indicates a patient is at risk for falling (Mathias et al., 1986). **Note:** The TUG has been found to have limited ability to predict falls in community-dwelling elderly and should not be used in isolation to identify individuals at high risk for falls in this setting (Barry et al., 2014).
7. Assess risk factors for falls in health care facility (e.g., being attached to equipment such as sequential compression hose, intravenous [IV] line, or oxygen tubing; improperly lighted room; clutter; obstructed walkway to bathroom; and frequently needed items that are difficult to reach.	Environmental barriers pose risk for falls.
8. Assess condition of equipment (i.e., legs on bedside commode, tips of walker).	Equipment in poor repair increases the risk for fall.
9. Assess patient's medical history for osteoporosis, being on anticoagulants, history of previous fracture, cancer, and recent chest or abdominal surgery.	Factors increase likelihood of injury from a fall.
10. Use a patient-centered approach. Determine what patient knows about risks for falling and steps that he or she can take to prevent falls.	Knowledge of fall risks influences one's ability to take needed precautions in reducing falling.
11. If patient is assessed to be a fall risk, apply color-coded wristband (see illustration). Some agencies institute fall risk signs on doors.	Color-coded yellow bands are easily recognizable.

PLANNING

1. Gather equipment and perform hand hygiene.	Organizes care. Reduces transmission of microorganisms.
2. Explain what you plan to do. Specifically discuss reasons that patient is at risk for falling. Include family caregivers (as appropriate) in discussion. Provide privacy. Be sure that patient is comfortable.	Reduces patient anxiety and promotes cooperation. Results in fall prevention measures that are patient centered and not just routine. Younger patients are very independent and often believe that they are not likely to fall.

IMPLEMENTATION

1. A adjust bed to low position with wheels locked (see illustration). *Option:* Place nonslip padded floor mats at exit side of bed.	Height of bed allows ambulatory patient to get in and out of bed easily and safely. Pads provide nonslippery surface on which to stand.
2. Encourage the use of properly fitted skid-proof footwear.	Prevents falls from slipping on floor.

STEP 11 Arm band alerts nursing staff to patient's risk of falling.

Brake lock

STEP 1 Hospital bed should be kept in lowest position with wheels locked and side rails up as appropriate.

STEP	RATIONALE
3. Orient patient to surroundings, call light, and routines to expect in plan of care.	Orientation to room and plan of care provides familiarity with environment and activities to anticipate.
a. Provide patient's hearing aid and glasses. Be sure that each is functioning/clean.	Enables patient to remain alert to conditions in environment.
b. Be sure that call light/bed control system is in an accessible location within patient's reach. Explain and demonstrate how to turn call light/intercom system on and off at bedside and in bathroom (see illustration). Have patient perform a return demonstration.	Knowledge of location and use of call light is essential for patient to be able to call for assistance quickly. Reaching for an object when in bed can lead to an accidental fall.
c. Explain to patient/family caregiver when and why to use call system (e.g., report pain, get out of bed, go to bathroom). Provide clear instructions to patient/family caregiver regarding mobility restrictions.	Increases likelihood that patient will call for help and of nurse being able to respond to patient's needs in a timely way.
4. Safe use of side rails	
a. Explain to patient and family members the reason for using side rails: moving and turning self in bed.	Promotes cooperation.
b. Check agency policy regarding side-rail use.	Side rails are restraint devices if they immobilize or reduce ability of a patient to move his or her arms, legs, body, or head freely.
• Dependent, less mobile patients: In a two-side rail bed, keep both rails up. (NOTE: Rails on newer hospital beds allow for room at foot of bed for patient to safely exit bed.) In a four-side rail bed, leave two upper rails up.	
• Patient able to get out of bed independently: In a four-side rail bed, leave two upper side rails up. In a two-side rail, keep only one rail up.	Allows for safe exit from bed.
5. Make the patient's environment safe.	
a. Remove excess equipment, supplies, and furniture from rooms and halls.	Reduces likelihood of falling or tripping over objects.
b. Keep floors clutter and obstacle free, particularly the path to the bathroom.	Reduces likelihood of falling or tripping over objects.
c. Coil and secure excess electrical, telephone, and any other cords or tubing.	Reduces the risk of entanglement.
d. Clean all spills promptly. Post a sign indicating a wet floor. Remove the sign when the floor is dry (usually done by housekeeping).	Reduces the risk of falling on slippery, wet surfaces.
e. Ensure adequate glare-free lighting; use a night-light at night.	Glare may be a problem for older adults because of vision changes.
f. Have assistive devices (e.g., cane, walker, bedside commode) on exit side of bed. Have chair back of commode placed against wall of room if possible.	Provides added support when transferring out of bed. Stabilizes commode.
g. Arrange personal items (e.g., water pitcher, telephone, reading materials, dentures) within patient's easy reach and in a logical way.	Facilitates independence and self-care; prevents falls related to reaching for hard-to-reach items.
h. Secure locks on beds, stretchers, and wheelchairs.	Prevents accidental movement of devices during patient transfer.
6. **Additional interventions for patients at moderate-to-high risk for falling** (based on fall risk assessment)	
a. Prioritize call-light responses to patients at high risk, using a team approach with all staff knowing responsibility to respond.	Ensures rapid response by a health care provider when patient calls for assistance.
b. Establish elimination schedule, using bedside commode when appropriate.	Proactive toileting keeps patients from being unattended with sudden urge to use toilet.

STEP 3b Nurse demonstrates use of call light to patient.

SKILL 27-1   FALL PREVENTION IN HEALTH CARE SETTINGS—cont'd

STEP	RATIONALE
CLINICAL DECISION: *Getting out of bed for toileting is a common event leading to a patient's fall (Tzeng, 2010), especially during evening or night hours when a room is darkened.*	
c. Stay with patient during toileting (standing outside bathroom door).	Patients often try to get up to stand and walk back to their bed from the bathroom without assistance.
d. Place patient in a geri chair or wheelchair with wedge cushion. Use wheelchair only for transport, not for sitting an extended time.	Maintains alignment and comfort and makes it difficult to exit chair.
e. Use a low bed that has low height above floor and apply floor mats.	Reduces fall-related injuries.
f. Activate a bed alarm for patient.	Alarm activates when patient rises off a sensor. Alarm sounds an alert to staff.
g. Confer with physical therapy on feasibility of gait training, weight-bearing activities, balance exercise, and strengthening exercises.	Exercise can reduce falls, fall-related fractures, and several risk factors for falls in individuals with low bone density and in older adults (deKam et al., 2009; Schubert, 2011).
h. Use sitters or restraints only when alternatives are exhausted.	A sitter is a nonprofessional staff member or volunteer who stays in a patient room to closely observe patients who are at risk for falling. Restraints should be used only as a final option (see Skill 27-2).
7. When ambulating a patient, have patient wear a gait belt and walk along patient's side (see Chapter 39).	Gait belt gives you a secure hold on patient during ambulation.
8. **Safe Transport Using a Wheelchair.**	
a. Determine level of assistance needed to transfer patient to wheelchair. Position wheelchair on same side of bed as patient's strong or unaffected side (see Chapter 39).	Patient's condition may require more than a one-person assist. Positioning of chair facilitates patient's ability to assist in transfer.
b. Place wedge cushion in chair (see illustration.)	Prevents patient from slipping out of chair.
c. Securely lock brakes on both wheels when transferring patient into or out of wheelchair.	Keeps chair steady and secure.
d. Raise footplates before transfer to chair; then lower footplates, placing patient's feet on them after he or she is seated.	Prevents tripping over footplate.
e. Have patient sit with buttocks well back in seat. *Option:* Apply a quick-release seat belt.	Prevents patient from sliding out of chair.
f. Back wheelchair into and out of elevator or door, leading with large rear wheels first (see illustration).	Prevents smaller front wheels from catching in crack between elevator and floor, causing chair to tip.
9. Remove unnecessary supplies. Perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1. Conduct hourly rounds.	Hourly rounding programs reduce patient falls, and call light use increases patients' perception of nursing responsiveness.
2. Evaluate patient's ability to use assistive devices such as walker or bedside commode.	Adjustments in devices may become necessary.
3. Evaluate for changes in motor, sensory, and cognitive status and review if any falls or injuries have occurred.	May require different interventions to be added. Fall outcomes determine success of plan.

STEP 8b Wheelchair with footplates raised and a wedge cushion in place.

STEP 8f Nurse backing wheelchair into elevator.

STEP	RATIONALE
4. Use ***Teach Back:*** State to the patient and family caregiver, "I want to be sure I explained clearly to you why you are more likely to fall than other patients. Can you tell me some of those reasons?" Evaluate whether patient/caregiver is able to explain fall risks. Revise your instruction now or develop plan for revised patient teaching to be implemented at an appropriate time if patient/caregiver is not able to teach back correctly.	Evaluates what patient and family caregiver are able to explain or demonstrate.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Patient starts to fall while ambulating with a nurse.
- Put both arms around patient's waist or grasp gait belt.
- Stand with feet apart to provide a broad base of support (see Figure 39-11, *A*).
- Extend one leg and let patient slide against it to the floor (see Figure 39-11, *B*).
- Bend knees and lower body as patient slides to floor (see Figure 39-11, *C*).

2. Patient falls.
- Call for assistance. Assess patient for injury and stay with patient until assistance arrives to help lift him or her to bed or wheelchair.
- Reinforce explanation of identified risks with patient and review safety measures needed to prevent a fall.
- Monitor patient closely after the fall since injuries are not always immediately apparent.

3. Patient/family caregiver is unable to explain fall risks.
- Offer re-explanation, using plain language, and consider use of printed materials if available.

RECORDING AND REPORTING

- Record in plan of care specific interventions to prevent falls and promote safety.
- Document your evaluation of patient learning.
- Report patient's fall risks and measures taken to reduce risks to all health care personnel.
- Report immediately to physician or health care provider if the patient sustains a fall or an injury.
- Complete an agency safety event or incident report noting objective details of fall (time, location, patient's condition, treatment, treatment response). Do not place report in patient medical record.
- Record events related to the fall and treatment in medical record.

HOME CARE CONSIDERATIONS

- Assess the patient's home environment for hazards and institute safety measures as appropriate, with patient and family partnering on decisions.
- Keep personal items in their familiar positions and within easy reach in rooms frequently used.
- If patient has a history of falls and lives alone, recommend that he or she wear an electronic Safe Patient Care device. The device is turned on by the wearer to alert a monitoring site to call emergency services for help.

SKILL 27-2 APPLYING PHYSICAL RESTRAINTS

DELEGATION AND COLLABORATION

The skill of assessing a patient's behavior, orientation to the environment, need for restraints, and appropriate use cannot be delegated. The application and routine checking of a restraint can be delegated to nursing assistive personnel (NAP). TJC (2009) requires training on first aid for anyone who monitors patients in restraints. The nurse instructs the NAP about:
- Appropriate restraint to use and correct placement of restraint.
- When and how to change patient's position and provide range-of-motion exercises, hydration, toileting, skin care, and time for socialization.
- When to report signs and symptoms of patient not tolerating restraint (e.g., agitation, change in skin integrity, circulation of extremities, or patient's breathing) and what to do.

EQUIPMENT
- Proper restraint
- Padding (if needed)

STEP	RATIONALE
ASSESSMENT	
1. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).
2. Assess patient's behavior (e.g., confusion; disorientation; agitation; restlessness; combativeness; inability to follow directions or repeated removal of tubing, dressing, or other therapeutic devices). Does patient create a risk to other patients?	If patient's behavior continues despite treatment or restraint alternatives, use of restraint is indicated. You use the least restrictive type of restraint.

SKILL 27-2	APPLYING PHYSICAL RESTRAINTS—cont'd

STEP	RATIONALE
3. Determine failure of restraint alternatives. Review facility policies and state laws regarding restraints. Check for a current health care provider's order. The licensed health care provider assesses the patient in person within 1 hour of initiation of restraints (TJC, 2009). Order must include purpose, type, location, and time or duration of restraint. Determine if signed consent for use of restraint is necessary (long-term care). Orders may be renewed according to time limits for a maximum of 24 consecutive hours (TJC, 2009).	A health care provider's order for the least restrictive type of restraint is required. Each original restraint order is limited to 4 hours for adults 18 years old and older, 2 hours for children 9 through 17 years old, and 1 hour for children younger than 9 years (TJC, 2009).

CLINICAL DECISION: *A licensed independent health care provider responsible for the care of the patient evaluates the patient in person within 1 hour of the initiation of restraint used for the management of violent or self-destructive behavior that jeopardizes the physical safety of the patient, staff, or others. A registered nurse or a physician assistant may conduct the in-person evaluation if trained in accordance with the requirements and consultations with the previously mentioned health care provider after the evaluation as determined by hospital policy (TJC, 2016).*

4. Review manufacturer's instructions for restraint application before entering patient's room. Determine most appropriate size restraint.	You need to be familiar with all devices used for patient care and protection. Incorrect application of restraint device results in patient injury or death.

PLANNING

1. Gather equipment and perform hand hygiene.	Promotes organization and reduces transmission of microorganisms.
2. Explain what you plan to do. Provide privacy. Be sure that patient is comfortable and in correct anatomical position.	Reduces patient anxiety and promotes cooperation; positioning prevents contractures and neurovascular impairment.

IMPLEMENTATION

1. Adjust bed to proper height and lower side rail on side of patient contact. Be sure that patient is comfortable and in proper body alignment.	Allows you to use proper body mechanics and prevents injury during restraint application. Positioning prevents contractures and neurovascular injury while restraint is in place.
2. Inspect area where restraint is to be placed. Note if there is any nearby tubing or device. Assess condition of skin, sensation, adequacy of circulation, and range of joint motion.	Restraints sometimes compress and interfere with functioning of devices or tubes. Assessment provides baseline to monitor patient's response to restraint.
3. Pad skin and bony prominences (as necessary) that will be under restraint.	Reduces friction and pressure from restraint to skin and underlying tissue.
4. Apply proper-size restraint. NOTE: Refer to manufacturer's directions.	
a. *Belt restraint:* Have patient in sitting position in bed. Apply belt over clothes, gown, or pajamas. Be sure to place restraint at waist, not chest or abdomen. Remove wrinkles or creases in clothing. Bring ties through slots in belt. Help patient lie down in bed. Have patient roll to side and avoid applying belt too tightly (see illustrations). *Option: Apply a belt restraint net.*	Restrains center of gravity and prevents patient from rolling off stretcher or sitting up while on stretcher or from falling out of bed. Tight application interferes with ventilation if belt moves up over abdomen or chest.
b. *Extremity (ankle or wrist) restraint:* Restraint made of soft quilted material or sheepskin with foam padding. Wrap limb restraint around wrist or ankle with soft part toward skin and secure snugly (not tightly) in place by Velcro strap or quick-release buckle. Insert two fingers under secured restraint (see illustration).	Restraint designed to immobilize one or all extremities. Maintain immobilization of extremity to protect patient from fall or accidental removal of therapeutic device (e.g., intravenous [IV] tube, Foley catheter). Tight application interferes with circulation and potentially causes neurovascular injury.

STEP 4a **A,** Apply belt restraint with patient sitting. **B,** A properly applied belt restraint allows patient to turn in bed. (Courtesy Posey Company, Arcadia, CA.)

STEP	RATIONALE

CLINICAL DECISION: *Patient with wrist and ankle restraints is at risk for aspiration if positioned supine. Place patient in lateral position or with head of bed elevated rather than supine.*

c. *Mitten restraint:* Thumbless mitten device restrains patient's hands. Place hand in mitten, being sure that Velcro strap is around wrist and not forearm (see illustration).	Prevents patient from dislodging invasive equipment, removing dressings, or scratching but allows greater movement than a wrist restraint. It is considered a restraint alternative if untethered and patient is physically and cognitively able to remove it.
d. *Elbow restraint (freedom splint):* Restraint consists of rigidly padded fabric that wraps around the arm and is closed with Velcro. The upper end has a clamp that hooks to the sleeve of a patient's gown or shirt (see illustration). Insert arm so elbow joint rests against padded area, keeping joint extended.	Commonly used with infants and children to prevent elbow flexion (e.g., with IV line placed in antecubital fossa). Restraint keeps elbow extended.

CLINICAL DECISION: *This text does not address application of vest restraints. Many health care agencies ban the use of jacket (vest) restraints because of their association with fatal injuries.*

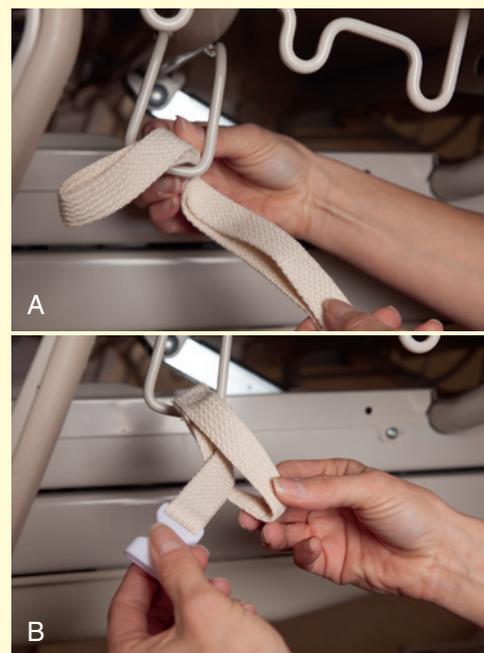
5. Attach restraint straps to portion of bedframe that moves when raising or lowering head of bed (see illustrations). Be sure that straps are secure. *Do not attach to side rails.* Attach restraint to chair frame for patient in chair or wheelchair, being sure that tie is out of patient's reach.	Properly positioned strap does not tighten and restrict circulation when bed is raised or lowered.

STEP 4b Insert two fingers under restraint to check for constriction.

STEP 4c Mitten restraint. (Courtesy Posey Company, Arcadia, CA.)

STEP 4d Freedom elbow restraint.

A

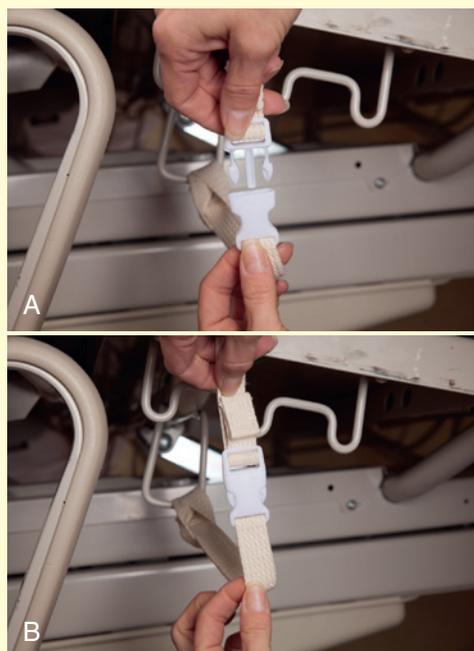
B


STEP 5 Attaching restraint buckle and strap to bedframe.

SKILL 27-2	APPLYING PHYSICAL RESTRAINTS—cont'd

STEP	RATIONALE
6. Secure restraints with quick-release buckle (see illustrations). *Do not tie strap in a knot.* Be sure that buckle is out of patient reach.	Allows for quick release in an emergency.
7. Double-check and insert two fingers under secured restraint. Assess proper placement of restraint, including skin integrity, pulses, skin temperature and color, and sensation of restrained body part.	Provides baseline assessment data if injury develops from restraint.
8. Remove restraint at least every 2 hours (TJC, 2016) or more frequently as determined by agency policy. Reposition patient, provide comfort and toileting measures, evaluate patient condition each time. If patient is violent or non-compliant, remove one restraint at a time and/or have staff assist while removing restraints.	Provides an opportunity to attend to patient's basic needs and determine need for continuation.
9. Secure call light or intercom system within reach.	Allows patient, family, or caregiver to obtain assistance quickly.
10. Leave bed or chair with wheels locked. Keep bed in lowest position.	Prevents bed or chair from moving if patient tries to get out. If patient falls with bed in lowest position, this reduces chance of injury.
11. Perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1. After application, evaluate patient for signs of injury every 15 minutes (e.g., circulation, vital signs, range of motion, physical and psychological status, and readiness for discontinuation. Perform visual checks if patient is too agitated to approach (TJC, 2015).	Frequent evaluation prevents injury to patient and ensures removal of restraint at earliest possible time. Frequency of monitoring guides staff in determining appropriate intervals for evaluation on the basis of patient's needs and condition, type of restraint used, risk associated with use of chosen intervention, and other relevant factors.
2. Evaluate patient's need for toileting, nutrition and fluids, hygiene, and elimination and release restraint at least every 2 hours.	Prevents injury to patient and attends to basic needs.
3. Evaluate patient for any complications of immobility.	Early detection of skin irritation, restricted breathing, or reduction in mobility prevents serious adverse events.
4. The licensed health care provider or registered nurse trained according to CMS requirements needs to evaluate patient within either 1 or 4 hours after initiation of restraints, depending on Medicare status of hospital (see agency policy).	Determines patient's immediate situation, reaction to restraints, medical and behavioral condition, and need to continue or terminate restraints (CMS, 2007).
5. After 24 hours, before writing a new order, the health care provider who is responsible for patient's care must see and assess patient.	Ensures that restraint application continues to be medically appropriate.
6. Observe IV catheters, urinary catheters, and drainage tubes to determine that they are positioned correctly and that therapy remains uninterrupted.	Reinsertion is uncomfortable and increases risk for infection or interrupts therapy.
7. Observe patient's behavior and reaction to presence of restraint.	Restraints can increase restlessness and agitation, resulting in harm.


STEP 6 Connecting the quick-release buckle.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Skin underlying restraint becomes reddened or damaged.
   - Provide appropriate skin/wound care (see Chapter 48).
   - Notify health care provider and reassess need for continued use of restraint or if you can use alternative measures.
   - Be sure that restraint is applied correctly and has adequate padding.
   - Remove restraints more frequently. Change wet or soiled restraints.
2. Patient has altered neurovascular status of an extremity such as cyanosis, pallor, and coldness of skin or complains of tingling, pain, or numbness.
   - Remove restraint immediately and notify health care provider. Stay with patient.
3. Patient becomes confused or agitated.
   - Identify reason for change in behavior and try to eliminate cause.
   - Use restraint alternatives.

RECORDING AND REPORTING

- Record nursing interventions, including restraint alternatives tried, in nurses' notes.
- Record patient's behavior before restraints were applied, level of orientation, and patient or family's understanding of application.
- Document your evaluation of patient/family learning.
- Record purpose for restraint, type and location of restraint used, time applied and discontinued, times restraint was released, and routine observations (e.g., skin color, pulses, sensation, vital signs, behavior) in nurses' notes and flow sheets.
- Record patient's level of orientation and behavior after restraint application. Record times patient was evaluated, attempts to use alternatives, and patient's response when restraint was removed.

HOME CARE CONSIDERATIONS

- A physical restraint is a device that requires a physician's order. Do not send a patient home with intent of restraining unless device is necessary to protect patient from injury. If patient's family wishes to use restraint at home, a physician's order is required, and you need to give clear instructions regarding proper application, care needed while in restraints, and complications for which to look. Carefully assess the family for competency and understanding of intent for using restraint.

KEY POINTS

- In the community a safe environment means that basic needs are achievable, physical hazards are reduced, transmission of pathogens and parasites is reduced, pollution is controlled, and sanitation is maintained.
- A safe health care environment is one that reduces the risk of injury, including minimizing falls, patient-inherent accidents, procedure-inherent accidents, and equipment-related accidents.
- Reduction of physical hazards in the environment includes providing adequate lighting, decreasing clutter, and securing the home.
- Reduce the transmission of pathogens through medical and surgical asepsis, immunization, adequate food sanitation, and appropriate disposal of human waste.
- Every developmental age involves specific safety risks.
- Children younger than 5 years of age are at greatest risk for home accidents that result in severe injury and death.
- Patient safety continues to be one of the most pressing health care challenges in the nation.
- Adolescents are at risk for injury from automobile accidents, suicide, and substance abuse.
- Threats to an adult's safety are frequently associated with lifestyle habits.
- Risks for injury for older patients are directly related to the physiological changes of the aging process.
- Nursing interventions for promoting safety are individualized for patients' developmental stage, lifestyle, and environment.
- Continually evaluate a patient's safety risk and update the nursing care plan appropriately.
- Fall risk prevention strategies are implemented on the basis of patients' risk factors, medical history, and condition of patient's environment.
- Use physical restraints only as a last resort, when patients' behavior places them or others at risk for injury.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Ms. Cohen is hospitalized for repair of a fractured hip after a fall at home. She requires intravenous (IV) antibiotics after surgery. Shortly after the first dose she became restless and started picking at her IV line and frequently tried to get out of bed. Several restraint alternatives were attempted; but, because of her restlessness, she was successful at pulling out her IV line and getting out of bed. It becomes necessary to restrain Ms. Cohen.

1. You know that a health care provider's order is required for the restraint. What are essential components of the restraint order?
2. Which assessments do you need to perform on Ms. Cohen while she is restrained?
3. The physician orders a belt restraint. Your assessment of Ms. Cohen the next day reveals that during the day she is alert and pleasantly confused but not attempting to get out of bed. Do you continue use of the restraint? Explain.

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A patient has been newly admitted to a medicine unit with a history of diabetes and advanced heart failure. The nurse is assessing the patient's fall risks. Place the following steps for measuring the "Timed Get-up and Go Test" (TUG) in the correct order:
   1. Have patient rise from straight-back chair without using arms for support.
   2. Begin timing.
   3. Tell patient to walk 10 feet as quickly and safely as possible to a line you marked on the floor, turn around, walk back, and sit down.
   4. Check time elapsed.
   5. Look for unsteadiness in patient's gait.
   6. Have patient return to chair and sit down without using arms for support.

2. A nurse knows that the people most at risk for accidental hypothermia are: (Select all that apply.)
   1. People who are homeless.
   2. People with respiratory conditions.
   3. People with cardiovascular conditions.
   4. The very old.
   5. People with kidney disorders.

3. A parent calls the pediatrician's office to ask about directions for using a car seat. Which of the following is the most correct set of instructions the nurse gives to this parent?
   1. Only infants and toddlers need to ride in the back seat.
   2. All toddlers can move to a forward facing car seat when they reach age 2.
   3. Toddlers must reach age 2 and the height/weight requirement before they ride forward facing.
   4. Toddlers must reach age 2 or the height or weight requirement before they ride forward facing.

4. The nursing assessment of a 78-year-old woman reveals orthostatic hypotension, weakness on the left side, and fear of falling. On the basis of the patient's data, which one of the following nursing diagnoses indicates an understanding of the assessment findings?
   1. *Activity Intolerance*
   2. *Impaired Bed Mobility*
   3. *Acute Pain*
   4. *Risk for Falls*

5. A couple who is caring for their aging parents are concerned about factors that put them at risk for falls. Which factors are most likely to contribute to an increase in falls in the elderly? (Select all that apply.)
   1. Inadequate lighting
   2. Throw rugs
   3. Multiple medications
   4. Doorway thresholds
   5. Cords covered by carpets
   6. Staircases with handrails

6. You are caring for a patient who frequently tries to remove his intravenous catheter and feeding tube. You have an order from the health care provider to apply a wrist restraint. Place the steps for applying a wrist restraint in the correct order.
   1. Be sure that patient is comfortable with arm in anatomic alignment.
   2. Wrap wrist with soft part of restraint toward skin and secure snugly.
   3. Identify patient using two identifiers.

   4. Introduce self and ask patient about his feelings of being restrained.
   5. Assess condition of skin where restraint will be placed.

7. The family of a patient who is confused and ambulatory insists that all four side rails be up when the patient is alone. What is the best action to take in this situation? (Select all that apply.)
   1. Contact the nursing supervisor.
   2. Restrict the family's visiting privileges.
   3. Ask the family to stay with the patient if possible.
   4. Inform the family of the risks associated with side-rail use.
   5. Thank the family for being conscientious and put the four rails up.
   6. Discuss alternatives that are appropriate for this patient with the family.

8. You are conducting an education class at a local senior center on safe-driving tips for seniors. Which of the following should you include? (Select all that apply.)
   1. Drive shorter distances
   2. Drive only during daylight hours
   3. Use the side and rearview mirrors carefully
   4. Keep a window rolled down while driving if has trouble hearing
   5. Look behind toward the blind spot
   6. Stop driving at age 75

9. The nursing assessment of an 80-year-old patient who demonstrates some confusion but no anxiety reveals that the patient is a fall risk because she continues to get out of bed without help despite frequent reminders. The initial nursing intervention to prevent falls for this patient is to:
   1. Place a bed alarm device on the bed.
   2. Place the patient in a belt restraint.
   3. Provide one-on-one observation of the patient.
   4. Apply wrist restraints.

10. A nurse is evaluating a patient who is in soft wrist restraints. Which of the following activities does the nurse perform? (Select all that apply.)
    1. Check the patient's peripheral pulse in the restrained extremity
    2. Evaluate the patient's need for toileting
    3. Offer the patient fluids if appropriate
    4. Release both limbs at the same time to perform range of motion (ROM)
    5. Inspect the skin under each restraint

11. You are admitting Mr. Jones, a 64-year-old patient who had a right hemisphere stroke and a recent fall. His wife stated that he has a history of high blood pressure, which is controlled by an antihypertensive and a diuretic. Currently he exhibits left-sided neglect and problems with spatial and perceptual abilities and is impulsive. He has moderate left-sided weakness that requires the assistance of two and the use of a gait belt to transfer to a chair. He currently has an intravenous (IV) line and a urinary catheter in place. Which factors increase his fall risk at this time? (Select all that apply.)
    1. Smokes a pack a day
    2. Used a cane to walk at home
    3. Takes antihypertensive and diuretics
    4. History of recent fall
    5. Neglect, spatial and perceptual abilities, impulsive
    6. Requires assistance with activity, unsteady gait
    7. IV line, urinary catheter

12. At 12 noon the emergency department nurse hears that an explosion has occurred in a local manufacturing plant. Which action does the nurse take first?

1. Prepare for an influx of patients
2. Contact the American Red Cross
3. Determine how to resume normal operations
4. Evacuate patients per the disaster plan

13. The nurse is caring for a patient who is having a seizure. Which of the following measures will protect the patient and the nurse from injury? (Select all that apply.)
    1. If patient is standing, attempt to get him or her back in bed.
    2. With patient on floor, clear surrounding area of furniture or equipment.
    3. If possible, keep patient lying supine.
    4. Do not restrain patient; hold limbs loosely if they are flailing.
    5. Never force apart a patient's clenched teeth.

14. What is your role as a nurse during a fire? (Select all that apply.)
    1. Help to evacuate patients
    2. Shut off medical gases
    3. Use a fire extinguisher
    4. Single carry patients out
    5. Direct ambulatory patients

15. A nurse is educating parents to look for clues in teenagers for possible substance abuse. Which environmental and psychosocial clues should the nurse include? (Select all that apply.)
    1. Blood spots on clothing
    2. Long-sleeved shirts in warm weather
    3. Changes in relationships
    4. Wearing dark glasses indoors
    5. Increased computer use

Answers: 1. 3, 1, 2, 5, 6, 4; **2.** 1, 3, 4; **3.** 4, 5; **4.** 1, 2, 3, 4, 5; **6.** 3, 4, 1, 5, 2; **7.** 3, 4, 6; **8.** 1, 2, 3, 4, 5; **9.** 1; **10.** 1, 2, 3, 5; **11.** 3, 4, 5, 6, 7; **12.** 1; **13.** 2, 4, 5; **14.** 1, 2, 3, 5; **15.** 1, 2, 3, 4.

Immobility

OBJECTIVES

- Discuss physiological and pathological influences on mobility.
- Identify changes in physiological and psychosocial function associated with immobility.
- Assess for correct and impaired body alignment and mobility.
- Formulate appropriate nursing diagnoses for patients with impaired mobility.
- Develop individualized nursing care plans for patients with impaired mobility.

- Compare and contrast active and passive range-of-motion exercises.
- Describe interventions for improving or maintaining patients' mobility.
- Evaluate patient outcomes as a result of a nursing plan for improving or maintaining mobility.

People are mobile for many purposes (e.g., expression of emotions with nonverbal gestures and meeting basic needs). Mobility is also essential for self-defense, activities of daily living (ADLs), and recreational activities. Many functions of the body depend on mobility. Intact musculoskeletal and nervous systems are necessary for optimal physical mobility and functioning. Clinical nursing practices related to mobility and immobility require the incorporation of scientific and nursing knowledge and skills to provide competent care.

SCIENTIFIC KNOWLEDGE BASE

Nature of Movement

Movement is a complex process that requires coordination between the musculoskeletal and nervous systems. As a nurse you will consider how a patient's physical and psychological condition affect body movement. **Body mechanics** is a term that describes the coordinated efforts of the musculoskeletal and nervous systems. Knowing how patients initiate movement and understanding your own movements requires a basic understanding of the physics surrounding body mechanics. The body mechanics applied in the lifting techniques historically used in nursing practice often cause debilitating injuries to nurses and other health care staff (Burnfield et al., 2013; Griffis, 2012). Today nurses use evidence-based information about body alignment, balance, gravity, and friction when implementing nursing interventions such as positioning patients, determining the risk of patient falls, and selecting the safest way to move or transfer patients (Healey and Darowski, 2012).

Alignment and Balance. The terms *body alignment* and **posture** are similar and refer to the positioning of the joints, tendons,

ligaments, and muscles while standing, sitting, and lying. **Body alignment** means that an individual's center of gravity is stable. Correct body alignment reduces strain on musculoskeletal structures, aids in maintaining adequate muscle tone, promotes comfort, and contributes to balance and conservation of energy. Without balance control the center of gravity is displaced.

Individuals require balance for maintaining a static position (e.g., sitting) and moving (e.g., walking). Disease, injury, pain, physical development (e.g., age), and life changes (e.g., pregnancy) compromise the ability to remain balanced. Medications that cause dizziness and prolonged immobility affect balance. Impaired balance is a major threat to mobility and physical safety and contributes to a fear of falling and self-imposed activity restrictions (McMahon and Fleury, 2012) (see Chapter 39).

Gravity and Friction. Weight is the force exerted on a body by gravity. The force of weight is always directed downward, which is why an unbalanced object falls. Unsteady patients fall if their center of gravity becomes unbalanced because of the gravitational pull on their weight.

To lift safely the lifter has to overcome the weight of the object and know its center of gravity. In symmetrical inanimate objects the center of gravity is at the exact center of the object. However, people are not geometrically perfect; their centers of gravity are usually at 55% to 57% of standing height and are in the midline, which is why only using principles of body mechanics in lifting patients often leads to injury of a nurse or other health care professional (see Chapter 39).

Friction is a force that occurs in a direction to oppose movement. The greater the surface area of the object that is moved, the greater is the friction. A larger object produces greater resistance to movement. In addition, the force exerted against the skin while the skin remains stationary and the bony structures move is called **shear.** Unfortunately a common example is when the head of a hospital bed is elevated beyond 60 degrees and gravity pulls a patient so that the bony skeleton moves toward the foot of the bed while the skin remains against the sheets. The blood vessels in the underlying tissue are stretched and damaged, resulting in impeded blood flow to the deep tissues. Ultimately pressure ulcers often develop within the undermined tissue; the surface tissue appears less affected (see Chapter 48). To decrease surface area and reduce friction when patients are unable to assist with moving up in bed, nurses use an ergonomic assistive device such as a full-body sling. This sling mechanically lifts a patient off the surface of a bed, thereby preventing friction, tearing, or shearing his or her delicate skin, and protects the nurse and other staff from injury (Burnfield et al., 2013).

Skeletal System. The skeletal system provides attachments for muscles and ligaments and the **leverage** necessary for mobility. Thus the skeleton is the supporting framework of the body and is made up of four types of bones: long, short, flat, and irregular. Bones are important for mobilization because they are firm, rigid, and elastic. The aging process changes the components of bone, which impacts mobility.

Firmness results from inorganic salts such as calcium and phosphate that are in the bone matrix. It is related to the rigidity of the bone, which is necessary to keep long bones straight, and enables bones to withstand weight bearing. Elasticity and skeletal flexibility change with age. For example, a newborn has a large amount of cartilage and is highly flexible but is unable to support weight. A toddler's bones are more pliable than those of an older person and are better able to withstand falls. Older adults, especially women, are more susceptible to

bone loss (resorption) and osteoporosis, which increase the risk of fractures.

The skeletal system has several functions. It protects vital organs (e.g., the skull around the brain and the ribs around the heart and lungs) and aids in calcium regulation. Bones store calcium and release it into the circulation as needed. Patients who have decreased calcium regulation and metabolism and who are immobile are at risk for developing osteoporosis and **pathological fractures** (fractures caused by weakened bone tissue) (see Chapter 39).

In addition, the internal structure of long bones contains bone marrow, participates in red blood cell (RBC) production, and acts as a reservoir for blood. Patients with altered bone marrow function or diminished RBC production tire easily because of reduced hemoglobin and oxygen-carrying ability. This fatigue decreases their mobility and increases the risk for falling.

Joints. Joints are the connections between bones. Each joint is classified according to its structure and degree of mobility. There are three classifications of joints: cartilaginous, fibrous, and synovial (McCance and Huether, 2014) (see Chapter 39).

Ligaments, Tendons, and Cartilage. Ligaments are white, shiny, flexible bands of fibrous tissue that bind joints together, connect bones and cartilages, and aid joint flexibility and support. Tendons are white, glistening, fibrous bands of tissue that connect muscle to bone and are strong, flexible, and inelastic. Cartilage is nonvascular (without blood vessels) supporting connective tissue located chiefly in the joints and thorax, trachea, larynx, nose, and ear. The characteristics of the cartilage change with the aging process (see Chapter 39).

Skeletal Muscle. Movement of bones and joints involves active processes that are carefully integrated to achieve coordination. Skeletal muscles, because of their ability to contract and relax, are the working elements of movement. Anatomical structure and attachment to the skeleton enhance contractile elements of the skeletal muscle (see Chapter 39).

Nervous System. The nervous system regulates movement and posture. The precentral gyrus, or motor strip, is the major voluntary motor area and is in the cerebral cortex. A majority of motor fibers descend from the motor strip and cross at the level of the medulla. Movement is impaired by disorders that alter neurotransmitter production, transfer of impulses from the nerve to the muscle, or activation of muscle activity (see Chapter 39).

Pathological Influences on Mobility

Many pathological conditions affect mobility. Although a complete description of each is beyond the scope of this chapter, an overview of four pathological influences is presented.

Postural Abnormalities. Congenital or acquired postural abnormalities affect the efficiency of the musculoskeletal system and body alignment, balance, and appearance. During assessment observe body alignment and ROM (see Chapter 39). Postural abnormalities can cause pain, impair alignment or mobility, or both. Knowledge about the characteristics, causes, and treatment of common postural abnormalities is necessary for lifting, transfer, and positioning (Table 28-1). Some postural abnormalities limit ROM. Nurses intervene to maintain maximum ROM in unaffected joints and then often collaborate with physical therapists to design interventions to strengthen affected muscles and joints, improve the patient's posture, and adequately use affected and unaffected muscle groups. Referral to and/or collaboration with a physical therapist enhances the nurse's interventions for a patient with a postural abnormality.

TABLE 28-1   Postural Abnormalities

Abnormality	Description	Cause	Possible Treatments* (McCance and Huether, 2014)
Torticollis	Inclining head to affected side, in which sternocleidomastoid muscle is contracted	Congenital or acquired condition	Surgery, heat, support, or immobilization, depending on cause and severity; gentle ROM
Lordosis	Exaggeration of anterior convex curve of lumbar spine	Congenital condition; temporary condition (e.g., pregnancy)	Spine-stretching exercises (based on cause)
Kyphosis	Increased convexity in curvature of thoracic spine	Congenital condition; rickets, osteoporosis; tuberculosis of spine	Spine-stretching exercises, sleeping without pillows, using bed board, bracing, surgical spinal fusion (based on cause and severity)
Scoliosis	Lateral S- or C-shaped spinal column with vertebral rotation, unequal heights of hips and shoulders	Sometimes a consequence of numerous congenital, connective tissue, and neuromuscular disorders	Approximately half of children with scoliosis require surgery. Nonsurgical treatment is with braces and exercises
Congenital hip dysplasia	Hip instability with limited abduction of hips and occasionally adduction contractures (head of femur does not articulate with acetabulum because of abnormal shallowness of acetabulum)	Congenital condition (more common with breech deliveries)	Maintenance of continuous abduction of thigh so head of femur presses into center of acetabulum; abduction splints, casting, surgery
Knock-knee (genu valgum)	Legs curved inward so knees come together as person walks	Congenital condition; rickets	Knee braces; surgery if not corrected by growth
Bowlegs (genu varum)	One or both legs bent outward at knee, which is normal until 2 to 3 years of age	Congenital condition; rickets	Slowing rate of curving if not corrected by growth; with rickets, increase of vitamin D, calcium, and phosphorus intake to normal ranges
Clubfoot	*95%:* Medial deviation and plantar flexion of foot (equinovarus) *5%:* Lateral deviation and dorsiflexion (calcaneovalgus)	Congenital condition	Casts, splints such as Denis Browne splint, and surgery (based on degree and rigidity of deformity)
Footdrop	Inability to dorsiflex and invert foot because of peroneal nerve damage	Congenital condition; trauma; improper position of immobilized patient	None (cannot be corrected); prevention through physical therapy; bracing with ankle-foot orthotic (AFO)
Pigeon toes	Internal rotation of forefoot or entire foot; common in infants	Congenital condition; habit	Growth; wearing reversed shoes

ROM, Range of motion.
*Severity of condition and cause dictate treatment, which is individualized to the patient's needs.

Muscle Abnormalities. Injury and disease lead to numerous alterations in musculoskeletal function. For example, the muscular dystrophies are a group of familial disorders that cause degeneration of skeletal muscle fibers. They are the most prevalent of the muscle diseases in childhood. Patients with muscular dystrophy experience progressive, symmetrical weakness and wasting of skeletal muscle groups, with increasing disability and deformity (McCance and Huether, 2014).

Damage to the Central Nervous System. Damage to any component of the central nervous system that regulates voluntary movement results in impaired body alignment, balance, and mobility. Trauma from a head injury, ischemia from a stroke (cerebrovascular accident [CVA]), or bacterial infection such as meningitis can damage the cerebellum or the motor strip in the cerebral cortex. Damage to the cerebellum causes problems with balance, and motor impairment is directly related to the amount of destruction of the motor strip. For example, a person with a right-sided cerebral hemorrhage with necrosis has destruction of the right motor strip that results in left-sided hemiplegia. Trauma to the spinal cord also impairs mobility. For example, a complete transection of the spinal cord results in a bilateral loss of voluntary motor control below the level of the trauma because motor fibers are cut.

Direct Trauma to the Musculoskeletal System. Direct trauma to the musculoskeletal system results in bruises, contusions, sprains, and fractures. A fracture is a disruption of bone tissue continuity. Fractures most commonly result from direct external trauma, but they also occur as a consequence of some deformity of the bone (e.g., pathological fractures of osteoporosis, Paget's disease, or osteogenesis imperfecta). Young children are usually able to form new bone more easily than adults and, as a result, have few complications after a fracture. Treatment often includes positioning the fractured bone in proper alignment and immobilizing it to promote healing and restore function. Even this temporary immobilization results in some **muscle atrophy,** loss of muscle tone, and joint stiffness.

NURSING KNOWLEDGE BASE

Fully understanding movement and mobility requires more than an overview of movement and the physiology and regulation of movement by the musculoskeletal and nervous systems. You need to know

how to apply these scientific principles in the clinical setting to determine the safest way to move patients and to understand the effect of immobility on the physiological, psychosocial, and developmental aspects of patient care.

Factors Influencing Mobility-Immobility

To determine how to move patients safely, you will assess their ability to move. **Mobility** refers to a person's ability to move about freely, and **immobility** refers to the inability to do so. Think of mobility as a continuum, with mobility on one end, immobility on the other, and varying degrees of partial immobility between the end points. Some patients move back and forth between mobility and immobility, but for others immobility is absolute and continues indefinitely. The terms *bed rest* and *impaired physical mobility* are used frequently when discussing patients on the mobility-immobility continuum.

Bed rest is an intervention that restricts patients to bed for therapeutic reasons. Although it is much less commonly used, health care providers most often prescribe this intervention. Bed rest has many different interpretations among health care professionals. The duration of bed rest depends on the illness or injury and a patient's prior state of health.

The effects of muscular deconditioning associated with lack of physical activity are often apparent in a matter of days. This cluster of symptoms is often referred to as the "hazards of immobility." The individual of average weight and height without a chronic illness on bed rest loses muscle strength from baseline levels at a rate of 3% a day. Immobility also is associated with cardiovascular, skeletal, and other organ changes. The term *disuse atrophy* describes the tendency of cells and tissue to reduce in size and function in response to prolonged inactivity resulting from bed rest, trauma, casting of a body part, or local nerve damage (McCance and Huether, 2014).

Periods of immobility due to disability or injury or prolonged bed rest during hospitalization cause major physiological, psychological, and social effects. These effects are gradual or immediate and vary from patient to patient. The greater the extent and the longer the duration of immobility, the more pronounced the consequences. The patient with complete mobility restrictions is continually at risk for the hazards of immobility. When possible, it is imperative that patients, especially older adults, have limited bed rest and that their activity is more than bed to chair. Loss of walking independence increases hospital stays, need for rehabilitation services, or nursing home placement. In addition, the deconditioning related to reduced walking increases the risk for patient falls (AAN, 2015; Pashikanti and Von Ah, 2012).

Systemic Effects. All body systems work more efficiently with some form of movement. Exercise has positive outcomes for all major systems of the body. When there is an alteration in mobility, each body system is at risk for impairment. The severity of the impairment depends on a patient's overall health, degree and length of immobility, and age. For example, older adults with chronic illnesses develop pronounced effects of immobility more quickly than do younger patients with the same immobility problem.

Metabolic Changes. Changes in mobility alter endocrine metabolism, calcium resorption, and functioning of the gastrointestinal system. The endocrine system, composed of hormone-secreting glands, maintains and regulates vital functions such as (1) response to stress and injury; (2) growth and development; (3) reproduction; (4) maintenance of the internal environment; and (5) energy production, use, and storage.

When injury or stress occurs, the endocrine system triggers a series of responses aimed at maintaining blood pressure and preserving life. It is important in maintaining homeostasis. Tissues and cells live in an internal environment that the endocrine system helps regulate through maintenance of sodium, potassium, water, and acid-base balance. It also regulates energy metabolism. Thyroid hormone increases the basal metabolic rate (BMR), and energy becomes available to cells through the integrated action of gastrointestinal and pancreatic hormones (McCance and Huether, 2014).

Immobility disrupts normal metabolic functioning, decreasing the metabolic rate; altering the metabolism of carbohydrates, fats, and proteins; causing fluid, electrolyte, and calcium imbalances; and causing gastrointestinal disturbances such as decreased appetite and slowing of peristalsis. However, in the presence of an infectious process, immobilized patients often have an increased BMR as a result of fever or wound healing because these increase cellular oxygen requirements (McCance and Huether, 2014).

A deficiency in calories and protein is characteristic of patients with a decreased appetite secondary to immobility. The body is constantly synthesizing proteins and breaking them down into amino acids to form other proteins (see Chapter 45). When the patient is immobile, his or her body often excretes more nitrogen (the end product of amino acid breakdown) than it ingests in proteins, resulting in **negative nitrogen balance**. Weight loss, decreased muscle mass, and weakness result from tissue catabolism (tissue breakdown) (McCance and Huether, 2014).

Another metabolic change associated with immobility is calcium resorption (loss) from bones. Immobility causes the release of calcium into the circulation. Normally the kidneys excrete the excess calcium. However, if they are unable to respond appropriately, hypercalcemia results. Pathological fractures occur if calcium resorption continues as a patient remains on bed rest or continues to be immobile (McCance and Huether, 2014).

Impairments of gastrointestinal functioning caused by decreased mobility vary. Difficulty in passing stools (constipation) is a common symptom, although pseudodiarrhea often results from a fecal impaction (accumulation of hardened feces). Be aware that this finding is not normal diarrhea, but rather liquid stool passing around the area of impaction (see Chapter 47). Left untreated, fecal impaction results in a mechanical bowel obstruction that partially or completely occludes the intestinal lumen, blocking normal propulsion of liquid and gas. The resulting fluid in the intestine produces distention and increases intraluminal pressure. Over time intestinal function becomes depressed, dehydration occurs, absorption ceases, and fluid and electrolyte disturbances worsen.

Respiratory Changes. Regular aerobic exercise enhances respiratory functioning. In contrast, lack of movement and exercise places patients at risk for respiratory complications. Patients who are immobile are at high risk for developing pulmonary complications such as **atelectasis** (collapse of alveoli) and **hypostatic pneumonia** (inflammation of the lung from stasis or pooling of secretions). Both decreased oxygenation and prolonged recovery add to patients' discomfort (Lewis et al., 2013). In atelectasis secretions block a bronchiole or a bronchus; and the distal lung tissue (alveoli) collapses as the existing air is absorbed, producing hypoventilation. The site of the blockage affects the severity of atelectasis. Sometimes an entire lung lobe or a whole lung collapses. At some point in the development of these complications, there is a proportional decline in the patient's ability to cough productively. Ultimately the distribution of mucus in the bronchi increases, particularly when the patient is in the supine, prone, or lateral position. Mucus accumulates in the dependent regions of the airways (Figure 28-1). Hypostatic pneumonia frequently results because mucus is an excellent place for bacteria to grow.

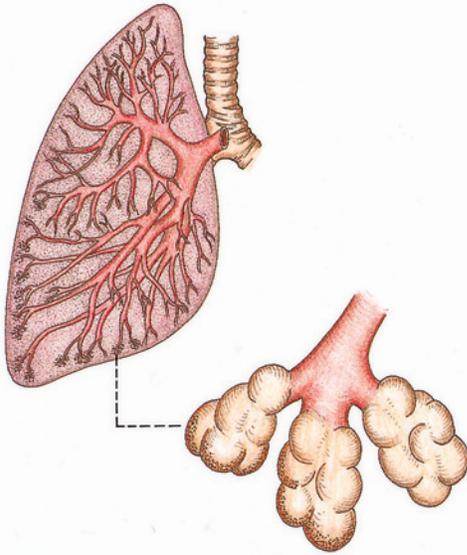
Cardiovascular Changes. Immobilization also affects the cardiovascular system, frequently resulting in orthostatic hypotension,


FIGURE 28-1 Pooling of secretions in dependent regions of lungs in supine position.
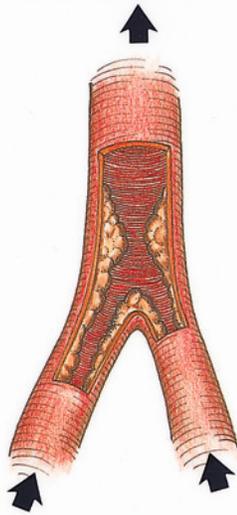

FIGURE 28-2 Thrombus formation in a vessel.

increased cardiac workload, and thrombus formation. **Orthostatic hypotension** is a drop of blood pressure greater than 20 mm Hg in systolic pressure or 10 mm Hg in diastolic pressure and symptoms of dizziness, light-headedness, nausea, tachycardia, pallor, or fainting when the patient changes from the supine to standing position (Ball et al., 2015). In the immobilized patient decreased circulating fluid volume, pooling of blood in the lower extremities, and decreased autonomic response occur. These are especially evident in the older adult.

As the workload of the heart increases, so does its oxygen consumption. Therefore the heart works harder and less efficiently during periods of prolonged rest. As immobilization increases, cardiac output falls, further decreasing cardiac efficiency and increasing workload.

Patients who are immobile are also at risk for thrombus formation. A **thrombus** is an accumulation of platelets, fibrin, clotting factors, and the cellular elements of the blood attached to the interior wall of a vein or artery, which sometimes occludes the lumen of the vessel (Figure 28-2). Three factors contribute to venous thrombus formation: (1) damage to the vessel wall (e.g., injury during surgical procedures), (2) alterations of blood flow (e.g., slow blood flow in calf veins associated

with bed rest), and (3) alterations in blood constituents (e.g., a change in clotting factors or increased platelet activity). These three factors are often referred to as *Virchow's triad* (McCance and Huether, 2014). As a nurse you will practice in numerous situations when deep vein thrombosis (DVT) must be prevented, especially during perioperative care (see Chapter 50).

Musculoskeletal Changes. Immobility affects the musculoskeletal system by causing permanent or temporary impairment or permanent disability. Restricted mobility sometimes results in loss of endurance, strength, and muscle mass and decreased stability and balance. Other effects of restricted mobility affecting the skeletal system are impaired calcium metabolism and joint mobility.

Muscle Effects. Because of protein breakdown, a patient loses lean body mass during immobility. The reduced muscle mass makes it difficult for patients to sustain activity without increased fatigue. If immobility continues and the patient does not exercise, there is further loss of muscle mass. Prolonged immobility often leads to disuse atrophy. Loss of endurance, decreased muscle mass and strength, and joint instability (see Skeletal Effects) place patients at risk for falls (see Chapter 39).

Skeletal Effects. Immobilization causes two skeletal changes: impaired calcium metabolism and joint abnormalities. Because immobilization results in bone resorption, the bone tissue is less dense or atrophied, and **disuse osteoporosis** results. When disuse osteoporosis occurs, a patient is at risk for pathological fractures.

Osteoporosis is a major health concern in this country. It is predicted that by 2025 it will be responsible for approximately three million fractures and $25.3 billion in costs each year. Furthermore, the National Osteoporosis Foundation (2014) reports that about 54 million Americans have osteoporosis and low bone mass. Studies suggest that approximately one in two women and up to one in four men age 50 and older will break a bone as a result of osteoporosis. Although primary osteoporosis is different in origin from the osteoporosis that results from immobility, it is imperative that nurses recognize that immobilized patients are at high risk for accelerated bone loss if they have primary osteoporosis.

Immobility can lead to joint contractures. A **joint contracture** is an abnormal and possibly permanent condition characterized by fixation of a joint. It is important to note that flexor muscles for joints are stronger than extensor muscles and therefore contribute to the formation of contractures. Disuse, atrophy, and shortening of the muscle fibers cause joint contractures. When a contracture occurs, the joint cannot achieve full ROM. Contractures sometimes leave a joint or joints in a nonfunctional position, as seen in patients who are permanently curled in a fetal position. Early prevention of contractures is essential (Box 28-1) (Clavet et al., 2011).

One common and debilitating contracture is footdrop (Figure 28-3). When **footdrop** occurs, the foot is permanently fixed in plantar flexion. Ambulation is difficult with the foot in this position because the patient cannot dorsiflex the foot. A patient with footdrop is unable to lift the toes off the ground. Patients who have suffered CVAs with resulting right- or left-sided paralysis (hemiplegia) are at risk for footdrop.

Urinary Elimination Changes. Immobility alters a patient's urinary elimination. In the upright position urine flows out of the renal pelvis and into the ureters and bladder because of gravitational forces. When a patient is recumbent or flat, the kidneys and ureters move toward a more level plane. Urine formed by the kidney needs to enter the bladder unaided by gravity. Because the peristaltic contractions of the ureters are insufficient to overcome gravity, the renal pelvis fills before urine enters the ureters (Figure 28-4). This condition is called **urinary stasis** and increases the risk of urinary tract infection and renal calculi

BOX 28-1   EVIDENCE-BASED PRACTICE

Patient Contractures and Treatments to Reduce Future Contractures for At-Risk Patients

PICO Question: Can the use of early correct positioning, range-of-motion (ROM) exercises, and mechanical treatment modalities such as dynamic and static splints reduce joint contractures in the lower extremities in patients with at-risk conditions compared with patients who do not have any early intervention?

Evidence Summary

Joint contractures are common preventable disorders that can result in significant long-term morbidity and reduced patient independence. Contracture is the shortening of the connective tissue and is an abnormal and possibly permanent condition characterized by decreased range of joint motion and/or fixation of the joint. Contractures occur following prolonged joint positioning (immobility), neurological disorders, and surgical joint manipulation (Furia et al., 2013). Evidence shows that early prevention of contractures is essential (Furia et al., 2013; Clavet et al., 2011). A systematic review of contracture reduction by Furia et al (2013) reported on the success of early intervention with splinting procedures. They noted that prompt use of splinting with prescribed range-of-motion exercises reduced contractures and improved active range of joint motion in affected lower extremities.

Application to Nursing Practice

- In conjunction with an interprofessional health care team, develop an early intervention protocol using prescribed positioning, range-of-motion exercises, and/or splints to reduce the risk for contracture formation (Furia et al., 2013).
- Health care agencies need to provide equipment (e.g., splints) and appropriate education for staff to reduce the risk of contractures.
- A collaborative plan of care, including a discharge plan, with a contracture prevention and muscle strengthening protocol must be developed on patient admission (Clavet et al., 2011).
- Use positioning, ROM exercises, and ROM devices according to the individualized need of the patient and as ordered (Furia et al., 2013).

ROM, Range of motion.

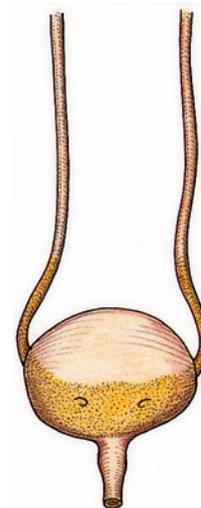
FIGURE 28-3 Footdrop. Ankle is fixed in plantar flexion. Normally ankle is able to flex *(dotted line),* which eases walking.


FIGURE 28-4 Stasis of urine with reflux to ureters.

(see Chapter 46). **Renal calculi** are calcium stones that lodge in the renal pelvis or pass through the ureters. Immobilized patients are at risk for calculi because they frequently have hypercalcemia.

As the period of immobility continues, fluid intake often diminishes. When combined with other problems such as fever, the risk for dehydration increases. As a result, urinary output declines on or about the fifth or sixth day after immobilization, and the urine becomes concentrated. This concentrated urine increases the risk for calculi formation and infection. Another cause of urinary tract infections in immobilized patients is the use of an indwelling urinary catheter.

Integumentary Changes. The changes in metabolism that accompany immobility add to the harmful effect of pressure on the skin in immobilized patients. This makes immobility a major risk factor for pressure ulcers. Any break in the integrity of the skin is difficult to heal. Preventing a pressure ulcer is much less expensive than treating one; therefore preventive nursing interventions are imperative (WOCN, 2010).

A **pressure ulcer** is an impairment of the skin as a result of prolonged ischemia (decreased blood supply) in tissues (see Chapter 48). An ulcer is characterized initially by inflammation and usually forms over a bony prominence. Ischemia develops when the pressure on the skin is greater than the pressure inside the small peripheral blood vessels supplying blood to the skin.

Tissue metabolism depends on the supply of oxygen and nutrients to and the elimination of metabolic wastes from the blood. Pressure affects cellular metabolism by decreasing or totally eliminating tissue circulation. When a patient lies in bed or sits in a chair, the weight of the body is on bony prominences. The longer the pressure is applied, the longer is the period of ischemia and therefore the greater the risk of skin breakdown. The prevalence of pressure ulcers is highest in long-term care facilities, whereas hospital-acquired pressure ulcers are the highest in adult intensive care units (Peterson et al., 2013).

Psychosocial Effects. Immobilization often leads to emotional and behavioral responses, sensory alterations, and changes in coping. Illnesses that result in limited or impaired mobility can cause social isolation and loneliness (Parker, 2012). Every patient responds to immobility differently.

Patients with restricted mobility may have some depression. Depression is an affective disorder characterized by exaggerated feelings of sadness, melancholy, dejection, worthlessness, emptiness, and hopelessness out of proportion to reality. It results from worrying about present and future levels of health, finances, and family needs. Because immobilization removes a patient from a daily routine, he or she has more time to worry about disability. Worrying quickly increases a patient's depression, causing withdrawal. Withdrawn patients often do not want to participate in their own care.

Developmental Changes

Immobility often leads to developmental changes in the very young and in older adults. The immobilized young or middle-age adult who has been healthy experiences few, if any, developmental changes. However, there are exceptions. For example, a mother with complications following birth has to go on bed rest and as a result cannot interact with her newborn as expected.

Infants, Toddlers, and Preschoolers. The newborn infant's spine is flexed and lacks the anteroposterior curves of the adult (see Chapter 12). As the baby grows, musculoskeletal development permits support of weight for standing and walking. Posture is awkward because the head and upper trunk are carried forward. Because body weight is not distributed evenly along a line of gravity, posture is off balance, and falls occur often. When an infant, toddler, or preschooler becomes immobilized, it is usually because of trauma or the need to correct a congenital skeletal abnormality. Prolonged immobilization delays a child's gross motor skills, intellectual development, and musculoskeletal development.

Adolescents. The adolescent stage usually begins with a tremendous increase in growth (see Chapter 12). When the activity level is reduced because of trauma, illness, or surgery, the adolescent is often behind peers in gaining independence and accomplishing certain skills such as obtaining a driver's license. Social isolation is a concern for this age-group when immobilization occurs.

Adults. An adult who has correct posture and body alignment feels good, looks good, and generally appears self-confident. The healthy adult also has the necessary musculoskeletal development and coordination to carry out ADLs (see Chapter 13). When periods of prolonged immobility occur, all physiological systems are at risk. In addition, the role of the adult often changes with regard to the family or social structure. Some adults lose their jobs, which affects their self-concept (see Chapter 34).

Older Adults. A progressive loss of total bone mass occurs with older adults. Some of the possible causes of this loss include decreased physical activity, hormonal changes, and bone resorption. The effect of bone loss is weaker bones. Older adults often walk more slowly, take smaller steps, and appear less coordinated. Prescribed medications alter their sense of balance or affect their blood pressure when they change position too quickly, increasing their risk for falls and injuries (see Chapter 14). The outcomes of a fall include not only possible injury but also hospitalization, loss of independence, psychological effects, and quite possibly death (McMahon and Fleury, 2012).

Older adults often experience functional status changes secondary to hospitalization and altered mobility status (Box 28-2). Immobilization of older adults increases their physical dependence on others and accelerates functional losses (Padula et al., 2009). Immobilization of some older adults results from a degenerative disease, neurological trauma, or chronic illness. In some it occurs gradually and progressively; in

BOX 28-2 FOCUS ON OLDER ADULTS

Functional Decline in Hospitalized Immobile Older Adults

For many older adults, admission to a hospital often results in functional decline despite the treatment for which they were admitted. Some older adults have problems related to mobility and quickly regress to a dependent state. Usual aging is associated with decreased muscle strength and aerobic capacity, which become exacerbated if a patient's nutritional state is poor.

- A nutritional assessment needs to be included in the plan of care for the older adult experiencing immobility.
- Anorexia and insufficient assistance with eating lead to malnutrition, which contributes to the known problems associated with immobility.
- Improved nutrition increases patient's ability to perform physical reconditioning exercises (Padula et al., 2009).
- There is a direct relationship between the success of older adults' rehabilitation and their nutritional status.

others, especially those who have had a stroke, it is sudden. When providing nursing care for an older adult, encourage the patient to perform as many self-care activities as possible, thereby maintaining the highest level of mobility. Sometimes nurses inadvertently contribute to a patient's immobility by providing unnecessary help with activities such as bathing and transferring.

❖ NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. Patients with preexisting mobility impairments and those who are at risk for immobility will greatly benefit from a care plan that improves the patient's functional status, promotes self-care, maintains psychological well-being, and reduces the hazards of immobility.

◆ Assessment

Your assessment of a patient must consider his or her normal mobility status, the effects of any diseases or conditions on mobility, and the patient's risks for mobility alterations as a result of treatments. Critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. Usually you will assess a patient's degree of mobility and immobility during the history interview and physical examination (Box 28-3). Keep in mind that the patient is a full partner in providing information and designing the plan of care. It is important to understand how any limitations in mobility are perceived by the patient. Has the patient had a disability for an extended period of time, and is he or she well adapted to the use of an assist device or even a wheelchair? Is the limitation in mobility sudden and unexpected, causing the patient to be fearful or full of questions? Always convey respect for the patient's preferences, values, and needs during assessment and when designing a plan of care (Ackley and Ladwig, 2014).

Mobility. Assessment of patient mobility focuses on ROM, gait, exercise and activity tolerance, and body alignment. When unsure of a patient's abilities, begin assessment of mobility with the patient in the most supportive position and move to higher levels according to his or her tolerance. Generally the assessment of movement starts while the patient is lying and proceeds to assessing sitting positions in

FIGURE 28-5 Planes of body.

bed, transfers to chair, and finally walking. This helps to protect the patient's safety.

Range of Motion. **Range of motion (ROM)** is the maximum amount of movement available at a joint in one of the three planes of the body: sagittal, transverse, or frontal (Figure 28-5). The sagittal plane is a line that passes through the body from front to back, dividing it into a left and right side. The frontal plane passes through the body from side to side and divides it into front and back. The transverse plane is a horizontal line that divides the body into upper and lower portions.

Ligaments, muscles, and the nature of the joint limit joint mobility in each of the planes. However, some joint movements are specific to each plane. In the sagittal plane, movements are flexion and extension (e.g., fingers and elbows), dorsiflexion, and plantar flexion (feet) and extension (e.g., hip). In the frontal plane movements are abduction and adduction (e.g., arms and legs) and eversion and inversion (feet). In the transverse plane movements are pronation and supination (hands) and internal and external rotation (hips).

Assessment of ROM is important as a baseline measure to determine a patient's mobility status and to later compare and evaluate whether a loss in joint mobility has occurred as a result of clinical changes or treatments. When assessing ROM, ask questions about and physically examine the patient for stiffness, swelling, pain, limited movement, and unequal movement. Chapter 31 describes specific techniques for measuring the degrees of motion in a joint. Patients whose mobility is restricted require ROM exercises to reduce the hazards of immobility. Limited ROM often indicates inflammation such as arthritis, fluid in the joint, altered nerve supply, or contractures. Increased mobility (beyond normal) of a joint sometimes indicates connective tissue disorders, ligament tears, or possible joint fractures.

Assess the type of ROM exercise that a patient is able to perform. First consider the medical plan of care and if active ROM exercises are appropriate; then assess the patient's ability to engage in active ROM exercises. ROM exercises are active (the patient moves all joints through his or her ROM unassisted), passive (the patient is unable to move independently, and the nurse moves each joint through its ROM), or somewhere in between (Table 28-2). For example, you might need to provide support for a weak patient while he or she performs most of the joint movement. Some patients are able to move some joints actively, whereas you will passively move others. Your assessment will help to determine the patient's need for assistance, teaching, or reinforcement. In general, exercises need to be as active as health and mobility allow. Contractures develop in joints that are not moved periodically through their full ROM. Assessment data from patients with limited joint movements vary on the basis of the area affected.

Neck. A flexion contracture of the neck is a serious disability because the patient's neck is permanently flexed with the chin close to or actually touching the chest. Assessment reveals altered body alignment, changes in the visual field, and decreased level of independent functioning.

Shoulder. One feature of the shoulder that sets it apart from other joints in the body is that the strongest muscle controlling it, the deltoid, is in complete elongation in the normal position. No other muscle exerts its full strength when in complete elongation. Patients with limited movement in the shoulder have difficulty moving their arms.

Elbow. The elbow functions optimally at an angle of approximately 90 degrees. An elbow fixed in full extension is disabling and limits a patient's independence.

Forearm. Most functions of the hand are best carried out with the forearm in moderate pronation. When the forearm is fixed in a position of full supination, the patient's use of the hand is limited.

Wrist. The primary function of the wrist is to place the hand in slight dorsiflexion, the position of functioning. When the wrist is fixed in even a slightly flexed position, the grasp is weakened.

Fingers and Thumb. The ROM in the fingers and thumb enables a patient to perform ADLs and activities requiring fine-motor skills such as carpentry, needlework, drawing, and painting. The functional position of the fingers and thumb is slight flexion of the thumb in opposition to the fingers.

Hip. Because the lower extremities are concerned chiefly with locomotion and weight bearing, stability of the hip joint is more important than its mobility. For example, if one hip has no mobility but is fixed in a neutral position and fully extended, it is possible to walk without a significant limp. However, contractures often fix the hip in positions

TABLE 28-2 Range-of-Motion Exercises

Body Part	Type of Joint	Type of Movement	Range (Degrees)	Primary Muscles
Neck, cervical spine	Pivotal	*Flexion:* Bring chin to rest on chest.	45	Sternocleidomastoid
		Extension: Return head to erect position.	45	Trapezius
		Hyperextension: Bend head back as far as possible.	10	Trapezius
		Lateral flexion: Tilt head as far as possible toward each shoulder.	40-45	Sternocleidomastoid
		Rotation: Turn head as far as possible in circular movement.	180	Sternocleidomastoid, trapezius
Shoulder	Ball and socket	*Flexion:* Raise arm from side position forward to position above head.	180	Coracobrachialis, biceps brachii, deltoid, pectoralis major
		Extension: Return arm to position at side of body.	45-60	
		Hyperextension: Move arm behind body, keeping elbow straight.	180	Latissimus dorsi, teres major, triceps brachii
			45-60	Latissimus dorsi, teres major, deltoid
		Abduction: Raise arm to side to position above head with palm away from head.	180	Deltoid, supraspinatus
		Adduction: Lower arm sideways and across body as far as possible.	320	Pectoralis major
		Internal rotation: With elbow flexed, rotate shoulder by moving arm until thumb is turned inward and toward back.	90	Pectoralis major, latissimus dorsi, teres major, subscapularis
		External rotation: With elbow flexed, move arm until thumb is upward and lateral to head.	90	Infraspinatus, teres major, deltoid
		Circumduction: Move arm in full circle (Circumduction is combination of all movements of ball-and-socket joint.)	360	Deltoid, coracobrachialis, latissimus dorsi, teres major
Elbow	Hinge	*Flexion:* Bend elbow so lower arm moves toward its shoulder joint and hand is level with shoulder.	150	Biceps brachii, brachialis, brachioradialis
		Extension: Straighten elbow by lowering hand.	150	Triceps brachii
Forearm	Pivotal	*Supination:* Turn lower arm and hand so palm is up.	70-90	Supinator, biceps brachii
		Pronation: Turn lower arm so palm is down.	70-90	Pronator teres, pronator quadratus
Wrist	Condyloid	*Flexion:* Move palm toward inner aspect of forearm.	80-90	Flexor carpi ulnaris, flexor carpi radialis
		Extension: Move fingers and hand posterior to midline.	80-90	Extensor carpi radialis brevis, extensor carpi radialis longus, extensor carpi ulnaris
		Hyperextension: Bring dorsal surface of hand back as far as possible.	80-90	Extensor carpi radialis brevis, extensor carpi radialis longus, extensor carpi ulnaris
		Abduction: Place hand with palm down and extend wrist laterally toward fifth finger.	Up to 30	Flexor carpi radialis, extensor carpi radialis brevis, extensor carpi radialis longus
		Adduction: Place hand with palm down and extend wrist medially toward thumb.	30-50	Flexor carpi ulnaris, extensor carpi ulnaris
Fingers	Condyloid hinge	*Flexion:* Make fist.	90	Lumbricales, interosseus volaris, interosseus dorsalis
		Extension: Straighten fingers.	90	Extensor digiti quinti proprius, extensor digitorum communis, extensor indicis proprius
		Hyperextension: Bend fingers back as far as possible.	30-60	Extensor digitorum
		Abduction: Spread fingers apart.	30	Interosseus dorsalis
		Adduction: Bring fingers together.	30	Interosseus volaris
Thumb	Saddle	*Flexion:* Move thumb across palmar surface of hand.	90	Flexor pollicis brevis
		Extension: Move thumb straight away from hand.	90	Extensor pollicis longus, extensor pollicis brevis
		Abduction: Extend thumb laterally (usually done when placing fingers in abduction and adduction).	30	Abductor pollicis brevis
		Adduction: Move thumb back toward hand.	30	Adductor pollicis obliquus, adductor pollicis transversus
		Opposition: Touch thumb to each finger of same hand.		Opponens pollicis, opponens digiti minimi

TABLE 28-2   Range-of-Motion Exercises—cont'd

Body Part	Type of Joint	Type of Movement	Range (Degrees)	Primary Muscles
Hip	Ball and socket	*Flexion:* Move leg forward and up.	90-120	Psoas major, iliacus, sartorius
		Extension: Move back beside other leg.	90-120	Gluteus maximus, semitendinosus, semimembranosus
		Hyperextension: Move leg behind body.	30-50	Gluteus maximus, semitendinosus, semimembranosus
		Abduction: Move leg laterally away from body.	30-50	Gluteus medius, gluteus minimus
		Adduction: Move leg back toward medial position and beyond if possible.	30-50	Adductor longus, adductor brevis, adductor magnus
		Internal rotation: Turn foot and leg toward other leg.	90	Gluteus medius, gluteus minimus, tensor fasciae latae
		External rotation: Turn foot and leg away from other leg.	90	Obturatorius internus, obturatorius externus
		Circumduction: Move leg in circle.		Psoas major, gluteus maximus, gluteus medius, adductor magnus
Knee	Hinge	*Flexion:* Bring heel back toward back of thigh.	120-130	Biceps femoris, semitendinosus, semimembranosus, sartorius
		Extension: Return leg to floor.	120-130	Rectus femoris, vastus lateralis, vastus medialis, vastus intermedius
Ankle	Hinge	*Dorsal flexion:* Move foot so toes are pointed upward.	20-30	Tibialis anterior
		Plantar flexion: Move foot so toes are pointed downward.	45-50	Gastrocnemius, soleus
Foot	Gliding	*Inversion:* Turn sole of foot medially.	10 or less	Tibialis anterior, tibialis posterior
		Eversion: Turn sole of foot laterally.	10 or less	Peroneus longus, peroneus brevis
Toes	Condyloid	*Flexion:* Curl toes downward.	30-60	Flexor digitorum, lumbricalis pedis, flexor hallucis brevis
		Extension: Straighten toes.	30-60	Extensor digitorum longus, extensor digitorum brevis, extensor hallucis longus
		Abduction: Spread toes apart.	15 or less	Abductor hallucis, interosseus dorsalis
		Adduction: Bring toes together.	15 or less	Adductor hallucis, interosseus plantaris

of deformity. Excessive abduction makes the affected leg appear too short, whereas excessive adduction makes it appear too long. In either case the patient has limited locomotion and walks with an obvious limp. Internal and external rotation contractures cause an abnormal and unbalanced gait.

Knee. A primary function of the knee is stability, which is achieved by ligaments and muscles supporting the joint. However, the knees cannot remain stable under weight-bearing conditions unless there is adequate quadriceps power to maintain them in full extension. An immobile knee joint results in serious disability. The degree of disability depends on the position in which the knee is stiffened. If it is fixed in full extension, the person needs to sit with the leg out in front. When the knee is flexed, the person limps while walking. The greater the flexion, the greater is the limp.

Ankle and Foot. Without full ROM of the ankle, gait deviations occur. If the joint is not stable, the person falls. When the person relaxes as in sleep or coma, the foot relaxes and assumes a position of plantar flexion. As a result, it becomes fixed in plantar flexion (footdrop), which impairs the ability to walk independently and increases the risk for falls.

Toes. Excessive flexion of the toes results in clawing. When this is a permanent deformity, the foot is unable to rest flat on the floor, and the patient is unable to walk properly. Flexion contractures are the most common foot deformity associated with reduced joint mobility.

Gait. The term **gait** describes a particular manner or style of walking. It is a coordinated action that requires the integration of sensory function, muscle strength, proprioception, balance, and a properly functioning CNS (vestibular system and cerebellum). A gait cycle begins with the heel strike of one leg and continues to the heel strike of the other leg. Assessing a patient's gait allows you to draw conclusions about balance, posture, and the ability to walk without assistance, all of which affect the risk for falling. Here are a few ways to assess a patient's gait:
1. Observe the patient entering the room, and note speed, stride, and balance.
2. Ask the patient to walk across the room, turn, and come back.
3. Ask the patient to walk heel-to-toe in a straight line. This may be difficult for older patients even in the absence of disease, so stay at the patient's side during the walk.

Exercise and Activity Tolerance. **Exercise** is physical activity for conditioning the body, improving health, and maintaining fitness. Nurses use it as therapy to correct a deformity or restore the overall body to a maximal state of health. When a person exercises, beneficial physiological changes occur in numerous body systems (see Chapter 39). You will assess a patient's exercise history by asking what exercise he or she normally engages in and the normal amount of exercise performed daily and weekly. For example, if a patient walks, what

distance does he or she typically walk, and how often? If a patient does not exercise regularly, you will want to focus on his or her activity tolerance.

Activity tolerance is the type and amount of exercise or work that a person is able to perform without undue exertion or possible injury. Assessment of activity tolerance is necessary when planning activity such as walking, ROM exercises, or ADLs. Activity tolerance assessment includes data from physiological, emotional, and developmental domains (see Chapter 39).

When a patient begins to walk, monitor for symptoms such as dyspnea, fatigue, or chest pain. If such symptoms develop, assess for a change in vital signs (heart rate and blood pressure). A weak or debilitated patient is unable to sustain even slight changes in activity because of the increased demand for energy. Seemingly simple tasks such as eating and moving in bed often result in extreme fatigue. When the patient experiences decreased activity tolerance, carefully assess how much time he or she needs to recover. Decreasing recovery time indicates improving activity tolerance.

People who are depressed, worried, or anxious are frequently unable to tolerate exercise. Depressed patients tend to withdraw rather than participate. Patients who worry or are frequently anxious expend a tremendous amount of mental energy and often report feeling fatigued. Because of this, they also experience physical and emotional exhaustion.

Developmental changes also affect activity tolerance. As an infant enters the toddler stage, the activity level increases, and the need for sleep declines. The child entering preschool or primary grades expends mental energy in learning and often requires more rest after school or before strenuous play. The adolescent going through puberty requires more rest because much body energy is expended for growth and hormone changes (see Chapter 43).

Changes still occur through the adult years, but many of them are related to work and lifestyle choices. Pregnancy causes fluctuations in a woman's activity tolerance, especially during the first and third trimesters, when she experiences increased fatigue. Hormonal changes and fetal development use body energy, and the woman is sometimes unable or unmotivated to carry out physical activities. During the last trimester fetal development consumes a great deal of the mother's energy; and the size and location of the fetus limit the ability to take a deep breath, resulting in less oxygen being available for physical activities.

As a person grows older, activity tolerance changes. Muscle mass is reduced, and posture and bone composition change. Changes in the cardiorespiratory system such as decreased maximum heart rate and lung compliance, which affect the intensity of exercise, often occur. As age progresses, some older individuals still exercise but do so at a reduced intensity. The more inactive a patient is, the more pronounced are these activity changes.

Body Alignment. Perform assessment of body alignment with the patient standing, sitting, or lying down. This assessment has the following objectives:

- Determining normal physiological changes in body alignment resulting from growth and development for each patient
- Identifying deviations in body alignment caused by incorrect posture
- Providing opportunities for patients to observe their posture
- Identifying learning needs of patients for maintaining correct body alignment
- Identifying trauma, muscle damage, or nerve dysfunction
- Obtaining information concerning other factors that contribute to incorrect alignment such as fatigue, malnutrition, and psychological problems

The first step in assessing body alignment is to put patients at ease so they do not assume unnatural or rigid positions. When assessing the body alignment of an immobilized or unconscious patient, remove pillows and positioning supports from the bed and place the patient in the supine position.

Standing. Characteristics of correct body alignment for the standing patient include the following:

1. The head is erect and midline.
2. When observed posteriorly, the shoulders and hips are straight and parallel.
3. When observed posteriorly, the vertebral column is straight.
4. When observed laterally, the head is erect, and the spinal curves are aligned in a reversed S pattern. The cervical vertebrae are anteriorly convex, the thoracic vertebrae are posteriorly convex, and the lumbar vertebrae are anteriorly convex.
5. When observed laterally, the abdomen is comfortably tucked in, and the knees and ankles are slightly flexed. The person appears comfortable and does not seem conscious of the flexion of knees or ankles.
6. The arms hang comfortably at the sides.
7. The feet are slightly apart to achieve a base of support, and the toes are pointed forward.
8. When viewing the patient from behind, the center of gravity is in the midline, and the line of gravity is from the middle of the forehead to a midpoint between the feet. Laterally the line of gravity runs vertically from the middle of the skull to the posterior third of the foot (Figure 28-6).

Sitting. Characteristics of correct alignment of the sitting patient include the following:

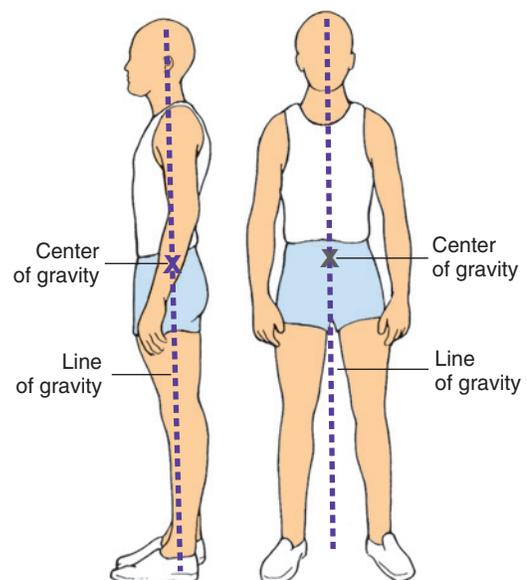
1. The head is erect, and the neck and vertebral column are in straight alignment.
2. The body weight is distributed evenly on the buttocks and thighs.
3. The thighs are parallel and in a horizontal plane.
4. Both feet are supported on the floor (Figure 28-7), and the ankles are flexed comfortably. With patients of short stature, use a footstool to ensure that ankles are flexed comfortably.
5. A 2.5- to 5-cm (1- to 2-inch) space is maintained between the edge of the seat and the popliteal space on the posterior surface


FIGURE 28-6 Correct body alignment when standing.

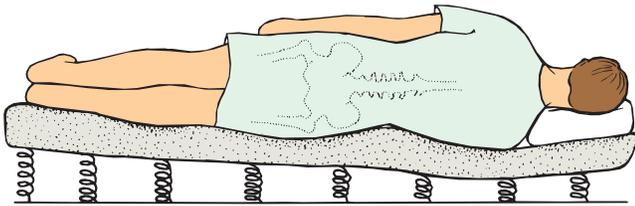
FIGURE 28-7 Correct body alignment when sitting.


FIGURE 28-8 Correct body alignment when lying down.

of the knee. This space ensures that there is no pressure on the popliteal artery or nerve to decrease circulation or impair nerve function.

6. The patient's forearms are supported on the armrest, in the lap, or on a table in front of the chair.

It is particularly important to assess alignment when sitting if the patient has muscle weakness, muscle paralysis, or nerve damage. Patients who have these problems have diminished sensation in the affected area and are unable to perceive pressure or decreased circulation. Proper alignment while sitting reduces the risk of musculoskeletal system damage in such a patient. The patient with severe respiratory disease sometimes assumes a posture of leaning on the table in front of the chair in an attempt to breathe more easily. This is called *orthopnea*.

Lying. People who are conscious have voluntary muscle control and normal perception of pressure. As a result, they usually assume a position of comfort when lying down. Because their ROM, sensation, and circulation are within normal limits, they change positions when they perceive muscle strain and decreased circulation.

Assess body alignment for a patient who is immobilized or bedridden with the patient in the lateral position. Remove all positioning supports from the bed except for the pillow under the head and support the body with an adequate mattress (Figure 28-8). This position allows for full view of the spine and back and helps provide other baseline body alignment data such as whether the patient is able to remain positioned without aid. The vertebrae are aligned, and the position does not cause discomfort. Patients with impaired mobility (e.g., traction or arthritis), decreased sensation (e.g., hemiparesis following a CVA), impaired circulation (e.g., diabetes), and lack of voluntary muscle control (e.g., spinal cord injury) are at risk for damage when lying down.

System	Assessment Techniques	Abnormal Findings
Metabolic	Inspection	Slowed wound healing, abnormal laboratory data
	Inspection	Muscle atrophy
	Anthropometric measurements (mid-upper arm circumference, triceps skinfold measurement)	Decreased amount of subcutaneous fat
	Palpation	Generalized edema
Respiratory	Inspection	Asymmetrical chest wall movement, dyspnea, increased respiratory rate
	Auscultation	Crackles, wheezes
Cardiovascular	Auscultation	Orthostatic hypotension
	Auscultation, palpation	Increased heart rate, third heart sound, weak peripheral pulses, peripheral edema
Musculoskeletal	Inspection, palpation	Decreased range of motion, erythema, increased diameter in calf or thigh
	Palpation	Joint contracture
	Inspection	Activity intolerance, muscle atrophy, joint contracture
Skin	Inspection, palpation	Break in skin integrity
Elimination	Inspection	Decreased urine output, cloudy or concentrated urine, decreased frequency of bowel movements
	Palpation	Distended bladder and abdomen
	Auscultation	Decreased bowel sounds

TABLE 28-3 Assessment of the Physiological Hazards of Immobility

Immobility. Assess the patient for the physiologic hazards of immobility while performing a head-to-toe physical assessment (Table 28-3) (see Chapter 31). In addition, focus on the patient's psychosocial and developmental dimensions.

Metabolic System. When assessing metabolic functioning, use **anthropometric measurements** (measures of height, weight, and skinfold thickness) to evaluate muscle atrophy. In addition, analyze intake and output records for fluid balance. Does intake equal output? Intake and output measurements help to determine whether a fluid imbalance exists (see Chapter 42). Dehydration and edema increase the rate of skin breakdown in a patient who is immobilized. Monitoring laboratory data such as levels of electrolytes, serum protein (albumin and total protein), and blood urea nitrogen (BUN) help you to determine metabolic functioning.

Monitoring food intake and elimination patterns and assessing wound healing help to determine altered gastrointestinal functioning and potential metabolic problems. If the patient has a wound, the rate of healing is affected by nutritional intake and nutrient absorption. Normal progression of healing indicates that metabolic needs of

injured tissues are being met. Anorexia commonly occurs in patients who are immobilized. Assess the patient's food intake before the meal tray is removed to determine the amount eaten. Assess his or her dietary patterns and food preferences at the onset of immobilization to help prevent nutritional imbalances (see Chapter 45).

Respiratory System. Perform a respiratory assessment at least every 2 hours for patients with restricted activity. Inspect chest wall movements during the full inspiratory-expiratory cycle. If a patient has an atelectatic area, chest movement is often asymmetrical. Auscultate the entire lung region to identify diminished breath sounds, crackles, or wheezes. Focus auscultation on the dependent lung fields because pulmonary secretions tend to collect in these lower regions. Assessment findings that indicate pneumonia include productive cough with greenish yellow sputum; fever; pain on breathing; and crackles, wheezes, and dyspnea.

Cardiovascular System. Cardiovascular nursing assessment of a patient who is immobilized includes blood pressure monitoring, evaluation of apical and peripheral pulses, and observation for signs of venous stasis (e.g., edema and delayed wound healing).

Although not all patients experience orthostatic hypotension, nurses monitor their vital signs during the first few attempts at sitting or standing (see Chapter 30), especially after periods of immobilization. Move a patient gradually during position changes and monitor him or her closely for dizziness while assessing the orthostatic blood pressures. The longer the period of immobility, the greater is the risk of hypotension when the patient stands (McCance and Huether, 2014).

Also assess apical and peripheral pulses (see Chapter 31). Recumbent positions increase cardiac workload and result in an increased pulse rate. In some patients, particularly older adults, the heart does not tolerate the increased workload, and a form of cardiac failure develops. A third heart sound, heard at the apex, is an early indication of congestive heart failure. Monitoring peripheral pulses allows you to evaluate the ability of the heart to pump blood. Immediately document and report the absence of a peripheral pulse in the lower extremities to the patient's health care provider, especially if the pulse was present previously.

Edema sometimes develops in patients who have had injury or whose heart is unable to handle the increased workload of bed rest. Because edema moves to dependent body regions, assessment of the patient experiencing immobility includes inspection of the sacrum, legs, and feet. If the heart is unable to tolerate the increased workload, peripheral body regions such as the hands, feet, nose, and earlobes are colder than central body regions. To assess for a deep vein thrombosis (DVT), remove the patient's elastic stockings and/or sequential compression devices (SCDs) every 8 hours (or according to agency policy) and observe the calves for redness, warmth, and tenderness. Homans' sign, or calf pain on dorsiflexion of the foot, is contraindicated in patients when a DVT is suspected and is no longer considered a reliable indicator in assessing for DVT.

Measure bilateral calf circumference and record it daily as an alternative assessment for DVT. To do this, mark a point on each calf 10 cm (3.9 inches) down from the midpatella. Measure the circumference each day using the mark for placement of the tape measure. Unilateral increases in calf circumference are an early indication of thrombosis. Because DVTs also occur in the thigh, take thigh measurements daily if the patient is prone to thrombosis. A dislodged venous thrombus, called an **embolus,** can travel through the circulatory system to the lungs and impair circulation and oxygenation, resulting in tachycardia and shortness of breath. Venous emboli that travel to the lungs are sometimes life threatening. More than 90% of all pulmonary emboli begin in the deep veins of the lower extremities (McCance and Huether, 2014).

Musculoskeletal System. Major musculoskeletal abnormalities to identify during nursing assessment include decreased muscle tone and strength, loss of muscle mass, reduced ROM, and contractures. The anthropometric measurements described previously indicate losses in muscle mass. During assessment of ROM (described earlier) you can detect muscle tone by asking the patient to relax and then passively moving each limb at several joints to get a feeling for any resistance or rigidity that may be present. You assess for muscle strength by having the patient assume a stable position and then performing maneuvers to demonstrate strength of the major muscle groups (see Chapter 31).

Physical assessment cannot identify disuse osteoporosis. However, patients on prolonged bed rest, postmenopausal women, patients taking steroids, and people with increased serum and urine calcium levels have a greater risk for bone demineralization. Consider the risk of disuse osteoporosis when planning nursing interventions. Although some falls result in injury, others occur because of pathological fractures secondary to osteoporosis.

Integumentary System. Continually assess the patient's skin for breakdown and color changes such as pallor or redness. Consistently use a standardized tool such as the Braden Scale. The screening tool identifies patients with a high risk for impaired skin integrity or early changes in the condition of patients' skin. Early identification allows for early intervention. Observe the skin often during routine care (e.g., when the patient is turned, during hygiene measures, and when providing for elimination needs). Frequent skin assessment, which can be as often as every hour and is based on patients' mobility, hydration, and physiological status, is essential to promptly identify changes in their skin and underlying tissues (see Chapter 48).

Elimination System. To determine the effects of immobility on elimination, assess the patient's total intake and output each shift and every 24 hours. Compare the amounts over time. Determine that the patient is receiving the correct amount and type of fluids orally or parenterally (see Chapter 42). Inadequate intake and output or fluid and electrolyte imbalances increase the risk for renal system impairment, ranging from recurrent infections to kidney failure. Dehydration also increases the risk for skin breakdown, thrombus formation, respiratory infections, and constipation.

Immobility impairs gastrointestinal peristalsis. Assessment of bowel elimination status includes the adequacy of a patient's dietary choices, bowel sounds, and the frequency and consistency of bowel movements (see Chapter 47). Accurate assessment enables you to intervene before constipation and fecal impaction occur.

Psychosocial Assessment. Many alterations in developmental functioning are related to immobility. Often these problems are interrelated, and it is imperative that nursing care focus on all dimensions. Often the focus of immobility is on the easily visible physical problems such as skin impairment, but do not overlook its psychosocial and developmental aspects.

Abrupt changes in personality often have a physiological cause such as surgery, a medication reaction, a pulmonary embolus, or an acute infection. For example, the primary symptom of compromised older patients with an acute urinary tract infection or fever is confusion. Identifying confusion is an important component of a nurse's assessment. Acute confusion in older adults is not normal; a thorough nursing assessment is the priority (Touhy and Jett, 2012).

Common reactions to immobilization include boredom and feelings of isolation, depression, and anger. Observe for changes in a patient's emotional status and listen carefully to family if they report emotional changes. Examples of change that indicate psychosocial concerns are a cooperative patient who becomes less cooperative or an independent patient who asks for more help than is necessary. Investigate reasons for such alterations. Identifying how the patient

usually copes with loss is vital (see Chapters 36 and 37). A change in mobility status, whether permanent or not, causes a grief reaction. Families are a key resource for information about behavior changes.

Identify and correct unexplained changes in the sleep-wake cycle. Nurses prevent or minimize most stimuli that interrupt the sleep-wake cycle (e.g., nursing activities, a noisy environment, or discomfort). However, some medications such as analgesics, sleeping pills, or cardiovascular drugs also cause sleep disturbances (see Chapter 43).

Because psychosocial changes usually occur gradually, observe the patient's behavior on a daily basis. If behavioral changes occur, determine the cause(s) and evaluate the changes. Identifying the cause helps you to design appropriate nursing interventions.

Developmental Assessment. Include a developmental assessment of patients who are immobilized. When caring for a young child, determine whether he or she is able to meet developmental tasks and is progressing normally. The child's development sometimes regresses or slows because he or she is immobilized. Design nursing interventions that maintain normal development and provide physical and psychosocial stimuli after identifying a child's developmental needs and assure the parents that developmental delays are usually temporary (see Chapter 12).

Immobilization of a family member changes family functioning. The family's response to this change often leads to problems, stress, and anxieties. When children see parents who are immobile, they sometimes have difficulty understanding what is occurring and coping.

Immobility has a significant effect on the older adult's levels of health, independence, and functional status. Nursing assessment enables the nurse to determine the patient's ability to meet needs independently and adapt developmental changes such as declining physical functioning and altered family and peer relationships. A decline in developmental functioning needs prompt investigation to determine why the change occurred and interventions that can return the patient to an optimal level of functioning as soon as possible. Activities that reduce immobility and promote participation in ADLs are vital to preventing functional decline (Nagarkar et al., 2014).

QSEN **QSEN: BUILDING COMPETENCY IN QUALITY IMPROVEMENT** Ms. Cavallo's skilled care unit is implementing a quality improvement (QI) project focused on prevention of falls. The unit has been experiencing a notable increase in the number of falls over the past several months. A review of the literature notes that the consequences of falls are many, including the need for additional care, psychological effects, and even death. You recognize the need to develop a collaborative plan of care that includes all health care professionals that work on the unit, the patients, and their families. What is the best method(s) for you to communicate your findings and strategies for fall prevention to all health care providers and family participating in Ms. Cavallo's care? How do you identify gaps between the unit and best practice? Which measures could you use to evaluate if change has taken place?

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

◆ **Nursing Diagnosis**

A patient who is experiencing an alteration in mobility often has one or more nursing diagnoses. The two diagnoses most directly related to mobility problems are *Impaired Physical Mobility* and *Risk for Disuse Syndrome.* The diagnosis of *Impaired Physical Mobility* applies to the patient who has some limitation but is not completely immobile. The diagnosis of *Risk for Disuse Syndrome* applies to the patient who is immobile and at risk for multisystem problems because of inactivity. Beyond these diagnoses, the list of potential diagnoses is extensive,

---

BOX 28-4   Nursing Diagnostic Process

Impaired Physical Mobility Related to Left Hip/Leg Pain

Assessment Activities	Defining Characteristics
Measure ROM during extension and flexion of the hip.	Patient has limited ROM in left hip/leg.
Observe patient attempt to move her left leg.	Patient has impaired movement attempting to move her left hip and leg.
Ask patient about perception of pain.	Patient complains of sharp pain (8 on scale of 0 to 10) in hip and leg when she tries to move it.
Ask patient about endurance and activity tolerance.	Patient reports no muscle strength in left leg. "I can't move it by myself."

ROM, Range of motion.

---

because immobility affects multiple body systems. Possible nursing diagnoses include the following:

- *Ineffective Airway Clearance*
- *Ineffective Coping*
- *Impaired Physical Mobility*
- *Impaired Urinary Elimination*
- *Risk for Impaired Skin Integrity*
- *Risk for Disuse Syndrome*
- *Social Isolation*

Assessment reveals clusters of data that indicate whether a patient is at risk or if a problem-focused diagnosis exists. The clusters of data reveal at-risk factors or defining characteristics that are observable assessment cues to support a problem-focused diagnostic label. In the case of a problem-focused diagnosis, the assessment data will reveal a related factor or causative factor for the diagnosis. Identifying the related factor allows you to identify the most appropriate interventions to manage or eliminate the related factor. Accurate identification of nursing diagnoses is important to planning patient-centered goals and subsequent nursing interventions that will best help the patient.

Impaired Physical Mobility related to reluctance to initiate movement requires slightly different interventions than *Impaired Physical Mobility* related to pain in the left shoulder. Thus it is critical that nursing assessment activities identify and cluster defining characteristics that ultimately support the nursing diagnosis selected (Box 28-4). The diagnosis related to reluctance to initiate movement requires interventions aimed at keeping the patient as mobile as possible and encouraging him or her to perform self-care and ROM. The diagnosis related to pain requires the nurse to assist the patient with comfort measures so he or she is then willing and more able to move. In both situations the nurse explains how activity enhances healthy body functioning.

Often the physiological dimension is the major focus of nursing care for patients with impaired mobility. Thus the psychosocial and developmental dimensions are neglected. Yet all dimensions are important to health. During immobilization some patients experience decreased social interaction and stimuli. These patients frequently use the nurse's call bell to request minor physical attention when their real need is greater socialization. Nursing diagnoses for health needs in developmental areas reflect changes from the patient's normal activities. Immobility leads to a developmental crisis if the patient is unable to resolve problems and continue to mature.

Immobility also leads to multiple complications (e.g., renal calculi, DVT, pulmonary emboli, or pneumonia). If these conditions develop,

collaborate with the health care provider or nurse practitioner for prescribed therapy to intervene. Be alert for and prevent these potential complications when possible.

◆ **Planning**

During planning, a nurse synthesizes information from resources such as knowledge of the role of respiratory and physical therapy, standards such as skin care guidelines from the Agency for Healthcare Research and Quality (Chou et al., 2013) and the Wound, Ostomy and Continence Nurses Society (WOCN, 2010), protocols for patients at risk for falls (AACN, 2014), attitudes such as creativity and perseverance, and past experiences with immobilized patients. Critical thinking ensures that the patient's plan of care integrates all that you know about the individual and key critical thinking elements. Professional standards are especially important to consider when you develop a plan of care. These standards often establish scientifically proven guidelines for selecting effective nursing interventions. Finally, as stated earlier, the patient is a full partner in designing the plan of care, and this input must be reflected when establishing the goals and outcomes.

Goals and Outcomes. Develop an individualized plan of care for each nursing diagnosis (see the Nursing Care Plan). Set realistic expectations for care and include the patient and family when possible. Set goals that are individualized, realistic, and measurable. The goals focus on preventing problems or risks to impaired body alignment and mobility.

Develop goals and expected outcomes to help patients achieve their highest level of mobility and reduce the hazards of immobility. For example, a patient who has left-sided paralysis following a stroke has two long-term goals. The first, directed toward improved mobility, is "Patient will use walker to ambulate safely in the home." A parallel goal directed toward the hazards of immobility is "Patient's skin will remain intact." Both of these goals are essential to restoring the patient's maximal mobility.

Because the patient has impaired sensation, both the patient and caregivers need to be aware of the patient's need to have the skin free of pressure. Expected outcomes for the goal of the skin remaining intact include the following:

• Patient's skin color and temperature return to normal baseline within 20 minutes of position change.
• Patient changes position at least every 2 hours.

Setting Priorities. The effect that problems have on a patient's mental and physical health determines the immediacy of any problem. Set priorities when planning care to ensure that immediate needs are met first. This is particularly important when patients have multiple diagnoses. Plan therapies according to severity of risks to the patient; and individualize the plan according to the patient's developmental stage, level of health, and lifestyle.

It is especially important in priority setting to make sure that you do not overlook potential complications. Many times actual problems such as pressure ulcers and disuse syndrome are addressed only after they develop. Therefore monitor the patient often, reinforcing prevention techniques to both the patient and other caregivers and supervising nursing assistive personnel in carrying out activities aimed at preventing complications of impaired mobility.

Teamwork and Collaboration. Care of the patient experiencing alterations in mobility requires a team approach. Nurses often delegate select interventions that are appropriate for nursing assistive personnel to perform. For example, in the case of postoperative patients who are at risk for respiratory problems from temporary immobility, nursing assistive personnel (NAP) can encourage the patient to do leg exercises, use the incentive spirometer, and cough and deep breathe (see Chapter 41). When patients have limited mobility as a result of paralysis, NAP can turn and position patients and apply elastic stockings. They can also help the nurse measure leg circumferences and height and weight.

Collaborate with other health care team members such as physical or occupational therapists when it is essential to consider mobility needs. Understanding the need for and having open communications with other members of the interdisciplinary care team results in better patient outcomes and hopefully prevents the hazards of immobility. It is through these collaborative efforts and teamwork that patients benefit most. For example, physical therapists are a resource for planning ROM or strengthening exercises, and occupational therapists are a resource for planning ADLs that patients need to modify or relearn. Wound care specialists and respiratory therapists are often involved in patient care, especially with patients who are experiencing complications related to their immobility. Consult a registered dietitian when the patient is experiencing nutritional problems; and refer him or her to a mental health advanced practice nurse, licensed social worker, or psychologist to assist with coping or other psychosocial issues.

Discharge planning begins when a patient enters the health care system. In anticipation of the patient's discharge from an institution, make appropriate referrals or consult a case manager or a discharge planner to ensure that the patient's needs are met at home. Consider the patient's home environment when planning therapies to maintain or improve body alignment and mobility. Referrals to home care or outpatient therapy are often needed.

◆ **Implementation**

Health Promotion. Health promotion activities include a variety of interventions such as education, prevention, and early detection. Examples of health promotion activities that address mobility and immobility include prevention of work-related injury, fall prevention measures, exercise, and early detection of scoliosis.

Prevention of Work-Related Musculoskeletal Injuries. The rate of work-related injuries in health care settings has increased in recent years. In 2006 there were 4.4 cases per 100 full-time workers who experienced occupational injury and illness compared with 5 cases per 100 for private industry overall. The rate for nursing homes was 10.1 cases per 100 workers (USDL, 2014). Most of these injuries occurred as a result of overexertion, which resulted in back injuries and other musculoskeletal problems. Back injuries are often the direct result of improper lifting and bending. The most common back injury is strain on the lumbar muscle group, which includes the muscles around the lumbar vertebrae. Injury to these areas affects the ability to bend forward, backward, and from side to side and limits the ability to rotate the hips and lower back. Research has demonstrated that ergonomic programs in health care facilities reduce costs, injuries to employees, and missed work days (Hunter et al., 2010).

Nurses and other health care staff are especially at risk for injury to lumbar muscles when lifting, transferring, or positioning immobilized patients. Therefore be aware of agency policies and protocols that protect staff and patients from injury. When lifting, assess the weight you will lift and determine the assistance you will need. Current evidence supports that using mechanical or other ergonomic assistive devices is the safest way to reposition and lift patients who are unable to do these activities themselves. Many agencies have developed special patient lift teams and have instituted a no-lift policy (see Chapter 39).

Exercise. Although many diseases and physical problems cause or contribute to immobility, it is important to remember that exercise programs enhance feelings of well-being and improve endurance,

◎ **NURSING CARE PLAN**

Impaired Physical Mobility

ASSESSMENT

Ms. Carmella Cavallo, a 97-year-old patient, is admitted to a skilled care unit for rehabilitation 10 days after the surgical procedure of fixation of a fractured left hip. She has a history of smoking but stopped 40 years ago. She has no cardiac problems and no hypertension. She experiences "aches" and "stiffness" in her knees but usually says that she "has no pain" when asked. The three small incisions are clean, dry, and intact. Staples were removed yesterday.

Assessment Activities	*Findings/Defining Characteristics**
Ask Ms. Cavallo to rate her pain on a scale of 0 to 10.	She rates her pain as a 2 on a scale of 0 to 10 at rest, but it **increases to an 8** with any movement of her left leg.
Assess Ms. Cavallo's ability to transfer.	She is **not able to transfer, even** with help from chair to bed.
Ask Ms. Cavallo how her surgery has affected her mobility.	She responds that she wants to get out of bed but, when she moves her left leg, her nonverbal signs indicate that she is in severe pain. She says that it is a "**sharp, stabbing pain.**"

*Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Impaired physical mobility related to musculoskeletal impairment from surgery and pain with movement

PLANNING

Goals	*Expected Outcomes*[†]
	Pain Control
Ms. Cavallo will have more pain relief during activity.	Ms. Cavallo's pain is less than 6 during activity.
	Body Positioning: Self-initiated
Ms. Cavallo will be able to transfer with assistive device by discharge.	Ms. Cavallo is able to move from her bed to her chair and back again using her walker and assist ×1 within 5 days.
	Ms. Cavallo is able to transfer from her chair to her bedside commode using her walker within 5 days.
	Ambulation
Ms. Cavallo will walk 100 feet using her walker by discharge.	Ms. Cavallo walks to her door and around her room with her walker within 10 days.
	Ms. Cavallo walks 100 feet at a slow pace using her walker 3 times a day in 14 days and increases the distance that she walks by 100 feet every day after that.

[†]Nursing outcomes classification from Moorhead S et al., editors: *Nursing outcomes classification (NOC),* ed 5, St Louis, 2013, Mosby.

INTERVENTIONS[‡]	**RATIONALE**
Exercise Therapy: Ambulation	
Consult with physical therapist on selection of transfer technique.	Ensures safe transfer technique with less risk of patient injury.
Instruct Ms. Cavallo on safe transfer and ambulation techniques in an environment with few distractions. Provide written materials and the use of the Teach Back method to reinforce verbal instructions.	Providing instruction in a quiet environment and the use of the Teach Back method enhances learning (Winifred, 2013).
Establish realistic increments for transferring and increasing distance for ambulation.	Physiotherapy exercises, physical activity, and setting realistic goals for ambulation encourage activity in older adults (Schiller et al., 2015).
Pain Management	
Administer pain medication on the basis of your assessment of Ms. Cavallo's needs and on a schedule rather than prn if patient exhibits signs of being in pain but does not request pain medication and dose is not relieving her pain.	Obtain order to adjust (increase or decrease dose) on the basis of her report of pain severity or her ability to perform activities of daily living (ADLs) (Botti et al., 2014).
Observe for overt and covert signs of pain when she is moving or attempting to implement plan from physical therapy (PT) and have prn dose of pain medication ordered if additional pain medication is needed for PT activities.	It is important for you to have "as needed" dose of pain medication for patient in case requires a supplemental dose.

[‡]Intervention classification labels from Bulechek GM et al., editors: *Nursing interventions classification (NIC),* ed 6, St Louis, 2013, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Mrs. Cavallo to rate her level of pain.	Ms. Cavallo reports pain at 5 during activity.	Ms. Cavallo has achieved improved pain control.
Ask Ms. Cavallo if her mobility has improved after therapy. Observe her transfer from bed to chair.	Ms. Cavallo is able to transfer from bed to chair using her walker and stand-by assistance of nurse.	Ms. Cavallo has achieved goal of transferring with walker and assistance.
Assess Ms. Cavallo as she walks in the hall; measure how far she walks.	Ms. Cavallo is able to walk 200 feet in the hall with her walker.	Activity level is improving. Continue interventions and continue to encourage ambulation.

BOX 28-5 CULTURAL ASPECTS OF CARE

Cultural Influences on Mobility

Many activities are specifically linked to an individual's culture such as time orientation, health care practices, nutritional habits, religious rituals, and family systems. Less attention has been given to the impact of culture on mobility. However, cultural influences have an important role in exercise and physical activity.

Culture influences an individual's preferences for activity and exercise. Certain cultures discourage involvement in organized recreational physical activities such as basketball, running, and aerobics. Ethnic dancing is an effective activity that is acceptable in many countries. Other cultures emphasize exercise in terms of activities of daily living such as walking, gardening, and prayer/meditation.

A sedentary lifestyle places an individual at risk for being overweight. Children from many cultures who live in the United States are becoming more sedentary. Therefore a national health approach is needed for communities to provide social and physical environments that promote healthy choices. From the earliest age preventive health practices should be included in the education process.

Implications for Patient-Centered Care

- Assess patterns of daily living and culturally prescribed activities before suggesting specific forms of exercise to patients.
- Help patients plan physical activities that are culturally acceptable.
- Exercise programs need to be flexible and accommodate family and community responsibilities of the culture.
- Encourage culturally specific and individually tailored interventions to facilitate commitment to exercise.
- Educate patients of all ages on the importance of exercise in preserving health and correct any misconceptions.

BOX 28-6 PATIENT TEACHING

Teaching Patients with Osteoporosis

Objective
- Patient will verbalize strategies to prevent or limit the severity of osteoporosis.

Teaching Strategies
- Instruct patient and/or family caregiver about common risk factors and how to modify lifestyle (e.g., smoking, caffeine, alcohol, hormone replacement as recommended by health care provider).
- Teach patient and/or caregiver the current recommended dietary allowances for calcium and review foods high in calcium (e.g., milk fortified with vitamin D, leafy green vegetables, yogurt, and cheese).
- Instruct patient and/or caregiver in appropriate types of weight-bearing exercises as recommended by health care provider or physical therapist to prevent injury or fractures.
- Teach patient and/or caregiver about safety, fall prevention, and strategies to create a safe home environment (e.g., remove scatter rugs; ensure that hallways, steps, and rooms are well lit) (McMahon and Fleury, 2012).
- Instruct patient and/or caregiver in self-administration of prescribed medication used to treat osteoporosis.
- Promote positive self-image in patient by providing realistic yet optimistic and positive feedback about changes in appearance and mobility.

Evaluation
- Patient and/or caregiver can verbalize *three lifestyle modifications* such as stopping smoking, reducing caffeine or alcohol intake, or increasing dietary calcium.
- Patient and/or caregiver can verbalize *at least four* foods high in calcium and vitamin D.
- Patient and/or caregiver can *demonstrate appropriate weight-bearing exercises* and plan times for exercise.
- Patient and/or caregiver verbalize *three safety strategies* that they can implement at home to prevent falls.
- Patient and/or caregiver verbalize *knowledge* about dosage schedule and side effects of osteoporosis medications.
- Patient and/or caregiver express positive but realistic feedback regarding effects of disease.

strength, and health. Exercise reduces the risk of many health problems such as cardiovascular disease, diabetes, and osteoporosis. It is important to give patients options for how to stay active and how to change their behavior if exercise has not been their routine. The Stanford Medicine (2015) chronic disease self-management program encourages appropriate exercise for maintaining and improving strength, flexibility, and endurance. As a nurse you can encourage all patients to find a type of exercise that meets their lifestyle and particular health-related needs. For example, a patient with severe arthritis of the knees might benefit from aquatic therapy (exercise in a pool) rather than walking. Encourage hospitalized patients to perform stretching, ROM exercises, and light walking within the limits of their condition (see Chapter 39). Collaboration with a physical therapist is recommended.

Nurses contribute to promoting health for many patients by encouraging or starting managed exercise programs. Exercise is a key prescription for health promotion of all patients, regardless of their age. In older adults routine exercise or activity helps maintain ROM and functional mobility and improves balance (Touhy and Jett, 2012; Edelman et al., 2013; Elliott, 2011). Take cultural preferences into consideration when helping patients design exercise plans (Box 28-5).

Bone Health in Patients with Osteoporosis. Patients at risk for or diagnosed with osteoporosis have special health promotion needs. Encourage patients at risk to be screened for osteoporosis and assess their diets for calcium and vitamin D intake. Patients who have lactose intolerance need dietary teaching about alternative sources of calcium.

For patients diagnosed with osteoporosis, early evaluation, consultation with, and referral to health care providers, dietitians, and physical therapists are important interventions, especially when they become immobilized. The goal of the patient with osteoporosis is to maintain independence with ADLs. Assistive ambulatory devices, adaptive clothing, and safety bars help the patient maintain independence. Patient teaching needs to focus on limiting the severity of the disease through diet and activity (Box 28-6).

Acute Care. Patients in acute care settings who experience altered physical mobility usually have some problems associated with the hazards of immobility such as impaired respiratory status, orthostatic hypotension, and impaired skin integrity. Therefore design nursing interventions to reduce the impact of immobility on body systems and prepare the patient for the restorative phase of care.

Metabolic System. Because the body needs protein to repair injured tissue and rebuild depleted protein stores, give the immobilized patient a high-protein, high-calorie diet. A high-calorie intake provides sufficient fuel to meet metabolic needs and replace subcutaneous tissue. Also ensure that the patient is taking vitamin B and C supplements when necessary. Supplementation with vitamin C is needed for skin integrity and wound healing; vitamin B complex assists in energy metabolism.

If the patient is unable to eat, nutrition must be provided parenterally or enterally. Total parenteral nutrition refers to delivery of

nutritional supplements through a central or peripheral intravenous catheter. Enteral feedings include delivery through a nasogastric, gastrostomy, or jejunostomy tube of high-protein, high-calorie solutions with complete requirements of vitamins, minerals, and electrolytes (see Chapter 45).

Respiratory System. Patients who are immobilized and have reduced ventilation can benefit from a variety of nursing interventions that promote lung expansion and removal of pulmonary secretions. Patients need to frequently fully expand their lungs to maintain their elastic recoil property. In addition, secretions accumulate in the dependent areas of the lungs. Often patients with restricted mobility experience weakness, and as this progresses the cough reflex gradually becomes inefficient. All of these factors put the patient at risk of developing pneumonia. The stasis of secretions in the lungs is life threatening for an immobilized patient.

Deep-breathing exercises, incentive spirometry, controlled coughing, and chest physiotherapy are among the nursing interventions available to expand the lungs, dislodge and mobilize stagnant secretions, and clear the lungs (Chapters 41 and 50). All of these interventions help reduce the risk of pneumonia. It is essential to implement pulmonary interventions early in all patients with limited mobility, even those who do not have pneumonia.

Encourage an immobile patient to deep breathe and cough every 1 to 2 hours. Teach alert patients to deep breathe or yawn every hour or to use an incentive spirometer (when ordered). Controlled coughing, a common therapy for postoperative patients, involves taking in three deep breaths and then coughing with the third exhalation.

Chest physiotherapy (CPT) (percussion and postural drainage) is another effective method for preventing pneumonia and keeping the airways clear (see Chapter 41). It helps the patient drain secretions from specific segments of the bronchi and lungs into the trachea so he or she is able to cough and expel them. Respiratory assessment findings identify areas of the lungs requiring CPT.

Ensure that patients who are immobile have an adequate fluid intake. Unless there is a medical contraindication, an adult needs to drink at least 1100 to 1400 mL of noncaffeinated fluids daily. This helps keep mucociliary clearance normal. Expect pulmonary secretions to be removed easily with coughing and appear thin, watery, and clear. Without adequate hydration, pulmonary secretions become thick and tenacious and difficult to remove. Offering fluids that patients prefer on a regularly timed schedule also helps with bowel and urine elimination and aids in maintaining circulation and skin integrity.

Cardiovascular System. The effects of bed rest or immobilization on the cardiovascular system include orthostatic hypotension, increased cardiac workload, and thrombus formation. Design nursing therapies to minimize or prevent these alterations.

Reducing Orthostatic Hypotension. When patients who are on bed rest or have been immobile move to a sitting or standing position, they often experience orthostatic hypotension. They have an increased pulse rate, a decreased pulse pressure, and a drop in blood pressure. If symptoms become severe enough, the patient can faint (McCance and Huether, 2014). To prevent injury, nurses implement interventions that reduce or eliminate the effects of orthostatic hypotension. Mobilize the patient as soon as the physical condition allows, even if this only involves dangling at the bedside or moving to a chair. This activity maintains muscle tone and increases venous return. Isometric exercises (i.e., activities that involve muscle tension without muscle shortening) have no beneficial effect on preventing orthostatic hypotension, but they improve activity tolerance. When getting an immobile patient up for the first time, assess the situation using a safe patient-handling algorithm (VISN8, 2015). This is a precautionary step that protects the

nurse and patient from injury and also allows the patient to do as much of the transfer as possible.

Reducing Cardiac Workload. A nursing intervention that reduces cardiac workload involves instructing patients to avoid using a Valsalva maneuver when moving up in bed, defecating, or lifting household objects. During a Valsalva maneuver a patient holds his or her breath and strains, which increases intrathoracic pressure and in turn decreases venous return and cardiac output. When the strain is released, venous return and cardiac output immediately increase, and systolic blood pressure and pulse pressure rise. These pressure changes produce a reflex bradycardia and possible decrease in blood pressure that can result in sudden cardiac death in patients with heart disease. Teach patients to breathe out while defecating, lifting, or moving side-to-side or up in bed and to not hold their breath and strain.

Preventing Thrombus Formation. The Centers for Medicare and Medicaid Services identified ten "Never Events" in 2008. A Never Event is a hospital-acquired event for which Medicare and other third-party payors will no longer pay hospitals at a higher rate for the increased costs of care. Deep vein thrombosis (DVT) is one of these Never Events. The most cost-effective way to address DVT is through an aggressive program of prophylaxis. Prevention of DVT is critical to reduce the risk of fatal and nonfatal pulmonary embolism. A prophylaxis program begins with identification of patients at risk and continues throughout their immobilization. This requires a collaborative role between nurses and health care providers. You will identify patient risk factors from the nursing assessment. There are nursing interventions you can employ to reduce the risk of thrombus formation in immobilized patients. Early ambulation; leg, foot, and ankle exercises; regularly provided fluids; frequent position changes; and patient teaching need to begin when a patient becomes immobile (see Chapter 50).

Prophylaxis also includes anticoagulation, mechanical prevention with graduated compression stockings, intermittent pneumatic compression devices, and foot pumps. Anticoagulation may include the use of aspirin, although this is somewhat controversial. Anticoagulants most often used include unfractionated heparin (UFH) (usually given as 5000 units two or three times daily), low-molecular-weight heparins (LMWH) (e.g., enoxaparin or dalteparin), vitamin K antagonists (e.g., warfarin, but also acenocoumarol, phenindione, and dicoumarol), and fondaparinux (a selective factor Xa inhibitor) (Cayley, 2007). Because bleeding is a potential side effect of anticoagulant medications, continually assess the patient for signs of bleeding such as hematuria, bruising, coffee ground–like vomitus or gastrointestinal aspirate, guaiac-positive stools, and bleeding gums.

SCDs and intermittent pneumatic compression (IPC) are used to prevent blood clots in the lower extremities. These consist of sleeves or stockings made of fabric or plastic that are wrapped around the leg and secured with Velcro (Box 28-7). Once they are applied, connect the sleeves to a pump that alternately inflates and deflates the stocking around the leg. A typical cycle is inflation for 10 to 15 seconds and deflation for 45 to 60 seconds. Inflation pressures average 40 mm Hg. Use of SCD/IPC on the legs decreases venous stasis by increasing venous return through the deep veins of the legs. For optimal results begin use of SCD/IPC as soon as possible and maintain it until the patient becomes fully ambulatory.

Elastic stockings (sometimes called *antiembolitic stockings*) also aid in maintaining external pressure on the muscles of the lower extremities and thus promote venous return (see Box 28-7). To obtain the correct size, measure the patient's calf, thigh, and leg length accurately. When considering applying graded compression stockings, first assess the patient's suitability for wearing them. Do not apply them if he or she has a local condition affecting the leg (e.g., any skin lesion, gangrenous condition, or recent vein ligation) because application

BOX 28-7 PROCEDURAL GUIDELINES

Applying Sequential Compression Devices and Elastic Stockings

Delegation Considerations

The skill of applying elastic stockings and sequential compression devices (SCDs) can be delegated to nursing assistive personnel (NAP). The nurse initially determines the size of elastic stockings and assesses the patient's lower extremities for signs and symptoms of DVT or impaired circulation. Instruct NAP to:

- Remove SCD sleeves before allowing patient to get out of bed.
- Notify nurse if patient complains of pain in leg or if discoloration develops in extremities.
- When applying elastic stockings, instruct patient to avoid activities that promote venous stasis (e.g., crossing legs, wearing garters).
- Elevate legs while sitting and before applying stockings to improve venous return.
- Take precautions and **Do Not** massage patient's legs.
- Avoid wrinkles in elastic stockings.

Equipment

Tape measure, powder or cornstarch (optional), Elastic or compression stockings, SCD insufflator with air hoses attached, adjustable Velcro compression stockings/SCD disposable sleeve(s), hygiene supplies

Steps

1. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.
2. Assess for risk factors in Virchow's triad:
   a. Hypercoagulability (e.g., clotting disorders [laboratory test results], fever, dehydration)
   b. Venous wall abnormalities found in patient medical history (i.e., history of orthopedic surgery, atherosclerosis)
   c. Blood stasis (e.g., immobility, obesity, pregnancy)

   CLINICAL DECISION: Clinical signs of thrombophlebitis vary according to the size and location of the thrombus. Signs and symptoms of superficial thrombosis include palpable veins and surrounding areas that are tender to the touch, reddened, and warm. Temperature elevation and edema may or may not be present. Signs and symptoms of deep vein thrombosis (DVT) include swollen extremity; pain; warm,

cyanotic skin; and temperature elevation. Homans' sign (pain in the calf on dorsiflexion of the foot) is no longer considered a reliable indicator (Ball et al., 2015; Grinage and Werner, 2013).

3. Assess condition of patient's skin and circulation to the legs (e.g., presence of pedal pulses, edema, discoloration of skin, skin temperature, capillary refill, presence of lesions or cuts). Assess for contraindications for use of elastic stockings or SCDs:
   a. Dermatitis or open skin lesions
   b. Recent skin graft
   c. Decreased arterial circulation in lower extremities as evidenced by cyanotic, cool extremities.
4. Obtain health care provider order.
5. When applying elastic stockings, use tape measure to measure patient's legs to determine proper stocking size.
6. Perform hand hygiene. Also provide hygiene to patient's lower extremities as needed.
7. Assemble and prepare equipment.
8. Explain procedure and reason for applying SCDs or elastic stockings.
9. Position patient in supine position. Elevate head of bed to comfortable level.
10. *Option:* When applying elastic stockings, apply a small amount of powder or cornstarch to legs provided that patient does not have sensitivity to either. Powder eases application of stockings.
11. Apply SCD Sleeve(s):
    a. Remove SCD sleeves from plastic cover; unfold and flatten.
    b. Arrange sleeve under patient's leg according to leg position indicated on inner lining of sleeve.
    c. Place patient's leg on SCD sleeve. Back of ankle should line up with ankle marking on inner lining of sleeve.
    d. Position back of knee with popliteal opening on the sleeve (see Illustration).
    e. Wrap SCD sleeve securely around patient's leg. Check fit of SCD sleeve by placing two fingers between patient's leg and sleeve (see illustration).

STEP 11d Position back of patient's knee with the popliteal opening.

STEP 11e Check fit of SCD sleeve.

Continued

BOX 28-7 PROCEDURAL GUIDELINES

Applying Sequential Compression Devices and Elastic Stockings—cont'd

    f. Attach SCD sleeve connector to plug on mechanical unit. Arrows on connector line up with arrows on plug from unit (see illustration).

    g. Turn mechanical unit on. Green light indicates that unit is functioning. Monitor functioning SCD through one full cycle of inflation and deflation. A typical cycle is inflation for 10 to 15 seconds and deflation for 45 to 60 seconds. Inflation pressures average 40 mm Hg.

    h. Reposition patient for comfort and perform hand hygiene.

    i. Remove compression stockings at least once per shift.

    j. Monitor skin integrity and circulation to patient's lower extremities as ordered or as recommended by SCD manufacturer.

12. Apply Elastic Stocking:

    a. Turn elastic stocking inside out by placing one hand into the sock, holding toe of sock with hand. Using other hand, pull sock over hand until reaching the heel (see illustration).

    b. Place patient's toes into foot of elastic stocking, making sure that stocking is smooth (see illustration).

    c. Slide remaining portion of stocking over patient's foot, being sure that toes are covered. Make sure that foot fits into toe and heel position of stocking (see illustration).

    d. Slide stocking up over patient's calf until stocking is completely extended. Be sure that stocking is smooth and that no ridges or wrinkles are present, particularly behind knee (see illustration).

    e. Instruct patient not to roll stockings partially down because constricting ring around leg can occlude circulation.

    f. Instruct patient not to massage legs.

    g. Reposition patient for comfort and perform hand hygiene.

    h. Remove stockings at least once per shift.

    i. Inspect stockings for wrinkles or constriction.

    j. Inspect elastic stockings to determine that there are no wrinkles, rolls, or binding.

STEP 11f Align arrows when connecting SCD to mechanical unit.

STEP 12a Turn stocking inside out: hold toe and pull through.

STEP 12b Place toes into foot of stocking.

STEP 12c Slide remaining portion of stocking over foot.

STEP 12d Slide stocking up leg until completely extended.

FIGURE 28-9 Continuous passive range-of-motion machine.

compromises circulation. Apply them properly and remove them at least once per shift. Be sure to assess circulation at the toes to ensure that the stockings are not too tight. Another device for preventing DVT is the venous plexus foot pump. It promotes circulation by mimicking the natural action of walking.

Proper positioning reduces a patient's risk of thrombus formation because compression of the leg veins is minimized. Therefore, when positioning patients, use caution to prevent pressure on the posterior knee and deep veins in the lower extremities. Teach patients to avoid the following: crossing the legs, sitting for prolonged periods of time, wearing clothing that constricts the legs or waist, and massaging the legs. Report suspected DVT immediately to the patient's health care provider. Elevate the leg but avoid pressure on the suspected thrombus area. Instruct the family, patient, and all health care personnel not to massage the area because of the danger of dislodging the thrombus.

ROM exercises reduce the risk of contractures and aid in preventing thrombi. Activity causes contraction of the skeletal muscles, which in turn exerts pressure on the veins to promote venous return, thereby reducing venous stasis. Specific exercises that help prevent thrombophlebitis are ankle pumps, foot circles, and knee flexion. Ankle pumps, sometimes called *calf pumps,* include alternating plantar flexion and dorsiflexion. Foot circles require the patient to rotate the ankle. Encourage patients to make the letters of the alphabet with their feet every 1 to 2 hours. Knee flexion involves alternately extending and flexing the knee. These exercises are sometimes referred to as *antiembolic exercises* and need to be done hourly while awake.

Musculoskeletal System. Exercises to prevent excessive muscle atrophy and joint contractures help maintain musculoskeletal function. If a patient is unable to move part or all of the body, perform passive ROM exercises for all immobilized joints while bathing the patient and at least 2 or 3 more times a day. If one extremity is paralyzed, teach the patient to put each joint independently through its ROM. Patients on bed rest need to have active ROM exercises incorporated into their daily schedules. Teach patients to also integrate exercises during ADLs.

Some orthopedic conditions require more frequent passive ROM exercises to restore the function of the injured joint after surgery. Patients with such conditions may use automatic equipment (continuous passive motion [CPM]) for passive ROM exercises) (Figure 28-9). The CPM machine moves an extremity to a prescribed angle for a prescribed period. Researchers continuously investigate uses for CPM. Patients who had a rotator cuff repair and received CPM therapy to their affected shoulder reported a decrease in pain in one study and improved muscle strength in another (DuPlessis et al., 2011). However, in a recent systematic review, CPM was shown to not have clinically important effects on active knee flexion, ROM, pain, function, or quality of life to justify its routine use for patients who undergo a total knee arthroplasty (Harvey, et al., 2014).

Integumentary System. The major risk to the skin from restricted mobility is the formation of pressure ulcers. Early identification of high-risk patients helps prevent pressure ulcers (see Chapter 48). Interventions aimed at prevention include turning and positioning and the use of therapeutic support surfaces to relieve pressure. Regular skin care (cleansing of soiled areas and use of moisturizers) aims to maintain the condition of the skin. Change the immobilized patient's position according to his or her activity level, perceptual ability, treatment protocols, and daily routines. For example, an obese patient or a very thin patient, both of whom have bowel incontinence, will require more frequent turning than standard practice. Although turning every 1 to 2 hours is standard practice for preventing ulcers, it is sometimes necessary to use support surface devices (e.g., air loss mattresses, heel boots, floatation mattresses) for relieving pressure.

Usually the time that a patient sits uninterrupted in a chair is limited to 1 hour. This interval is shortened in patients who are at very high risk for skin breakdown. Reposition patients frequently because uninterrupted pressure causes skin breakdown. Teach patients to shift their weight in a chair every 15 minutes. Chair-bound patients need to have a device for the chair that reduces pressure (Chou et al., 2013).

Elimination System. The nursing interventions for maintaining optimal urinary functioning are directed at keeping the patient well hydrated and preventing urinary stasis, calculi, and infections without causing bladder distention. Adequate hydration (e.g., at least 1100 to 1400 mL of noncaffeinated fluids daily) helps prevent renal calculi and urinary tract infections. The well-hydrated patient needs to void large amounts of dilute urine that is approximately equal to fluid intake. Also record the frequency and consistency of bowel movements. Provide a diet rich in fluids, fruits, vegetables, and fiber to facilitate normal peristalsis. If a patient is unable to maintain regular bowel patterns, stool softeners, cathartics, or enemas are sometimes necessary. If the patient is incontinent, modify the care plan to include toileting aids and a hygiene schedule so the increased urinary output does not cause skin breakdown.

Psychosocial Changes. Use assessment data to identify the psychosocial effects of prolonged immobilization. People who have a tendency toward depression or mood swings are at greater risk for developing psychosocial effects during bed rest or immobilization.

Anticipate changes in the patient's psychosocial status and provide routine and informal socialization. Observe the patient's ability to cope with restricted mobility. In institutional health care settings do not schedule nursing care activities between 10:00 PM and 7:00 AM to minimize sleep interruptions. For example, administer medications and assess vital signs when you enter the room to turn the patient or provide special skin care. If the nursing care plan is not improving coping patterns, consult a clinical nurse specialist, counselor, social worker, spiritual adviser, or other health care professional. Incorporate their recommendations into the care plan.

Nurses provide meaningful stimuli to maintain a patient's orientation. Plan nursing activities so a patient is able to talk and interact with staff. If possible, place him or her in a room with others who are mobile and interactive. If a private room is required, ask staff members to visit throughout the shift to provide meaningful interaction. A daily newspaper helps the patient keep track of events and time. Bedside conversations at appropriate moments familiarize him or her with nursing activities, meals, and visiting hours. Books help occupy the patient when he or she is alone. The patient can participate in craft activities. iPods, MP3 players, radio, television, and videotapes provide stimulation and help pass the time.

Involve patients in their care whenever possible. For example, encourage the patient to determine when the bed should be made. Some patients rest better during the night when fresh sheets are put on in the evening rather than in the morning. The patient needs to provide as much self-care as possible. Keep hygiene and grooming articles within easy reach. Encourage patients to wear their glasses or artificial teeth and shave or apply makeup. People use these activities to maintain their body image, thus improving their outlook.

Developmental Changes. Ideally immobilized patients continue normal development. Nursing interventions can help. Nursing care needs to provide mental and physical stimulation, particularly for a young child. Incorporate play activities into the care plan. For example, completing puzzles helps a child to develop fine-motor skills, and reading helps him or her develop cognitively. Encourage parents to stay with a child who is hospitalized. Place a child who is immobilized with children of the same age who are not immobilized unless a contagious disease is present. Allow the child to participate in nursing interventions such as dressing changes, cast care, and care of traction. The nurse needs to recognize significant changes from normal behavioral patterns and consult with a pediatric clinical nurse specialist, counselor, or other health care professional.

Restricted mobility of older patients presents unique nursing problems. Older patients who are frail or have chronic illnesses are often at increased risk for the psychosocial hazards of immobility. Maintaining a calendar and clock with a large dial, conversing about current events and family members, and encouraging visits from significant others reduce the risk of social isolation. Spending time in the room talking and listening to the patient also helps reduce the risk of social isolation.

Nurses need to encourage older immobilized patients to perform as many ADLs as independently as possible. Patients need to continue to perform personal grooming if they did so before their mobility was restricted. This type of activity preserves the patient's dignity and gives him or her a sense of accomplishment.

Positioning Techniques. Patients with impaired nervous, skeletal, or muscular system functioning and increased weakness and fatigue often require help from nurses for positioning and maintenance of proper body alignment while in bed or sitting (see Skill 28-1 on pp. 432-438). Several positioning devices are available for maintaining good body alignment for patients. Pillows are positioning aids and are sometimes readily available. Before using a pillow, determine whether

FIGURE 28-10 Trochanter roll.

it is the proper size. A thick pillow under a patient's head increases cervical flexion, which is not desirable. A thin pillow under bony prominences does not protect skin and tissue from damage caused by pressure. When additional pillows are unavailable or if they are an improper size, use folded sheets, blankets, or towels as positioning aids.

Apply positioning boots to prevent footdrop by maintaining the feet in dorsiflexion. Ankle-foot orthotic (AFO) devices also help maintain dorsiflexion. Patients who wear positioning boots or AFOs need to have these removed periodically (e.g., 2 hours on, 2 hours off).

A **trochanter roll** prevents external rotation of the hips when a patient is in a supine position. To form a trochanter roll, fold a cotton bath blanket lengthwise to a width that extends from the greater trochanter of the femur to the lower border of the popliteal space (Figure 28-10). Place the blanket under the buttocks and roll it counterclockwise until the thigh is in neutral position or inward rotation. When the hip is aligned correctly, the patella faces directly upward. Use sandbags in place of or in addition to trochanter rolls. Sandbags are sandfilled plastic tubes or bags that are shaped to body contours. Hand rolls maintain the thumb in slight adduction and in opposition to the fingers, which maintain a functional position. Evaluate the hand roll to make sure that the hand is indeed in a functional position. Hand rolls are most often used with patients whose arms are paralyzed or who are unconscious. Do not use rolled washcloths as hand rolls because they do not keep the thumb well abducted, especially in patients who have a spastic paralysis. Hand-wrist splints are individually molded for a patient to maintain proper alignment of the thumb (slight adduction) and wrist (slight dorsiflexion). Use splints only on the patient for whom they were made and follow the splint schedule (e.g., wear for 2 hours, remove for 2 hours).

The **trapeze bar** is a triangular device that hangs down from a securely fastened overhead bar that is attached to the bedframe. It allows a patient to pull with the upper extremities to raise the trunk off the bed, assist in transfer from bed to wheelchair, or perform upperarm exercises (Figure 28-11). It increases independence, maintains upper-body strength, and decreases the shearing action from sliding across or up and down in bed.

Although each procedure for positioning has specific guidelines, there are universal steps to follow for patients who require positioning assistance. Following the guidelines reduces the risk of injury to the musculoskeletal system when a patient is sitting or lying. When joints

FIGURE 28-11 Patient using trapeze bar.

are unsupported, their alignment is impaired. Likewise, if joints are not positioned in a slightly flexed position, their mobility is decreased. During positioning also assess for pressure points. When actual or potential pressure areas exist, nursing interventions involve removal of the pressure, thus decreasing the risk for development of pressure ulcers and further trauma to the musculoskeletal system. In these patients use the 30-degree lateral position.

Supported Fowler's Position. In the supported Fowler's position the head of the bed is elevated 45 to 60 degrees, and the patient's knees are slightly elevated without pressure to restrict circulation in the lower legs. The patient's illness and overall condition influence the angle of head and knee elevation and the length of time that the patient needs to remain in the supported Fowler's position. Supports need to permit flexion of the hips and knees and proper alignment of the normal curves in the cervical, thoracic, and lumbar vertebrae. The following are common trouble areas for a patient in the supported Fowler's position:

- Increased cervical flexion because the pillow at the head is too thick and the head thrusts forward
- Extension of the knees, allowing the patient to slide to the foot of the bed
- Pressure on the posterior aspect of the knees, decreasing circulation to the feet
- External rotation of the hips
- Arms hanging unsupported at the patient's sides
- Unsupported feet or pressure on the heels
- Unprotected pressure points at the sacrum and heels
- Increased shearing force on the back and heels when the head of the bed is raised greater than 60 degrees

Supine Position. Patients in the supine position rest on their backs. In the supine position the relationship of body parts is essentially the same as in good standing alignment, except that the body is in the horizontal plane. Use pillows, trochanter rolls, and hand rolls or arm splints to increase comfort and reduce injury to the skin or musculoskeletal system. The mattress needs to be firm enough to support the cervical, thoracic, and lumbar vertebrae. Shoulders are supported, and the elbows are slightly flexed to control shoulder rotation. A foot support prevents footdrop and maintains proper alignment. The following are some common trouble areas for patients in the supine position:

- Pillow at the head that is too thick, increasing cervical flexion
- Head flat on the mattress
- Shoulders unsupported and internally rotated
- Elbows extended
- Thumb not in opposition to the fingers
- Hips externally rotated
- Unsupported feet
- Unprotected pressure points at the occipital region of the head, vertebrae, coccyx, elbows, and heels

Prone Position. The patient in the prone position lies face or chest down. Often his or her head is turned to the side; but, if a pillow is under the head, it needs to be thin enough to prevent cervical flexion or extension and maintain alignment of the lumbar spine. Placing a pillow under the lower leg permits dorsiflexion of the ankles and some knee flexion, which promote relaxation. If a pillow is unavailable, the ankles need to be in dorsiflexion over the end of the mattress. Although the prone position is seldom used in practice, consider this as an alternative, especially in patients who normally sleep in this position. The prone position also may have some benefits in patients with acute respiratory distress syndrome and acute lung injury (Barbas et al., 2012). Specialty beds that safely position acutely ill patients in the prone position are available. Assess for and correct any of the following potential trouble points with patients in the prone position:

- Neck hyperextension
- Hyperextension of the lumbar spine
- Plantar flexion of the ankles
- Unprotected pressure points at the chin, elbows, female breasts, hips, knees, and toes

Side-Lying Position. In the side-lying (or lateral) position the patient rests on the side with the major portion of body weight on the dependent hip and shoulder. A 30-degree lateral position is recommended for patients at risk for pressure ulcers (see Chapter 48) (Chou et al., 2013). Trunk alignment needs to be the same as in standing. The patient needs to maintain the structural curves of the spine, the head needs to be supported in line with the midline of the trunk, and rotation of the spine needs to be avoided. The following trouble points are common in the side-lying position:

- Lateral flexion of the neck
- Spinal curves out of normal alignment
- Shoulder and hip joints internally rotated, adducted, or unsupported
- Lack of foot support
- Lack of protection for pressure points at the ear, shoulder, anterior iliac spine, trochanter, and ankles
- Excessive lateral flexion of the spine if the patient has large hips and a pillow is not placed superior to the hips at the waist

Sims' Position. Sims' position differs from the side-lying position in the distribution of the patient's weight. In Sims' position the patient places the weight on the anterior ileum, humerus, and clavicle. Trouble points common in Sims' position include the following:

- Lateral flexion of the neck
- Internal rotation, adduction, or lack of support to the shoulders and hips
- Lack of foot support
- Lack of protection for pressure points at the ileum, humerus, clavicle, knees, and ankles

Moving Patients. When moving a patient during repositioning, a safe transfer is the first priority. Patients require various levels of assistance to move up in bed, move to the side-lying position, or sit up at the side of the bed. For example, a young, healthy woman may need support as she sits at the side of the bed for the first time after childbirth, whereas an older man may need help from two or more nurses to do the same task 1 to 2 days after surgery.

Always ask patients to help to their fullest extent possible. To determine what a patient is able to do alone and how many people are needed to help move him or her in bed, assess him or her to determine whether the illness contradicts exertion (e.g., cardiovascular disease). Next determine whether the patient comprehends what is expected. For example, a patient recently medicated for postoperative pain is too lethargic to understand instructions; thus to ensure safety two nurses are necessary to move him or her. Then determine his or her comfort level. It is important to evaluate your personal strength and knowledge of the procedure. Finally determine whether the patient is too heavy or immobile for you to move alone (VISN8, 2015) (see Chapter 39).

Restorative and Continuing Care. The goal of restorative care for the patient who is immobile is to maximize functional mobility and independence and reduce residual functional deficits such as impaired gait and decreased endurance. The focus in restorative care is not only on ADLs that relate to physical self-care but also on **instrumental activities of daily living (IADLs)**. IADLs are activities that are necessary to be independent in society beyond eating, grooming, transferring, and toileting and include such skills as shopping, preparing meals, banking, and taking medications.

Nurses use many of the same interventions as described in the health promotion and acute care sections, but the emphasis is on working collaboratively with patients and their significant others and with other health care professionals to facilitate the patient's return to maximal functional ability in both ADLs and IADLs.

Intensive specialized therapy such as occupational or physical therapy is common. If the patient is in a rehabilitation institution, he or she likely goes to the therapy department 2 to 3 times a day. The nurse's role is to work collaboratively with these professionals and reinforce exercises and teaching. For example, after a stroke, a patient likely receives gait training from a physical therapist; speech rehabilitation from a speech therapist; and help from an occupational therapist for ADLs such as dressing, bathing and toileting, or household chores. The therapy is not always able to restore total functional health, but it often helps the patient adapt to the mobility limitations or complications. Equipment frequently used to help patients adapt to mobility limitations includes walkers, canes, wheelchairs, and assistive devices such as toilet seat extenders, reaching sticks, special silverware, and clothing with Velcro closures.

Range-of-Motion Exercises. To ensure adequate joint mobility, teach the patient about ROM exercises. Walking also increases joint mobility. Patients with restricted mobility are unable to perform some or all ROM exercises independently. Provide ROM exercises to maintain maximum joint mobility. To ensure that patients routinely receive ROM exercises, schedule them at specific times, perhaps with another nursing activity such as during the patient's bath. This enables the nurse to systematically reassess mobility while improving the patient's ROM. In addition, bathing usually requires that extremities and joints are put through complete ROM.

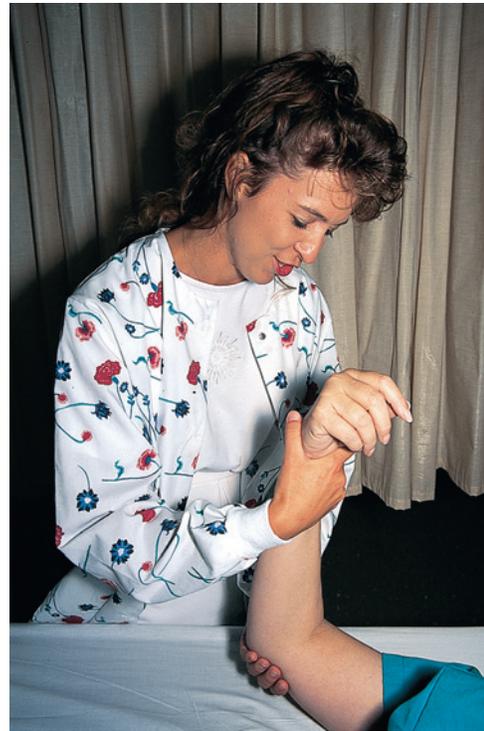
Passive ROM exercises begin as soon as a patient's ability to move an extremity or joint is lost. Carry out movements slowly and smoothly, just to the point of resistance; ROM should not cause pain. **Never force**


FIGURE 28-12 Supporting joint by holding distal and proximal areas adjacent to joint.

FIGURE 28-13 Cradling distal portion of extremity.

a joint beyond its capacity. Each movement needs to be repeated 5 times during a session.

When performing passive ROM exercises, stand at the side of the bed closest to the joint being exercised. Use a head-to-toe sequence and move from larger to smaller joints. If an extremity is to be moved or lifted, place a cupped hand under the joint to support it, support the joint by holding the adjacent distal and proximal areas (Figure 28-12), or support the joint with one hand and cradle the distal portion of the extremity with the remaining arm (Figure 28-13). See Table 28-2 for detailed ROM for each joint. Appropriate ROM exercises are based on the patient and the affected joint.

Walking. When a patient has a limited ability to walk, assess his or her activity tolerance, tolerance to the upright position (orthostatic hypotension), strength, the presence of pain, coordination, and balance to determine the amount of assistance needed. Explain how far the

FIGURE 28-14 A, Stand with feet apart to provide broad base of support. **B,** Extend one leg and let patient slide against it to the floor. **C,** Bend knees to lower body as patient slides to floor.

patient should try to walk, who is going to help, when the walk will take place, and why walking is important. Some settings have distances marked along hallways to measure a patient's progress. Other facilities use accelerometers to measure distance walked. In addition, determine with the patient how much independence he or she can assume.

Check the environment to be sure that there are no obstacles in the patient's path. Clear chairs, over-bed tables, and wheelchairs out of the way so the patient has ample room to walk safely. Before starting, establish rest points in case activity tolerance is less than estimated or the patient becomes dizzy. For example, place a chair in the hall for the patient to rest if needed. A nurse who does not have a lot of strength and who is unable to ambulate a patient alone needs to request help and ensure that the patient has an assistive device such as a walker (see Chapter 39). A nurse stands on either side of the patient, and each holds one side of the gait belt.

Provide support at the waist by using a **gait belt** so the patient's center of gravity remains midline. While walking, the patient should not lean to one side because this alters the center of gravity, distorts balance, and increases the risk of falling. Return a patient who at any point appears unsteady or complains of dizziness to a nearby bed or chair. If the patient faints or begins to fall, assume a wide base of support with one foot in front of the other, thus supporting the body weight (Figure 28-14, *A, B, C*). Then gently lower the patient to the floor, protecting the head. Although lowering a patient to the floor is not difficult, the nursing student needs to practice this technique with a friend or classmate before attempting it in a clinical setting.

Patients with **hemiplegia** (one-sided paralysis) or **hemiparesis** (one-sided weakness) often need assistance with walking. When an assistive device is used, stand on the patient's affected side and support him or her with a gait belt. Providing support by holding the patient's arm is incorrect because the nurse cannot easily support the patient's weight to lower him or her to the floor if he or she faints or falls. In addition, if the patient falls with the nurse holding an arm, a shoulder joint may be dislocated.

◆ Evaluation

Through the Patient's Eyes. Just as it was important to include the patient during the assessment and planning phase of the care plan, it is essential to have the patient's evaluation of the plan of care. Were the goals met, or is more work required? You must now determine with the patient and others involved with care if the goals or outcomes established with and for the patient have indeed been met; what still needs to be achieved from the patient's perspective; and whether it is necessary to revise a new plan of care. In other words, how have the patient's expectations changed and in what ways?

Patient Outcomes. From your perspective as the nurse, you are to evaluate expected outcomes and a patient's response to nursing care and compare the patient's actual outcomes with the outcomes selected during planning such as his or her ability to maintain or improve body alignment, joint mobility, walking, moving, or transferring. Evaluate the effectiveness of specific interventions designed to promote body alignment, improve mobility, and protect the patient from the hazards of immobility. Evaluate the patient's and family's understanding of all teaching provided as well. The continuous nature of evaluation allows you to determine whether new or revised therapies are required and if new nursing diagnoses have developed.

When outcomes are not met, consider asking the following questions:

- Are there ways we can assist you to increase your activity?
- Which activities are you having trouble completing right now?
- How do you feel about not being able to dress yourself and make your own meals?
- Which exercises do you find most helpful?
- What goals for your activity would you like to set now?

Once these questions have been asked and you have addressed the limited mobility and its associated problems through the patient's eyes, you are prepared to adjust the plan of care to address the remaining clinical problems that your patient is experiencing related to immobility.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with the members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient-centered care.

- Determine the amount and type of assistance required for safe positioning, including any transfer equipment and the number of personnel to safely transfer and prevent harm to patient and health care providers.

- Raise the side rail on the side of the bed opposite of where you are standing to prevent the patient from falling out of bed on that side.
- Arrange equipment (e.g., intravenous lines, feeding tube, indwelling catheter) so it does not interfere with the positioning process.
- Evaluate the patient for correct body alignment and pressure risks after repositioning.

SKILL 28-1   MOVING AND POSITIONING PATIENTS IN BED

DELEGATION CONSIDERATIONS

The skill of moving and positioning patients in bed can be delegated to nursing assistive personnel (NAP). The nurse is responsible for assessing the patient's level of comfort and for any hazards of immobility. Instruct NAP about:

- Any moving and positioning imitations unique to patient.
- Individual needs for body alignment (e.g., patient with spinal cord injury).
- Scheduled times to reposition patient through the shift.
- When to request assistance (e.g., if the patient has a spinal cord injury, when the patient is unable to assist the nurse, has a lot of equipment, or is confused).

EQUIPMENT

- Pillows, drawsheet
- Therapeutic boots, splints if needed
- Trochanter roll
- Hand rolls
- Side rails
- Appropriate safe patient–handling assistive device (e.g., friction-reducing device)

STEP	RATIONALE
ASSESSMENT	
1. Identify patient using two identifiers (e.g., name and birthday or name and medical record number), according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).
2. Assess patient's body alignment and comfort level while he or she is lying down.	Provides baseline data for later comparisons. Determines ways to improve position and alignment.
3. Assess for risk factors that contribute to complications of immobility:	Increased risk factors require more frequent repositioning.
a. Paralysis, hemiparesis resulting from a cerebrovascular accident (CVA); decreased sensation	Paralysis impairs movement; muscle tone changes; sensation is often affected. Because of difficulty in moving and poor awareness of involved body part, patient is unable to protect and position body part for self (Lewis et al., 2013).
b. Impaired mobility from traction, arthritis, or other contributing disease processes	Traction or arthritic changes of affected extremity result in decreased range of motion (ROM).
c. Impaired circulation	Decreased circulation to skin and underlying tissue predisposes patient to pressure ulcers.
d. *Age:* Very young, older adults	Premature and young infants require frequent turning because their skin is fragile. Normal physiological changes associated with aging predispose older adults to greater risks for developing complications of immobility (Drake et al., 2012).
e. *Sensation:* Decreased from CVA, paralysis, neuropathy.	Because of poor awareness of body part or reduced sensation, patient is unable to protect and position body part from pressure.
f. Level of consciousness and mental status	Determines need for special aids or devices. Patients with altered levels of consciousness may not understand instructions or be able to help during positioning.
4. Assess patient's physical ability to help with moving and positioning:	Enables nurse to use patient's mobility, coordination, and strength; determines need for additional help. Ensures patient's and nurse's safety (VISN8, 2015).
a. Age	Some older adults move more slowly with less strength.
b. Disease process	Cardiopulmonary disease requires patient to have head of bed elevated.
c. Strength, coordination	Determines amount of assistance provided by patient during position change.
d. ROM	Limited ROM contraindicates certain positions.
5. Assess patient's height, weight, and body shape.	Devices used for safe patient handling have different weight restrictions; bariatric patients require special beds, lifts, wheelchairs, and toileting and bathing equipment (Pierson and Fairchild, 2013).
6. Assess health care provider's orders before positioning. Clarify whether any positions are contraindicated because of patient's condition (e.g., spinal cord injury; respiratory difficulties; certain neurological conditions; presence of incisions, drains, and tubing).	Placing patient in an inappropriate position causes injury.
7. Assess for presence of tubes, incisions, and equipment (e.g., traction).	Alters positioning procedure and affects patient's ability to independently change positions.

STEP	RATIONALE
8. Assess condition of patient's skin (see Chapter 31).	Provides baseline to determine effects of positioning.
9. Assess ability and motivation of patient and family caregivers to participate in moving and positioning patient in bed in anticipation of discharge to home.	Determines ability of patient and caregivers to help with positioning.

PLANNING

1. Collect appropriate equipment. Get extra help as needed. Close door to room or bedside curtains.	Having appropriate number of people to position patient prevents patient and nurse injury. Provides for patient privacy.
2. Perform hand hygiene.	Reduces transfer of microorganisms.
3. Raise level of bed to comfortable working height. Remove all pillows and devices used for positioning.	Raises work toward nurse's center of gravity. Reduces any interference during positioning.
4. Explain procedure to patient.	Helps to relieve anxiety and allows patient to participate more actively.

IMPLEMENTATION

1. Assist Patient in Moving Up in Bed	Determines degree of risk in repositioning patient and technique required to safely assist patient.
a. ***Can patient assist?***	
(1) Fully able to assist, nurse assistance not needed; nurse stands by to assist.	
(2) Partially able to assist; patient can assist with nurse using positioning cues or aids (e.g., drawsheet or friction-reducing device).	

CLINICAL DECISION: *Before lowering head of bed to flatten bed, account for all tubing, drains, and equipment to prevent dislodgement or tipping if caught in mattress or bedframe as bed is lowered.*

b. ***Assist patient moving up in bed, using a drawsheet (two or three nurses).***	This is not a one-person task. Helping a patient move up in bed without help from other co-workers or without the aid of an assistive device (i.e., friction-reducing pad) is not recommended or considered safe for the patient or nurse (ANA, 2010; CDC, 2009). If the patient is unable to fully assist, refer to Step 1c.
(1) Place patient supine with head of bed flat. A nurse stands on each side of bed.	Enables nurse to assess body alignment. Reduces pull of gravity on patient's upper body.
(2) Remove pillow from under head and shoulders and place it at head of bed.	Prevents striking patient's head against head of bed.
(3) Turn patient side to side to place drawsheet under patient, extending from shoulders to thighs.	Supports patient's body weight and reduces friction during movement.
(4) Return patient to supine position.	Even distribution of patient's weight makes lifting and positioning easier.
(5) Fanfold drawsheet on both sides, with each nurse grasping firmly near patient.	Provides strong handles to grip drawsheet without slipping.

CLINICAL DECISION: *Protect patient's heels from shearing force by having a third nurse lift heels while moving patient up in bed.*

(6) Nurses place their feet apart with forward-backward stance. Flex knees and hips. On the count of three, shift weight from front to back leg and move patient and drawsheet to desired position in bed (see illustration).	Facing direction of movement ensures proper balance. Shifting weight reduces force needed to move load. Flexing knees lowers center of gravity and uses thigh muscles instead of back muscles.

STEP 1b(6) A and **B,** Moving immobile patient up in bed with drawsheet.

SKILL 28-1	MOVING AND POSITIONING PATIENTS IN BED—cont'd

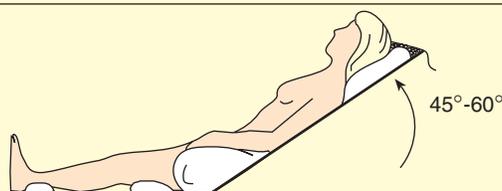
STEP	RATIONALE
c. *Assist moving up in bed using a friction-reducing device (three nurses assist).*	Patients weighing less than 200 pounds require at least three nurses; patients over 200 pounds require mechanical assist device.
(1) Position patient as in Steps 1b (1-3).	Prepares patient for placement of friction-reducing device.
(2) With patient already on side, place friction-reducing device under draw-sheet and then have patient turn over to other side.	Prevents friction from contact of skin with board.
(3) Move patient up in bed by having two nurses grasp drawsheet and one hold on to friction-reducing device. Follow Steps 1b(5-6), moving patient up in bed.	The slide board remains stationary, provides a slippery surface to reduce friction, and allows the patient to move easily up in bed.
2. Position patient in one of the following positions using correct body alignment to protect pressure areas. Begin with patient lying supine and move up in bed following either Steps 1b or 1c.	Prevents injury to the patient's musculoskeletal system
a. *Positioning patient in supported Fowler's position (see illustration):*	
(1) With patient supine, elevate head of bed 45 to 60 degrees if not contraindicated.	Increases comfort, improves ventilation, and increases patient's opportunity to socialize or relax.
(2) Rest head against mattress or on small pillow.	Prevents flexion contractures of cervical vertebrae.
(3) Use pillows to support arms and hands if patient does not have voluntary control or use of hands and arms.	Prevents shoulder dislocation from effect of downward pull of unsupported arms, promotes circulation by preventing venous pooling, and prevents flexion contractures of arms and wrists.
(4) Position small pillow at lower back.	Supports lumbar vertebrae and decreases flexion of vertebrae.
(5) Place small pillow under thigh. Support calves with pillows.	Prevents hyperextension of knee and occlusion of popliteal artery from pressure from body weight. Heels should not be in contact with bed to prevent prolonged pressure of mattress on heels. This is sometimes referred to as "floating" heels.
(6) *Option:* Use a heel pressure–relieving device (pillow or heel boot).	Pressure on the heels must be relieved by off-loading, which is done by regular repositioning or using a purpose-made pressure-relieving device. When pillows are used, they must be repositioned each time the patient moves (Bangova, 2013).

CLINICAL DECISION: *To keep feet in proper alignment and prevent footdrop, use foot support devices (check agency policy). In addition, a foot cradle is often used for patients with poor peripheral circulation as a means of reducing pressure on the tips of patient's toes.*

---

b. *Positioning hemiplegic patient in supported Fowler's position:*	
(1) Elevate head of bed 45 to 60 degrees. Adjust head of bed according to patient's condition. For example, those with increased risk of pressure ulcers remain at 30-degree angle (semi-Fowler's) (see Chapter 48).	Increases comfort, improves ventilation, and increases patient's opportunity to relax.
(2) Position patient in sitting position as straight as possible.	Counteracts tendency to slump toward affected side. Improves ventilation and cardiac output; decreases intracranial pressure. Improves patient's ability to swallow and helps to prevent aspiration of food, liquids, and gastric secretions.
(3) Position head on small pillow with chin slightly forward. If patient is totally unable to control head movement, avoid hyperextension of neck.	Prevents hyperextension of neck. Too many pillows under head cause or worsen neck flexion contracture.
(4) Provide support for involved arm and hand on overbed table in front of patient. Place arm away from patient's side and support elbow with pillow.	Paralyzed muscles do not automatically resist pull of gravity as they do normally. As a result, shoulder subluxation, pain, and edema may occur.

CLINICAL DECISION:
- *Position flaccid hand in normal resting position with wrist slightly extended, arches of hand maintained, and fingers partially flexed; use section of rubber ball cut in half; clasp patient's hands together.*
- *Position spastic hand with wrist in neutral position or slightly extended; extend fingers with palm down or leave them in relaxed position palm up. At times it is difficult to position spastic hands without the use of specially made splints for the patient.*

45°-60°


STEP 2a Supported Fowler's position.

STEP	RATIONALE
(5) Place trochanter rolls (rolled blanket) alongside of patient's legs.	Reduces external rotation of hip.
(6) If needed, support feet in dorsiflexion with therapeutic boots or splints (check agency policy) (see illustration).	Maintains foot in dorsiflexion and prevents footdrop. Pillows prevent stimulation to ball of foot by hard surface, which has a tendency to increase muscle tone in patient with extensor spasticity of lower extremity.
c. *Positioning patient in supported supine position:*	
(1) Be sure that patient is comfortable on back with head of bed flat.	Some patients' physical conditions do not tolerate supine position.
(2) Place small rolled towel under lumbar area of back.	Provides support for lumbar spine.
(3) Place pillow under upper shoulders, neck, or head.	Maintains correct alignment and prevents flexion contractures of cervical vertebrae.
(4) Place trochanter rolls or sandbags parallel to lateral surface of patient's thighs if patient is immobile.	Reduces external rotation of hip.
(5) Position patient's heels in heel boots or other heel pressure-relief device (check agency policy).	Heel pressure-relief devices are more effective than pillows for consistently reducing pressure from the mattress on the heels.
(6) If needed, support feet in dorsiflexion with foot support devices (check agency policy).	Maintains foot in dorsiflexion and prevents footdrop. Pillows prevent stimulation to ball of foot by hard surface, which has tendency to increase muscle tone in patient with extensor spasticity of lower extremity.
(7) Place pillows under pronated forearms, keeping upper arms parallel to patient's body (see illustration).	Reduces internal rotation of shoulder and prevents extension of elbows. Maintains correct body alignment.
(8) Place hand rolls in patient's hands. Consider physical therapy referral for use of hand splints.	Reduces extension of fingers and abduction of thumb. Maintains thumb slightly adducted and in opposition to fingers.
d. *Positioning hemiplegic patient in supine position:*	
(1) Be sure that patient is comfortable on back with head of bed flat.	Some patients' physical conditions do not tolerate supine position.
(2) Place folded towel or small pillow under shoulder of affected side.	Decreases possibility of pain, joint contracture, and subluxation. Maintains mobility in muscles around shoulder to permit normal movement patterns.
(3) Keep affected arm away from body with elbow extended and palm up. (Alternate position is to place arm out to side, with elbow bent and hand toward head of bed.)	Maintains mobility in arm, joints, and shoulder to permit normal movement patterns. (Alternate position counteracts limitation of ability of arm to rotate outward at shoulder [external rotation]. Need external rotation to raise arm overhead without pain.)

CLINICAL DECISION: *Position affected hand in one of the recommended positions for flaccid or spastic hand.*

(4) Place folded towel under hip of involved side.	Diminishes effect of spasticity in entire leg by controlling hip position.
(5) Flex affected knee 30 degrees by supporting it on pillow or folded blanket.	Slight flexion breaks up abnormal extension pattern of leg. Extensor spasticity is most severe when patient is supine.
(6) If needed, support feet in dorsiflexion with foot support devices (check agency policy).	Maintains foot in dorsiflexion and prevents footdrop. Pillows prevent stimulation to ball of foot by hard surface, which has tendency to increase muscle tone in patient with extensor spasticity of lower extremity.
e. *Positioning patient in prone position, using two to three nurses:*	In certain patients with pulmonary conditions such as acute respiratory distress syndrome, the use of the prone position can help improve oxygenation.
(1) With head of bed flat and one nurse standing on each side of bed, roll patient to one side while placing arm on side to be turned along side of body.	Prepares patient for positioning.

STEP 2b(6) Foot boot with lower leg extension.

STEP 2c(7) Supported supine position with pillows in place.

SKILL 28-1   MOVING AND POSITIONING PATIENTS IN BED—cont'd

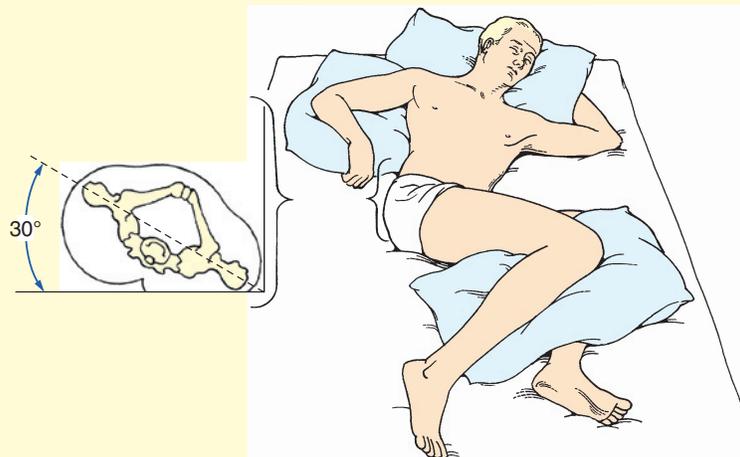
STEP	RATIONALE
(2) Roll patient over arm positioned close to body, with elbow straight and hand under hip. Position on abdomen in center of bed.	Positions patient correctly so alignment can be maintained.
(3) Turn patient's head to one side and support it with small pillow (see illustration).	Reduces flexion or hyperextension of cervical vertebrae.
(4) Place small pillow under patient's abdomen below level of diaphragm.	Reduces pressure on breasts of some female patients and decreases hyperextension of lumbar vertebrae and strain on lower back. Improves breathing by reducing mattress pressure on diaphragm.
(5) Support arms in flexed position level at shoulders.	Maintains proper body alignment. Support reduces risk of joint dislocation.
(6) Support lower legs with pillows to elevate toes.	Prevents footdrop. Reduces external rotation of hips. Eliminates mattress pressure on toes.
f. ***Positioning patient in 30-degree lateral (side-lying) position (one nurse):***	
(1) Lower head of bed completely or as low as patient can tolerate.	Provides position of comfort for patient and removes pressure from bony prominences on back.
(2) Position patient in supine position on side of bed opposite direction toward which patient is to be turned. Move upper trunk, supporting shoulders first, followed by moving lower trunk, supporting hips. Raise side rails and move to opposite side of bed.	Provides room for patient to turn to side. Use of safe patient-handling equipment reduces workload of caregivers and enhances safety (Burnfield et al., 2013; Griffis, 2012).
(3) Prepare to turn patient onto side. Flex patient's knee that will not be next to mattress. Place one hand on patient's knee and one hand on patient's shoulder.	Use of leverage makes turning to side easy.
(4) Roll patient onto side toward you.	Rolling decreases trauma to tissues. In addition, patient is positioned so leverage on hip makes turning easy.
(5) Place pillow under patient's head and neck.	Maintains alignment. Reduces lateral neck flexion. Decreases strain on sternocleidomastoid muscle.
(6) Bring dependent shoulder blade forward.	Prevents patient's weight from resting directly on shoulder joint.
(7) Position both arms in slightly flexed position. Support upper arm by pillow level with shoulder; support the other arm with mattress.	Decreases internal rotation and adduction of shoulder. Supporting both arms in slightly flexed position protects joint and improves ventilation because chest is able to expand more easily.
(8) Place your hands under patient's hips and bring dependent hip slightly forward so angle from hip to mattress is approximately 30 degrees.	The 30-degree lateral position reduces pressure on trochanter.
(9) Place small tuck-back pillow behind patient's back. (Make by folding pillow lengthwise. Smooth area is slightly tucked under patient's back.)	Provides support to maintain patient on side.
(10) Place pillow under semiflexed upper leg level at hip from groin to foot (see illustration).	Flexion prevents hyperextension of leg. Maintains leg in correct alignment. Prevents pressure on bony prominences.
(11) Support feet in dorsiflexion with foot support devices (check agency policy).	Maintains foot in dorsiflexion and prevents footdrop. Pillows prevent stimulation to ball of foot by hard surface, which has tendency to increase muscle tone in patient with extensor spasticity of lower extremity.
g. ***Positioning patient in Sims' (semi-prone) position (one nurse):***	
(1) Position patient in supine position on side of bed opposite direction toward which patient is to be turned. Move upper trunk, supporting shoulders first; move lower trunk, supporting hips. Raise side rails and move to opposite side of bed.	Prepares patient for positioning.
(2) Move to other side of bed and turn patient on side. Position in lateral position, lying partially on abdomen, with dependent shoulder lifted out and arm placed at patient's side.	Patient is rolled only partially on abdomen.

STEP 2e(3) Prone position with pillows supporting lower legs.

STEP	RATIONALE
(3) Place small pillow under patient's head.	Patient is rolled only partially on abdomen.
(4) Place pillow under flexed upper arm, supporting arm level with shoulder.	Maintains proper alignment and prevents lateral neck flexion. Prevents internal rotation of shoulder.
(5) Place pillow under flexed upper leg, supporting leg level with hip.	Prevents internal rotation of hip and adduction of leg. Flexion prevents hyperextension of leg. Reduces mattress pressure on knees and ankles.
(6) Support feet in dorsiflexion with foot support devices (check agency policy).	Maintains foot in dorsiflexion and prevents footdrop. Pillows prevent stimulation to ball of foot by hard surface, which has tendency to increase muscle tone in patient with extensor spasticity of lower extremity.

h. *Logrolling patient (three nurses):*

> **CLINICAL DECISION:** *Supervise and assist NAP when there is a health care provider's order to logroll a patient. Patients who have suffered from spinal cord injury or are recovering from neck, back, or spinal surgery often need to keep the spinal column in straight alignment to prevent further injury.*

(1) Place patient in supine position on side of bed opposite direction to be turned.	Prepares patient for turning onto side.
(2) Place small pillow between patient's knees.	Prevents tension on spinal column and adduction of hip.
(3) Cross patient's arms on chest.	Prevents injury to arms.
(4) Position two nurses or other staff members on side of bed to which patient will be turned. Position third nurse or staff member on other side of bed (see illustration). If needed, four nurses are used; fourth nurse stands on same side as third nurse.	Distributes weight equally among nurses.
(5) Fanfold or roll drawsheet alongside of patient.	Provides strong handles to grip the drawsheet or pull sheet without slipping.
(6) With one nurse grasping drawsheet at lower hips and thighs and the other nurse grasping drawsheet at patient's shoulders and lower back, roll patient as one unit in a smooth, continuous motion on the count of three (see illustration).	This maintains proper alignment by moving all body parts at the same time, preventing tension or twisting of the spinal column.


STEP 2f(10) Thirty-degree lateral position with pillows in place.

STEP 2h(4) Preparing patient for logroll.

STEP 2h(6) Move patient as a unit, logrolling onto side.

SKILL 28-1	MOVING AND POSITIONING PATIENTS IN BED—cont'd

STEP	RATIONALE
(7) Nurse on opposite side of bed places pillows along length of patient (see illustration).	Pillows keep patient aligned.
(8) Gently lean patient as a unit back toward pillows for support (see illustration).	Ensures continued straight alignment of spinal column, preventing injury.
3. Perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1. Evaluate patient's body alignment, position, and level of comfort (using pain scale). Patient's body should be supported by adequate mattress, and vertebral column is properly aligned.	Determines effectiveness of positioning. Patients who have adequate pain control and are comfortable maintain proper positioning.
2. Measure ROM.	Determines if joint contracture is developing.
3. Observe skin for areas of erythema or breakdown, especially under bony prominences.	Indicates complications of immobility or improper positioning of body part. Determines if need exists for increasing frequency of repositioning patient.
4. Use *Teach Back* to determine patient and family understanding of moving and positioning. State, "I want to be sure I explained how proper moving and positioning prevents risk for injury while providing you safe care. Can you explain to me why it is important we move and position you often?" Revise your instruction now or develop plan for revised patient teaching if patient is not able to teach back correctly.	Evaluates what the patient is able to explain or demonstrate.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Joint contractures develop or worsen.
  - Consult physical and/or occupational therapy.
  - Ensure that activity and ROM orders are implemented consistently.

2. Skin shows areas of erythema and breakdown.
  - Increase frequency of turning and repositioning
  - Place turning schedule above patient's bed.
  - Implement other activities per agency skin care policy or protocol (e.g., assess more frequently, consult dietitian, place patient on pressure-relieving mattress).

3. Patient avoids moving.
  - Administer analgesia as ordered by a health care provider to ensure patient's comfort before moving if he or she is in pain.
  - Allow pain medication to take effect before proceeding.
  - Provide patient education about benefits of moving.

RECORDING AND REPORTING

- Document repositioning or turning and any relevant observations during procedure (e.g., condition of skin, joint movement, patient's ability to assist with positioning) in nurses' notes.
- Report observations at change of shift hand-off.
- Document your evaluation of patient learning.

HOME CARE CONSIDERATIONS

- Teach family how to use safe patient-handling equipment if necessary.
- Teach patient and family about the signs of skin breakdown and the importance of safety during positioning for patients with decreased sensation.

STEP 2h(7) Place pillows along patient's back for support.

STEP 2h(8) Gently lean patient as a unit against pillows.

KEY POINTS

- Use findings from evidence-based nursing research about safe patient handling to prevent injuries to nurses and patients when moving and transferring.
- Coordination and regulation of muscle groups depend on muscle tone; activity of antagonistic, synergistic, and antigravity muscles; and neural input to muscles.
- Body alignment is the condition of joints, tendons, ligaments, and muscles in various body positions.
- Balance occurs when there is a wide base of support, the center of gravity falls within the base of support, and a vertical line falls from the center of gravity through the base of support.
- Developmental stages influence body alignment and mobility; the greatest impact of physiological changes on the musculoskeletal system is observed in children and older adults.
- The risk of disabilities related to immobilization depends on the extent and duration of immobilization and the patient's overall level of health.
- Immobility presents hazards in the physiological, psychological, and developmental dimensions.
- The nursing process and critical thinking assist you in providing care for patients who are experiencing or are at risk for the adverse effects of impaired body alignment and immobility.
- Patients with impaired body alignment require nursing care to maintain correct positioning such as the supported Fowler's, supine, prone, side-lying, and Sims' positions.
- Patient movement algorithms serve as assessment tools and guide safe patient handling and movement.
- Appropriate friction-reducing assistive devices and mechanical lifts need to be used for patient transfers when applicable.
- No-lift policies benefit all members of the health care system: patients, nurses, and administration.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Ms. Cavallo, 97 years of age, has been a resident at the rehabilitation unit for 6 weeks. She has been receiving rehabilitation therapy following the repair of her fractured left hip. The nursing assistive personnel (NAP) tells you that Ms. Cavallo has not been finishing her meals over the past 2 days because of poor appetite. As you enter her room with a food tray today, she states, "Go away and take that tray of food with you. I'm tired of all of this, and I just want to stay in bed today." You explore why she feels this way. You discover that she does not like the foods that are being prepared for her and she does not feel strong enough to use her walker. She states, "I'm afraid that I'm going to fall because I don't feel strong enough to get out of bed and use my walker."

1. On the basis of these data, you develop a nursing diagnosis of *Deficient Knowledge (Imbalanced Nutrition: Less Than Body Requirements) related to lack of information*. Identify one goal, two expected outcomes, and three related nursing interventions with rationales that will help her meet the identified goal and outcomes.
2. You finish teaching Ms. Cavallo about the importance of a balanced diet and how it will help her regain strength to ambulate. As you are doing her morning assessment, you notice that she has a reddened area on her coccyx.
   a. Which risk factors contribute to this finding?
   b. In addition to a balanced diet, which other nursing interventions would be good to include in her plan of care?

3. You convince Ms. Cavallo to eat a balanced diet of three meals and two snacks high in protein. Describe the decision-making process you use to ensure that Ms. Cavallo continues to recognize the importance of a balanced diet. Include essential assessment data that you need to ensure that she continues to have an intake of proper foods.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. An older adult has limited mobility as a result of a total knee replacement. During assessment you note that the patient has difficulty breathing while lying flat. Which of the following assessment data support a possible pulmonary problem related to impaired mobility? (Select all that apply.)
   1. B/P = 128/84
   2. Respirations 26/min on room air
   3. HR 114
   4. Crackles over lower lobes heard on auscultation
   5. Pain reported as 3 on scale of 0 to 10 after medication
2. A patient has been on bed rest for over 4 days. On assessment, the nurse identifies the following as a sign associated with immobility:
   1. Decreased peristalsis
   2. Decreased heart rate
   3. Increased blood pressure
   4. Increased urinary output
3. The nurse puts elastic stockings on a patient following major abdominal surgery. The nurse teaches the patient that the stockings are used after a surgical procedure to _____.
4. A nurse is teaching a community group about ways to minimize the risk of developing osteoporosis. Which of the following statements reflect understanding of what was taught? (Select all that apply.)
   1. "I usually go swimming with my family at the YMCA 3 times a week."
   2. "I need to ask my doctor if I should have a bone mineral density check this year."
   3. "If I don't drink milk at dinner, I'll eat broccoli or cabbage to get the calcium that I need in my diet."
   4. "I'll check the label of my multivitamin. If it has calcium, I can save money by not taking another pill."
   5. "My lactose intolerance should not be a concern when considering my calcium intake."
5. A nurse is caring for an older adult who has had a fractured hip repaired. In the first few postoperative days, which of the following nursing measures will best facilitate the resumption of activities of daily living for this patient?
   1. Encouraging use of an overhead trapeze for positioning and transfer
   2. Frequent family visits
   3. Assisting the patient to a wheelchair once per day
   4. Ensuring that there is an order for physical therapy
6. An older-adult patient has been bedridden for 2 weeks. Which of the following complaints by the patient indicates to the nurse that he or she is developing a complication of immobility?
   1. Loss of appetite
   2. Gum soreness

3. Difficulty swallowing
4. Left ankle joint stiffness

7. A patient is receiving 5000 units of heparin subcutaneously every 12 hours while on prolonged bed rest to prevent thrombophlebitis. Because bleeding is a potential side effect of this medication, the nurse should continually assess the patient for the following signs of bleeding: (Select all that apply.)
1. Bruising
2. Pale yellow urine
3. Bleeding gums
4. Coffee ground–like vomitus
5. Light brown stool

8. The nurse is caring for a patient whose calcium intake must increase because of high risk factors for osteoporosis. Which of the following menus should the nurse recommend?
1. Cream of broccoli soup with whole wheat crackers, cheese, and tapioca for dessert
2. Hot dog on whole wheat bun with a side salad and an apple for dessert
3. Low-fat turkey chili with sour cream with a side salad and fresh pears for dessert
4. Turkey salad on toast with tomato and lettuce and honey bun for dessert

9. The nurse evaluates that the NAP has applied a patient's sequential compression device (SCD) appropriately when which of the following is observed? (Select all that apply.)
1. Initial patient measurement is made around the calves
2. Inflation pressure averages 40 mm Hg
3. Patient's leg placed in SCD sleeve with back of knee aligned with popliteal opening on the sleeve.
4. Stockings are removed every 2 hours during application.
5. Yellow light indicates SCD device is functioning.

10. A patient on prolonged bed rest is at an increased risk to develop this common complication of immobility if preventive measures are not taken:
1. Myoclonus
2. Pathological fractures
3. Pressure ulcers
4. Pruritus

11. The effects of immobility on the cardiac system include which of the following? (Select all that apply.)

1. Thrombus formation
2. Increased cardiac workload
3. Weak peripheral pulses
4. Irregular heartbeat
5. Orthostatic hypotension

12. To prevent complications of immobility, what would be the most effective activity on the first postoperative day for a patient who has had abdominal surgery?
1. Turn, cough, and deep breathe every 30 minutes while awake
2. Ambulate patient to chair in the hall
3. Passive range of motion 4 times a day
4. Immobility is not a concern the first postoperative day

13. Which of the following nursing interventions should be implemented to maintain a patent airway in a patient on bed rest?
1. Isometric exercises
2. Administration of low-dose heparin
3. Suctioning every 4 hours
4. Use of incentive spirometer every 2 hours while awake

14. Place the following options in the order in which elastic stockings should be applied.
1. Identify patient using two identifiers.
2. Smooth any creases or wrinkles.
3. Slide the remainder of the stocking over the patient's heel and up the leg
4. Turn the stocking inside out until heel is reached.
5. Assess the condition of the patient's skin and circulation of the legs.
6. Place toes into foot of the stocking.
7. Use tape measure to measure patient's legs to determine proper stocking size.

15. Which of the following are physiological outcomes of immobility?
1. Increased metabolism
2. Reduced cardiac workload
3. Decreased lung expansion
4. Decreased oxygen demand

Answers: 1. 2, 3, 4; **2.** 1; **3.** Promote venous return to the heart; **4.** 1, 2, 3; **5.** 1; **6.** 4; **7.** 1, 3, 4; **8.** 1; **9.** 2, 3; **10.** 3; **11.** 1, 2, 5; **12.** 2; **13.** 4; **14.** 1, 5, 7, 4, 6, 3, 2; **15.** 3.

Infection Prevention and Control

The incidence of patients developing infections as the direct result of contact during health care is increasing. Based on a large sample of U.S. acute care hospitals, a Center for Disease Control and Prevention (CDC) survey found that, on any given day, about 1 in 25 hospital patients has at least one health care–associated infection (CDC, 2015a). Current trends, public awareness, and rising costs of health care have increased the importance of infection prevention and control. The Joint Commission (TJC) (2016) views this as a patient safety issue.

Infection prevention and control are essential for creating a safe health care environment for patients, families, and health care staff. Nurses are essential in infection prevention and control. Patients in all health care settings are at risk for acquiring infections because of lower resistance to pathogens; increased exposure to pathogens, some of which may be resistant to most antibiotics; and invasive procedures. Health care workers are at risk for exposure to pathogens as a result of contact with patient blood, body fluids, and contaminated equipment and

surfaces. By practicing basic infection prevention and control techniques, you avoid spreading pathogens to patients and sustaining an exposure when providing direct care.

Patients and their families need to be able to recognize sources of infection and understand measures used to protect themselves. Patient teaching must include basic information about infection, the various modes of transmission, and appropriate methods of prevention such as hand hygiene and covering a cough.

Health care workers protect themselves from contact with infectious material, sharps injury, and/or exposure to a communicable disease by applying knowledge of the infectious process and using appropriate personal protective equipment (PPE). Increases in multidrug-resistant organisms (MDROs), health care–acquired infections (HAIs), and concern about diseases such as hepatitis B virus (HBV) and hepatitis C virus (HCV), human immunodeficiency virus (HIV) infection, and tuberculosis (TB) require a greater emphasis on infection prevention and control techniques (CDC, 2006, 2007, 2013a).

SCIENTIFIC KNOWLEDGE BASE

Nature of Infection

An **infection** is the invasion of a susceptible host (e.g., human being) by **pathogens** or microorganisms, resulting in disease. It is important to know the difference between an infection and colonization. **Colonization** is the presence and growth of microorganisms within a host but without tissue invasion or damage (Tweeten, 2014). Disease or infection results only if the pathogens multiply and alter normal tissue function. Some **infectious** diseases such as viral meningitis and pneumonia have a low or no risk for transmission. Although these illnesses can be serious for patients, they do not pose a risk to others, including caregivers.

If an infectious disease can be transmitted directly from one person to another, it is termed a **communicable disease** (Tweeten, 2014). If the pathogens multiply and cause clinical signs and symptoms, the infection is **symptomatic**. If clinical signs and symptoms are not present, the illness is termed **asymptomatic**. HCV is an example of a communicable disease that can be asymptomatic. It is most efficiently transmitted through the direct passage of blood into the skin from a percutaneous exposure, even if the source patient is asymptomatic (CDC, 2010a).

Chain of Infection

The presence of a pathogen does not mean that an infection will occur. Infection occurs in a cycle that depends on the presence of all of the following elements:

- An infectious agent or pathogen
- A reservoir or source for pathogen growth
- A port of exit from the reservoir
- A mode of transmission
- A port of entry to a host
- A susceptible host

Infection can develop if this chain remains uninterrupted (Figure 29-1). Preventing infections involves breaking the chain of infection.

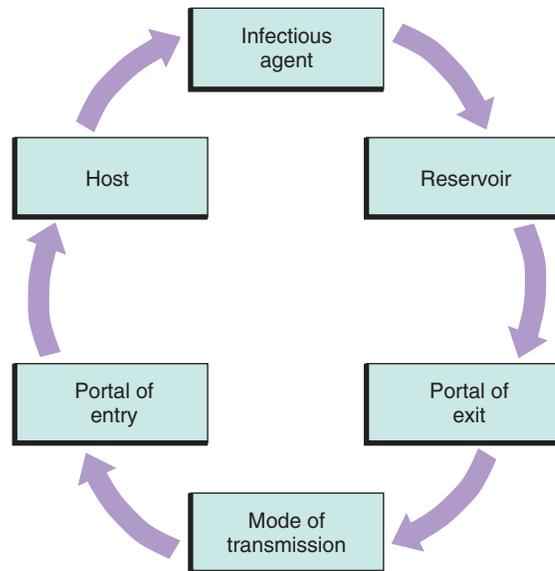
Infectious Agent. Microorganisms include bacteria, viruses, fungi, and protozoa (Table 29-1). Microorganisms on the skin are either resident or transient flora. Resident organisms (normal flora) are permanent residents of the skin and within the body, where they survive and multiply without causing illness (CDC, 2008a; WHO, 2009). The potential for microorganisms or parasites to cause disease depends on the number of microorganisms present; their **virulence**,


FIGURE 29-1 Chain of infection.

or ability to produce disease; their ability to enter and survive in a host; and the susceptibility of the host. Resident skin microorganisms are not virulent. However, these skin microorganisms can cause serious infection when surgery or other invasive procedures allow them to enter deep tissues or when a patient is severely **immunocompromised** (has an impaired immune system).

Transient microorganisms attach to the skin when a person has contact with another person or object during normal activities. For example, when you touch a contaminated gauze dressing or cleanse a patient following diarrheal episode, transient bacteria adhere to your skin. These organisms may be readily transmitted unless removed using hand hygiene (Ellingson et al., 2014). If hands are visibly soiled with proteinaceous material or care is being provided to a patient with *Clostridium difficile (C. difficile),* washing with soap and water is the preferred practice (Oughton et al., 2009). If hands are not visibly soiled, use of an alcohol-based hand product or handwashing with soap and water is acceptable for disinfecting hands of health care workers. Hand hygiene is the most effective way to break the chain of infection (CDC, 2008a; WHO, 2009).

Reservoir. A **reservoir** is a place where microorganisms survive, multiply, and await transfer to a susceptible host. Common reservoirs are humans and animals (hosts), insects, food, water, and organic matter on inanimate surfaces (fomites). Frequent reservoirs for HAIs include health care workers, especially their hands; patients; equipment; and the environment. Human reservoirs are divided into two types: those with acute or symptomatic disease and those who show no signs of disease but are carriers of it. Humans can transmit microorganisms in either case. Animals, food, water, insects, and inanimate objects can also be reservoirs for infectious organisms. To thrive organisms require a proper environment, including appropriate food, oxygen, water, temperature, pH, and light.

Food. Microorganisms require nourishment. Some such as *Clostridium perfringens,* the microbe that causes gas gangrene, thrive on organic matter. Others such as *Escherichia coli* consume undigested foodstuff in the bowel. Carbon dioxide and inorganic material such as soil provide nourishment for other organisms.

Oxygen. **Aerobic** bacteria require oxygen for survival and for multiplication sufficient to cause disease. Aerobic organisms cause more infections in humans than anaerobic organisms. An example of an

TABLE 29-1 Common Pathogens and Some Infections or Diseases They Produce		
Organism	**Major Reservoir(s)**	**Major Infections/Diseases**
Bacteria		
Escherichia coli	Colon	Gastroenteritis, urinary tract infection
Staphylococcus aureus	Skin, hair, anterior nares, mouth	Wound infection, pneumonia, food poisoning, cellulitis
Streptococcus (beta-hemolytic group A) organisms	Oropharynx, skin, perianal area	"Strep throat," rheumatic fever, scarlet fever, impetigo, wound infection
Streptococcus (beta-hemolytic group B) organisms	Adult genitalia	Urinary tract infection, wound infection, postpartum sepsis, neonatal sepsis
Mycobacterium tuberculosis	Droplet nuclei from lungs, larynx	Tuberculosis
Neisseria gonorrhoeae	GU tract, rectum, mouth	Gonorrhea, pelvic inflammatory disease, infectious arthritis, conjunctivitis
Rickettsia rickettsii	Wood tick	Rocky Mountain spotted fever
Staphylococcus epidermidis	Skin	Wound infection, bacteremia
Viruses		
Hepatitis A virus	Feces	Hepatitis A
Hepatitis B virus	Blood and certain body fluids, sexual contact	Hepatitis B
Hepatitis C virus	Blood, certain body fluids, sexual contact	Hepatitis C
Herpes simplex virus (type 1)	Lesions of mouth or skin, saliva, genitalia	Cold sores, aseptic meningitis, sexually transmitted disease, herpetic whitlow
Human immunodeficiency virus (HIV)	Blood, semen, vaginal secretions via sexual contact	Acquired immunodeficiency syndrome (AIDS)
Fungi		
Aspergillus organisms	Soil, dust, mouth, skin, colon, genital tract	Aspergillosis, pneumonia, sepsis
Candida albicans	Mouth, skin, colon, genital tract	Candidiasis, pneumonia, sepsis
Protozoa		
Plasmodium falciparum	Blood	Malaria

Modified from Brown M: Microbiology basics. In Grota P, editor: *APIC text of infection control and epidemiology,* Washington, DC, 2014, Association for Professionals in Infection Control and Epidemiology.

aerobic organism is *Staphylococcus aureus.* **Anaerobic** bacteria thrive where little or no free oxygen is available. Anaerobes typically cause infections deep within the pleural cavity, in a joint, or in a deep sinus tract. An example of an anaerobic organism is *Bacteroides fragilis,* an organism that is part of the normal flora of the human colon but can cause infection if displaced into the bloodstream or surrounding tissue following surgery or injury.

Water. Most organisms require water or moisture for survival. For example, a frequent place for microorganisms is the moist drainage from a surgical wound. Some bacteria assume a form, called a *spore,* which is resistant to drying, and can live on inanimate surfaces for long periods of time. A common spore-forming bacterium is *C. difficile,* an organism that causes antibiotic-induced diarrhea.

Temperature. Microorganisms can live only in certain temperature ranges. Each species of bacteria has a specific temperature at which it grows best. The ideal temperature for most human pathogens is 20° to 43°C (68° to 109°F). For example, *Legionella pneumophila* grows best in water at 25° to 42°C (77° to 108°F). Cold temperatures tend to prevent growth and reproduction of bacteria (**bacteriostasis**). A temperature or chemical that destroys bacteria is **bactericidal.**

pH. The acidity of an environment determines the viability of microorganisms. Most microorganisms prefer an environment within a pH range of 5.0 to 7.0. Bacteria in particular thrive in urine with an alkaline pH.

Light. Microorganisms thrive in dark environments such as those under dressings and within body cavities.

Portal of Exit. After microorganisms find a site to grow and multiply, they need to find a portal of exit if they are to enter another host and cause disease. Portals of exit include sites such as blood, skin and mucous membranes, respiratory tract, genitourinary (GU) tract, gastrointestinal (GI) tract, and transplacental (mother to fetus). Some viruses such as Ebola virus are transmitted through direct contact with the blood or body fluids of a person who is sick with Ebola. However, droplets (e.g., splashes or sprays) of respiratory or other secretions from a person who is sick with Ebola could also be infectious. Therefore certain precautions (called standard, contact, and droplet precautions) are recommended for use in health care settings to prevent the transmission of the virus from patients who are sick with Ebola to health care personnel and other patients or family members (CDC, 2015b).

Skin and Mucous Membranes. The skin is considered a portal of exit because any break in the integrity of the skin and mucous membranes allows pathogens to exit the body. This may be exhibited by the presence of purulent drainage.

Respiratory Tract. Pathogens that infect the respiratory tract such as the influenza virus are released from the body when an infected person sneezes or coughs.

Urinary Tract. Normally urine is sterile. However, when a patient has a urinary tract infection (UTI), microorganisms exit during urination.

Gastrointestinal Tract. The mouth is one of the most bacterially contaminated sites of the human body, but most of the organisms are normal floras. Organisms that are normal floras in one person can be pathogens in another. For example, organisms exit when a person expectorates saliva. In addition, gastrointestinal portals of exit include emesis, bowel elimination, drainage of bile via surgical wounds, or drainage tubes.

Reproductive Tract. Organisms such as *Neisseria gonorrhea* and HIV exit through a man's urethral meatus or a woman's vaginal canal during sexual contact.

Blood. The blood is normally a sterile body fluid; however, in the case of communicable diseases such as HBV, HCV, or HIV, it becomes a reservoir for pathogens. Organisms exit from wounds, venipuncture sites, hematemesis, and bloody stool.

Modes of Transmission. Each disease has a specific mode of transmission. Many times you are able to do little about the infectious agent or the susceptible host; but, by practicing infection prevention and control techniques such as hand hygiene, you interrupt the mode of transmission (Box 29-1). The same microorganism is sometimes transmitted by more than one route. For example, varicella zoster (chickenpox) is spread by the airborne route in droplet nuclei or by direct contact.

The major route of transmission for pathogens identified in the health care setting is the unwashed hands of the health care worker (CDC, 2008a; Ellingson et al., 2014; WHO, 2009). Equipment used within the environment (e.g., a stethoscope, blood pressure cuff, or bedside commode) often becomes a source for the transmission of pathogens.

Portal of Entry. Organisms enter the body through the same routes they use for exiting. For example, during venipuncture when a needle pierces a patient's skin, organisms enter the body if proper skin preparation is not performed first. Factors such as a depressed immune system that reduce body defenses enhance the chances of pathogens entering the body.

Susceptible Host. **Susceptibility** to an infectious agent depends on an individual's degree of resistance to pathogens. Although everyone is constantly in contact with large numbers of microorganisms, an infection does not develop until an individual becomes susceptible to the strength and numbers of the microorganisms. A person's natural defenses against infection and certain risk factors (e.g., age, nutritional status, presence of chronic disease, trauma, and smoking) affect susceptibility (resistance) (Roach, 2014). Organisms such as *S. aureus* with resistance to key antibiotics are becoming more common in all health care settings, but especially acute care. The increased resistance is associated with the frequent and sometimes inappropriate use of antibiotics over the years in all settings (i.e., acute care, ambulatory care, clinics, and long-term care) (Arnold, 2014).

THE INFECTIOUS PROCESS

By understanding the chain of infection, you have knowledge that is vital in preventing infections. When the patient acquires an infection, observe for signs and symptoms of infection and take appropriate actions to prevent its spread. Infections follow a progressive course (Box 29-2).

BOX 29-1 Modes of Transmission

Contact

Direct
- Person-to-person (fecal, oral) physical contact between source and susceptible host (e.g., touching patient feces and then touching your inner mouth or consuming contaminated food)

Indirect
- Personal contact of susceptible host with contaminated inanimate object (e.g., needles or sharp objects, dressings, environment)

Droplet
- Large particles that travel up to 3 feet during coughing, sneezing, or talking and come in contact with susceptible host

Airborne
- Droplet nuclei or residue or evaporated droplets suspended in air during coughing or sneezing or carried on dust particles

Vehicles
- Contaminated items
- Water
- Drugs, solutions
- Blood
- Food (improperly handled, stored, or cooked; fresh or thawed meats)

Vector
- External mechanical transfer (flies)
- Internal transmission such as parasitic conditions between **vector** and host such as:
  - Mosquito
  - Louse
  - Flea
- Tick

Modified from Tweeten S: General principles of epidemiology. In Grota P, editor: *APIC text of infection control and epidemiology,* Washington, DC, 2014, Association for Professionals in Infection Control and Epidemiology.

If an infection is **localized** (e.g., a wound infection), a patient usually experiences localized symptoms such as pain, tenderness, warmth, and redness at the wound site. Use standard precautions, appropriate PPE, and hand hygiene when assessing the wound. The use of these precautions and hand hygiene blocks the spread of infection to other sites or other patients. An infection that affects the entire body instead of just a single organ or part is **systemic** and can become fatal if undetected and untreated.

The course of an infection influences the level of nursing care provided. The nurse is responsible for properly administering antibiotics, monitoring the response to drug therapy (see Chapter 32), using proper hand hygiene, and standard precautions. Supportive therapy includes providing adequate nutrition and rest to bolster defenses of the body against the infectious process. The course of care for the patient often has additional effects on body systems affected by the infection.

Defenses Against Infection

The body has natural defenses that protect against infection. Normal floras, body system defenses, and inflammation are all nonspecific defenses that protect against microorganisms regardless of prior

BOX 29-2 Course of Infection by Stage

Incubation Period
Interval between entrance of pathogen into body and appearance of first symptoms (e.g., chickenpox, 14 to 16 days after exposure; common cold, 1 to 2 days; influenza, 1 to 4 days; measles, 10 to 12 days; mumps, 16 to 18 days; Ebola 2 to 21 days (CDC, 2015b).

Prodromal Stage
Interval from onset of nonspecific signs and symptoms (malaise, low-grade fever, fatigue) to more specific symptoms. (During this time microorganisms grow and multiply, and patient may be capable of spreading disease to others.) For example, herpes simplex begins with itching and tingling at the site before the lesion appears.

Illness Stage
Interval when patient manifests signs and symptoms specific to type of infection. For example, strep throat is manifested by sore throat, pain, and swelling; mumps is manifested by high fever, parotid and salivary gland swelling.

Convalescence
Interval when acute symptoms of infection disappear. (Length of recovery depends on severity of infection and patient's host resistance; recovery may take several days to months.)

---

exposure. If any of these body defenses fail, an infection usually occurs and leads to a serious health problem.

Normal Floras. The body normally contains microorganisms that reside on the surface and deep layers of skin, in the saliva and oral mucosa, and in the GI and GU tracts. A person normally excretes trillions of microbes daily through the intestines. **Normal floras** do not usually cause disease when residing in their usual area of the body but instead participate in maintaining health.

Normal floras of the large intestine exist in large numbers without causing illness. They also secrete antibacterial substances within the walls of the intestine. The normal floras of the skin exert a protective, bactericidal action that kills organisms landing on the skin. The mouth and pharynx are also protected by floras that impair growth of invading microbes. Normal floras maintain a sensitive balance with other microorganisms to prevent infection. Any factor that disrupts this balance places a person at increased risk for acquiring a disease. For example, the use of **broad-spectrum antibiotics** for the treatment of infection can lead to **suprainfection**. A suprainfection develops when broad-spectrum antibiotics eliminate a wide range of normal flora organisms, not just those causing infection. When normal bacterial floras are eliminated, body defenses are reduced, which allows disease-producing microorganisms to multiply, causing illness (Arnold, 2014).

Body System Defenses. A number of body organ systems have unique defenses against infection (Table 29-2). The skin, respiratory tract, and GI tract are easily accessible to microorganisms. Pathogenic organisms can adhere to the surface skin, be inhaled into the lungs, or be ingested with food. Each organ system has defense mechanisms physiologically suited to its specific structure and function. For example, the lungs cannot completely control the entrance of microorganisms. However, the airways are lined with moist mucous membranes and hairlike projections, or cilia, that rhythmically beat to move mucus or cellular debris up to the pharynx to be expelled through swallowing.

Inflammation. The cellular response of the body to injury, infection, or irritation is termed *inflammation*. Inflammation is a protective vascular reaction that delivers fluid, blood products, and nutrients to an area of injury. The process neutralizes and eliminates pathogens or dead (**necrotic**) tissues and establishes a means of repairing body cells and tissues. Signs of localized inflammation include swelling, redness, heat, pain or tenderness, and loss of function in the affected body part. When inflammation becomes systemic, other signs and symptoms develop, including fever, increased white blood cells (WBCs), malaise, anorexia, nausea, vomiting, lymph node enlargement, or organ failure.

Physical agents, chemical agents, or microorganisms trigger the inflammatory response. Mechanical trauma, temperature extremes, and radiation are examples of physical agents. Chemical agents include external and internal irritants such as harsh poisons or gastric acid. Sometimes microorganisms also trigger this response.

After tissues are injured, a series of well-coordinated events occurs. The inflammatory response includes vascular and cellular responses, formation of inflammatory **exudates** (fluid and cells that are discharged from cells or blood vessels [e.g., pus or serum]), and tissue repair.

Vascular and Cellular Responses. Acute inflammation is an immediate response to cellular injury. Rapid vasodilation occurs, allowing more blood near the location of the injury. The increase in local blood flow causes the redness and localized warmth at the site of inflammation.

Injury causes tissue damage and possibly necrosis. As a result the body releases chemical mediators that increase the permeability of small blood vessels; and fluid, protein, and cells enter interstitial spaces. The accumulation of fluid appears as localized swelling (**edema**). Another sign of inflammation is pain, which is caused by the swelling of inflamed tissues that increases pressure on nerve endings. As a result of the physiological inflammatory response, the involved body part may have a temporary loss of function. For example, a localized infection of the hand causes the fingers to become swollen, painful, and discolored. Joints become stiff as a result of swelling, but function of the fingers returns when inflammation subsides.

The cellular response of inflammation involves WBCs arriving at the site. WBCs pass through blood vessels and into the tissues. Phagocytosis is a process that involves the destruction and absorption of bacteria. Through the process of phagocytosis, specialized WBCs, called neutrophils and monocytes, ingest and destroy microorganisms or other small particles. If inflammation becomes systemic, other signs and symptoms develop. Leukocytosis, or an increase in the number of circulating WBCs, is the response of the body to WBCs leaving blood vessels. In the adult a serum WBC count is normally 5,000 to 10,000/mm^3 but typically rises to 15,000 to 20,000/mm^3 and higher during inflammation. Fever is caused by phagocytic release of pyrogens from bacterial cells, which causes a rise in the hypothalamic set point (see Chapter 30).

Inflammatory Exudate. Accumulation of fluid, dead tissue cells, and WBCs forms an exudate at the site of inflammation. Exudate may be **serous** (clear, like plasma), **sanguineous** (containing red blood cells), or **purulent** (containing WBCs and bacteria). Usually the exudate is cleared away through lymphatic drainage. Platelets and plasma proteins such as fibrinogen form a meshlike matrix at the site of inflammation to prevent its spread.

Tissue Repair. When there is injury to tissue cells, healing involves the defensive, reconstructive, and maturative stages (see Chapter 48). Damaged cells eventually are replaced with healthy new cells. The new cells undergo a gradual maturation until they take on the same structural characteristics and appearance as the previous cells. If inflammation is chronic, tissue defects sometimes fill with fragile **granulation**

TABLE 29-2   Natural Defense Mechanisms Against Infection

Defense Mechanisms	Action	Factors That May Alter Defense Mechanisms
Skin		
Intact multilayered surface (first line of defense against infection)	Provides barrier to microorganisms and antibacterial activity	Cuts, abrasions, puncture wounds, areas of maceration
Shedding of outer layer of skin cells	Removes organisms that adhere to outer layers of skin	Failure to bathe regularly, improper handwashing technique
Sebum	Contains fatty acid that kills some bacteria	Excessive bathing
Mouth		
Intact multilayered mucosa	Provides mechanical barrier to microorganisms	Lacerations, trauma, extracted teeth
Saliva	Washes away particles containing microorganisms. Contains microbial inhibitors (e.g., lysozyme)	Poor oral hygiene, dehydration
Eye		
Tearing and blinking	Provides mechanisms to reduce entry (blinking) or help wash away (tearing) particles containing pathogens, thus reducing dose of organisms	Injury, exposure—splash/splatter of blood or other potentially infectious material into eye
Respiratory Tract		
Cilia lining upper airway, coated by mucus	Traps inhaled microbes and sweeps them outward in mucus to be expectorated or swallowed	Smoking, high concentration of oxygen and carbon dioxide, decreased humidity, cold air
Macrophages	Engulf and destroy microorganisms that reach alveoli of lung	Smoking
Urinary Tract		
Flushing action of urine flow	Washes away microorganisms on lining of bladder and urethra	Obstruction to normal flow by urinary catheter placement, obstruction from growth or tumor, delayed micturition
Intact multilayered epithelium	Provides barrier to microorganisms	Introduction of urinary catheter, continual movement of catheter in urethra can facilitate migration of organisms to bladder
Gastrointestinal Tract		
Acidity of gastric secretions	Prevents retention of bacterial contents	Administration of antacids
Rapid peristalsis in small intestine		Delayed motility resulting from impaction of fecal contents in large bowel or mechanical obstruction by masses
Vagina		
At puberty normal flora causing vaginal secretions to achieve low pH	Inhibit growth of many microorganisms	Antibiotics and oral contraceptives disrupting normal flora

tissue that eventually takes the form of a scar at the completion of the healing process. The scar and surrounding tissues are not as strong as normal tissue and may be more susceptible to injury from pressure, shear, or friction, which increase the risk for pressure ulcer development (see Chapter 48).

Health Care–Associated Infections

Patients in health care settings, especially hospitals and long-term care facilities, have an increased risk of acquiring infections. **Health care–associated infections (HAIs)** result from the delivery of health services in a health care facility. They occur as the result of invasive procedures, antibiotic administration, the presence of **multidrug-resistant organisms** (MDROs), and breaks in infection prevention and control activities. The number of health care employees having direct contact with a patient, the type and number of invasive procedures, the therapy received, and the length of hospitalization influence the risk of infection. Major sites for HAIs include surgical or traumatic wounds, urinary and respiratory tracts, and the bloodstream (Box 29-3).

HAIs significantly increase costs of health care. Older adults have increased susceptibility to these infections because of their affinity to chronic disease and the aging process itself (Box 29-4). Extended stays in health care institutions, increased disability, increased costs of antibiotics, and prolonged recovery times add to the expenses both of the patient and the health care institution and funding bodies (e.g., Medicare). Costs for HAIs are often not reimbursed; as a result, prevention has a beneficial financial impact and is an important part of managed care. TJC lists several national safety goals focusing on the care of older adults (e.g., ensuring that older adults receive influenza and pneumonia vaccines, preventing infection after surgery) (TJC, 2016).

Improperly performing hand hygiene increases patient risk for all types of health care–associated infections.

Urinary Tract
- Unsterile insertion of urinary catheter
- Improper positioning of the drainage tubing
- Open drainage system
- Catheter and tube becoming disconnected
- Drainage bag port touching contaminated surface
- Improper specimen collection technique
- Obstructing or interfering with urinary drainage
- Urine in catheter or drainage tube being allowed to reenter bladder (reflux)
- Repeated catheter irrigations
- Improper perineal hygiene

Surgical or Traumatic Wounds
- Improper skin preparation before surgery (e.g., shaving versus clipping hair; not performing a preoperative bath or shower)
- Failure to clean skin surface properly
- Failure to use aseptic technique during operative procedures and dressing changes
- Use of contaminated antiseptic solutions

Respiratory Tract
- Contaminated respiratory therapy equipment
- Failure to use aseptic technique while suctioning airway
- Improper disposal of secretions

Bloodstream
- Contamination of intravenous (IV) fluids by tubing
- Insertion of drug additives to IV fluid
- Addition of connecting tube or stopcocks to IV system
- Improper care of needle insertion site
- Contaminated needles or catheters
- Failure to change IV access at first sign of infection or at recommended intervals
- Improper technique during administration of multiple blood products
- Improper care of peritoneal or hemodialysis shunts
- Improperly accessing an IV port

BOX 29-4   **FOCUS ON OLDER ADULTS**

Risks for Infection

- An age-related functional deterioration in immune system function, termed *immune senescence,* increases the susceptibility of the body to infection and slows overall immune response (Larbi et al., 2013).
- Older adults are less capable of producing lymphocytes to combat challenges to the immune system. When antibodies are produced, the duration of their response is shorter, and fewer cells are produced (Roach, 2014).
- Risks associated with the development of infections or HAIs in older patients include poor nutrition, unintentional weight loss, lack of exercise, poor social support, and low serum albumin levels (Meiner, 2014).
- Flu and pneumonia vaccinations are recommended for the older-adult population to reduce their risk for infectious diseases.
- Teach older adults and their families how to reduce the risk for infections by using proper hand hygiene practices.

Patients who develop HAIs often have multiple illnesses, are older adults, or are poorly nourished and may have a compromised immune system; thus they are more susceptible to infections. In addition, many patients have a lowered resistance to infection because of underlying medical conditions (e.g., diabetes mellitus or cancer) that impair or damage the immune response of the body. Invasive treatment devices such as intravenous (IV) catheters or indwelling urinary catheters impair or bypass the natural defenses of the body against microorganisms. Critical illness increases patients' susceptibility to infections, especially multidrug-resistant bacteria. Meticulous hand hygiene practices, the use of chlorhexidine washes for bathing and personal hygiene care, and advances in intensive care unit (ICU) infection prevention help to prevent these infections (Doyle et al., 2011; Kassakian et al., 2011).

HAI infections are either exogenous or endogenous. An **exogenous infection** comes from microorganisms found outside the individual, such as *Salmonella, Clostridium tetani,* and *Aspergillus.* These microorganisms do not exist as normal floras. An **endogenous infection** occurs when part of the patient's flora becomes altered and an overgrowth results (e.g., staphylococci, enterococci, yeasts, and streptococci). This often happens when a patient receives broad-spectrum antibiotics that alter the normal floras. When sufficient numbers of microorganisms normally found in one body site move to another site, an endogenous infection develops. The number of microorganisms needed to cause an HAI depends on the virulence of the organism, the susceptibility of the host, and the body site affected.

Iatrogenic infections are a type of HAI caused by an invasive diagnostic or therapeutic procedure. For example, procedures such as a bronchoscopy and treatment with broad-spectrum antibiotics increase the risk for certain infections (Arnold, 2014; Day, 2014). Use critical thinking when practicing aseptic techniques during the performance of procedures. Follow basic infection prevention and control policies and procedures to reduce the risk of HAIs. Always consider the patient's risks for infection and anticipate how the approach to care increases or decreases the risk.

NURSING KNOWLEDGE BASE

Body substances such as feces, urine, and wound drainage contain potentially infectious microorganisms. Health care workers are at risk for exposure to microorganisms in the hospital and/or home setting (Fiutem, 2014). The meticulous use of specific infection prevention practices reduces the risk of cross-contamination and transmission of infection to other patients when caring for a patient with a known or suspected infection (CDC, 2007).

Serious infections are ongoing challenges to clinicians, and they create feelings of anxiety, frustration, loneliness, and anger in patients and/or their families (Nesher et al., 2014). These feelings worsen when patients are isolated to prevent transmission of a microorganism to other patients or health care staff. Isolation disrupts normal social relationships with visitors and caregivers. Patient safety is usually an additional risk for the patient on isolation precautions (Monsees, 2014). For example, an older patient with a chronic illness is more at risk for a HAI. When family members fear the possibility of developing the infection, they may avoid contact with the patient. Some patients perceive the simple procedures of proper hand hygiene and gown and glove use as evidence of rejection. Help patients and families reduce some of these feelings by discussing the disease process; explaining isolation procedures; and maintaining a friendly, understanding manner.

When establishing a plan of care, it is important to know how a patient reacts to an infection or infectious disease. The challenge is to

identify and support behaviors that maintain human health or prevent infection.

Factors Influencing Infection Prevention and Control

Multiple factors influence a patient's susceptibility to infection. It is important to understand how each of these factors alone or in combination increases this risk. When more than one factor is present, a patient's susceptibility often increases, which affects length of stay, recovery time, and/or overall level of health following an illness. Understanding these factors helps to assess and care for a patient who has an infection or is at risk for one.

Age. Throughout life a person's susceptibility to infection changes. For example, an infant has immature defenses against infection. Born with only the antibodies provided by the mother, the infant's immune system is incapable of producing the necessary immunoglobulins and WBCs to adequately fight some infections. However, breastfed infants often have greater immunity than bottle-fed infants because they receive their mother's antibodies through the breast milk. As the child grows the immune system matures; but the child is still susceptible to organisms that cause the common cold; intestinal infections; and infectious diseases such as mumps, measles, and chickenpox (if not vaccinated).

The young or middle-age adult has refined defenses against infection. Viruses are the most common cause of communicable illness in young or middle-age adults. Since 2000 there has been a major effort to vaccinate all children against all infectious diseases for which vaccines are available. Vaccine-preventable disease levels are at or near record lows (CDC, 2011a).

Defenses against infection change with aging (Larbi et al., 2013). The immune response, particularly cell-mediated immunity, declines. Older adults also undergo alterations in the structure and function of the skin, urinary tract, and lungs. For example, the skin loses its turgor, and the epithelium thins. As a result it is easier to tear or abrade the skin, which increases the potential for invasion by pathogens. In addition, older adults who are hospitalized or reside in an assisted-living or residential care facility are at risk for airborne infections. Ensuring that health care workers are vaccinated against influenza reduces the transmission of this illness in older adults (Thomas et al., 2013).

Nutritional Status. A patient's nutritional health directly influences susceptibility to infection. A reduction in the intake of protein and other nutrients such as carbohydrates and fats reduces body defenses against infection and impairs wound healing (see Chapter 48). Patients with illnesses or problems that increase protein requirements, such as extensive burns and febrile conditions, are at further risk. For example, patients who have undergone surgery require increased protein. A thorough diet history is necessary. Determine a patient's normal daily nutrient intake and whether preexisting problems such as nausea, impaired swallowing, or oral pain alter food intake. Confer with a dietitian to assist in calculating the calorie count of foods ingested.

Stress. The body responds to emotional or physical stress by the general adaptation syndrome (see Chapter 38). During the alarm stage the basal metabolic rate increases as the body uses energy stores. Adrenocorticotropic hormone increases serum glucose levels and decreases unnecessary antiinflammatory responses through the release of cortisone. If stress continues or becomes intense, elevated cortisone levels result in decreased resistance to infection. Continued stress leads to exhaustion, which causes depletion in energy stores, and

the body has no resistance to invading organisms. The same conditions that increase nutritional requirements such as surgery or trauma also increase physiological stress.

Disease Process. Patients with diseases of the immune system are at particular risk for infection. Leukemia, acquired immunodeficiency syndrome (AIDS), lymphoma, and aplastic anemia are conditions that compromise a host by weakening defenses against infectious organisms. For example, patients with leukemia are unable to produce enough WBCs to ward off infection. Patients with HIV are often unable to ward off simple infections and are prone to opportunistic infections.

Patients with chronic diseases such as diabetes mellitus and multiple sclerosis are also more susceptible to infection because of general debilitation and nutritional impairment. Diseases that impair body system defenses such as emphysema and bronchitis (which impair ciliary action and thicken mucus), cancer (which alters the immune response), and peripheral vascular disease (which reduces blood flow to injured tissues) increase susceptibility to infection. Patients with burns have a high susceptibility to infection because of the damage to skin surfaces. The greater the depth and extent of the burns, the higher is the risk for infection.

❖ NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

◆ Assessment

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Determine how the patient feels about the illness or risk for infection. Assess his or her defense mechanisms, susceptibility, and knowledge of how infections are transmitted (Table 29-3). Conduct a review of systems and travel history with the patient and family to reveal any risks for exposure to a communicable disease. Immunization and vaccination history is also very useful. It is important to be thorough in assessing a patient's clinical condition. A medication history is necessary to identify medications that increase a patient's susceptibility to infection. An analysis of laboratory findings provides information about a patient's defense against infection. The early recognition of infection or risk factors helps you make the correct nursing diagnosis and establish a treatment plan.

Through the Patient's Eyes. Some patients with infection have a variety of problems. It is important to ask specific questions to determine the patient's and family's needs related to the risk for infection or disease status (Box 29-5). These needs vary from patient to patient and include physical, psychological, social, or economic needs. Patients with chronic or serious infection, especially communicable infections such as TB or AIDS, experience psychological and social problems from self-imposed isolation or rejection by friends and family. Ask the patient how the infection affects the ability to maintain relationships and perform activities of daily living. Determine whether chronic infection has drained the patient's financial resources. Ask about his or her expectations of care and determine how much he or she wants to be involved in planning care. Some patients and their families wish to know more about the disease process, whereas others only want to know the interventions necessary to treat the infection. In addition,

TABLE 29-3 Assessing the Risk of Infection in Adults

Risk Factor	Causes	Outcome
Chronic disease	COPD, heart failure, diabetes	Pneumonia, skin breakdown, venous stasis ulcers
Lifestyle—high-risk behaviors	Exposure to communicable/infectious diseases, use of IV drugs and other drugs/substances	STIs, HIV, HBV, HCV, opportunistic infections, viral infections, yeast infections, liver failure
Occupation	Health care worker; miner, unemployed, homeless	Exposure to blood and body fluids increase risk of infection; black lung disease, pneumonia, TB, poor nutritional intake; lack of access to medical care; stress
Diagnostic procedures	Invasive radiology, transplant	Multiple IV lines, immunosuppressive drugs
Heredity	Sickle cell disease, diabetes	Anemia, delayed healing
Travel history	West Nile virus, SARS, avian flu, *Hantavirus*	Meningitis, acute respiratory distress
Trauma	Fractures, internal bleeding	Sepsis, secondary infection
Nutrition	Obesity, anorexia	Impaired immune response

Modified from Tweeten SM: General principles of epidemiology. In Grota P, editor: *APIC text of infection control and epidemiology,* Washington, DC, 2014, Association for Professionals in Infection Control and Epidemiology. *COPD,* Chronic obstructive pulmonary disease; *HBV,* hepatitis B virus; *HCV,* hepatitis C virus; *HIV,* human immunodeficiency virus; *IV,* intravenous; *SARS,* severe acute respiratory syndrome; *STIs,* sexually transmitted infections; *TB,* tuberculosis.

BOX 29-5 Nursing Assessment Questions

Risk Factors
- Do you have any recent cuts or lacerations? Show me the location.
- Describe for me any illnesses or diseases that you have and those for which you receive treatment.
- Tell me about any recent diagnostic testing you have undergone, such as colonoscopy or cystoscopy?

Possible Existing Infections
- Do you have or feel like you have a fever?
- Do you have any cuts or wounds with drainage?
- Do you have any pain/burning during urination?
- Do you have a cough? Is there any sputum?

Recent Travel History
- Have you traveled outside the United States in the past 6 months?
- Are you a resident of or have you travelled within the last 21 days to a country where an Ebola outbreak is occurring (CDC, 2015c)?
- Were any of the people you visited or traveled with ill?

Medication History
- List for me the medications you are currently taking.
- Describe any over-the-counter medications or herbals that you are currently taking.

Stressors
- Tell me about any major lifestyle change occurring such as the loss of employment or place of residence, divorce, or disability.

there are emerging infections throughout the globe, and it is important to also obtain travel history from your patients. Encourage patients to verbalize their expectations so you are able to establish interventions to meet patients' priorities.

Status of Defense Mechanisms. Review physical assessment findings (see Chapter 31) and the patient's medical condition to determine the status of normal defense mechanisms against infection. For example, any break in the skin such as an ulcer on the foot of a patient who has diabetes is a potential site for infection. Any reduction in the primary or secondary defenses of the body against infection such as a weakened ability to cough places a patient at increased risk.

Patient Susceptibility. As noted previously, assess the patient's age, nutritional status, presence of chronic illnesses, stress, and disease process to identify factors that influence susceptibility to infection. Gather information about each factor through your interview and the patient's and family's medical history.

Medical Therapy. Some drugs and medical therapies compromise immunity to infection. Assess your patient's medication history to determine whether he or she takes any medications that increase infection susceptibility. These include any over-the-counter medications and herbal supplements. A review of therapies received within the health care setting further reveals risks. For example, adrenal corticosteroids, prescribed for several conditions, are antiinflammatory drugs that cause protein breakdown and impair the inflammatory response against bacteria and other pathogens. Cytotoxic and antineoplastic drugs attack cancer cells but also cause the side effects of bone marrow depression and normal cell toxicity, which affects the response of body against pathogens.

Clinical Appearance. The signs and symptoms of infection may be local or systemic. Localized infections are most common in areas of skin or mucous membrane breakdown such as surgical and traumatic wounds, pressure ulcers, oral lesions, and abscesses.

To assess an area for localized infection, first inspect it for redness, warmth, and swelling caused by inflammation. Because there may be drainage from open lesions or wounds, wear clean gloves. Infected drainage may be yellow, green, or brown, depending on the pathogen. For example, green nasal secretions often indicate a sinus infection. Ask the patient about pain or tenderness around the site. Some patients complain of tightness and pain caused by edema. If the infected area is large enough, movement is restricted. Gentle palpation of an infected area usually results in some degree of tenderness. Wear protective eyewear and a surgical mask when there is a risk for splash or spray with blood or body fluids.

Systemic infections cause more generalized symptoms than local infection. These symptoms often include fever, fatigue, nausea/

vomiting, and malaise. Lymph nodes that drain the area of infection often become enlarged, swollen, and tender during palpation. For example, an abscess in the peritoneal cavity causes enlargement of lymph nodes in the groin. An infection of the upper respiratory tract causes cervical lymph node enlargement. If an infection is serious and widespread, all major lymph nodes may enlarge.

Systemic infections sometimes develop after treatment for localized infection has failed. Be alert for changes in a patient's level of activity and responsiveness. As systemic infections develop, an elevation in body temperature can lead to episodes of increased heart and respiratory rates and low blood pressure. Involvement of major body systems produces specific symptoms. For example, a pulmonary infection results in a productive cough with purulent sputum. A UTI results in cloudy, foul-smelling urine.

An infection does not always present with typical signs and symptoms in all patients. For example, some older adults have an advanced infection before it is identified. Because of the aging process, there is a reduced inflammatory and immune response. Older adults have increased fatigue and diminished pain sensitivity. A reduced or absent fever response often occurs from chronic use of aspirin or nonsteroidal antiinflammatory drugs. Atypical symptoms such as confusion, incontinence, or agitation may be the only symptoms of an infectious illness (Roach, 2014). For example, as many as 20% of older adults with pneumonia do not have the typical signs and symptoms of fever, shaking, chills, and colored productive sputum. Often the only symptoms are an unexplained increase in heart rate, confusion, or generalized fatigue. A pneumonia vaccine is available and recommended for all people with chronic respiratory problems and those over 65 years of age.

Laboratory Data. Review laboratory data as soon as the results are available. Laboratory values such as increased WBCs and/or a positive blood culture often indicate infection (Table 29-4). However, laboratory values are not enough to detect infection. It is possible that a contaminated specimen was collected because of poor technique (e.g., a blood sample is mixed with IV fluid because it is improperly collected

from an indwelling line; a urine specimen is contaminated because of poor perineal cleansing). You need to assess other clinical signs of infection. A culture result may show growth of an organism in the absence of infection. For example, in the older adult bacterial growth in urine without clinical symptoms does not always indicate the presence of a UTI (Roach, 2014). Also know that laboratory values often vary from laboratory to laboratory. Be sure to know the standard range of laboratory values for the laboratory in your facility.

◆ **Nursing Diagnosis**
During assessment gather objective data such as inspection of an open incision or a reduced caloric intake record and subjective data such as a patient's complaint of tenderness over a surgical wound site. Review the data carefully, looking for clusters of defining characteristics or risk factors that create a pattern. This pattern suggests a specific nursing diagnosis (Box 29-6). The following are examples of nursing diagnoses that often apply to patients with infection:
- Risk for Infection
- Imbalanced Nutrition: Less Than Body Requirements
- Impaired Oral Mucous Membrane
- Risk for Impaired Skin Integrity
- Social Isolation
- Impaired Tissue Integrity

It is necessary to validate data such as inspecting the integrity of a wound more carefully and to review laboratory findings to confirm a diagnosis. Success in planning appropriate nursing interventions depends on the accuracy of the diagnostic statement and the ability to meet the patient's needs. A patient will have defining characteristics for a problem focused diagnosis, and it is individualized with the addition of an accurate *related* factor in the diagnostic statement. For example, minimizing the risk for infection in a patient with a diagnosis of *Impaired Oral Mucous Membrane related to mouth breathing* requires frequent and proper oral hygiene measures. Minimizing the risk for infection in a patient with a nursing diagnosis of *Imbalanced Nutrition: Less Than Body Requirements related to inability to absorb nutrients* requires good nutritional support and fluid balance. At-risk diagnoses

TABLE 29-4 Laboratory Tests to Screen for Infection

Laboratory Value	Normal (Adult) Values	Indication of Infection
White blood cell (WBC) count	5000-10,000/mm^3	Increased in acute infection, decreased in certain viral or overwhelming infections
Erythrocyte sedimentation rate	Up to 15 mm/hr for men and 20 mm/hr for women	Elevated in presence of inflammatory process
Iron level	80-180 mcg/mL for men 60-160 mcg/ml for women	Decreased in chronic infection
Cultures of urine and blood	Normally sterile, without microorganism growth	Presence of infectious microorganism growth
Cultures and Gram stain of wound, sputum, and throat	No WBCs on Gram stain, possible normal flora	Presence of infectious microorganism growth and WBCs on Gram stain
Differential Count (Percentage of Each Type of White Blood Cell)		
Neutrophils	55%-70%	Increased in acute suppurative (pus-forming) infection, decreased in overwhelming bacterial infection (older adult)
Lymphocytes	20%-40%	Increased in chronic bacterial and viral infection, decreased in sepsis
Monocytes	2%-8%	Increased in protozoan, rickettsial, and tuberculosis infections
Eosinophils	1%-4%	Increased in parasitic infection
Basophils	0.5%-1.5%	Normal during infection

BOX 29-6 Nursing Diagnostic Process

Risk for Infection

Assessment Activities	Defining Characteristics
Check results of laboratory tests.	WBC count 5000/mm^3
Review current medications.	Patient receiving antibiotics and oral antidiabetic medications
Identify potential sites of infection.	IV catheter in right forearm, in place for 3 days
	Foley catheter draining cloudy amber-colored urine

IV, Intravenous; *WBC,* white blood cell.

such as *Risk for Infection* require careful identification of relevant risk factors.

◆ Planning

Goals and Outcomes. The patient's care plan is based on each nursing diagnosis and related factor (see the Nursing Care Plan). Develop a plan that sets realistic outcomes so interventions are purposeful, direct, and measurable. For example, when you care for a patient with broken skin and obesity, the nursing diagnosis of *Risk for Infection* would require you to implement skin and wound care measures to promote healing. The expected outcome of "absence of drainage" sets a target for measuring the patient's improvement. Common goals of care applicable to patients with infection often include the following:

- Preventing further exposure to infectious organisms
- Controlling or reducing the extent of infection
- Maintaining resistance to infection
- Verbalizing understanding of infection prevention and control techniques (e.g., hand hygiene)

Patients often have multiple nursing diagnoses that are interrelated, and one diagnosis affects other diagnoses. A concept map for Mrs. Andrews helps to show the relationships among multiple nursing diagnoses (Figure 29-2).

Setting Priorities. Establish priorities for each diagnosis and related goals of care. For example, you are caring for a patient with cancer who develops an open wound and is unable to tolerate solid foods. The priority of administering therapies to promote wound healing such as improved nutritional intake overrides the goal of educating the patient to assume self-care therapies at home. When the patient's condition improves, the priorities change, and patient education will then become an essential intervention. Patient priorities can change quickly in the acute care environment.

Teamwork and Collaboration. The development of a care plan includes prevention and infection control practices provided by multiple disciplines. Select interventions in collaboration with the patient, the family caregiver, and health care providers such as the dietitian or respiratory therapist. Know the patient's sociocultural preferences to help you identify the most appropriate types of interventions (Box 29-7). In addition, consult with an expert in infection control in planning the patient's care. Before discharge consult with case management to complete a home assessment and identify home health needs. Case managers work with the patient, family, and home care services to ensure that a safe discharge plan is in place.

⊕ BOX 29-7 CULTURAL ASPECTS OF CARE

Implications for Infection Control and Isolation Procedures

Various cultural practices and beliefs present challenges to health care providers when infection control and isolation procedures are needed. Patients' health care practices and beliefs influence their decisions to seek treatment for an infection or to use methods to prevent infections. In the United States cities and rural areas have immigrant populations that hold on to the health care practices of their country of origin. Some of the immigrant population may come from war-torn countries where health care was limited and infections were rampant. In addition, some of these patients may fear isolation equipment, which for some may indicate that they have a deadly disease or that harm will come to them or their family. It is important to meet the cultural needs of the patients but also to integrate best practices related to infection control and, when needed, isolation procedures. Although gender-congruent caregivers are important for many cultures, the cultural aspects of care for infection control must expand beyond that premise.

Implications for Patient-Centered Care

- Identify the best method for communication and patient teaching for the patient and family. This may include a community elder, an interpreter, or a family member.
- Determine initially if the patient has any signs of fear, anxiety, or confusion about his condition and treatment plan.
- Reinforce that infection control and isolation procedures are designed for patient safety. Use simple language to explain.
- Explain each item used for infection control and isolation procedures and obtain feedback from the patient to determine his or her level of understanding.
- Be aware that in some cultures touch from a person who is not a family member is not appropriate. Thus prepare the patient by explaining why you need to touch and, when possible, ask permission. For example, "I need to check your arm that has an IV line. May I do that now?"
- If the patient seems fearful of the isolation equipment, continually reinforce why you are wearing the equipment.
- Culturally sensitive care is necessary to identify unique approaches to help patients who are on isolation precautions to understand why the precautions are necessary, answer any questions, and allay patient's and/or family's fear.

IV, Intravenous.

When care continues into the patient's home, the home care nurse plans to ensure that the home environment supports good infection prevention and control practices. For example, if a patient does not have running water yet requires wound care, even simple hand hygiene with soap and water is difficult to achieve. Home health nurses instruct patients to perform hand hygiene with either bottled water and soap or alcohol-based hand products.

◆ Implementation

By identifying and assessing a patient's risk factors and implementing appropriate measures, you can effectively reduce the risk of infection.

Health Promotion. Use your critical thinking skills to prevent an infection from developing or spreading. In the home and community settings, review with and teach patients and their family caregivers about ways to strengthen a potential host's defenses against infection. Nutrition support, rest, personal hygiene, maintenance of

◎ **NURSING CARE PLAN**

Risk for Infection

ASSESSMENT

Mrs. Andrews has diabetes mellitus, urinary incontinence, and degenerative disk disease. She had surgery on her lower spine late last night. She is currently experiencing pain along her incision and is having difficulty walking. Cody is the nursing student assigned to care for Mrs. Andrews. During hand-off report, Cody finds out that Mrs. Andrews needs to wear a brace when she is out of bed, is having difficulty turning herself when she is in bed, and needs incisional dressing change because of contamination from urine following an episode of incontinence. The surgeon comes in before Cody's assessment and removes the dressing, leaving the incision open to air. The physical therapist plans to help Mrs. Andrews transfer into a chair after breakfast.

Assessment Activities	*Findings/Defining Characteristics*[*]
Review Mrs. Andrews' chart for laboratory data that reflects infection (e.g., white blood cell [WBC] count).	The **WBC count is 9500.**
Inspect incision area.	**Incision** edges are slightly pink; edges approximated but edematous; no drainage noted.
Review risk factors for infection.	Has had **diabetes mellitus** for past 16 years; states blood sugars have been "poorly controlled" for the past year. Dietary assessment reflects malnutrition before surgery. Is **taking a glucocorticosteroid,** which reduces inflammation and suppresses the immune system.

[*]**Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Risk for infection

PLANNING

Goals	*Expected Outcomes (NOC)*[†]
	Immune Status
Mrs. Andrews will remain free from symptoms of infection.	Mrs. Andrews remains afebrile.
	Mrs. Andrews has no signs or symptoms of infection (e.g., incision intact; edges approximated; no redness, swelling, or drainage).
	Knowledge: Infection Management
Mrs. Andrews will describe ways to prevent infection before discharge.	Mrs. Andrews identifies signs and symptoms of infection by the end of today.
	Mrs. Andrews demonstrates appropriate hand hygiene before discharge.
	Mrs. Andrews identifies who will help assess incisional site when she goes home.

[†]Outcome classification labels from Moorhead S et al.: *Nursing outcomes classification (NOC),* ed 5, St Louis, 2013, Mosby.

INTERVENTIONS (NIC)[‡]	**RATIONALE**
Infection Protection	
Teach Mrs. Andrews how to perform hand hygiene correctly.	Meticulous hand hygiene reduces bacterial counts on the hands (Hass, 2014). Patient can easily come in contact with organisms in the health care environment that can cause infection.
Monitor Mrs. Andrews frequently to prevent urine contamination of the incision site.	Offer bedpan/restroom frequently to decrease risk for incontinence.
Provide Mrs. Andrews with incontinence panties that she wears at home.	Absorbent padding will wick away urine from Mrs. Andrew's incision.
Help Mrs. Andrews identify a family member to check the incision until it is healed and teach Mrs. Andrews and the family member signs and symptoms of infection.	Mrs. Andrews will be unable to visualize incision since it is on her back; she will need a family member to help monitor healing of the surgical site.

[‡]Intervention classification labels from Bulecheck GM et al.: *Nursing interventions classification (NIC),* ed 6, St Louis, 2013, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Compare Mrs. Andrews' body temperature with baseline.	Mrs. Andrews has an oral temperature of 38° C (100.4° F).	Mrs. Andrews is suspected to have infection at this time.
Ask Mrs. Andrews to describe signs and symptoms to report to health care provider.	Mrs. Andrews is unable to identify temperature range to report; unable to identify signs of wound infection.	Mrs. Andrews has minimal understanding of signs and symptoms to report. Will require additional instruction and include an information sheet on signs and symptoms of infection.
Observe for signs of infection at incisional site (e.g., redness, warmth, and wound discharge).	Incision shows has signs of infection: redness, warmth, and a small amount of tan drainage.	Incision is showing signs of infection at this time.

CONCEPT MAP

Nursing diagnosis: Anxiety
- Change in health status
- States is worried about getting an infection
- Family member states patient "seems more rattled than usual"

Interventions
- Teach relaxation techniques
- Develop therapeutic relationship with patient
- Encourage patient to voice fears and concerns

Nursing diagnosis: Impaired skin integrity
- Recent surgery
- Incision along spine
- Needs to wear brace when out of bed
- Urinary incontinence

Interventions
- Assess skin carefully along incision and at pressure points around brace
- Turn and reposition patient at least every 2 hours when in bed
- Consult with registered dietitian to optimize nutritional intake
- Check frequently for toileting to prevent incontinence
- Provide incontinence pads or pants

Primary health problem: Degenerative disk disease with recent corrective surgery, diabetes mellitus, urinary incontinence
Priority assessments: Wound status, mobility, coping strategies

Nursing diagnosis: Impaired physical mobility
- Changes in gait
- Difficulty turning self in bed

Interventions
- Consult with physical therapist to begin rehabilitation as soon as possible following surgery
- Apply brace when getting patient out of bed
- Treat pain as needed to encourage increased activity

Nursing diagnosis: Risk for infection
- Taking glucocorticosteroids to decrease inflammatory response
- Uncontrolled diabetes mellitus
- Urinary incontinence

Interventions
- Perform meticulous hand hygiene
- Assess incision at least once a shift for signs of infection
- Teach patient to report signs of infection to health care provider
- Keep patient clean and dry

——— Link between medical diagnosis and nursing diagnosis   - - - - Link between nursing diagnoses

FIGURE 29-2 Concept map for Mrs. Andrews.

physiological protective mechanisms, and recommended immunizations protect patients. Explain infection prevention and control principles such as hand hygiene and methods for proper disposal of medical waste. Based on your assessment of a patient's cultural practices, integrate infection prevention and control measures into the patient's daily lifestyle practices.

Nutrition. Nutritional requirements for your patients will vary depending on their age and condition. A proper diet helps the immune system function and consists of a variety of foods from all food groups (see Chapter 45). Collaborate with registered dietitians, the patient, and the family to select the correct foods. Recommend ways to prepare foods that the patient will enjoy. Teach patients the importance of a proper diet in maintaining immunity and preventing infection.

Hygiene. Personal hygiene measures (see Chapter 40) reduce microorganisms on the skin and maintain the integrity of mucous membranes such as the mouth and vagina. Patients and family caregivers need to understand techniques for cleansing the skin and how to avoid spread of microorganisms in body secretions or excretions. For example, teach female patients how to wash their perineum from clean to dirty, from the urethra down toward the rectum, using a clean washcloth with each wipe.

Immunization. Immunization programs for infants and children have decreased the occurrence of childhood diphtheria, whooping cough, and measles. For example, according to the CDC (2015d), DTaP vaccination for whooping cough is effective for up to 8 or 9 out of 10 children who receive it, but protection fades over time. About 7 out of

10 children are fully protected 5 years after getting their last dose of DTaP. Getting a vaccine is recommended because children who still get whooping cough are much more likely to have a mild illness compared with those who never received the vaccine (CDC, 2015d). More recently developed vaccines for hepatitis A and chickenpox (varicella) provide immunity to adults and children. Advise parents about the advantages of immunizations; but also make them aware of the contraindications for certain vaccines, especially in pregnant and lactating women. You can access the most current immunization schedule at http://www.cdc.gov/vaccines/schedules/hcp/index.html.

Adequate Rest and Regular Exercise. Adequate rest and regular exercise help prevent infection. Physical exercise increases lung capacity, circulation, energy, and endurance. It also decreases stress and improves appetite, sleeping, and elimination. Help patients with a schedule that balances regular exercise with the need for rest and sleep.

Acute Care.
Treatment of an infectious process includes eliminating the infectious organisms and supporting a patient's defenses. To identify the causative organisms, you will collect specimens of body fluids such as sputum or drainage from infected body sites for cultures. When the disease process or causative organism is identified, the health care provider prescribes the most effective treatment (e.g., antimicrobials).

Systemic infections require measures to prevent complications of fever (see Chapter 30). Maintaining intake of fluids prevents dehydration resulting from diaphoresis. The patient's increased metabolic rate requires an adequate nutritional intake, which may be provided through intravenous parenteral nutrition. Rest preserves energy for the healing process.

Localized infections often require measures to assist removal of debris to promote healing. You apply principles of wound care to remove infected drainage from wound sites and support the integrity of healing wounds (see Chapter 48). When changing a dressing, wear a mask and goggles or a mask with a face shield if splashing or spraying with blood or body fluids is anticipated. Apply gloves to reduce the transmission of microorganisms into the wound. Apply special dressings to facilitate removal of drainage and promote healing of wound margins. Sometimes a surgeon will insert drainage tubes to remove infected drainage from body cavities (see Chapter 48). Use medical and surgical aseptic techniques to manage wounds and ensure correct handling of all drainage or body fluids.

During the course of infection, support the patient's body defense mechanisms. For example, if a patient has diarrhea, maintain skin integrity by frequent cleansing, application of a skin-barrier cream, and frequent repositioning to prevent breakdown and the entrance of additional microorganisms. Other routine hygiene measures such as cleaning the oral cavity and bathing protect the skin and mucous membranes from invasion and overgrowth of organisms.

Medical Asepsis.
Asepsis is the absence of pathogenic (disease-producing) microorganisms. Aseptic technique refers to the practices/procedures that help reduce the risk for infection. The two types of aseptic technique are medical and surgical asepsis. Basic medical aseptic techniques break the chain of infection. Use these techniques for all patients, even when no infection is diagnosed. Aggressive preventive measures are highly effective in reducing HAIs. Hand hygiene, barrier techniques, and routine environmental cleaning are examples of **medical asepsis**. Principles of medical asepsis are also commonly followed in the home; examples are performing hand hygiene with soap and water before preparing food, after using the bathroom, or after touching what are interpreted as dirty objects. It is important to include cultural or social beliefs of the patient and family.

Control or Elimination of Infectious Agents. With the increased use of disposable equipment, nurses are often less aware of disinfection and sterilization procedures. The proper cleaning, disinfection, and sterilization of contaminated objects significantly reduce and/or eliminate microorganisms (CDC, 2008b; Rutala and Weber, 2014). In health care facilities a sterile processing department is responsible for the disinfection and sterilization of reusable supplies and equipment. However, nurses sometimes need to perform these functions in the home care setting. Many principles of cleaning and disinfection also apply to the home, so it becomes your role to educate patients and family caregivers on these techniques.

Cleaning. Cleaning is the removal of organic material (e.g., blood) or inorganic material (e.g., soil) from objects and surfaces (Rutala and Weber, 2014). In general, cleaning involves the use of water, a detergent/disinfectant, and proper mechanical scrubbing. Cleaning occurs before disinfection and sterilization procedures.

When an object comes in contact with an infectious or potentially infectious material, it is contaminated. If the object is disposable, it is discarded. Reusable objects need to be cleaned thoroughly before reuse and then either disinfected or sterilized according to manufacturer recommendations. Failure to follow manufacturer recommendations transfers liability from the manufacturer to the health care facility or agency if an infection results from improper processing.

Apply protective eyewear (or a face shield) and utility (dishwashing style) gloves when cleaning equipment that is soiled by organic material such as blood, fecal matter, mucus, or pus. Protective barriers provide protection from potentially infectious organisms. A brush and detergent or soap are necessary for cleaning. The following steps ensure that an object is clean:

1. Rinse the contaminated object or article with cold running water to remove organic material. Hot water causes the protein in organic material to coagulate and stick to objects, making removal difficult.
2. After rinsing, wash the object with soap and warm water. Soap or detergent reduces the surface tension of water and emulsifies dirt or remaining material. Rinse the object thoroughly.
3. Use a brush to remove dirt or material in grooves or seams. Friction dislodges contaminated material for easy removal. Open hinged items for cleaning.
4. Rinse the object in warm water.
5. Dry the object and prepare it for disinfection or sterilization if indicated by classification of the item (i.e., critical, semicritical, or noncritical).
6. The brush, gloves, and sink used to clean the equipment are considered contaminated and are cleaned and dried according to policy.

Disinfection and Sterilization. Disinfection and sterilization use both physical and chemical processes that disrupt the internal functioning of microorganisms by destroying cell proteins. **Disinfection** describes a process that eliminates many or all microorganisms, with the exception of bacterial spores, from inanimate objects (Rutala and Weber, 2014). There are two types of disinfection: (1) the disinfection of surfaces, and (2) high-level disinfection, which is required for some patient care items such as endoscopes and bronchoscopes. **Sterilization** eliminates or destroys all forms of microbial life, including spores (Rutala and Weber, 2014). Sterilization methods include processing items using steam, dry heat, hydrogen peroxide plasma, or ethylene oxide (ETO). The decision to clean, clean and disinfect, or sterilize depends on the intended use of a contaminated item (Box 29-8). Be familiar with the health care facility or agency policy and procedures for cleaning, handling, and delivering care items for eventual disinfection and sterilization. Workers in the central processing area who are

BOX 29-8 Categories for Sterilization, Disinfection, and Cleaning

Critical Items

Items that enter sterile tissue or the vascular system present a high risk of infection if they are contaminated with microorganisms, especially bacterial spores. *Critical items* must be *sterile*. These items include:
- Surgical instruments
- Cardiac or intravascular catheters
- Urinary catheters
- Implants

Semicritical Items

Items that come in contact with mucous membranes or nonintact skin also present a risk. These objects must be free of all microorganisms (except bacterial spores). *Semicritical items* must be *high-level disinfected (HLD)* or *sterilized.* These items include:
- Respiratory and anesthesia equipment
- Endoscopes
- Endotracheal tubes
- GI endoscopes
- Diaphragm fitting rings

After rinsing, dry items and store in a manner to protect from damage and contamination.

Noncritical Items

Items that come in contact with intact skin but not mucous membranes must be clean. *Noncritical items* must be *disinfected*. These items include:
- Bedpans
- Blood pressure cuffs
- Bedrails
- Linens
- Stethoscopes
- Bedside trays and patient furniture
- Food utensils

TABLE 29-5 Examples of Disinfection and Sterilization Processes

Characteristics	Examples of Use
Moist Heat	
Steam is moist heat under pressure. When exposed to high pressure, water vapor reaches a temperature above boiling point to kill pathogens and spores.	Autoclave sterilizes heat-tolerant surgical instruments and semi-critical patient care items.
Chemical Sterilants—High-Level Disinfection (HLD)	
A number of chemical disinfectants are used in health care. These include alcohols, chlorines, formaldehyde, glutaraldehyde, hydrogen peroxide, iodophors, phenolics, and quaternary ammonium compounds. Each product performs in a unique manner and is used for a specific purpose.	Chemicals disinfect heat-sensitive instruments and equipment such as endoscopes and respiratory therapy equipment.
Ethylene Oxide (ETO) Gas	
This gas destroys spores and microorganisms by altering the metabolic processes of cells. Fumes are released within an autoclave-like chamber. ETO gas is toxic to humans, and aeration time varies with products.	This gas sterilizes most medical materials.
Boiling Water	
Boiling is least expensive for use in the home. Bacterial spores and some viruses resist boiling. It is not used in health care facilities.	Boiling is commonly used in the home for items such as urinary catheters, suction tubes, and drainage collection devices.

specially trained in disinfection and sterilization perform most of the procedures. The following factors influence the efficacy of the disinfecting or sterilizing method:

- *Concentration of solution and duration of contact.* A weakened concentration or shortened exposure time lessens its effectiveness.
- *Type and number of pathogens.* The greater the number of pathogens on an object, the longer the required disinfecting time.
- *Surface areas to treat.* All dirty surfaces and areas need to be fully exposed to disinfecting and sterilizing agents. The type of surface is an important factor. Is the surface porous or nonporous?
- *Temperature of the environment.* Disinfectants tend to work best at room temperature.
- *Presence of soap.* Soap causes certain disinfectants to be ineffective. Thorough rinsing of an object is necessary before disinfecting.
- *Presence of organic materials.* Disinfectants become inactivated unless blood, saliva, pus, or body excretions are washed off.

Table 29-5 lists processes for disinfection and sterilization and their characteristics. Some delicate instruments requiring sterilization cannot tolerate steam and must be processed with gas or plasma.

Protection of the Susceptible Host. A patient's resistance to infection improves as you protect normal body defenses against infection. Intervene to maintain the normal reparative processes of the body (Box 29-9). Nurses also protect themselves and others through the use of isolation precautions.

Control or Elimination of Reservoirs of Infection. In order to control or eliminate the numbers and types of organisms in reservoir sites, eliminate sources of body fluids, drainage, or solutions that possibly harbor microorganisms. Eliminating reservoirs of infection (e.g., emptying urinary drainage bags), controlling portals of exit and entry (e.g., using antiseptic wipes on IV tubing ports), and avoiding actions that transmit microorganisms prevent bacteria from finding a new site in which to grow (Box 29-10). Be aware of the state regulations for the handling and disposal of medical (infectious) waste. Occupational Safety and Health Administration (OSHA) regulations address the handling and disposal of blood and body fluids that potentially pose a risk for the transmission of bloodborne pathogens. These regulations defer to state laws and regulations (OSHA, 2011b).

Control of Portals of Exit/Entry. To control organisms exiting via the respiratory tract, cover your mouth or nose when coughing or sneezing. Teach patients, health care staff, patient's families, and visitors about respiratory hygiene or **cough etiquette**. The use of posters and written material explaining cough etiquette to learners

<table>
<tr><td>

BOX 29-9 Infection Prevention and Control: Protecting the Susceptible Host

Protecting Natural Defense Mechanisms
- Regular bathing removes transient microorganisms from the surface of the skin. Lubrication helps keep the skin hydrated and intact. In some situations a chlorhexidine (CHG) wash is required if there is a risk for *methicillin-resistant Staphylococcus aureus* (MRSA) or other resistant bacteria (CDC, 2013b).
- Perform regular oral hygiene. Saliva contains enzymes that promote digestion and has a bactericidal action to maintain control of bacteria. Flossing removes tartar and plaque that cause germ infection.
- Maintenance of adequate fluid intake promotes normal urine formation and a resultant outflow of urine to flush the bladder and urethral lining of microorganisms.
- For patients who are physically dependent or immobilized, encourage routine coughing and deep breathing to keep lower airways clear of mucus.
- Encourage proper immunization of children or adult patients who are exposed to certain infectious microorganisms. Children are vaccinated for measles, mumps, rubella, chickenpox, diphtheria, and other vaccine-preventable diseases. Adults receive one booster of tetanus-diphtheria-acellular pertussis (Tdap), annual flu vaccine, and others as recommended by the Centers for Disease Control and Prevention (CDC) (2010a). Older adults should receive a pneumococcal vaccine and an annual influenza vaccine.

Maintaining Healing Processes
- Promote intake of adequate fluids and a well-balanced diet containing essential proteins, vitamins, carbohydrates, and fats. The nurse also uses measures to increase the patient's appetite.
- Promote a patient's comfort and sleep so energy stores are replaced daily.
- Help the patient learn techniques to reduce stress.

</td><td>

BOX 29-10 Infection Prevention and Control to Reduce Reservoirs of Infection

Bathing
- Use soap and water to remove drainage, dried secretions, or excess perspiration.

Dressing Changes
- Change dressings that become wet and/or soiled (see Chapter 48).

Contaminated Articles
- Place tissues, soiled dressings, or soiled linen in fluid-resistant bags for proper disposal.

Contaminated Sharps
- Place all needles, safety needles, and needleless systems into puncture-proof containers, which should be located at the site of use. Federal law requires the use of needle-safe technology. Blood tube holders are single use only (OSHA, 2012).

Bedside Unit
- Keep table surfaces clean and dry.

Bottled Solutions
- Do not leave bottled solutions open.
- Keep solutions tightly capped.
- Date bottles when opened and discard in 24 hours.

Surgical Wounds
- Keep drainage tubes and collection bags patent to prevent accumulation of serous fluid under the skin surface.

Drainage Bottles and Bags
- Wear gloves and protective eyewear if splashing or spraying with contaminated blood or body fluids is anticipated.
- Empty and dispose of drainage suction bottles according to agency policy.
- Empty all drainage systems on each shift unless otherwise ordered by a health care provider.
- Never raise a drainage system (e.g., urinary drainage bag) above the level of the site being drained unless it is clamped off.

</td></tr>
</table>

is beneficial. Cough etiquette has become more important because of concerns for transmission of respiratory infections such as *Mycobacterium tuberculosis,* severe acute respiratory syndrome (SARS), and H1N1 influenza (CDC, 2007, 2010b). The elements of a respiratory hygiene or cough etiquette is summarized in Table 29-6 (CDC, 2007).

Another way of controlling the exit of microorganisms is by using Standard Precautions (see Table 29-6) when handling body fluids such as urine, feces, and wound drainage. Wear clean gloves if there is a chance of contact with any blood or body fluids and perform hand hygiene after providing care. Be sure to bag contaminated items (e.g., linen) appropriately.

Many measures that control the exit of microorganisms also control their entrance. Maintaining the integrity of skin and mucous membranes reduces the chances of microorganisms reaching a host. Keep a patient's skin well lubricated by using lotion as appropriate. Patients who are immobilized and debilitated are particularly susceptible to skin breakdown. Do not position patients on tubes or objects that cause breaks in the skin. It is important to turn and position patients before their skin becomes reddened. Frequent oral hygiene prevents drying of mucous membranes. A water-soluble ointment keeps the patient's lips well lubricated.

After elimination instruct women to clean the rectum and perineum by wiping from the urinary meatus toward the rectum. Cleaning in a direction from the least to the most contaminated area helps reduce GU infections. Meticulous and frequent perineal care is especially important in older-adult women who wear disposable incontinence pads.

Another cause for entrance of microorganisms into a host is improper handling and management of urinary catheters and drainage sets (see Chapter 46). Keep the point of connection between a catheter and drainage tube closed and intact. As long as such systems are closed, their contents are considered sterile. Outflow spigots on drainage bags should also remain closed to prevent entrance of bacteria. Minimize movement of the catheter at the urethra by stabilizing it with tape or a securing device to reduce chances of microorganisms ascending the urethra into the bladder. Do not share urine-measuring containers among patients. Sometimes you care for patients with closed drainage systems that collect wound drainage, bile, or other body fluids. Make sure that the site from which a drainage tube exits remains clear of excess moisture or accumulated drainage. Keep all tubing connected throughout use and only open drainage receptacles when it is necessary to discard or measure the volume of drainage (see Chapter 48).

Control of Transmission. Effective prevention and control of infection requires you to remain aware of the modes of transmission of microorganisms and ways to control them. In any health care setting a patient usually has a personal set of care items. Sharing bedpans, urinals, bath basins, and eating utensils among patients easily leads to cross-infection. When using a stethoscope, always wipe off the bell,

diaphragm, and ear tips with a disinfectant such as an alcohol wipe before proceeding to the next patient. Ear tips are a common location for staphylococcal organisms (Whittington et al., 2009). In facilities where HAI diarrhea occurs, electronic thermometers are not recommended for rectal temperatures. You usually use oral or tympanic thermometers to assess temperature. Do not use electronic thermometers for patients on contact isolation.

Always be careful when handling exudate such as urine, feces, emesis, and blood. Contaminated fluids easily splash while being discarded in toilets or hoppers. Urinals and bedpans need to be emptied at water level to reduce the risk of splash or splatter, and gloves and protective eyewear are worn. Appropriately dispose of disposable soiled items in trash bags. Dispose of items contaminated with large amounts of blood in biohazard bags. Know the location of biohazard bags; it may differ among facilities. Handle laboratory specimens from all patients as if they were infectious and place them in designated biohazard containers or bags for transport or disposal. Because certain microorganisms travel easily through the air, do not shake linens or bedclothes. Dust with a treated or dampened cloth to prevent dust particles from entering the air.

To prevent transmission of microorganisms through individual contact, do not allow soiled items and equipment to touch your clothing. A common error is to carry dirty linen in the arms against your uniform. Use fluid-resistant linen bags or carry soiled linen with hands held out from the body. Cover laundry hampers and empty them before they become overloaded. **Never put clean or soiled linens on the floor.**

You will learn to follow **standard precautions** to prevent and control infection transmission. Standard precautions apply to contact with blood, body fluid, nonintact skin, and mucous membranes from all patients. These precautions protect patients and provide protection for health care workers.

Hand Hygiene. The most effective basic technique in preventing and controlling the transmission of infection is hand hygiene (see Skill 29-1 on pp. 471-473) (Mathur, 2011; WHO, 2009). **Hand hygiene** is a general term that applies to four techniques: handwashing, antiseptic hand wash, antiseptic hand rub, or surgical hand antisepsis. **Handwashing** is defined by the CDC (2008a) as the vigorous, brief rubbing together of all surfaces of lathered hands, followed by rinsing under a stream of warm water for 15 seconds. The fundamental principle behind handwashing is removing microorganisms mechanically from the hands and rinsing with water. Handwashing does not kill microorganisms. An antiseptic hand wash means washing hands with warm water and soap or other detergents containing an antiseptic agent, Some antiseptics kill bacteria and some viruses. An antiseptic hand rub means applying an antiseptic hand-rub product to all surfaces of the hands to reduce the number of microorganisms present. Ethanol-based hand antiseptics containing 60% to 90% alcohol appear to be the most effective against common pathogens found on the hands (CDC, 2008a). Alcohol-based products are more effective for standard handwashing or hand antisepsis (nonsoiled hands) by health care workers than regular soap or antimicrobial soaps (CDC, 2008a). Surgical hand antisepsis is an antiseptic hand-wash or hand-rub technique that surgical personnel perform before surgery to eliminate transient and reduce resident hand flora. Antiseptic detergent preparations have persistent antimicrobial activity (CDC, 2008a; WHO, 2009).

According to the World Health Organization (2009), hand cleansing practices are likely established in the first 10 years of a person's life. This imprinting affects an individual's attitudes about hand cleansing throughout life. This is called inherent hand hygiene (WHO, 2009). Attitudes toward handwashing in situations such as the delivery of

health care are called elective handwashing practices (WHO, 2009). In many patient populations, inherent and elective handwashing are influenced by cultural factors. Thus hand hygiene is often performed for hygienic reasons, rituals, and symbolic reasons. It is important to learn the significance hand hygiene holds for an individual.

The use of alcohol-based hand rubs is recommended by the CDC (2008a) to improve hand hygiene practices, protect health care workers' hands, and reduce the transmission of pathogens to patients and personnel in health care settings. Alcohols have excellent germicidal activity and are as effective as soap and water. However, alcohol-based hand antiseptics are not effective on hands that are visibly dirty or are contaminated with organic materials (CDC, 2013). Boyce et al. (2002) and the WHO (2009) recommend the following hand hygiene guidelines:

1. When hands are visibly dirty, when hands are soiled with blood or other body fluids, before eating, and after using the toilet, wash hands with water and either a nonantimicrobial or antimicrobial soap.
2. Wash hands if exposed to spore-forming organisms such as *C. difficile, Bacillus anthracis, or Norovirus* (CDC, 2014).
3. If hands are not visibly soiled (WHO, 2009), use an alcohol-based, waterless antiseptic agent for routinely decontaminating hands in the following clinical situations:
   - Before, after, and between direct patient contact (e.g., taking a pulse, lifting a patient)
   - Before putting on sterile gloves and before inserting invasive devices such as a peripheral vascular catheter or urinary catheter
   - After contact with body fluids or excretions, mucous membranes, nonintact skin, and wound dressings (even if gloves are worn)
   - When moving from a contaminated to a clean body site during care
   - After contact with surfaces or objects in the patient's room (e.g., overbed table, IV pump)
   - After removing gloves (CDC, 2008a)

Remember, contaminated hands of health care workers are a primary source of infection transmission in health care settings. It is recommended that health care workers have well-manicured nails and refrain from wearing artificial nails to reduce microorganism transmission.

Infection can easily be transmitted by visitors of patients in health care settings. A study by Birnbach (2012) and colleagues showed that a coordinated effort is needed to increase visitor hand hygiene compliance, including an evaluation of access to an alcohol-based hand sanitizer, education of visitors on the importance of hand hygiene, and evaluation of corresponding changes in hand hygiene behavior. Instruct patients and visitors about proper hand hygiene technique, the reason for it, and the times for performing it. If health care is to continue at home, teach patients and family caregivers to wash their hands before eating or handling food; after handling contaminated equipment, linen, or organic material; and after elimination. In health care settings, encourage visitors to wash their hands before eating or handling food; after coming in contact with infected patients; and after handling contaminated equipment, patient furniture, or organic material (Gould et al., 2011).

You are responsible for providing the patient and family with a safe environment. Recently the CDC (2015e) launched its Clean Hands Save Lives Campaign. It highlights for consumers the five simple and effective steps (Wet, Lather, Scrub, Rinse, Dry) to take to reduce the spread of diarrheal and respiratory illnesses and thus to stay healthy. Many hospitals encourage patients to follow the recommendations

of TJC's "Speak Up" campaign. TJC together with the Centers for Medicare and Medicaid Services urge patients to take a role in preventing health care errors by becoming active, involved, and informed participants on the health care team. The program features brochures, posters, and buttons on a variety of patient safety topics. One recommendation is to have patients speak up to be sure the health care provider has cleaned his or her hands or wears gloves when providing care.

The effectiveness of infection prevention practices such as hand hygiene depends on the conscientiousness and consistency in using proper technique by all health care providers. It is human nature to forget key procedural steps or, when hurried, to take shortcuts that break aseptic procedures. However, failure to comply with basic

procedures places patients at risk for infections that can seriously impair recovery or lead to death.

Isolation and Isolation Precautions. In 2007 the Hospital Infection Control Practices Advisory Committee (HICPAC) of the CDC published revised guidelines for isolation precautions. HICPAC recommended that facilities modify the guidelines according to need and as dictated by federal, state, or local regulations. The guidelines contain recommendations for respiratory hygiene/cough etiquette as part of Standard Precautions. The CDC recommendations contain two tiers of precautions (Table 29-6). The first and most important tier is called *Standard Precautions*, which are designed to be used for the care of all patients, in all settings, regardless of risk or presumed infection

---

TABLE 29-6 Centers for Disease Control and Prevention Isolation Guidelines

Standard Precautions (Tier One) for Use with All Patients

- Standard precautions apply to blood, blood products, all body fluids, secretions, excretions (except sweat), nonintact skin, and mucous membranes.
- Perform hand hygiene before, after, and between direct contact with patients. (Examples of between-contact activities are cleaning hands after a patient care activity, moving to a non–patient care activity, and cleaning hands again before returning to perform patient contact.)
- Perform hand hygiene after contact with blood, body fluids, mucous membranes, nonintact skin, secretions, excretions, or wound dressings; after contact with inanimate surfaces or articles in a patient room; and immediately after gloves are removed.
- When hands are visibly soiled or contaminated with blood or body fluids, wash them with either a nonantimicrobial or an antimicrobial soap and water.
- When hands are not visibly soiled or contaminated with blood or body fluids, use an alcohol-based, waterless antiseptic agent to perform hand hygiene (WHO, 2009).
- Wash hands with nonantimicrobial soap and water if contact with spores (e.g., *Clostridium difficile*) is likely to have occurred.
- Do not wear artificial fingernails or extenders if duties include direct contact with patients at high risk for infection and associated adverse outcomes.
- Wear gloves when touching blood, body fluids, secretions, excretions, nonintact skin, mucous membranes, or contaminated items or surfaces is likely. Remove gloves and perform hand hygiene between patient care encounters and when going from a contaminated to a clean body site.
- Wear personal protective equipment (PPE) when the anticipated patient interaction indicates that contact with blood or body fluids may occur.
- A private room is unnecessary unless the patient's hygiene is unacceptable (e.g., uncontained secretions, excretions, or wound drainage).
- Discard all contaminated sharp instruments and needles in a puncture-resistant container. Health care facilities must make available needleless devices. Any needles should be disposed of uncapped, or a mechanical safety device is activated for recapping.
- *Respiratory hygiene/cough etiquette:* Have patients cover the nose/mouth when coughing or sneezing; use tissues to contain respiratory secretions and dispose in nearest waste container; perform hand hygiene after contacting respiratory secretions and contaminated objects/materials; contain respiratory secretions with procedure or surgical mask; spatial separation of at least 3 feet away from others if coughing.

Transmission-Based Precautions (Tier Two) for Use with Specific Types of Patients

Category	Infection/Condition	Barrier Protection
Airborne precautions (droplet nuclei smaller than 5 microns)	Measles, chickenpox (varicella), disseminated varicella zoster, pulmonary or laryngeal tuberculosis	Private room, negative-pressure airflow of at least 6 to 12 exchanges per hour via high-efficiency particulate air (HEPA) filtration; mask or respiratory protection device, N95 respirator (depending on condition)
Droplet precautions (droplets larger than 5 microns; being within 3 feet of the patient)	Diphtheria (pharyngeal), rubella, streptococcal pharyngitis, pneumonia or scarlet fever in infants and young children, pertussis, mumps, *Mycoplasma* pneumonia, meningococcal pneumonia or sepsis, pneumonic plague	Private room or cohort patients; mask or respirator required (depending on condition) (refer to agency policy)
Contact precautions (direct patient or environmental contact)	Colonization or infection with multidrug-resistant organisms such as VRE and MRSA, *Clostridium difficile*, shigella, and other enteric pathogens; major wound infections; herpes simplex; scabies; varicella zoster (disseminated); respiratory syncytial virus in infants, young children, or immunocompromised adults	Private room or cohort patients (see agency policy), gloves, gowns (Patients may leave their room for procedures or therapy if infectious material is contained or covered, placed in a clean gown, and if hands are cleaned.)
Protective environment	Allogeneic hematopoietic stem cell transplants	Private room; positive airflow with 12 or more air exchanges per hour; HEPA filtration for incoming air; mask to be worn by patient when out of room during times of construction in area

Adapted from Centers for Disease Control and Prevention, Hospital Infection Control Practice Advisory Committee: Guidelines for isolation precautions in hospitals, *MMWR Morb Mortal Wkly Rep* 57/RR-16:39, 2007.
MRSA, Methicillin-resistant *Staphylococcus aureus; VRE,* vancomycin-resistant enterococcus.

status. Standard Precautions are the primary strategies (including barrier precautions) for prevention of infection transmission and apply to contact with blood, body fluids, nonintact skin, mucous membranes, and equipment or surfaces contaminated with potentially infectious materials. Basically, in the acute care setting a nurse will follow standard precautions in all aspects of care. This includes barrier precautions and the appropriate use of PPE such as gowns, gloves, masks, eyewear, and other protective devices or clothing. The choice of barriers depends on the task being performed and the patient's disease. Standard precautions applies to all patients because every patient has the potential to transmit infection via blood and body fluids, and the risk for infection transmission is unknown. Respiratory hygiene/cough etiquette applies to any person with signs of respiratory infection, including cough, congestion, rhinorrhea, or increased production of respiratory secretions when entering a health care site. Educating health care staff, patients, and visitors to follow respiratory hygiene/cough etiquette protect both patients and health care workers.

The second tier of precautions (see Table 29-6) includes precautions designed for the care of patients who are known or suspected to be infected or colonized with microorganisms transmitted by droplet, airborne, or contact routes (CDC, 2007; Brisko, 2009). There are four types of transmission-based precautions, which are based on the mode of transmission of a disease: **Airborne, Droplet, Contact,** and **Protective Environment Precautions.** These precautions are for patients with highly transmissible pathogens. The protective environment category is designed for patients who have undergone transplants and gene therapy (CDC, 2007).

- *Contact precautions:* Used for direct and indirect contact with patients and their environment. Direct contact refers to the care and handling of contaminated body fluids. Contact precautions require a gown and gloves. An example includes blood or other body fluids from an infected patient that enter the health care worker's body through direct contact with compromised skin or mucous membranes. Indirect contact involves the transfer of an infectious agent through a contaminated intermediate object such as contaminated instruments or hands of health care workers. The health care worker may transmit microorganisms from one patient site to another if hand hygiene is not performed between patients (CDC, 2007).
- *Droplet precautions:* Focus on diseases that are transmitted by large droplets (greater than 5 microns) expelled into the air and by being within 3 feet of a patient. Droplet precautions require the wearing of a surgical mask when within 3 feet of the patient, proper hand hygiene, and some dedicated-care equipment. An example is a patient with influenza.
- *Airborne precautions:* Focus on diseases that are transmitted by smaller droplets, which remain in the air for longer periods of time. This requires a specially equipped room with a negative air flow referred to as an *airborne infection isolation room.* Air is not returned to the inside ventilation system but is filtered through a high-efficiency particulate air (HEPA) filter and exhausted directly to the outside. All health care personnel wear an N95 respirator every time they enter the room.
- *Protective environment:* Focuses on a very limited patient population. This form of isolation requires a specialized room with positive airflow. The airflow rate is set at greater than 12 air exchanges per hour, and all air is filtered through a HEPA filter. Patients must wear masks when out of their room during times of construction in area.

Health care facilities are required to have the capability of isolating patients. However, not all communicable diseases require placing a patient in a special private room. You can conduct many isolation practices in standard rooms using barrier precautions.

Because of the resurgence of TB, the CDC (2007) developed guidelines to prevent its transmission to health care workers and stresses the importance of isolation for the patient with known or suspected TB in a special negative pressure room. Close the doors to the patient's room to control direction of airflow. You must wear a special high-filtration particulate respirator on entering a respiratory isolation rooms. A respirator must be fitted to your facial size and characteristics. When worn correctly, particulate respirators and masks have a tighter face seal and filter at a higher level than routine surgical masks.

Multidrug-resistant organisms (MDROs) such as methicillin-resistant *Staphylococcus aureus* (MRSA), vancomycin-resistant enterococcus (VRE) and *Clostridium difficile* (*C. diff*) are more common as a cause of colonization and HAIs. MDROs have developed a resistance to one or more broad spectrum antibiotics, making the organisms hard to treat effectively. Major efforts have been in place for a number of years to reduce the incidence of HAIs caused by these dangerous organisms. For example, evidence shows that the percentage of central line bloodstream infections (see Chapter 42) caused by MRSA, VRE, and gram-negative bacteria have declined (CDC, 2011b). Unlike MRSA and VRE, *C. difficile* (which is transmitted by the fecal-oral route) is harder to eliminate from the environment. It is a spore-forming microorganism, meaning it can remain on surfaces (e.g., bedside table, stethoscope) in a dormant state for long periods of time. To reduce the risk of cross-contamination among patients, use Contact Precautions in addition to Standard Precautions when caring for patients with MDROs.

Regardless of the type of isolation or barrier protection you use, follow these basic principles when caring for patients:

- Understand how certain diseases are transmitted and which protective barriers to use.
- Use thorough hand hygiene before entering and leaving the room of a patient in isolation.
- Dispose of contaminated supplies and equipment in a manner that prevents spread of microorganisms to other people as indicated by the mode of transmission of the organism.
- Protect all people who might be exposed during transport of a patient outside the isolation room.

Psychological Implications of Isolation. The psychological effects of being in an isolation room must be considered in your care of patients. Many patients find positive aspects of being accommodated in a single room; however, the overall experience of isolation is commonly viewed negatively (Barratt, 2010). Isolation imposes barriers to the expression of a patient's identity and normal interpersonal relationships and affects the delivery of quality care. When a patient requires isolation in a private room, a sense of loneliness sometimes develops because normal social relationships become disrupted. This situation can be psychologically harmful, especially for children. A study noted that patients in isolation suffered more depression and anxiety and were less satisfied with their care (Abad et al., 2010). Patients' body images become altered as a result of the infectious process. Some feel unclean, rejected, lonely, or guilty. Infection prevention and control practices further intensify these beliefs of difference or undesirability. Isolation disrupts normal social relationships with visitors and caregivers. Take the opportunity to listen to a patient's concerns or interests. If you rush care or show a lack of interest in a patient's needs, he or she feels rejected and even more isolated.

Before you institute isolation measures, the patient and family need to understand the nature of the disease or condition, the purposes of isolation, and steps for following specific precautions. If they are able to participate in maintaining infection prevention and control

practices, the chances of reducing the spread of infection increase. Teach the patient and family to perform hand hygiene and use barrier protection if appropriate. Demonstrate each procedure; be sure to give the patient and family an opportunity for practice. It is also important to explain how infectious organisms are transmitted so the patient and family understand the difference between contaminated and clean objects. Explaining and demonstrating these procedures, especially hand hygiene, help the family to consistently practice correct hand hygiene and prescribed isolation measures (Gould et al., 2011).

Take measures to improve a patient's sensory stimulation during isolation. Make sure that the room environment is clean and pleasant. Open drapes or shades and remove excess supplies and equipment. Listen to the patient's concerns or interests. Mealtime is a particularly good opportunity for conversation. Providing comfort measures such as repositioning, a back massage, or a warm sponge bath increase physical stimulation. Depending on the patient's condition, encourage him or her to walk around the room or sit up in a chair. Recreational activities such as board games, reading, or cards are options for keeping a patient mentally stimulated.

Explain to the family the patient's risk for depression or loneliness (Abad et al., 2010). Encourage visiting family members to avoid expressions or actions that convey revulsion or disgust related to infection prevention and control practices. Discuss ways to provide meaningful stimulation.

The Isolation Environment. Private rooms used for isolation sometimes provide negative-pressure airflow to prevent infectious particles from flowing out of a room to other rooms and the air handling system. Special rooms with positive-pressure airflow are also used for highly susceptible immunocompromised patients such as recipients of transplanted organs. On the door or wall outside the room a nurse posts a card listing precautions for the isolation category in use according to health care facility policy. The card is a handy reference for health care personnel and visitors and alerts anyone who might enter the room accidentally that special precautions must be followed.

An area immediately outside an isolation room or an adjoining anteroom needs to contain hand hygiene and PPE supplies. Soap and antiseptic (antimicrobial) solutions are also available. Personnel and visitors perform hand hygiene before entering a patient's room and again before leaving the room. If toilet facilities are unavailable, there are special procedures for handling portable commodes, bedpans, or urinals.

All patient care rooms, including those used for isolation, should contain an impervious bag for soiled or contaminated linen and a trash container with plastic liners. Impervious receptacles prevent transmission of microorganisms by preventing leaking and soiling of the outside surface. A disposable rigid container needs to be available in the room to discard used sharps such as safety needles and syringes.

Remain aware of infection prevention and control techniques while working with patients in protected environments. You need to feel comfortable performing all procedures and yet remain conscious of infection prevention and control principles. Depending on the microorganism and mode of transmission, evaluate which articles or equipment to take into an isolation room. For example, the CDC (2007) recommends the dedicated use of articles such as stethoscopes, sphygmomanometers, and thermometers in the isolation room of a patient infected or colonized with VRE. Do not use these devices on other patients unless they are first adequately cleaned and disinfected. Box 29-11 describes the procedures to perform when using shared equipment.

Personal Protective Equipment. The PPE, specialized clothing or equipment (e.g., gowns, masks or respirators, protective eyewear and gloves) that you wear for protection against exposure to infectious materials, should be readily available in a patient care area (CDC, 2007). You choose the equipment to use depending on the task to be performed.

Gowns. The primary reason for gowning is to prevent soiling clothes during contact with a patient. Gowns or cover-ups protect health care personnel and visitors from coming in contact with infected material and blood or body fluids. Gowns are often required, depending on the expected amount of exposure to infectious material. Gowns used for barrier protection are made of a fluid-resistant material. Change gowns immediately if damaged or heavily contaminated.

Isolation gowns usually open at the back and have ties or snaps at the neck and waist to keep the gown closed and secure. Gowns need to be long enough to cover all outer garments. Long sleeves with tight-fitting cuffs provide added protection. No special technique is required for applying clean gowns as long as they are fastened securely. However, carefully remove gowns to minimize contamination of the hands and uniform and discard them after removal.

BOX 29-11 PROCEDURAL GUIDELINES

Caring for a Patient on Isolation Precautions

Delegation Considerations

The skill of caring for a patient on isolation precautions can be delegated to nursing assistive personnel (NAP). However, it is the nurse who assesses the patient's status and isolation indications. Instruct NAP about:
- Reason patient is on isolation precautions.
- Precautions about bringing equipment into the patient's room.
- Special precautions regarding individual patient needs such as transportation to diagnostic tests.

Equipment

Personal protective equipment (PPE) determined by type of isolation—gloves, gowns, masks, protective eyewear, or face shield—that may be needed; supplies depend on procedures performed in room; sharps container; disposable blood pressure (BP) cuff.

Steps
1. Assess isolation indications (e.g., patient's medical history for exposure, laboratory tests, and wound drainage).
2. Review laboratory test results to identify type of microorganism for which the patient is isolated and if patient is immunocompromised.
3. Review agency policies and precautions necessary for the specific isolation system and consider care measures you will perform while in patient's room.
4. Review nurses' notes or speak with colleagues regarding patient's emotional state and adjustment to isolation.
5. Determine if patient has latex allergy to avoid sensitivity or allergic reaction.
6. Perform hand hygiene and prepare all equipment that you need to take into patient's room. In some cases equipment remains in the room (stethoscope

Continued

or BP cuff). Decide which isolation equipment is necessary before entering the patient's room. For example, decide if you need a gown and gloves for a patient in contact precautions or a special respirator mask for a patient on airborne precautions.

7. Prepare for entrance into isolation room:
   a. Apply cover gown, being sure that it covers all outer garments. Pull sleeves down to wrist. Tie securely at neck and waist (see illustration).

STEP 7a Tie gown at waist.

   b. Apply either surgical mask or fitted respirator around mouth and nose. (Type depends on type of precautions and agency policy.) The nurse must have a medical evaluation and be fit tested before using a respirator (OSHA, 2011a).
   c. If needed, apply eyewear or goggles snugly around face and eyes. If prescription glasses are worn, side shield may be used.
   d. Apply clean gloves. (NOTE: Wear unpowdered latex-free gloves if patient has a history of latex allergy.) Wear gloves within gown; bring glove cuffs over edge of gown sleeves (see illustration).

STEP 7d Apply gloves over gown sleeves.

8. Enter patient's room. Arrange supplies and equipment. (If equipment will be removed from room for reuse, place on clean paper towel.)
9. Explain purpose of isolation and necessary precautions to patient and family. Offer opportunity to ask questions. Discuss types of activities patient may wish to try to stay occupied. Assess for evidence of emotional problems that can occur from isolation.

10. Assess vital signs (see Chapter 30).
    a. If patient is infected or colonized with a resistant organism (e.g., VRE, MRSA, or C. diff), equipment remains in room. This includes stethoscope and BP cuff.
    b. If stethoscope is to be reused, clean diaphragm or bell with alcohol. Set aside on clean surface.
    c. Use individual electronic or disposable thermometer.

    CLINICAL DECISION: If disposable thermometer indicates a fever, assess for other signs/symptoms. Confirm fever using an alternative thermometer. Do not use electronic thermometer if patient is suspected or confirmed to have *Clostridium difficile* (Cohen et al., 2010)

11. Administer medications (see Chapter 32).
    a. Give oral medication in wrapper or cup.
    b. Dispose of wrapper or cup in plastic-lined receptacle.
    c. Wear gloves when administering an injection.
    d. Discard safety needle and syringe or uncapped needle into sharps container.
    e. Place reusable syringe (e.g., Carpujet) on a clean towel for eventual removal and disinfection.
    f. If you are not wearing gloves and hands come into contact with contaminated article or body fluids, perform hand hygiene as soon as possible.
12. Administer hygiene, encouraging patient to discuss questions or concerns about isolation. Provide informal teaching at this time.
    a. Avoid allowing gown to become wet. Carry wash basin out away from gown; avoid leaning against any wet surface.
    b. Remove linen from bed; avoid contact with gown. Place in linen bag according to agency policy.
    c. Provide clean bed linen and a set of towels.
    d. Change gloves and perform hand hygiene if they become solid and further care is necessary.
13. Collect specimens.
    a. Place specimen containers on clean paper towel in patient's bathroom. Follow procedure for collecting specimen of body fluids.
    b. Transfer specimen to container without soiling outside of container. Place container in plastic bag and place label on outside of bag or per agency policy. Label specimen in front of patient (TJC, 2016).
    c. Perform hand hygiene and reglove if additional procedures are needed.
    d. Check label on specimen for accuracy (warning labels are often used, depending on agency policy). Send to laboratory. Label containers with a biohazard label (see illustration).

STEP 13d Specimen container placed in biohazard bag.

14. Dispose of linen and trash bags as they become full.
   a. Use sturdy, moisture-resistant single bags to contain soiled articles. Use double bag if outside of bag is contaminated.
   b. Tie bags securely at top in knot (see illustration).

STEP 14b Tie trash bag securely.

15. Remove all reusable equipment. Clean any contaminated surfaces (see health care facility or agency policy).
16. Resupply room as needed. Have a staff member outside isolation room hand you new supplies.
17. Explain to patient when you plan to return to room. Ask whether patient requires any personal care items, books, or magazines.
18. Leave isolation room. The order for removing PPE depends on what was needed for the type of isolation. The sequence listed is based on full PPE being required.
   a. Remove gloves. Remove one glove by grasping cuff and pulling glove inside out over hand. With ungloved hand tuck finger inside cuff of remaining glove and pull it off, inside out (see illustration).

STEP 18a Remove glove.

   b. Remove eyewear/face shield or goggles.
   c. Untie waist and neck strings of gown. Allow gown to fall from shoulders. Remove hands from sleeves without touching outside of gown. Hold gown inside at shoulder seams and fold inside out. Discard in laundry bag if fabric or in trash can if gown is disposable.
   d. Remove mask: If mask loops over your ears, remove from ears and pull away from face. For a tie-on mask, untie *top* mask strings; hold strings; untie bottom strings, pull mask away from face, and drop it into trash receptacle. Do not touch outer surface of mask (see illustrations).

STEP 18d A, Untie top strings of mask. **B,** Drop mask into trash.

   e. Perform hand hygiene.
   f. Leave room and close door if necessary. (Make sure that door is closed if patient is on airborne precautions.)
   g. Dispose of all contaminated supplies and equipment in a manner that prevents spread of microorganisms to other people (see health care facility or agency policy).

Masks. Masks provide respiratory protection. Wear full-face protection (with eyes, nose, and mouth covered) when you anticipate splashing or spraying of blood or body fluid into the face. Also wear masks when working with a patient placed on airborne or droplet precautions. If a patient is on airborne precautions for TB, apply an OSHA-approved respirator-style mask. The mask protects you from inhaling microorganisms and small-particle droplet nuclei that remain suspended in the air from a patient's respiratory tract. The surgical mask protects a wearer from inhaling large-particle aerosols that travel short distances (3 feet). When caring for patients on droplet or airborne precautions, apply a mask (surgical or respirator) when entering the isolation room.

At times a patient who is susceptible to infection wears a mask to prevent inhalation of pathogens. Patients on droplet or airborne precautions who are transported outside of their rooms need to wear a surgical mask to protect other patients and personnel. Masks prevent transmission of infection by direct contact with mucous membranes (CDC, 2005a). A mask discourages the wearer from touching the eyes, nose, or mouth (Box 29-12).

A properly applied mask fits snugly over the mouth and nose so pathogens and body fluids cannot enter or escape through the sides. If a person wears glasses, the top edge of the mask fits below the glasses so they do not cloud over as the person exhales. Keep talking to a minimum while wearing a mask to reduce respiratory airflow. A mask that has become moist does not provide a barrier to microorganisms and is ineffective. You need to discard it. Never reuse a disposable mask. Warn patients and family members that a mask can cause a sensation of smothering. If family members become uncomfortable, they should leave the room and discard the mask.

Specially fitted respiratory protective devices (N95 respirator masks) are required when caring for patients on airborne precautions such as patients with known or suspected TB (Figure 29-3) (CDC, 2005a). The mask must have a higher filtration rating than regular surgical masks and be fitted snugly to prevent leakage around the sides. Be aware of health care facility policy regarding the type of respiratory protective device required. Special fit testing is required to establish the size and ability of the nurse to wear this type of mask (CDC, 2005a).

Eye Protection. Use either special glasses or goggles when performing procedures that generate splash or splatter. Examples of such procedures include irrigation of a large abdominal wound or insertion of an arterial catheter when the nurse assists a health care provider. A

BOX 29-12 PROCEDURAL GUIDELINES

Applying a Surgical Type of Mask

Delegation Considerations
The skill of applying a surgical mask can be delegated when NAP are trained in required sterile procedure. The nurse informs NAP to:
- Put on the mask following the appropriate steps.
- Change the mask if it becomes moist or contaminated.
- Remove the mask when leaving the patient's room.

Equipment
Disposable mask

Steps
1. Find top edge of mask (some have a thin metal strip along edge). Pliable metal fits snugly against bridge of nose. Others offer an occlusive fit that does not require an adjustment.
2. Hold mask by top two strings or loops. Secure two top ties at top of back of head (see illustration), with ties above ears. (*Alternative:* Slip loops over each ear.)

STEP 2 Securing top two ties of a tie-on mask.

3. Tie two lower ties snugly around neck with mask well under chin (see illustration).

STEP 3 Securing lower ties of a tie-on mask.

4. Gently pinch upper metal band around bridge of nose.
   NOTE: Change mask if wet, moist, or contaminated.
5. Remove mask by untying *bottom* mask strings and then top strings; pull mask away from face and drop into trash receptacle. (Do not touch outer surface of mask.)

nurse who wears prescription glasses uses removable, reusable, or disposable side shields over them (OSHA, 2011b). Eyewear is available in the form of plastic glasses or goggles. The eyewear needs to fit snugly around the face so fluids cannot enter between the face and the glasses.

Gloves. Gloves help to prevent the transmission of pathogens by direct and indirect contact. The CDC (2007) notes that you need to wear clean gloves when touching blood, body fluid, secretions, excretions (except sweat), moist mucous membranes, nonintact skin, and contaminated items or surfaces. Change gloves and perform hand hygiene between tasks and procedures on the same patient after contact with material that contains a high concentration of microorganisms. Remove gloves promptly after use, before touching noncontaminated items and environmental surfaces, and before going to another patient. Perform hand hygiene immediately to avoid transfer of microorganisms to other patients or environments. Because of allergy or sensitivity to latex gloves, facilities provide nonlatex gloves to reduce the incidence of health care providers developing latex allergy or sensitivity. Most facilities are working to become latex free to protect health care providers and patients.

When full PPE is necessary, first perform hand hygiene, then apply a gown, apply mask and eyewear or goggles (as needed), and end with applying gloves. Clean gloves are easy to apply and fit either hand. Pull the cuffs of the glove up over the wrists or over the cuffs of the gown. If you notice a break or tear in a glove while providing care, change gloves. If you do not plan to have additional contact with the patient, reapplying gloves is unnecessary. Perform hand hygiene when gloves are removed.

Instruct family members visiting patients on isolation precautions how to apply gloves properly. Demonstrate application of gloves to family members and explain the reason for the use of gloves. Emphasize the importance of performing hand hygiene after removing gloves.

Specimen Collection. Many laboratory studies are often necessary when a patient is suspected of having an infectious or communicable disease (Box 29-13). You collect body fluids and secretions suspected of containing infectious organisms for culture and sensitivity tests. After a specimen is sent to a laboratory, the laboratory technologist identifies the microorganisms growing in the culture. Additional test results indicate antibiotics to which the organisms are resistant or sensitive. Sensitivity reports determine which antibiotics used in treatment are effective and need to be ordered for treatment.

Obtain all culture specimens using clean gloves and sterile equipment. Collecting fresh material such as wound drainage from the site of infection ensures that neighboring microbes do not contaminate a specimen. Seal all specimen containers tightly to prevent spillage and contamination of the outside of the container.

Bagging Trash or Linen. Bagging contaminated items prevents accidental exposure of personnel and contamination of the surrounding environment. Double bagging is not recommended. Studies demonstrate that this procedure is not necessary to prevent and control infection (CDC, 2007). The use of a single, intact, standard-size linen bag that is not overfilled and tied securely is adequate to prevent infection transmission. Check the color code of bag that your facility uses for bagging these items.

Transporting Patients. Before transferring patients to wheelchairs or stretchers, give them clean gowns to serve as robes. Patients infected with organisms transmitted by the airborne route normally leave their rooms only for essential purposes such as diagnostic procedures or surgery. When a patient has an airborne infection, he or she must wear a mask when leaving the room. Notify personnel in diagnostic or procedural areas or the operating room of the type of isolation precautions the patient requires. Some patients being transported drain body fluids onto a stretcher or wheelchair. Use an extra layer of sheets to

---

BOX 29-13   Specimen Collection Techniques*

Ensure that all specimen containers used have the biohazard symbol on the outside (Pagana and Pagana, 2014). Also follow agency policy in confirming proper labeling of all specimen containers (i.e., labelling in front of patient).

Wound Specimen
Perform hand hygiene and apply clean gloves. Clean site with sterile water or saline before wound specimen collection with a clean swab. Wipe from edges outward to remove old exudate (see Chapter 48). Remove gloves, perform hand hygiene, and apply gloves and use sterile cotton-tipped swab or syringe to collect as much drainage as possible. Have clean test tube or culture tube on clean paper towel. After swabbing center of wound site, grasp collection tube with a paper towel. Carefully insert swab without touching outside of tube. After securing top of tube, label specimen container with patient name and identifying information, then transfer tube into labeled biohazard bag for transport and perform hand hygiene.

Blood Specimen
(This procedure is often performed by a laboratory technician.)
    Wearing gloves, clean venipuncture site with antiseptic swab; move the first swab back and forth on horizontal plane, another swab on the vertical plane, and the last swab in a circular motion from site outward for 5 cm (2 inches) lasting a total of 30 seconds. Allow area to dry. Clean tops of culture bottles for 15 seconds with agency-approved cleansing solution. Use a 20-mL needle-safe syringe and collect up to 10 to 15 mL of blood per culture bottle (check health care facility or agency policy). Perform venipuncture at two different sites to decrease likelihood of both specimens being contaminated with skin flora. Place blood culture bottles on a clean paper towel on bedside table or other surface; swab off bottle tops with alcohol. Inject an appropriate amount of blood into each bottle. If collecting aerobic and anaerobic specimens, inject blood into the aerobic bottle (first) and the anaerobic bottle (second). Transfer labeled specimen into clean, labeled biohazard bag for transport. Remove gloves and perform hand hygiene.

Stool Specimen
Wearing gloves, use clean cup with seal top (need not be sterile) and a tongue blade to collect a small amount, approximately 2 to 3 cm (1 inch) of stool. Place cup on clean paper towel in patient's bathroom. Using tongue blade, collect needed amount of feces from patient's bedpan. Transfer feces to cup without touching outside surface of cup. Dispose of tongue blade and place seal on cup. Transfer labeled specimen into clean labeled biohazard bag for transport. Remove gloves and perform hand hygiene.

Urine Specimen
Apply gloves, cleanse needleless port on urinary catheter and, using a needleless safety syringe, collect 1 to 5 mL of urine. Fill sterile specimen tube and place on clean towel in patient's bathroom. Instruct patient to follow procedure to obtain a clean voided specimen (see Chapter 46) if not catheterized. Secure top of transfer container, label container in front of patient, and place in a biohazard bag with label attached. Remove gloves and perform hand hygiene.

*Health care facility or agency policies may differ on type of containers and amount of specimen material required.

---

cover the stretcher or seat of the wheelchair. Be sure to clean the equipment with an approved germicide after patient use and before another patient uses the shared equipment.

Role of the Infection Control Professional. An infection control professional is a valuable resource for helping nurses control HAIs. These professionals are specially trained in infection prevention

---

QSEN **QSEN: BUILDING COMPETENCY IN EVIDENCE-BASED PRACTICE** You notice that, although a number of patients on your unit are in isolation for *C. difficile,* many unit staff are not following agency protocol of gowning and gloving before entering an isolation room. When you bring this to your co-workers' attention, their response is that the precautions are not really necessary because they are not in contact with the patient's stool. You have heard that the organism is very hardy and can live on inanimate objects such as bedrails and door knobs but are unsure of how you know this or how the isolation protocol was developed within your organization. Where could you find evidence to help your colleagues understand why contact precautions are necessary at all times?

(e) *Answers to QSEN Activities can be found on the Evolve website.*

---

and control. They are responsible for advising health care personnel regarding infection prevention and control practices and monitoring infections within the hospital. An infection control professional's responsibilities often include:

- Identifying and recommending adoption of evidence-based practices for prevention of HAIs
- Providing staff and patient education on infection prevention and control.
- Developing and reviewing infection prevention and control policies and procedures
- Recommending appropriate isolation procedures for specific patients.
- Screening patient records for community-acquired infections that are reportable to the public health department.
- Consulting with employee health departments concerning recommendations to prevent and control the spread of infection among personnel such as TB testing.
- Gathering statistics regarding the **epidemiology** (cause and effect) of HAIs.
- Notifying the public health department of incidences of communicable diseases within the facility.
- Consulting with all hospital departments to investigate unusual events or clusters of infection.
- Monitoring antibiotic-resistant organisms in the institution.

Infection Prevention and Control for Hospital Personnel.
Health care workers are continually at risk for exposure to infectious microorganisms. Numerous efforts have been made by health care agencies to improve health care provider compliance with hand hygiene, including increased access to automatic alcohol-based hand sanitizers, posted reminders, and sensor monitoring of sanitizer use (Box 29-14). The World Health Organization recently released a new initiative for improving compliance of health care workers with hand hygiene. The WHO's Five Moments for Hand Hygiene has emerged from the WHO Guidelines on Hand Hygiene in Health Care to add value to any hand hygiene improvement strategy (WHO, 2015). The Five Moments defines the key moments for hand hygiene, overcoming misleading language and complicated descriptions.

Patient Education.
Often patients need to learn to use infection prevention and control practices at home (Box 29-15). Preventive technique becomes almost second nature to the nurse who practices it daily. However, patients are less aware of factors that promote the spread of infection or ways to prevent its transmission. The home environment may not always lend itself to infection prevention and control. Often you help a patient adapt according to the resources available to maintain hygienic techniques. Generally patients in a home

BOX 29-14 EVIDENCE-BASED PRACTICE
Health Care Worker Compliance with Hand Hygiene

PICO Question: Does the use of bundled evidence-based interventions compared with standard practice improve health care worker compliance in performing hand hygiene?

Evidence Summary
There have been numerous studies examining the use of bundled interventions for improving hand hygiene (HH), including combinations of interventions such as staff education, reminders (e.g., posters, electronic voice prompts), performance feedback, administrative support, and access to alcohol-based hand rub (e.g., wall-mounted dispensers, pocket size bottles, or both) (Schweizer et al., 2014). Most studies have been conducted in Intensive Care units or acute care units, however other study locations have included long-term care facilities and outpatient clinics. Evidence for the use of bundled interventions to improve HH compliance is promising, but higher quality studies are needed to validate these results and examine questions such as which specific interventions should be included in a bundle (Schweizer et al., 2014). A systematic review of studies by Luangasanatip et al. (2015) suggests that the WHO-5 Moments for Hand Hygiene is effective and that compliance can be further improved by adding interventions including goal setting, reward incentives, and accountability. In a number of the studies analyzed, improvements in hand hygiene were associated with reductions in at least one measure of hospital acquired infection and/or resistance rates (Luangasanatip et al., 2015).

Application to Nursing Practice
- Follow the WHO-5 Moments:
  Before Patient Contact
  WHEN? Clean your hands before touching a patient when approaching him or her.
  WHY? To protect the patient against harmful germs carried on your hands.
  Before an Aseptic Task
  WHEN? Clean your hands immediately before any aseptic task.
  WHY? To protect the patient against harmful germs, including the patient's own germs, entering his or her body.
  After Body Fluid Exposure Risk
  WHEN? Clean your hands immediately after an exposure risk to body fluids (and after glove removal).
  WHY? To protect yourself and the health care environment from harmful patient germs.
  After Patient Contact
  WHEN? Clean your hands after touching a patient and his or her immediate surroundings when leaving.
  WHY? To protect yourself and the health care environment from harmful patient germs.
  After Contact with Patient Surroundings
  WHEN? Clean your hands when leaving after touching any object or furniture in the patient's immediate surroundings, even without touching the patient.
  WHY? To protect yourself and the health care environment from harmful patient germs.
- Adding supplemental interventions, including goal setting, reward incentives, and accountability to the WHO-5 Moments strategy leads to additional improvements in hand hygiene compliance.

---

care setting have a decreased risk of infection because of decreased exposure to resistant organisms such as those found in a health care facility and fewer invasive procedures. However, it is important to educate patients and their family caregivers about infection prevention and control techniques.

BOX 29-15   PATIENT TEACHING

Infection Prevention and Control

Objective
- Patient and/or caregiver will use proper infection prevention and control practices when performing a clean dressing change.

Teaching Strategies
- Demonstrate proper hand hygiene, explaining that patient and/or caregiver needs to perform it before and after all treatments and when infected body fluids are contacted.
- Instruct patient and/or caregiver about the signs and symptoms of wound infection and when to notify the health care provider.
- Instruct patient and/or caregiver to place contaminated dressings and other disposable items containing infectious body fluids in impervious plastic or brown paper bags. Place needles in metal or hard plastic containers such as coffee cans or laundry detergent bottles and tape the openings shut. *Some states have specific requirements for sharps disposal. Check local regulations.*
- Instruct patient and/or caregiver to separate linen soiled with wound drainage from other laundry. Wash in warm water with detergent. There are no special recommendations for setting a dryer temperature (CDC, 2007).

Evaluation
- Ask patient or caregiver to describe techniques used to reduce transmission of infection.
- Have patient or caregiver demonstrate hand hygiene and dressing change techniques.
- Ask patient or caregiver to describe signs of a wound infection.
- Ask patient or caregiver when to notify the health care provider if signs and symptoms of infection are present.

Surgical Asepsis.   **Surgical asepsis** or sterile technique prevents contamination of an open wound, serves to isolate an operative area from the unsterile environment, and maintains a sterile field for surgery. Surgical asepsis includes procedures used to eliminate all microorganisms, including pathogens and spores, from an object or area (Rutala and Weber, 2014). In surgical asepsis an area or object is considered contaminated if touched by any object that is not sterile. It demands the highest level of aseptic technique and requires that all areas be kept free of infectious microorganisms.

Use surgical asepsis in the following situations:
- During procedures that require intentional perforation of the patient's skin, such as insertion of peripheral IV catheters or a central intravenous line
- When the integrity of the skin is broken as a result of trauma, surgical incision, or burns
- During procedures that involve invasive procedures such as insertion of a urinary catheter or surgical instruments into sterile body cavities such as insertion of a wound drain

Although surgical asepsis is common in the operating room, labor and delivery area, and major diagnostic areas, you also use surgical aseptic techniques at the patient's bedside (e.g., when inserting IV or urinary catheters, suctioning the tracheobronchial airway, and sterile dressing changes). A nurse in an operating room follows a series of steps to maintain sterile technique, including applying a mask, protective eyewear, and a cap; performing a surgical hand scrub; and applying a sterile gown and gloves. In contrast, a nurse performing a dressing change at a patient's bedside only performs hand hygiene and applies gloves. For certain procedures (e.g., changing a central line dressing) the nurse also uses a mask and gown (see agency policy). Regardless

of the procedures followed or the setting, the nurse always recognizes the importance of strict adherence to aseptic principles (Iwamoto and Post, 2014).

Patient Preparation for a Sterile Procedure. Because surgical asepsis requires exact techniques, you need to have the patient's full cooperation. Therefore assess a patient's understanding of the sterile procedure and explain the reasons for not moving or interfering with the procedure. Certain patients fear moving or touching objects during a sterile procedure, whereas others try to help. Explain how you will perform a procedure and what the patient can do to avoid contaminating sterile items, including the following:
- Avoid sudden movements of body parts covered by sterile drapes.
- Refrain from touching sterile supplies, drapes, or the nurse's gloves and gown.
- Avoid coughing, sneezing, or talking over a sterile area.

Certain sterile procedures last an extended time. Assess a patient's needs and anticipate factors that may disrupt a procedure. If a patient is in pain, administer ordered analgesics about a half an hour before a sterile procedure begins. Ask a patient if he or she needs to use the bathroom or a bedpan. Often patients have to assume relatively uncomfortable positions during sterile procedures. Help a patient assume the most comfortable position possible. Finally a patient's condition sometimes results in actions or events that contaminate a sterile field. For example, a patient with a respiratory infection transmits organisms by coughing or talking. Anticipate such a problem and place a surgical mask on him or her before the procedure begins.

Principles of Surgical Asepsis. Performing sterile aseptic procedures requires a work area in which objects can be handled with minimal risk of contamination. A sterile field provides a sterile surface for placement of sterile equipment. It is an area considered free of microorganisms and consists of a sterile kit or tray, a work surface draped with a sterile towel or wrapper, or a table covered with a large sterile drape (Murphy, 2014). When beginning a surgically aseptic procedure, nurses follow certain principles to ensure maintenance of asepsis. Failure to follow these principles places patients at risk for infection. The following principles are important:

1. *A sterile object remains sterile only when touched by another sterile object.* This principle guides a nurse in placement of sterile objects and how to handle them.
   a. Sterile touching sterile remains sterile (e.g., use sterile gloves or sterile forceps to handle objects on a sterile field).
   b. Sterile touching clean becomes contaminated (e.g., if the tip of a syringe or other sterile object touches the surface of a clean disposable glove, the object is contaminated).
   c. Sterile touching contaminated becomes contaminated (e.g., when a nurse touches a sterile object with an ungloved hand, the object is contaminated).
   d. Sterile state is questionable (e.g., when you find a tear or break in the covering of a sterile object). Discard it regardless of whether the object itself appears untouched.
2. *Only sterile objects may be placed on a sterile field.* All items are properly sterilized before use. Sterile objects are kept in clean, dry storage areas. The package or container holding a sterile object must be intact and dry. A package that is torn, punctured, wet, or open is considered unsterile.
3. *A sterile object or field out of the range of vision or an object held below a person's waist is contaminated.* Nurses never turn their back on a sterile field or tray or leave it unattended. Contamination can occur accidentally by a dangling piece of clothing or an unknowing patient touching a sterile object. Any object held below waist level is considered contaminated

because it cannot be viewed at all times. Keep sterile objects in front with the hands as close together as possible.

4. *A sterile object or field becomes contaminated by prolonged exposure to air.* Avoid activities that create air currents such as excessive movements or rearranging linen after a sterile object or field becomes exposed. When you open sterile packages, it is important to minimize the number of people walking into an area. Microorganisms also travel by droplet through the air. Do not talk, laugh, sneeze, or cough over a sterile field or when gathering and using sterile equipment. When opening sterile packages, hold the item or piece of equipment as close as possible to the sterile field without touching the sterile surface.

5. *When a sterile surface comes in contact with a wet, contaminated surface, the sterile object or field becomes contaminated by capillary action.* If moisture leaks through the protective covering of a sterile package, microorganisms travel to the sterile object. When stored sterile packages become wet, discard the objects immediately or send the equipment for resterilization. When working with a sterile field or tray, you may have to pour sterile solutions. Any spill is a source of contamination unless on a sterile surface that moisture cannot penetrate. Urinary catheterization trays contain sterile supplies that rest in a sterile, plastic container. In contrast, if you place a piece of sterile gauze in its wrapper on a patient's bedside table and the table surface is wet, the gauze is considered contaminated.

6. *Fluid flows in the direction of gravity.* A sterile object becomes contaminated if gravity causes a contaminated liquid to flow over the surface of the object. To avoid contamination during a surgical hand scrub, hold your hands above your elbows. This allows water to flow downward without contaminating your hands and fingers. The principle of water flow by gravity is also the reason for drying from fingers to elbows, with hands held up, after the scrub.

7. *The edges of a sterile field or container are considered to be contaminated.* Frequently you place sterile objects on a sterile towel, drape, or tray (Figure 29-4). Because the edge of the drape touches an unsterile surface such as a table or bed linen, a 2.5-cm (1-inch) border around the drape is considered contaminated. Objects placed on the sterile field need to be inside this border. The edges of sterile containers become exposed to air after they are open and thus are contaminated. After you remove a sterile needle from its protective cap or forceps from a container, the objects must not touch the edge of the container.

FIGURE 29-4 Placing sterile item on sterile field.

Performing Sterile Procedures. Assemble all of the equipment that will be needed before a procedure. Have a few extra supplies available in case objects accidentally become contaminated. Do not leave a sterile area. Before a sterile procedure, explain each step so the patient can cooperate fully. If an object becomes contaminated during the procedure, do not hesitate to discard it immediately.

Donning and Removing Caps, Masks, and Eyewear. Wear a surgical mask and eyewear without a cap for any sterile procedures on a general nursing unit. Eyewear is worn as a part of standard precautions if there is a risk of fluid or blood splashing into your eyes. For sterile surgical procedures, you first apply a clean cap that covers all of your hair and then the surgical mask and eyewear. A mask must fit snugly around the face and nose. After wearing a mask for several hours, the area over the mouth and nose often becomes moist. Because moisture promotes the growth of microorganisms, change the mask if it becomes moist.

Protective glasses or goggles fit snugly around the forehead and face to fully protect the eyes. Wear eyewear only for procedures that create the risk of body fluids splashing into the eyes. Remove PPE in the following order: gloves, face shield or goggles, gown, and mask or respirator (CDC, 2005b). After removing all PPE, perform hand hygiene.

Opening Sterile Packages. Sterile items such as syringes, gauze dressings, or catheters are packaged in paper or plastic containers and are impervious to microorganisms as long as they are dry and intact. Some institutions wrap reusable supplies (e.g., operating room instruments) in a double thickness of paper, linen, or muslin. These packages are permeable to steam and thus allow for steam autoclaving. Sterile items are kept in clean, enclosed storage cabinets and separated from dirty equipment.

Sterile supplies have chemical tapes indicating that a sterilization process has taken place. The tapes change color during the process. Failure of the tapes to change color means that the item is not sterile. Health care facilities follow the principles of event-related sterility, a concept that items are considered sterile if the packaging is uncompromised (Jefferson and Young, 2014). Never use a sterile item if the packaging is open or soiled or shows evidence that the package had been wet. Before opening a sterile item, perform hand hygiene. Inspect the supplies for package integrity and sterility and assemble the supplies in the work area such as the bedside table or treatment room before opening packages. A bedside table or countertop provides a large, clean working area for opening items. Keep the work area above waist level. Do not open sterile supplies in a confined space where contamination might occur.

Opening a Sterile Item on a Flat Surface. You must open sterile packages without contaminating the contents. Commercially packaged items are usually designed so you only have to tear away or separate the paper or plastic cover. Hold the item in one hand while pulling the wrapper away with the other (Figure 29-5). Take care to keep the inner contents sterile before use. You may use a sterile wrapper from a commercial kit or a sterile paper or linen wrapper from an institutional pack to create a sterile field on which to work. Use the inner surface of the package (except for the 2.5 cm [1-inch] border around the edges) as a sterile field to add sterile items. You can grasp the 2.5 cm (1-inch) border to maneuver the field on a table surface (see Skill 29-2 on pp. 473-476).

Opening a Sterile Item While Holding It. To open a small sterile item, hold the package in your nondominant hand while opening the top flap and pulling it away from you. Using the dominant hand, carefully open the sides and innermost flap away from the enclosed sterile item in the same order previously mentioned. You open the item in a hand so you can pass it to a person wearing sterile gloves or transfer it to a sterile field.

FIGURE 29-5 Nurse opens sterile package on work area above waist level.

Preparing a Sterile Field. When performing sterile procedures, you need a sterile work area that provides room for handling and placing sterile items. A **sterile field** is an area free of microorganisms and prepared to receive sterile items. You prepare the field by using the inner surface of a sterile wrapper as the work surface or by using a sterile drape or dressing tray. After creating the surface for the sterile field, add sterile items by placing them directly on the field or transferring them with a sterile forceps (see Skill 29-2). Discard an object that comes in contact with the 2.5 cm (1-inch) border.

Sometimes you will wear sterile gloves while preparing items on a sterile field. If you do this, you can touch the entire drape, but sterile items must be handed over by an assistant. The gloves cannot touch the wrappers of sterile items.

Pouring Sterile Solutions. Often you have to pour sterile solutions into sterile containers. A bottle containing a sterile solution is sterile on the inside and contaminated on the outside; the neck of the bottle is also contaminated, but the inside of the bottle cap is considered sterile. After you remove the cap or lid, you hold it in your hand or place its sterile side (inside) up on a clean surface. This means that you are able to see the inside of the lid as it rests on the table surface. Never rest a bottle cap or lid on a sterile surface, even though the inside of the cap is sterile. The outer edge of the cap is unsterile and contaminates the surface. Placing a sterile cap down on an unsterile surface increases the chances of the inside of the cap becoming contaminated.

Hold the bottle with its label in the palm of the hand to prevent the possibility of the solution wetting and fading the label. Before pouring the solution into the container, pour a small amount (1 to 2 mL) into a disposable cap or plastic-lined waste receptacle. The discarded solution cleans the lip of the bottle. Keep the edge of the bottle away from the edge or inside of the receiving container. Pour the solution slowly to avoid splashing the underlying drape or field. Never hold the bottle so high above the container that even slow pouring causes splashing. Hold the bottle outside the edge of the sterile field.

Surgical Scrub. Patients undergoing operative procedures are at an increased risk for infection. Nurses working in operating rooms perform surgical hand antisepsis (see Skill 29-3 on pp. 476-478) to decrease and suppress the growth of skin microorganisms under the gloved hand in case of glove tears. A surgical hand scrub must eliminate the transient flora and reduce the resident flora on the hands. For maximum elimination of bacteria, remove all jewelry and keep the nails clean and short. Do not wear chipped nail polish, artificial nails, or extenders because they often hold a greater number of bacteria (AORN, 2014; WHO, 2009). Nurses who have active skin infections, open lesions or cuts, or respiratory infections should be excluded from the surgical team.

During surgical hand antisepsis the nurse scrubs from fingertips to elbows with an antiseptic soap before each surgical procedure. Research studies vary on the optimum duration of a surgical hand scrub (WHO, 2009). Chlorhexidine gluconate has been found to be more effective than povidone iodine as a cleansing agent, although both can be found in health care agencies. Thus the type of product used for cleansing will influence the time required for hand antisepsis (CDC, 2008a; WHO 2009). The traditional scrub time in the United States for both the initial and the subsequent scrub is 5 minutes, but research has shown effectiveness can be gained when scrubs are performed for 2, 3 and 6 minutes (WHO, 2009). Follow manufacturer recommendation for scrub solutions. For many years preoperative handwashing protocols required nurses to scrub with a brush. However, this practice damages the skin. Scrubbing with a disposable sponge or combination sponge-brush reduces bacterial counts on the hands as effectively as scrubbing with a brush. However, several studies suggest that neither a brush nor a sponge is necessary to reduce bacterial counts on the hands, especially when using an alcohol-based product (CDC, 2008a).

Applying Sterile Gloves. Sterile gloves are an additional barrier to bacterial transfer. There are two gloving methods: open and closed. Nurses who work on general nursing units use open gloving before procedures such as dressing changes or urinary catheter insertions. The closed-gloving method, which you perform after applying a sterile gown, is practiced in operating rooms and special treatment areas (see Skills 29-4 and 29-5 on pp. 479-482). Make sure to select the proper glove size; the glove should not stretch so tightly that it can tear easily, yet it must be tight enough that you can pick up objects easily.

Donning a Sterile Gown. Nurses wear sterile gowns when assisting at the sterile field in the operating room, delivery room, and special treatment areas. It allows the nurse to handle sterile objects and also be comfortable with less risk of contamination. The sterile gown acts as a barrier to decrease shedding of microorganisms from skin surfaces into the air and thus prevents wound contamination. Nurses caring for patients with large open wounds or assisting health care providers during major invasive procedures (e.g., inserting an arterial catheter) also wear sterile gowns. The circulating nurse generally does not wear one.

The nurse does not apply a sterile gown until after applying a mask and surgical cap and completing surgical handwashing. He or she picks up the gown from a sterile pack, or an assistant hands the gown to the nurse. Only a certain portion of the gown (i.e., the area from the anterior waist to, but not including, the collar and the anterior surface of the sleeves) is considered sterile. The back of the gown, the area under the arms, the collar, the area below the waist, and the underside of the sleeves are not sterile because the nurse cannot keep these areas in constant view and ensure their sterility (see Skill 29-4 on pp. 479-480).

Exposure Issues. Patients and health care personnel, including housekeepers and maintenance personnel, are at risk for acquiring infections from accidental needlesticks. In the past, a stray needle lying in bed linen or carelessly thrown into a wastebasket served as a prime source for exposure to bloodborne pathogens. With the passage of the Needlestick Safety and Prevention Act in 2000 (OSHA, 2012) and the implementation of safety needle devices, the incidence rate of sharps injuries has decreased. All sharps must now be either needle safe or needleless. After administering an injection or inserting an IV catheter, place the used needle safety device in a puncture-resistant box (see Chapter 32). Sharps boxes must be at the site of use; this is an Occupational Safety and Health Administration (OSHA) requirement.

HBV and HCV are the infections most commonly transmitted by contaminated needles (Box 29-16). Report any contaminated

---

BOX 29-16 **Hepatitis B Vaccination and Follow-Up After Hepatitis C and Human Immunodeficiency Virus Exposure**

1. Health care employers shall make available the hepatitis B vaccine and vaccination series to all employees who may have occupational exposures. If an employee declines the vaccine, he or she must sign a declination form. Evaluation and follow-up care is available to all employees who have been exposed.
2. Hepatitis B vaccinations are made available to employees within 10 working days of assignment—this means before starting to provide patient care and after receiving education and training on the vaccine.
3. A blood test (titer) is offered in some facilities 1 to 2 months after completing the three-dose vaccine series (check the health care facility or agency policy).
4. Vaccine is offered at no cost to employees. At present the vaccine does not require any boosters.
5. After exposure no treatment is needed if there is a positive blood titer on file. If no positive titer is on file, follow CDC guidelines.

Exposure to Hepatitis C Virus

1. If the source patient is positive for hepatitis C virus (HCV), the employee receives a baseline test.
2. At 4 weeks after exposure the employee should be offered an HCV-RNA test to determine if he or she contracted HCV.
3. If positive, the employee starts treatment.
4. There is no prophylactic treatment for HCV after exposure.
5. Early treatment for infection can prevent chronic infection.

Exposure to Human Immunodeficiency Virus

1. If the patient is positive for human immunodeficiency virus (HIV) infection, a viral load study should be performed to determine the amount of virus present in the blood.
2. If the exposure meets the CDC criteria for HIV prophylactic treatment (PEP), it should be started as soon as possible, preferably within 24 hours after the exposure (CDC, 2005b).

All medical evaluations and procedures, including the vaccine and vaccination series and evaluation after exposure (prophylaxis), are made available at no cost to at-risk employees.

A confidential written medical evaluation will be available to employees with exposure incidents.

From Occupational Safety and Health Administration: Occupational Safety and Health Act of 2001, 2001, 2005, http://www.cdc.gov. *CDC*, Centers for Disease Control and Prevention; *RNA*, ribonucleic acid; *PEP*, postexposure prophylaxis.

---

needlestick immediately. Additional criteria for exposure reporting include blood or other potentially infectious materials (OPIMs) in direct contact with an open area of the skin, blood or OPIM that is splashed into a health care worker's eye or mouth or up the nose, and cuts with a sharp object that is covered with blood or OPIM.

Follow-up for risk of acquiring infection begins with source patient testing. Access to testing the source patient is stated in the testing law for each state. Some states have deemed consent, which means that the state has granted the patient's consent to be tested. Other states require that the patient consent to testing for the presence of bloodborne pathogens. Know the testing policies in the facility and state in which you practice. Health care facilities and agencies and workers' compensation require exposed employees to complete an injury report and seek appropriate treatment if needed. The need for treatment is linked

to the results of a risk assessment and the testing of the patient. Test the patient for HIV, HBV, and HCV. If positive for HIV or HCV, testing for syphilis may be indicated because of the incidence of coinfection (CDC, 2005b, 2010a). It is required that an exposed employee be given the patient's testing results. This is *not* a violation of the Health Insurance Portability and Accountability Act (HIPAA) of 1996. Both the CDC and OSHA state that this information must be given to the exposed health care worker contingent on the health care worker's willingness to be tested.

Testing the exposed employee at the time of the exposure is not needed immediately unless required by the state testing law. If the patient tests positive for a bloodborne pathogen or if the source patient is unknown, prophylactic treatment is recommended for the employee.

Exposures also occur involving non-bloodborne pathogens. Airborne and droplet diseases pose a risk to the nonimmune nurse. The CDC (2010c) has published a list of recommended immunizations and vaccinations for health care workers, including hepatitis B vaccine; TB testing; annual influenza vaccine; measles, mumps, rubella (MMR); chickenpox vaccine; and tetanus, diphtheria, and pertussis. Employee health should review your health history and offer appropriate prevention. Declination forms are needed if these are declined (OSHA, 2011b).

◆ **Evaluation**

Measure the success of infection prevention and control techniques by determining whether you achieved the goals for reducing or preventing infection. Document the patient's response to therapies for infection prevention and control. A clear description of any signs and symptoms of systemic or local infection is necessary to give all nurses a baseline for comparative evaluation.

Through the Patient's Eyes. Patients generally expect to be safe and protected when receiving health care. A patient at risk for infection needs to understand the measures needed to reduce or prevent microorganism growth and spread. Providing patients and/or family caregivers the opportunity to discuss infection prevention and control measures or to demonstrate procedures such as hand hygiene reveals their ability to comply with therapy. Be sure that you understand the patient's perceptions of how infection spreads, his or her expectations for self-care, and how it can affect him or her as you evaluate the results of your instruction. Sometimes patients require new information, or previously instructed information needs reinforcement.

Patient Outcomes. A comparison of a patient's response before and after an infection control measure, such as the absence of fever or wound infection, is an example of an expected outcome for measuring the success of nursing interventions. Observe wounds during dressing changes to determine the degree of wound healing. Monitor patients, especially those at risk, for signs and symptoms of infection. For example, a patient who has undergone a surgical procedure is at risk for infection at the surgical site and other invasive sites such as the venipuncture site or central line sites. In addition, the patient is at risk for a respiratory tract infection as a result of decreased mobility and for a UTI if an indwelling catheter is present. Observe all invasive and surgical sites for swelling, erythema, or purulent drainage. Monitor breath sounds for changes and observe sputum character for change in color or consistency. Review laboratory test results for leukocytes. For example, leukocytosis in the urine often indicates a UTI. The absence of signs or symptoms of infection is the expected outcome of infection prevention and control.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

- Use clean gloves when you anticipate contact with body fluids and nonintact skin or mucous membranes when there is a risk of drainage.

- Use gown, mask, and eye protection when there is a risk for splash.
- Keep bedside table surfaces clutter free, clean, and dry when performing aseptic procedures.
- Clean all equipment that is shared between patients.
- Ensure that patients cover mouth and nose when coughing or sneezing, use tissues to contain respiratory secretions, and dispose of tissues in waste receptacle.

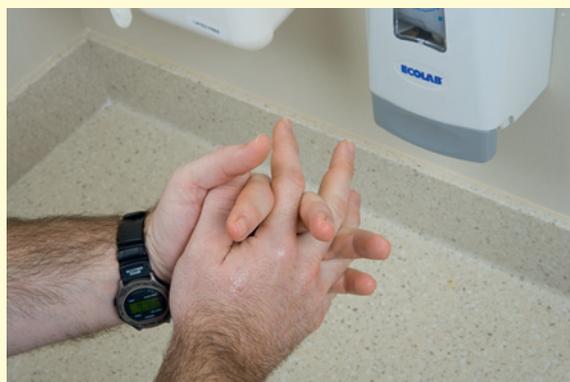
SKILL 29-1	HAND HYGIENE

DELEGATION CONSIDERATIONS
The skill of hand hygiene is performed by all caregivers. Instruct all caregivers to use proper hand hygiene.

EQUIPMENT
- Antiseptic hand rub
  - Alcohol-based, waterless, antiseptic-containing emollient
- Handwashing
  - Easy-to-reach sink with warm running water
  - Antimicrobial or nonantimicrobial soap
  - Paper towels or air dryer
  - Disposable nail cleaner (optional)

STEP	RATIONALE
1. Inspect surface of your hands for breaks or cuts in skin or cuticles. Cover any skin lesions with a dressing before providing care. If lesions are too large to cover, you may be restricted from direct patient care (CDC, 2008a).	Open cuts or wounds can harbor high concentrations of microorganisms. Health care facility or agency policy often prevents nurses from caring for high-risk patients if open lesions are present on hands.
2. Inspect hands for visible soiling.	If hands are visibly soiled, you will use soap and water until soil is removed.
3. Inspect condition of nails. Natural tips need to be less than $\frac{1}{4}$ inch long and free of artificial nails, extenders, or polish (especially cracked polish). Check agency policy.	Subungual areas of hands harbor high concentrations of bacteria. Long nails and chipped or old polish increase the number of bacteria residing on hands. Artificial applications increase microbial load on hands (CDC, 2008a).
4. Push wristwatch and long uniform sleeves above wrists. Avoid wearing rings.	Provides complete access to fingers, hands, and wrists. Some studies show that skin underneath rings carries a higher bacterial load. Gram-negative bacilli, enterobacteria, and *Staphylococcus aureus* are more common under rings (Messano, 2013).
5. Antiseptic hand rub	
a. Following manufacturer directions apply an ample amount of product to palm of one hand (see illustration).	Enough product is needed to thoroughly cover the hands.
b. Rub hands together, covering all surfaces of hands and fingers with antiseptic (see illustration).	Covering all aspects of the hands kills transient bacteria; ensures complete antimicrobial action.
c. Rub hands together for several seconds until alcohol is completely dry. Allow hands to dry before applying gloves.	Provides enough time for antimicrobial solution to be effective.

CLINICAL DECISION: *If hands feel dry after rubbing hands together for 10 to 15 seconds, an insufficient volume of product likely was applied (Boyce et al., 2002).*

STEP 5a Apply waterless antiseptic to hands.


STEP 5b Rub hands thoroughly.

SKILL 29-1	HAND HYGIENE—cont'd

STEP	RATIONALE

6. Handwashing with antiseptic soap

a. Stand in front of sink, keeping hands and uniform away from sink surface. (If hands touch sink during handwashing, repeat process.)	Inside of sink is a contaminated area. Reaching over sink increases risk of touching edge, which is contaminated.
b. Turn on water. Turn faucet on or push knee pedals laterally or press pedals with foot to regulate flow and temperature (see illustration).	Knee pedals within the operating room and treatment areas are preferred to prevent hand contact with faucet. Faucet handles are likely to be contaminated with organic debris and microorganisms (AORN, 2014).
c. Avoid splashing water against uniform.	Microorganisms travel and grow in moisture.
d. Regulate flow of water so temperature is warm.	Warm water removes less of the protective oils than hot water.
e. Wet hands and wrists thoroughly under running water. Keep hands and forearms lower than elbows during washing.	Hands are the most contaminated parts to be washed. Water flows from least to most contaminated area, rinsing microorganisms into the sink.
f. Apply 3 to 5 mL of antiseptic soap and rub hands together vigorously, lathering thoroughly (see illustration).	Ensures that all surface areas of the hands and fingers are cleaned.

CLINICAL DECISION: *The decision whether to use a nonantimicrobial soap, antimicrobial soap, or alcohol-based hand antiseptic depends on the procedure, the patient's immune status, and the type of infection the patient has (CDC, 2008a).*

g. Wash hands using plenty of lather and friction for at least 15 seconds. Interlace fingers and rub palms and back of hands with circular motion at least 5 times each. Keep fingertips down to facilitate removal of microorganisms.	Soap cleans by emulsifying fat and oil and lowering surface tension. Friction and rubbing mechanically loosen and remove dirt and transient bacteria. Interlacing fingers and thumbs ensures that all surfaces are cleansed. Adequate time is needed to expose skin surfaces to antimicrobial agent.
h. Areas under fingernails are often soiled. Clean them with fingernails of other hand and additional soap with an orangewood stick (optional).	Areas under nails are often highly contaminated, which increases the risk of infection for the nurse or patient.
i. Rinse hands and wrists thoroughly, keeping hands down and elbows up (see illustration).	Rinsing mechanically washes away dirt and microorganisms.
j. Dry hands thoroughly from fingers to wrists and forearms with paper towel, single-use cloth, or warm air dryer.	Drying from cleanest (fingertips) to least clean (forearms) area avoids contamination. Drying hands prevents chapping and roughened skin.
k. If used, discard paper towel in proper receptacle.	Prevents transfer of microorganisms.
l. Turn off water with foot or knee pedals. To turn off hand faucet, use clean, dry paper towel; avoid touching handles with hands (see illustration).	Wet towel and hands allow transfer of pathogens from faucet to hands. Faucet handles are contaminated.

STEP 6b Turn on water.

STEP 6f Lather hands thoroughly.

STEP 6i Rinse hands.

STEP 6l Turn off faucet.

HOME CARE CONSIDERATIONS
- Evaluate the handwashing facilities in a patient's home, including the availability of warm running water and soap, to determine the potential for contamination, how close the facilities are to the patient, and available supplies in the area.
- Anticipate the need for alternative handwashing products such as alcohol-based hand rubs and/or detergent-containing towels.
- Instruct the patient and primary caregiver in proper techniques and situations for handwashing.

SKILL 29-2	PREPARATION OF STERILE FIELD	

DELEGATION CONSIDERATIONS
The skill of preparing a sterile field cannot be delegated to nursing assistive personnel (NAP). A surgical technician may prepare a sterile field as indicated by health care facility policy.

EQUIPMENT
- Sterile pack (commercial or institution wrapped)
- Sterile drape to be used as a sterile field
- Sterile gloves (optional, check agency policy)
- Sterile solution and equipment specific to the procedure
- Waist-high table or countertop surface
- Appropriate personal protective equipment (PPE) (see agency policy)

STEP	RATIONALE
1. Complete all priority care tasks before beginning procedure.	Sterile field should be prepared as close as possible to time of use (AORN, 2014).
2. Ask visitors to step out of room briefly during procedure.	Traffic and movement increase potential for spread of microorganisms through air currents.
3. Select a clean, dry work surface above waist level.	A sterile object held below the waist is contaminated.
4. Assemble necessary equipment and check expiration dates or labels and condition of supply packaging for sterility of equipment.	Preparation of equipment in advance prevents break in technique. Equipment that has evidence of previously being open, soiled, or wet is considered unsterile.
5. Apply PPE as needed (consult agency policy).	Controls the spread of microorganisms.
6. Perform hand hygiene.	Reduces transmission of microorganisms.
7. Prepare sterile field.	
a. Prepare sterile commercial kit or tray containing sterile items	
(1) Place sterile kit or pack containing sterile items on work surface above waist level.	Ensures sterility of packaged drape.
(2) Open outside cover and remove kit from dust cover. Place on work surface.	Inner kit remains sterile.
(3) Grasp outer edge of tip of outermost flap.	Outer surface of package is considered unsterile. There is a 2.5-cm (1-inch) border around any sterile drape or wrap that is considered unsterile.
(4) Open outermost flap away from body, keeping arm outstretched and away from the sterile field (see illustration).	Reaching over sterile field contaminates it.
(5) Grasp outer edge of first side of flap.	Outer border is considered unsterile.
(6) Open side flap, pulling to side and allowing it to lie flat on table surface (see illustration). Keep arm to the side and do not extend it over sterile surface.	Drape or flap should lie flat so it will not accidentally rise up and contaminate inner surface or sterile items placed on its surface.

STEP 7a(4) Open outermost flap of sterile kit away from body.

STEP 7a(6) Open first side flap, pulling to side.

SKILL 29-2	PREPARATION OF STERILE FIELD—cont'd

STEP	RATIONALE
(7) Grasp outer edge of second side flap. Repeat for opening second side of package, pulling out to side (see illustration).	
(8) Grasp outer edge of last and innermost flap.	
(9) Stand away from sterile package and pull flap back, allowing it to fall flat on work surface (see illustration).	Reaching over sterile field contaminates it.
b. Sterile linen-wrapped package	
(1) Place package on flat work surface.	
(2) Remove sterilization tape and seal and unwrap both layers, following Steps 7a(1-9) as with sterile kit (see illustrations).	Tape and seal confirms sterility.
(3) Use opened package wrapper as sterile field.	Inner surface of wrapper is considered sterile.
c. Sterile drape	
(1) Place pack containing sterile drape on work surface. Follow Steps 7a(1-9) to open.	Ensures sterility of packaged drape.

STEP 7a(7) Open second side flap, pulling to side.

STEP 7a(9) Open last and innermost flap, standing away from sterile field.

STEP 7b(2) **A,** Nurse opens top flap away from body. **B,** Nurse's arm is kept out away from sterile field while opening a side flap. **C,** Nurse opens second side flap, keeping arm away from sterile field. **D,** Nurse opens back flap.

STEP	RATIONALE

    (2) Apply sterile glove.
        NOTE: This is an option, depending on health care facility policy. You may touch outer 2.5-cm (1-inch) border of drape without wearing gloves.

    (3) Grasp folded top edge of drape with fingertips of one hand. Gently lift drape up from its wrapper without touching any object.

    If sterile object touches any nonsterile object, it becomes contaminated.

    (4) Allow drape to unfold, keeping it above waist and work surface and away from body. (Carefully discard outer wrapper with other hand.)

    Object held below person's waist or above chest is contaminated.

    (5) With other hand grasp adjacent corner of drape. Hold drape straight over work surface (see illustration).

    Drape can now be placed properly with two hands.

    (6) Holding drape, first position bottom half over top half of intended work surface (see illustration).

    Prevents nurse from reaching over sterile field.

    (7) Allow top half of drape to be placed over bottom half of work surface (see illustration).

    A flat sterile surface is now available for placement of sterile items.

8. Adding sterile items

    a. Open sterile item (following package directions) while holding outside wrapper in nondominant hand.

    Frees dominant hand for unwrapping outer wrapper.

    b. Carefully peel wrapper onto nondominant hand.

    Item remains sterile. Inner surface of wrapper covers hand, making it sterile.

    c. Being sure wrapper does not fall down on sterile field, place item onto field at angle. *Do not hold arm over sterile field* (see illustration).

    Prevents reaching over field and contaminating its surface.

    d. Dispose of outer wrapper.

    Prevents accidental contamination of sterile field.

STEP 7c(5) Hold drape straight up and away from body.

STEP 7c(6) Lay bottom half over work surface.

STEP 7c(7) Place top half of drape over work surface.

STEP 8c Add item to sterile field.

SKILL 29-2	PREPARATION OF STERILE FIELD—cont'd

STEP	RATIONALE
9. Pour sterile solution.	
a. Verify contents and expiration date of solution.	Ensures proper solution and sterility of contents.
b. Be sure that receptacle for solution is located near or on sterile work surface edge. Sterile kits have cups or plastic molded sections into which you can pour fluids.	Prevents reaching over sterile field.
c. Remove sterile seal and cap from bottle in an upward motion. With solution bottle held away from sterile field, with the label facing up and the bottle lip 1 to 2 inches above inside of receiving container, slowly pour contents into container (see illustration).	Prevents contamination of bottle lip and keeps inside of cap sterile. Edge and outside of bottle are considered contaminated. Slow pouring prevents splashing liquids, which causes fluid permeation of sterile barrier (called *strike through*) and results in contamination.
10. Perform procedure using sterile technique.	Prevents transmission of infection to patient.

STEP 9c Pour solution into receiving container on sterile field.

RECORDING AND REPORTING

- It is not necessary to record or report this procedure.

SKILL 29-3	SURGICAL HAND ASEPSIS

DELEGATION CONSIDERATIONS

The skill of surgical hand asepsis can be delegated to properly trained surgical technicians (know the state Nurse Practice Act).

EQUIPMENT

- Deep sink with foot or knee controls for dispensing water and soap (faucets should be high enough for hands and forearms to fit comfortably)
- Antimicrobial agent approved by the health care facility
- Surgical scrub sponge with plastic nail pick (optional)
- Paper face mask, cap or hood, surgical shoe covers
- Sterile towel
- Sterile pack containing sterile gown
- Protective eyewear (glasses or goggles)

STEP	RATIONALE
1. Consult manufacturer policy regarding required length of time and antiseptic to use for hand antisepsis. Chlorhexidine has been found to be more effective than povidone iodine (WHO, 2009).	Guidelines vary regarding ideal time needed and antiseptic to use for surgical scrub. Most facilities in the United States follow 5 minutes for hand scrub (WHO, 2009).
2. Remove bracelets, rings, and watches.	Jewelry may harbor or protect microorganisms from removal. Allergic skin reactions may occur as a result of scrub agent or glove powder accumulating under jewelry (Messano, 2013).
3. Be sure that fingernails are short, clean, and healthy. Artificial nails should be removed. Natural nails should be less than $\frac{1}{4}$ inch long from fingertip.	Long nails and chipped or old polish increase number of bacteria residing on nails. Long fingernails can puncture gloves, causing contamination. Artificial nails are known to harbor gram-negative microorganisms and fungus (AORN, 2014; CDC, 2008a).

CLINICAL DECISION: *Remove nail polish if chipped or worn longer than 4 days because it likely will harbor microorganisms (AORN, 2014).*

STEP	RATIONALE
4. Inspect condition of cuticles, hands, and forearms for abrasions, cuts, or open lesions.	These conditions increase likelihood of more microorganisms residing on skin surfaces. Broken skin permits microorganisms to enter layers of the skin, providing deeper microbial breeding grounds (AORN, 2014).
5. Apply surgical shoe covers, cap or hood, face mask, and protective eyewear.	Mask prevents escape into air of microorganisms that can contaminate hands. Other protective wear prevents exposure to blood and body fluid splashes during the procedure.
6. Turn on water using knee or foot controls and adjust to comfortable temperature.	Knee or foot controls prevent contamination of hands after scrub.
7. Prescrub wash/rinse: Wet hands and arms under running lukewarm water and lather with detergent to 5 cm (2 inches) above elbows. (Hands need to be above elbows at all times.)	Water runs by gravity from fingertips to elbows. Hands become cleanest part of upper extremity. Keeping hands elevated allows water to flow from least to most contaminated areas. Washing a wide area reduces risk of contaminating overlying gown that the nurse later applies.
8. Rinse hands and arms thoroughly under running water. Remember to keep hands above elbows.	Rinsing removes transient bacteria from fingers, hands, and forearms.
9. Under running water clean under nails of both hands with nail pick. Discard after use (see illustration).	Removes dirt and organic material that harbor large numbers of microorganisms.
10. Surgical hand scrub (with sponge or sponge brush)	
a. Wet clean sponge and apply antimicrobial agent. Visualize each finger, hand, and arm as having four sides. Wash all four sides effectively. Scrub the nails of one hand with 15 strokes. Scrub the palm, each side of thumb and fingers, and posterior side of hand with 10 strokes each (see illustration).	Friction loosens resident bacteria that adhere to skin surfaces. Ensures coverage of all surfaces. Scrubbing is performed from cleanest area (hands) to marginal area (upper arms).
b. Divide the arm mentally into thirds: scrub each third 10 times (AORN, 2014) (see illustration). Some health care facility policies require scrub by total time (e.g., 5 minutes) rather than number of strokes. Rinse brush and repeat sequence for the other arm. A two-sponge method may be substituted (check health care facility policy).	Eliminates transient microorganisms and reduces resident hand flora.
c. Discard brush. Flex arms and rinse from fingertips to elbows in one continuous motion, allowing water to run off at elbow (see illustration).	Hands remain the cleanest part of upper extremities.

STEP 9 Clean under fingernails.

STEP 10a Scrub side of fingers.

STEP 10b Scrub forearms.

STEP 10c Rinse arms.

SKILL 29-3	SURGICAL HAND ASEPSIS—cont'd

STEP	RATIONALE
d. Turn off water with foot or knee control, with hands elevated in front of and away from body. Enter operating room suite by backing into room.	Keeps hands free of microorganisms.
e. Approach sterile setup; grasp sterile towel, taking care not to drip water onto sterile setup.	Water contaminates sterile setup.
f. Bending slightly at waist, keeping hands and arms above waist and outstretched, grasp one end of sterile towel and dry one hand, moving from fingers to elbow in a rotating motion (see illustrations).	Avoids sterile towel from contacting unsterile scrub attire and transferring contamination to hands. Dry skin from cleanest (hands) to least clean (elbows).
g. Repeat drying method for other hand by carefully reversing towel or using a new sterile towel.	Prevents accidental contamination.
h. Drop towel into linen hamper or circulating nurse's hand.	Prevents accidental contamination.
11. *Optional:* Brushless antiseptic hand rub	
a. After prescrub wash (see Step 7), dry hands and forearms thoroughly with paper towel.	Promotes reduction in microorganisms on all surfaces of hands and arms.
b. Dispense 2 mL of antimicrobial agent hand preparation into palm of one hand. Dip fingertips of opposite hand into hand preparation and work it under nails. Spread remaining hand preparation over hand and up to just above elbow, covering all surfaces (see illustrations).	
c. Using another 2 mL of hand preparation, repeat with other hand.	
d. Dispense another 2 mL of hand preparation into either hand and reapply to all aspects of both hands up to wrist. Allow to dry thoroughly before donning gloves.	Ensures complete antiseptic coverage of all hand surfaces.
12. Proceed with sterile gowning (see Skill 29-4).	

RECORDING AND REPORTING

- It is not necessary to record or report this procedure.
- Report any skin dermatitis to employee health or infection control per agency policy.

STEP 10f A, Grasp sterile towel. **B,** Drying sequence.

STEP 11b Application of antimicrobial agent for brushless hand scrub. Nurse using 3M Avagard. (Photos courtesy 3M Health Care.)

SKILL 29-4	APPLYING A STERILE GOWN AND PERFORMING CLOSED GLOVING

DELEGATION CONSIDERATIONS

Applying a sterile gown and closed gloving can be delegated to a properly trained surgical technician (know the state Nurse Practice Act).

EQUIPMENT

- Package of proper-size sterile gloves (latex free if nurse or patient has sensitivity or allergy)
- Sterile pack containing sterile gown
- Clean, flat, dry surface
- Paper face masks, cap or hood, surgical shoe covers
- Protective eyewear/face shield

STEP	RATIONALE

APPLYING STERILE GOWN

1. Before entering operating room or treatment area, apply cap, face mask, eyewear, and foot covers (paper or cloth covers fit over work shoes).

   Prevents hair and air droplet nuclei from contaminating sterile work areas. Eyewear protects mucous membranes of eye. Foot covers reduce contamination from shoes.

2. Perform thorough surgical hand wash (see Skill 29-3).

   Removes transient and resident bacteria from fingers, hands, and forearms.

3. Circulating nurse assists by opening sterile pack containing sterile gown (folded inside out).

   Outer surface of gown remains sterile.

4. Circulating nurse prepares glove package by peeling outer wrapper open while keeping inner contents sterile. Places inner glove package on sterile field created by sterile outer wrapper.

   Keeps gloves sterile and allows nurse who has scrubbed to handle sterile items.

5. Reach down to sterile gown package; lift folded gown directly upward and step back away from table.

   Provides wide margin of safety, avoiding contamination of gown.

6. Holding folded gown, locate neckband. With both hands grasp inside front of gown just below neckband.

   Clean hands can touch inside of gown without contaminating outer surface.

7. Allow gown to unfold, keeping inside of gown toward body. Do not touch outside of gown with bare hands.

   Outside of gown is sterile surface.

8. With hands at shoulder level, slip both arms into armholes simultaneously (see illustration). Ask circulating nurse to bring gown over your shoulders by reaching inside to arm seams and pulling gown on, leaving sleeves covering hands.

   Careful application prevents contamination. Gown covers hands to prepare for closed gloving.

9. Have circulating nurse securely tie back of gown at neck and waist (see illustration). (If gown is wraparound style, do not touch sterile flap to cover it until you are gloved.)

   Gown must completely enclose underlying garments.

PERFORMING CLOSED GLOVING

10. Closed gloving

    a. With hands covered by gown sleeves, open inner sterile glove package (see illustration).

    Hands remain clean. Sterile gown cuff touches sterile glove surface.

STEP 8 Place arms in sleeves.

STEP 9 Circulating nurse ties scrub gown.

STEP 10a Scrub nurse opens glove package.

SKILL 29-4	APPLYING A STERILE GOWN AND PERFORMING CLOSED GLOVING—cont'd

STEP	RATIONALE
b. With dominant hand inside gown cuff, pick up glove for nondominant hand by grasping folded cuff.	Sterile gown touches sterile glove.
c. Extend nondominant forearm with palm up and place palm of glove against palm of nondominant hand. Glove fingers point toward elbow.	Positions glove for application over cuffed hand, keeping glove sterile.
d. Grasp back of glove cuff with covered dominant hand and turn glove cuff over end of nondominant hand and gown cuff (see illustration).	Seal created by glove cuff over gown prevents exit of microorganisms over operative sterile field.
e. Grasp top of glove and underlying gown sleeve with covered dominant hand. Carefully extend fingers into glove, being sure that glove cuff covers gown cuff.	
f. Glove dominant hand in same manner, reversing hands (see illustration). Use gloved nondominant hand to pull on glove. Keep hand inside sleeve (see illustration).	Sterile touches sterile.
g. Be sure that fingers are fully extended into both gloves.	Ensures that nurse has full dexterity while using gloved hand.
11. For wraparound sterile gowns: take gloved hand and release fastener or ties in front of gown.	Front of gown is sterile.
12. Hand paper tab connected to sterile tie to circulating nurse, who is nonsterile (see illustration). Circulating nurse stands still as you turn completely around to left, allowing for margin of safety as gown wraps around and covers your back. Take back sterile tie from circulating nurse and secure tie to gown.	Contact with team member could contaminate gown and gloves. Gown must enclose undergarments.

RECORDING AND REPORTING

• It is not necessary to record or report this procedure.

STEP 10d Glove is applied to left hand as right hand remains inside cuff.

STEP 12 Hand tie to sterile team member.

STEP 10f Second glove is applied.

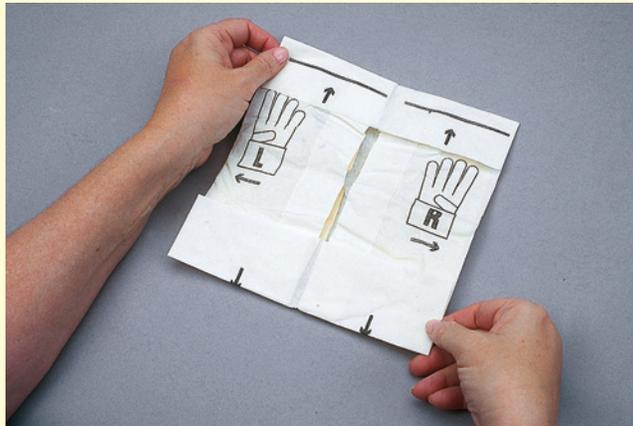
SKILL 29-5	OPEN GLOVING

DELEGATION CONSIDERATIONS

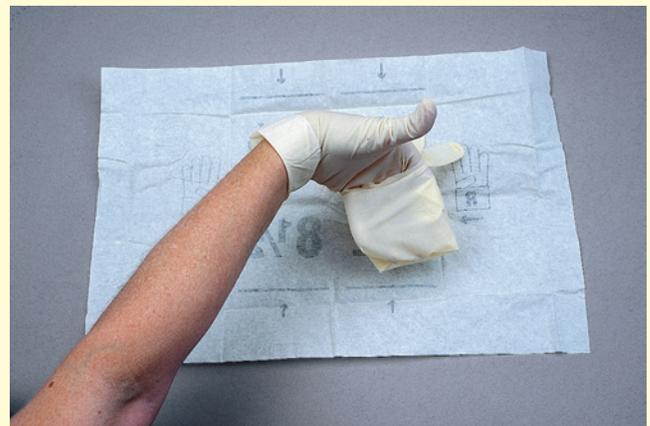
The skill of open gloving can be delegated when personnel are trained to perform a sterile procedure.

EQUIPMENT

- Sterile gloves (proper size)

STEP	RATIONALE
1. Perform thorough hand hygiene.	Removes bacteria from skin surfaces and reduces transmission of infection.
2. Remove outer glove package wrapper by carefully separating and peeling apart sides.	Prevents inner glove package from accidentally opening and touching contaminated objects.
3. Grasp inner package and lay it on clean, flat surface just above waist level. Open package, keeping gloves on wrappers inside surface (see illustration).	Sterile object held below waist is contaminated. Inner surface of glove package is sterile.
4. Identify right and left glove. Each glove has cuff approximately 5 cm (2 inches) wide. Glove dominant hand first.	Proper identification of gloves prevents contamination by improper fit. Gloving of dominant hand first improves dexterity.
5. With thumb and first two fingers of nondominant hand, grasp edge of cuff of glove for dominant hand. Touch only inside surface of glove.	Inner edge of cuff lies against skin and thus is not sterile.
6. Carefully pull glove over dominant hand, leaving cuff and being sure that it does not roll up wrist. Be sure that thumb and fingers are in proper spaces (see illustration).	If outer surface of glove touches hand or wrist, it is contaminated.
7. With gloved dominant hand, slip fingers underneath cuff of second glove (see illustration).	Cuff protects gloved fingers. Sterile touching sterile prevents glove contamination.


STEP 3 Open package.

STEP 6 Pull glove over dominant hand.


STEP 7 Slip fingers underneath cuff of second glove.

SKILL 29-5	OPEN GLOVING—cont'd

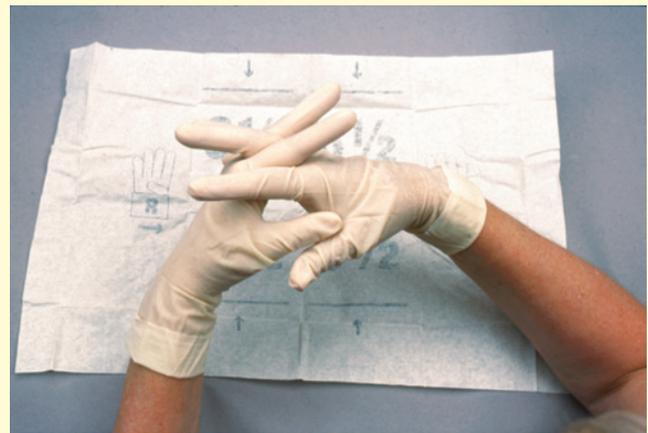
STEP	RATIONALE
8. Carefully pull second glove over nondominant hand. Do not allow fingers and thumb of gloved dominant hand to touch any part of exposed nondominant hand. Keep thumb of dominant hand abducted back (see illustration).	Contact of gloved hand with exposed hand results in contamination.
9. After second glove is on, interlock fingers of gloved hands and hold away from body above waist level until beginning procedure (see illustration).	Prevents accidental contamination from hand movement.

GLOVE DISPOSAL

10. Grasp outside of one cuff with other gloved hand; avoid touching wrist. Pull halfway down palm of hand. Take thumb of half-ungloved hand and place under cuff of other glove.	Minimizes contamination of underlying skin.
11. Pull glove off, turning it inside out. Discard in receptacle.	Outside of glove does not touch skin surface.
12. Take fingers of bare hand and tuck inside remaining glove cuff. Peel glove off, inside out. Discard in receptacle.	

RECORDING AND REPORTING

- It is not necessary to record or report this procedure.

STEP 8 Pull second glove over nondominant hand.


STEP 9 Hands are interlocked.

KEY POINTS

- Hand hygiene practices are the most important techniques to use in the prevention and control of infection.
- The potential for microorganisms to cause disease depends on the number of organisms, virulence, and ability to enter and survive in a host and susceptibility of the host.
- Normal body floras help to resist infection by releasing antibacterial substances and inhibiting multiplication of pathogenic microorganisms.
- An infection can develop as long as the six elements composing the infection chain are uninterrupted.
- Microorganisms are transmitted by direct and indirect contact, airborne spread, and vectors and contaminated articles.
- Increasing age, poor nutrition, stress, inherited conditions, chronic disease, and treatments or conditions that compromise the immune response increase susceptibility to infection.
- The major sites for HAIs include the urinary and respiratory tracts, bloodstream, and surgical or traumatic wounds.
- Invasive procedures, medical therapies, long hospitalization, and contact with health care personnel increase a hospitalized patient's risk for acquiring an HAI.
- Isolation practices may prevent personnel and patients from acquiring infections and transmitting microorganisms to other people.

- Standard precautions involve the use of generic barrier techniques when caring for all patients.
- Proper cleaning requires mechanical removal of all soil from an object or area.
- The overall experience of isolation is commonly viewed negatively due to barriers affecting the expression of a patient's identity and normal interpersonal relationships.
- An infection prevention and control professional monitors the incidence of infection within an institution, introduces evidence-based practices and provides educational and consulting services.
- Surgical asepsis requires more stringent techniques than medical asepsis and is directed at eliminating microorganisms.
- If the skin is broken or if an invasive procedure into a body cavity normally free of microorganisms is performed, follow surgical aseptic practices.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mrs. Andrews shares that she has had some wetness on her back and has been using tissues to wipe off and scratch her back. She also is having increased incision pain. She attributes her symptoms to the back brace because "it makes me sweat and itch." Her daughter noted that the incision was reddened with a small amount of drainage

coming from the site. Mrs. Andrews was seen by the surgeon, and an incision and drainage of the back wound were performed.

1. What do you need to include when assessing the wound for infection?
2. If Mrs. Andrews were to develop a systemic infection as a result of the localized wound infection, which assessments would you expect to find? Explain your answers.
3. Which methods of infection control do you need to use when caring for Mrs. Andrews?

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

▌ REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. What is the most effective way to control transmission of infection?
   1. Isolation precautions
   2. Identifying the infectious agent
   3. Hand hygiene practices
   4. Vaccinations
2. A patient who has been isolated for *Clostridium difficile (C. difficile)* asks you to explain what he should know about this organism. What is the most appropriate information to include in patient teaching? (Select all that apply.)
   1. The organism is usually transmitted through the fecal-oral route.
   2. Hands should always be cleaned with soap and water versus alcohol-based hand sanitizer.
   3. Everyone coming into the room must be wearing a gown and gloves.
   4. While the patient is in contact precautions, he cannot leave the room.
   5. *C. difficile* dies quickly once outside the body.
3. Your assigned patient has a leg ulcer that has a dressing on it. During your assessment you find that the dressing is saturated with purulent drainage. Which action would be best on your part?
   1. Reinforce dressing with a clean, dry dressing and call the health care provider.
   2. Remove wet dressing and apply new dressing using sterile procedure.
   3. Put on gloves before removing the old dressing; then obtain a wound culture.
   4. Remove saturated dressing with gloves, remove gloves, then perform hand hygiene and apply new gloves before putting on a clean dressing.
4. A patient is diagnosed with methicillin-resistant *Staphylococcus aureus* (MRSA) pneumonia. Which type of isolation precaution is *most* appropriate for this patient?
   1. Reverse isolation
   2. Droplet precautions
   3. Standard precautions
   4. Contact precautions
5. A family member is providing care to a loved one who has an infected leg wound. What should the nurse instruct the family member to do after providing care and handling contaminated equipment or organic material?
   1. Wear gloves before eating or handling food.
   2. Place any soiled materials into a bag and double bag it.
   3. Have the family member check with the health care provider about need for immunization.
   4. Perform hand hygiene after care and/or handling contaminated equipment or material.
6. A patient is isolated for pulmonary tuberculosis. The nurse notes that the patient seems to be angry, but he knows that this is a normal response to isolation. Which is the best intervention?
   1. Provide a dark, quiet room to calm the patient.
   2. Reduce the level of precautions to keep the patient from becoming angry.
   3. Explain the reasons for isolation procedures and provide meaningful stimulation.
   4. Limit family and other caregiver visits to reduce the risk of spreading the infection.
7. When should a nurse wear a mask? (Select all that apply.)
   1. The patient's dental hygiene is poor.
   2. The nurse is assisting with an aerosolizing respiratory procedure such as suctioning.
   3. The patient has acquired immunodeficiency syndrome (AIDS) and a congested cough.
   4. The patient is in droplet precautions.
   5. The nurse is assisting a health care provider in the insertion of a central line catheter.
8. Which type of personal protective equipment are staff required to wear when caring for a pediatric patient who is placed into airborne precautions for confirmed chickenpox/herpes zoster? (Select all that apply.)
   1. Disposable gown
   2. N 95 respirator mask
   3. Face shield or goggles
   4. Surgical mask
   5. Gloves
9. The infection control nurse has asked the staff to work on reducing the number of iatrogenic infections on the unit. Which of the following actions on your part would contribute to reducing health care–acquired infections? (Select all that apply.)
   1. Teaching correct handwashing to assigned patients
   2. Using correct procedures in starting and caring for an intravenous infusion
   3. Providing perineal care to a patient with an indwelling urinary catheter
   4. Isolating a patient who has just been diagnosed as having tuberculosis
   5. Decreasing a patient's environmental stimuli to decrease nausea
10. Which of the following actions by the nurse comply with core principles of surgical asepsis? (Select all that apply.)
    1. Set up sterile field before patient and other staff come to the operating suite.
    2. Keep the sterile field in view at all times.
    3. Consider the outer 2.5 cm (1 inch) of the sterile field as contaminated.
    4. Only health care personnel within the sterile field must wear personal protective equipment.
    5. The sterile gown must be put on before the surgical scrub is performed.
11. A patient has an indwelling urinary catheter. Why does an indwelling urinary catheter present a risk for urinary tract infection? (Select all that apply.)
    1. It allows migration of organisms into the bladder.
    2. The insertion procedure is not done under sterile conditions.
    3. It obstructs the normal flushing action of urine flow.
    4. It keeps an incontinent patient's skin dry.
    5. The outer surface of the catheter is not considered sterile.

12. Put the following steps for removal of protective barriers after leaving an isolation room in order.
    1. Remove gloves.
    2. Perform hand hygiene.
    3. Remove eyewear or goggles.
    4. Untie top and then bottom mask strings and remove from face.
    5. Untie waist and neck strings of gown. Remove gown, rolling it onto itself without touching the contaminated side.

13. What does it mean when a patient is diagnosed with a multidrug-resistant organism in his or her surgical wound? (Select all that apply.)
    1. There is more than one organism in the wound that is causing the infection.
    2. The antibiotics the patient has received are not strong enough to kill the organism.
    3. The patient will need more than one type of antibiotic to kill the organism.
    4. The organism has developed a resistance to one or more broad-spectrum antibiotics, indicating that the organism will be hard to treat effectively.
    5. There are no longer any antibiotic options available to treat the patient's infection.

14. A patient's surgical wound has become swollen, red, and tender. The nurse notes that the patient has a new fever, purulent wound drainage, and leukocytosis. Which interventions would be appropriate and in what order?
    1. Notify the health care provider of the patient's status.
    2. Reassure the patient and recheck the wound later.
    3. Support the patient's fluid and nutritional needs.
    4. Use aseptic technique to change the dressing.

15. Which of these statements are true regarding disinfection and cleaning? (Select all that apply.)
    1. Proper cleaning requires mechanical removal of all soil from an object or area.
    2. General environmental cleaning is an example of medical asepsis.
    3. When cleaning a wound, wipe around the wound edge first and then clean inward toward the center of the wound.
    4. Cleaning in a direction from the least to the most contaminated area helps reduce infections.
    5. Disinfecting and sterilizing medical devices and equipment involve the same procedures.

Vital Signs

- Explain the principles and mechanisms of thermoregulation.
- Describe nursing measures that promote heat loss and heat conservation.
- Discuss physiological changes associated with fever.
- Accurately assess body temperature, pulse, respirations, oxygen saturation, and blood pressure.
- Explain the physiology of normal regulation of blood pressure, pulse, oxygen saturation, and respirations.
- Describe factors that cause variations in body temperature, pulse, oxygen saturation, respirations, capnography, and blood pressure.
- Describe cultural and ethnic variations with blood pressure assessment.

- Identify ranges of acceptable vital sign values for an infant, a child, and an adult.
- Explain variations in technique used to assess an infant's, a child's, and an adult's vital signs.
- Describe the benefits and precautions involving self-measurement of blood pressure.
- Identify when to measure vital signs.
- Accurately record and report vital sign measurements.
- Appropriately delegate measurement of vital signs to nursing assistive personnel.

Vital signs, p. 486

The most frequent and routine measurements obtained by health care providers are those of temperature, pulse, blood pressure (BP), respiratory rate, and oxygen saturation. As indicators of health status, these measures indicate the effectiveness of circulatory, respiratory, neural, and endocrine body functions. Because of their importance, they are referred to as **vital signs.** Pain, a subjective symptom, is often called another vital sign and is frequently measured with the others (see Chapter 44).

Measurement of vital signs provides data to determine a patient's usual state of health (baseline data). Many factors such as the temperature of the environment, the patient's physical exertion, and the effects of illness cause vital signs to change, sometimes outside an acceptable range. Assessment of vital signs provides data to identify nursing diagnoses, implement planned interventions, and evaluate outcomes of care. An alteration in vital signs signals a change in physiological function and the need for medical or nursing intervention.

Vital signs are a quick and efficient way of monitoring a patient's condition or identifying problems and evaluating his or her response to intervention. When you learn the physiological variables influencing vital signs and recognize the relationship of their changes to one another and to other physical assessment findings, you can make precise determinations about a patient's health problems. Vital signs and other physiological measurements are the basis for clinical decision making and problem solving. Many facilities adopt Early Warning Scores determined by vital sign data entered into the electronic medical record to alert nurses to potential changes in their patients' conditions.

GUIDELINES FOR MEASURING VITAL SIGNS

Vital signs are a part of the assessment database. You include them in a complete physical assessment (see Chapter 31) or obtain them individually to assess a patient's condition. Establishing a database of vital signs during a routine physical examination serves as a baseline for future assessments. A patient's needs and condition determine when, where, how, and by whom vital signs are measured. You need to measure them correctly, and at times you appropriately delegate their measurement. You also need to know expected values (Box 30-1), interpret your patient's values, communicate findings appropriately, and begin interventions as needed. Use the following guidelines to incorporate measurements of vital signs into nursing practice:

- Measuring vital signs is your responsibility. You may delegate measurement of vital signs in selected situations (e.g., in stable patients). However, it is your responsibility to review vital sign data, interpret their significance, and critically think through decisions about interventions.
- Assess equipment to ensure that it is working correctly and provides accurate findings.
- Select equipment on the basis of the patient's condition and characteristics (e.g., do not use an adult-size BP cuff for a child).

- Know the patient's usual range of vital signs. These values can differ from the acceptable range for that age or physical state. The patient's usual values serve as a baseline for comparison with later findings. Thus you are able to detect a change in condition over time.
- Know your patient's medical history, therapies, and prescribed medications. Some illnesses or treatments cause predictable changes in vital signs. Some medications affect one or more vital signs.
- Control or minimize environmental factors that affect vital signs. For example, assessing a patient's temperature in a warm, humid room may yield a value that is not a true indicator of his or her condition.
- Use an organized, systematic approach when taking vital signs. Each procedure requires a step-by-step approach to ensure accuracy.
- On the basis of a patient's condition, collaborate with health care providers to decide the frequency of vital sign assessment. In the hospital health care providers order a minimum frequency of vital sign measurements for each patient. Following surgery or treatment intervention you measure vital signs more frequently to detect complications. In a clinic or outpatient setting you take vital signs before the health care provider examines the patient and after any invasive procedures. As a patient's physical condition worsens, it is often necessary to monitor vital signs as often as every 5 to 10 minutes. The nurse is responsible for judging whether more frequent assessments are necessary (Box 30-2).
- Use vital sign measurements to determine indications for medication administration. For example, give certain cardiac drugs only within a range of pulse or BP values. Administer antipyretics when temperature is elevated outside of the acceptable range for the patient. Know the acceptable ranges for your patients before administering medications.
- Analyze the results of vital sign measurement on the basis of patient's condition and past medical history.
- Verify and communicate significant changes in vital signs. Baseline measurements provide a starting point for identifying and accurately interpreting possible changes. When vital signs appear abnormal, have another nurse or health care provider repeat the measurement to verify readings. Inform the charge

---

BOX 30-1 Vital Signs

Acceptable Ranges for Adults

Temperature Range
Average temperature range: 36° to 38° C (96.8° to 100.4° F)
Average oral/tympanic: 37° C (98.6° F)
Average rectal: 37.5° C (99.5° F)
Axillary: 36.5° C (97.7° F)

Pulse
60 to 100 beats/min, strong and regular

Pulse Oximetry (SpO₂)
Normal: SpO_2 ≥95%

Respirations
Adult: 12 to 20 breaths/min, deep and regular

Blood Pressure
Systolic <120 mm Hg
Diastolic <80 mm Hg
Pulse pressure: 30 to 50 mm Hg

Capnography (EtCO₂)
Normal: 35-45 mm Hg

BOX 30-2 When to Measure Vital Signs

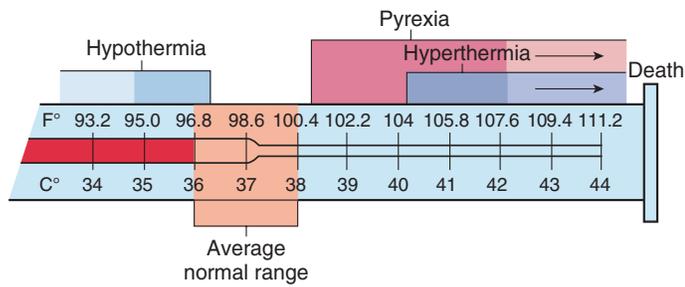
- On admission to a health care facility
- When assessing a patient during home care visits
- In a hospital on a routine schedule according to the health care provider's order or hospital standards of practice before, during, and after a surgical procedure or invasive diagnostic procedure
- Before, during, and after a transfusion of blood products
- Before, during, and after the administration of medication or therapies that affect cardiovascular, respiratory, or temperature-control functions
- When a patient's general physical condition changes (e.g., loss of consciousness or increased intensity of pain)
- Before, during, and after nursing interventions influencing a vital sign (e.g., before a patient previously on bed rest ambulates or before a patient performs range-of-motion exercises)
- When a patient reports nonspecific symptoms of physical distress (e.g., feeling "funny" or "different")


FIGURE 30-1 Ranges of normal temperature values and abnormal body temperature alterations.

nurse or health care provider immediately, document findings in your patient's record, and report vital sign changes to nurses during hand-off communication (TJC, 2016)
- Instruct the patient or family caregiver in vital sign assessment and the significance of findings.

BODY TEMPERATURE

Physiology

Body temperature is the difference between the amount of heat produced by body processes and the amount lost to the external environment.

Heat Produced − Heat Lost = Body Temperature

Despite extremes in environmental conditions and physical activity, temperature-control mechanisms of humans keep body **core temperature** (temperature of the deep tissues) relatively constant (Figure 30-1). However, surface temperature varies, depending on blood flow to the skin and the amount of heat lost to the external environment. Body tissues and cells function efficiently within a narrow range, from 36° to 38°C (96.8° to 100.4°F), but no single temperature is normal for all people.

The site of temperature measurement (oral, rectal, tympanic membrane, temporal artery, esophageal, pulmonary artery, axillary, or even urinary bladder) is one factor that determines a patient's temperature. For healthy young adults the average oral temperature is 37°C (98.6°F). In the elderly population the average core temperature ranges from 35° to 36.1°C (95° to 97°F) as a result of decreased immunity (Touhy and Jett, 2014). The time of day also affects body temperature, with the lowest temperature at 6:00 AM and the highest temperature at 4:00 PM in healthy people. Invasive measurements such as with a pulmonary artery catheter are considered core temperatures; whereas axillary temperatures are reflective of the surface temperature of the body. It is important to remember that a consistent body temperature measurement from a single site allows you to monitor patterns of your patient's body temperature. As you assess these temperature trends, you can collaborate with the health care team to determine if a body temperature measurement site is more appropriate.

Body Temperature Regulation. Physiological and behavioral mechanisms regulate the balance between heat lost and heat produced, or **thermoregulation**. For the body temperature to stay constant and within an acceptable range, various mechanisms maintain the relationship between heat production and heat loss. Apply knowledge of temperature-control mechanisms to promote temperature regulation.

Neural and Vascular Control. The hypothalamus, located between the cerebral hemispheres, controls body temperature the same way a thermostat works in the home. A comfortable temperature is the "set point" at which a heating system operates. In the home a drop in environmental temperature activates the furnace, whereas a rise in temperature shuts the system down.

The hypothalamus senses minor changes in body temperature. The anterior hypothalamus controls heat loss, and the posterior hypothalamus controls heat production. When nerve cells in the anterior hypothalamus become heated beyond the set point, impulses are sent out to reduce body temperature. Mechanisms of heat loss include sweating, vasodilation (widening) of blood vessels, and inhibition of heat production. The body redistributes blood to surface vessels to promote heat loss.

If the posterior hypothalamus senses that body temperature is lower than the set point, the body initiates heat-conservation mechanisms. Vasoconstriction (narrowing) of blood vessels reduces blood flow to the skin and extremities. Compensatory heat production is stimulated through voluntary muscle contraction and muscle shivering. When vasoconstriction is ineffective in preventing additional heat loss, shivering begins. Disease or trauma to the hypothalamus or the spinal cord, which carries hypothalamic messages, causes serious alterations in temperature control.

Heat Production. Temperature regulation depends on normal heat production processes. Heat produced by the body is a by-product of metabolism, which is the chemical reaction in all body cells. Food is the primary fuel source for metabolism. Activities requiring additional chemical reactions increase the metabolic rate. As metabolism increases, additional heat is produced. When metabolism decreases, less heat is produced. Heat production occurs during rest, voluntary movements, involuntary shivering, and nonshivering thermogenesis.

- Basal metabolism accounts for the heat produced by the body at absolute rest. The average **basal metabolic rate (BMR)** depends on the body surface area. Thyroid hormones also affect the BMR. By promoting the breakdown of body glucose and fat, thyroid hormones increase the rate of chemical reactions in almost all cells of the body. When large amounts of thyroid hormones are secreted, the BMR can increase 100% above normal. The absence of thyroid hormones reduces the BMR by half, causing a decrease in heat production. The male sex hormone testosterone increases BMR. Men have a higher BMR than women.
- Voluntary movements such as muscular activity during exercise require additional energy. The metabolic rate increases during activity, sometimes causing heat production to increase up to 50 times normal.
- **Shivering** is an involuntary body response to temperature differences in the body. The skeletal muscle movement during shivering requires significant energy. Shivering sometimes increases heat production 4 to 5 times greater than normal. The heat that is produced helps equalize the body temperature, and the shivering ceases. In vulnerable patients shivering seriously drains energy sources, resulting in further physiological deterioration.
- **Nonshivering thermogenesis** occurs primarily in neonates. Because neonates cannot shiver, a limited amount of vascular brown tissue, present at birth, is metabolized for heat production.

Heat Loss. Heat loss and heat production occur simultaneously. The structure of the skin and exposure to the environment result in constant, normal heat loss through radiation, conduction, convection, and evaporation.

Radiation is the transfer of heat from the surface of one object to the surface of another without direct contact between the two. As much as 85% of the surface area of the human body radiates heat to the environment. Peripheral vasodilation increases blood flow from the internal organs to the skin to increase radiant heat loss. Peripheral vasoconstriction minimizes radiant heat loss. Radiation increases as the temperature difference between the objects increases. Radiation heat loss can be considerable during surgery when the patient's skin is exposed to a cool environment. However, if the environment is warmer than the skin, the body absorbs heat through radiation.

The patient's position enhances radiation heat loss (e.g., standing exposes a greater radiating surface area, and lying in a fetal position minimizes heat radiation). Help promote heat loss through radiation by removing clothing or blankets. Covering the body with dark, closely woven clothing decreases the amount of heat lost from radiation.

Conduction is the transfer of heat from one object to another with direct contact. Solids, liquids, and gases conduct heat through contact. When the warm skin touches a cooler object, heat is lost. Conduction normally accounts for a small amount of heat loss. Applying an ice pack or bathing a patient with a cool cloth increases conductive heat loss. Applying several layers of clothing reduces conductive loss. The body gains heat by conduction when it makes contact with materials warmer than skin temperature (e.g., application of an aquathermia pad).

Convection is the transfer of heat away by air movement. A fan promotes heat loss through convection. The rate of heat loss increases when moistened skin comes into contact with slightly moving air.

Evaporation is the transfer of heat energy when a liquid is changed to a gas. The body continuously loses heat by evaporation. Approximately 600 to 900 mL a day evaporates from the skin and lungs, resulting in water and heat loss. By regulating perspiration or sweating, the body promotes additional evaporative heat loss. When body temperature rises, the anterior hypothalamus signals the sweat glands to release sweat through tiny ducts on the surface of the skin. Sweat evaporates, resulting in heat loss. During physical exercise over 80% of the heat produced is lost by evaporation.

Diaphoresis is visible perspiration primarily occurring on the forehead and upper thorax, although you can see it in other places on the body. For each hour of exercise in hot conditions $\frac{1}{2}$ to 2 L of body fluid can be lost in sweat (Rowland, 2011). Excessive evaporation causes skin scaling and itching and drying of the nares and pharynx. A lowered body temperature inhibits sweat gland secretion. People who have a congenital absence of sweat glands or a serious skin disease that impairs sweating are unable to tolerate warm temperatures because they cannot cool themselves adequately.

Skin in Temperature Regulation. The skin regulates temperature through insulation of the body, vasoconstriction (which affects the amount of blood flow and heat loss to the skin), and temperature sensation. The skin, subcutaneous tissue, and fat keep heat inside the body. People with more body fat have more natural insulation than do slim and muscular people.

The way the skin controls body temperature is similar to the way an automobile radiator controls engine temperature. An automobile engine generates a great deal of heat. Water is pumped through the engine to collect the heat and carry it to the radiator, where a fan transfers the heat from the water to the outside air. In the human body the internal organs produce heat; during exercise or increased sympathetic stimulation (such as in the stress response) the amount of heat produced is greater than the usual core temperature. Blood flows from the internal organs, carrying heat to the body surface. The skin has many blood vessels, especially the areas of the hands, feet, and ears. Blood flow through these vascular areas of the skin varies from minimal flow to as much as 30% of the blood ejected from the heart. Heat transfers from the blood, through vessel walls, to the surface of the skin and is lost to the environment through the heat-loss mechanisms. The core temperature of the body remains within safe limits.

The degree of vasoconstriction determines the amount of blood flow and heat loss to the skin. If the core temperature is too high, the hypothalamus inhibits vasoconstriction. As a result, blood vessels dilate, and more blood reaches the surface of the skin. On a hot, humid day the blood vessels in the hands are dilated and easily visible. In contrast, if the core temperature becomes too low, the hypothalamus initiates vasoconstriction, and blood flow to the skin lessens to conserve heat.

Behavioral Control. Healthy individuals are able to maintain comfortable body temperature when exposed to temperature extremes. The ability of a person to control body temperature depends on (1) the degree of temperature extreme, (2) the person's ability to sense feeling comfortable or uncomfortable, (3) thought processes or emotions, and (4) the person's mobility or ability to remove or add clothes. Individuals are unable to control body temperature if any of these abilities is lost. For example, infants are able to sense uncomfortable warm conditions but need help to change their environment. Older adults sometimes need help to detect cold environments and minimize heat loss. Illnesses, a decreased level of consciousness, or impaired thought processes result in an inability to recognize the need to change behavior for temperature control. When temperatures become extremely hot or cold, health-promoting behaviors such as removing or adding clothing have a limited effect on controlling temperature.

Factors Affecting Body Temperature

Many factors affect body temperature. Changes in body temperature within an acceptable range occur when physiological or behavioral mechanisms alter the relationship between heat production and heat loss. Be aware of these factors when assessing temperature variations and evaluating deviations from normal.

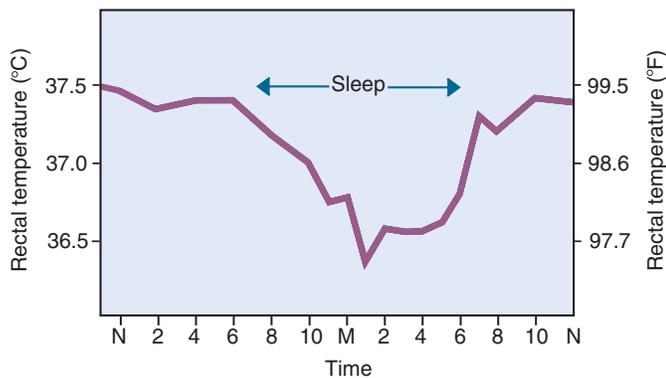
Age. At birth the newborn leaves a warm, relatively constant environment and enters one in which temperatures fluctuate widely. Temperature-control mechanisms are immature. An infant's temperature responds drastically to changes in the environment. Take extra care to protect newborns from environmental temperatures. Provide adequate clothing and avoid exposing infants to temperature extremes. A newborn loses up to 30% of body heat through the head and therefore needs to wear a cap to prevent heat loss. When protected from environmental extremes, the newborn's body temperature is usually within 35.5° to 37.5°C (95.9° to 99.5°F).

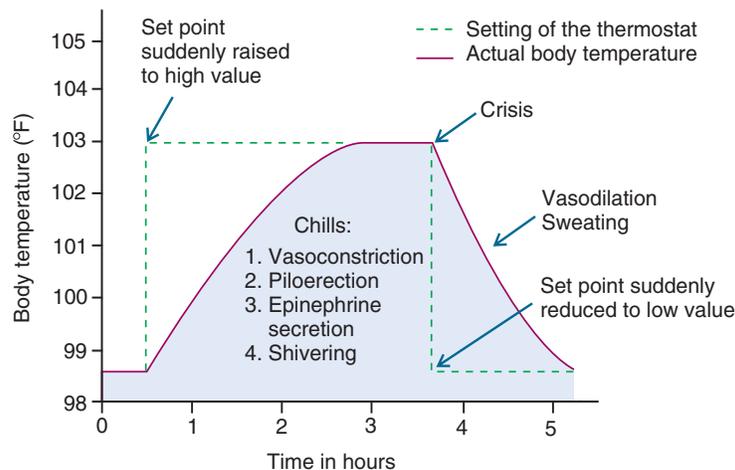
Temperature regulation is unstable until children reach puberty. The usual temperature range gradually drops as individuals approach older adulthood. The older adult has a narrower range of body temperatures than the younger adult. Oral temperatures of 35°C (95°F) are sometimes found in older adults in cold weather. However, the average body temperature of older adults is approximately 35° to 36.1°C (95° to 97°F). Older adults are particularly sensitive to temperature extremes because of deterioration in control mechanisms, particularly poor vasomotor control (control of vasoconstriction and vasodilation), reduced amounts of subcutaneous tissue, reduced sweat gland activity, and reduced metabolism.

Exercise. Muscle activity requires an increased blood supply and carbohydrate and fat breakdown. Any form of exercise increases metabolism and heat production and thus body temperature. Prolonged strenuous exercise such as long-distance running temporarily raises body temperature.

Hormone Level. Women generally experience greater fluctuations in body temperature than men. Hormonal variations during the menstrual cycle cause body temperature fluctuations. Progesterone levels rise and fall cyclically during the menstrual cycle. When progesterone levels are low, the body temperature is a few tenths of a degree below the baseline level. The lower temperature persists until ovulation occurs. During ovulation greater amounts of progesterone enter the circulatory system and raise the body temperature to previous baseline levels or higher. These temperature variations help to predict a woman's most fertile time to achieve pregnancy.

Body temperature changes also occur in women during menopause (cessation of menstruation). Women who have stopped menstruating often experience periods of intense body heat and sweating lasting from 30 seconds to 5 minutes. During these periods often intermittent skin temperature increases up to 4°C (7.2°F), referred to as hot flashes. This is caused by the instability of the vasomotor controls for vasodilation and vasoconstriction.

Circadian Rhythm. Body temperature normally changes 0.5° to 1°C (0.9° to 1.8°F) during a 24-hour period. However, temperature is one of the most stable rhythms in humans. The temperature is usually lowest between 1:00 and 4:00 AM (Figure 30-2). During the day body temperature rises steadily to a maximum temperature value at about 4:00 PM and then declines to early-morning levels. Temperature patterns are not automatically reversed in people who work at night and sleep during the day. It takes 1 to 3 weeks for the




cycle to reverse. In general the circadian temperature rhythm does not change with age.

Stress. Physical and emotional stress increase body temperature through hormonal and neural stimulation (see Chapter 38). These physiological changes increase metabolism, which increases heat production. A patient who is anxious about entering a hospital or a health care provider's office often has a higher normal temperature.

Environment. Environment influences body temperature. When placed in a warm room a patient may be unable to regulate body temperature by heat-loss mechanisms, and the body temperature may elevate. If the patient is outside in the cold without warm clothing, body temperature may be low as a result of extensive radiant and conductive heat loss. Environmental temperatures affect infants and older adults more often because their temperature-regulating mechanisms are less efficient.

Temperature Alterations. Changes in body temperature outside the usual range are related to excessive heat production, excessive heat loss, minimal heat production, minimal heat loss, or any combination of these alterations.

Fever. Fever, or **pyrexia**, occurs because heat-loss mechanisms are unable to keep pace with excessive heat production, resulting in an abnormal rise in body temperature. A fever is usually not harmful if it stays below 39°C (102.2°F) in adults or below 40°C (104°F) in children. A single temperature reading does not always indicate a fever. In addition to physical signs and symptoms of infection, fever determination is based on several temperature readings at different times of the day compared with the usual value for that person at that time.

A true fever results from an alteration in the hypothalamic set point. **Pyrogens** such as bacteria and viruses elevate body temperature. They act as antigens, triggering immune system responses. The hypothalamus reacts to raise the set point, and the body responds by producing and conserving heat. Several hours pass before the body temperature reaches the new set point. During this period a person experiences chills, shivers, and feels cold, even though the body temperature is rising (Figure 30-3). The chill phase resolves when the new set point, a higher temperature, is achieved. During the next phase, the plateau, the chills subside, and the person feels warm and dry. If the new set point is "overshot" or the pyrogens are removed (e.g., destruction of bacteria by antibiotics), the third phase of a **febrile** episode

FIGURE 30-2 Temperature cycle for 24 hours.

FIGURE 30-3 Effect of changing set point of hypothalamic temperature control during a fever. (Modified from Guyton AC, Hall JE: *Textbook of medical physiology,* ed 12, Philadelphia, 2011, Saunders.)

BOX 30-3 Patterns of Fever

Sustained: A constant body temperature continuously above 38°C (100.4°F) that has little fluctuation

Intermittent: Fever spikes interspersed with usual temperature levels (Temperature returns to acceptable value at least once in 24 hours.)

Remittent: Fever spikes and falls without a return to acceptable temperature levels.

Relapsing: Periods of febrile episodes and periods with acceptable temperature values (Febrile episodes and periods of normothermia are often longer than 24 hours.)

TABLE 30-1 Classification of Hypothermia

	Celsius	Fahrenheit
Mild	34°-36°	93.2°-96.8°
Moderate	30°-34°	86.0°-93.2°
Severe	<30°	<86°

occurs. The hypothalamus set point drops, initiating heat-loss responses. The skin becomes warm and flushed because of vasodilation. Diaphoresis assists in evaporative heat loss. When the fever "breaks," the patient becomes **afebrile.**

Fever is an important defense mechanism. Mild temperature elevations as high as 39°C (102.2°F) enhance the immune system of the body. During a febrile episode white blood cell production is stimulated. Increased temperature reduces the concentration of iron in the blood plasma, suppressing the growth of bacteria. Fever also fights viral infections by stimulating interferon, the natural virus-fighting substance of the body.

Fevers and fever patterns serve a diagnostic purpose. Fever patterns differ, depending on the causative pyrogen (Box 30-3). The increase or decrease in pyrogen activity results in fever spikes and declines at different times of the day. The duration and degree of fever depend on the strength of the pyrogen and the ability of the individual to respond. The term **fever of unknown origin (FUO)** refers to a fever with an undetermined cause.

During a fever cellular metabolism increases, and oxygen consumption rises. Body metabolism increases 10% for every degree Celsius of temperature elevation. Heart and respiratory rates increase to meet the metabolic needs of the body for nutrients. The increased metabolism uses energy that produces additional heat. If a patient has a cardiac or respiratory problem, the stress of a fever is great. A prolonged fever weakens a patient by exhausting energy stores. Increased metabolism requires additional oxygen. If the body cannot meet the demand for additional oxygen, cellular hypoxia (inadequate oxygen) occurs. Myocardial hypoxia produces angina (chest pain). Cerebral hypoxia produces confusion. Interventions during a fever include oxygen therapy. When water loss through increased respiration and diaphoresis is excessive, the patient is at risk for fluid volume deficit. Dehydration is a serious problem for older adults and children with low body weight. Maintaining optimum fluid volume status is an important nursing action (see Chapter 42).

Hyperthermia. An elevated body temperature related to the inability of the body to promote heat loss or reduce heat production is **hyperthermia.** Whereas fever is an upward shift in the set point, hyperthermia results from an overload of the thermoregulatory mechanisms of the body. Any disease or trauma to the hypothalamus impairs heat-loss mechanisms. **Malignant hyperthermia** is a hereditary condition of uncontrolled heat production that occurs when susceptible people receive certain anesthetic drugs.

Heatstroke. Heat depresses hypothalamic function. Prolonged exposure to the sun or a high environmental temperature overwhelms the heat-loss mechanisms of the body. These conditions cause **heatstroke,** defined as a body temperature of 40°C (104°F) or more (Goforth and Kazman, 2015). Heatstroke is a dangerous heat emergency with a high mortality rate. Patients at risk include the very young or very old and those who have cardiovascular disease,

hypothyroidism, diabetes, or alcoholism. Also at risk are those who take medications that decrease the ability of the body to lose heat (e.g., phenothiazines, anticholinergics, diuretics, amphetamines, and beta-adrenergic receptor antagonists) and those who exercise or work strenuously (e.g., athletes, construction workers, and farmers).

Signs and symptoms of heatstroke include giddiness, confusion, delirium, excess thirst, nausea, muscle cramps, visual disturbances, and even incontinence. Vital signs reveal a body temperature sometimes as high as 45°C (113°F), with an increase in heart rate (HR) and lowering of BP. The most important sign of heatstroke is hot, dry skin. Victims of heatstroke do not sweat because of severe electrolyte loss and hypothalamic malfunction. If the condition progresses, a patient with heatstroke becomes unconscious, with fixed, nonreactive pupils. Permanent neurological damage occurs unless cooling measures are rapidly started.

Heat Exhaustion. **Heat exhaustion** occurs when profuse diaphoresis results in excess water and electrolyte loss. Caused by environmental heat exposure, a patient exhibits signs and symptoms of deficient fluid volume (see Chapter 42). First aid includes transporting him or her to a cooler environment and restoring fluid and electrolyte balance.

Hypothermia. Heat loss during prolonged exposure to cold overwhelms the ability of the body to produce heat, causing hypothermia. **Hypothermia** is classified by core temperature measurements (Table 30-1). It is sometimes unintentional such as falling through the ice of a frozen lake. Occasionally hypothermia is intentionally induced during surgical or emergency procedures to reduce metabolic demand and the need of the body for oxygen.

Accidental hypothermia usually develops gradually and goes unnoticed for several hours. When skin temperature drops below 34°C (93.2°F), the patient suffers uncontrolled shivering, loss of memory, depression, and poor judgment. As the body temperature falls lower, HR, respiratory rate, and BP fall. The skin becomes cyanotic. Patients experience cardiac dysrhythmias, loss of consciousness, and unresponsiveness to painful stimuli if hypothermia progresses. In cases of severe hypothermia a person demonstrates clinical signs similar to those of death (e.g., lack of response to stimuli and extremely slow respirations and pulse). When you suspect hypothermia, assessment of core temperature is critical. A special low-reading thermometer is required because standard devices do not register below 35°C (95°F).

Frostbite occurs when the body is exposed to subnormal temperatures. Ice crystals form inside the cells, and permanent circulatory and tissue damage occurs. Areas particularly susceptible to frostbite are the earlobes, tip of the nose, and fingers and toes. The injured area becomes white, waxy, and firm to the touch. The patient loses sensation in the affected area. Interventions include gradual warming measures, analgesia, and protection of the injured tissue.

❖ NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

Knowledge of the physiology of body temperature regulation is essential to assess and evaluate a patient's response to temperature alterations and intervene safely. Implement independent measures to increase or minimize heat loss, promote heat conservation, and increase comfort. These measures complement the effects of medically ordered therapies during illness. You also provide education to family members, parents of children, or other caregivers.

◆ Assessment

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. Identify your patient's values, beliefs, current treatments, and expectations regarding fever management. When possible, select the temperature site preferred by the patient. Include the patient's preferences when selecting nonpharmacological interventions for hyperthermia (e.g., cooling blankets, tepid baths, fans).

Sites. Core and surface body temperature can be measured at several sites. Intensive care units use the core temperatures of the pulmonary artery, esophagus, and urinary bladder. These measurements require the use of continuous invasive devices placed in body cavities or organs and continually display readings on an electronic monitor.

Use a thermometer to obtain intermittent temperature measurements from the mouth, rectum, tympanic membrane, or temporal artery. Axillary temperature measurements, obtained by placing a thermometer under the axillae, are not recommended in adults because they have been shown to be inaccurate and poorly reflect core temperature (Haugan et al., 2012; Reynolds et al., 2014). However, axillary measurements have been shown to be as reliable as rectal temperature measurement in stable infants (Charafeddine et al., 2014). You can apply noninvasive chemically prepared thermometer patches to the skin. Oral, rectal, and skin temperature sites rely on effective blood circulation at the measurement site. The heat of the blood is conducted to the thermometer probe. Tympanic temperature relies on the radiation of body heat to an infrared sensor. Because the tympanic membrane shares the same arterial blood supply as the hypothalamus, it is a core temperature. Temporal artery measurements detect the temperature of cutaneous blood flow.

To ensure accurate temperature readings, measure each site correctly (see Skill 30-1 on pp. 512-517). The temperature obtained varies, depending on the site used, but it is usually between 36°C (96.8°F) and 38°C (100.4°F). Rectal temperatures are usually 0.5°C (0.9°F) higher than oral temperatures. Each of the common temperature measurement sites has advantages and disadvantages (Box 30-4). Choose the safest and most accurate site for each patient. When possible, use the same site when repeated measurements are necessary.

Thermometers. Two types of thermometers are available for measuring body temperature: electronic and disposable. The mercury-in-glass thermometer, once the standard device, has been eliminated from health care facilities because of the environmental hazards of mercury. However, some patients still use mercury-in-glass thermometers at home. When you find a mercury-in-glass thermometer in the home, teach the patient about safer temperature devices and encourage the disposal of mercury products at appropriate neighborhood hazardous disposal locations. Disposable digital thermometers are readily available for use in the home setting. Home disposable thermometers are useful for temperature screening but are not as accurate as nondisposable electronic thermometers (Counts et al., 2014).

Each device measures temperature using the Celsius or Fahrenheit scale. Electronic thermometers convert the temperature scales by activating a switch. When it is necessary to convert temperature readings, use the following formulas:

1. To convert Fahrenheit to Celsius, subtract 32 from the Fahrenheit reading and multiply the result by 5/9.

$$C = (F - 32) \times 5/9$$
$$\text{Example: } 40°C = (104°F - 32) \times 5/9$$

2. To convert Celsius to Fahrenheit, multiply the Celsius reading by 9/5 and add 32 to the product.

$$F = (9/5 \times °C) + 32$$
$$\text{Example: } 104°F = (9/5 \times 40°C) + 32°$$

Electronic Thermometer. The electronic thermometer consists of a rechargeable battery-powered display unit, a thin wire cord, and a temperature-processing probe covered by a disposable probe cover (Figure 30-4). Separate unbreakable probes are available for oral and rectal use. Electronic thermometers provide two modes of operation: a 4-second predictive temperature and a 3-minute standard temperature. Nurses use the 4-second predictive mode, which improves measurement accuracy. A sound signals, and a reading appears on the display unit when the peak temperature reading has been measured.

Another form of electronic thermometer is used exclusively for tympanic temperature. An otoscope-like speculum with an infrared sensor tip detects heat radiated from the tympanic membrane. Within seconds of placement in the auditory canal, a sound signals, and a reading appears on the display unit when the peak temperature reading has been measured.

Another form of electronic thermometer measures the temperature of the superficial temporal artery. A handheld scanner with an infrared sensor tip detects the temperature of cutaneous blood flow by sweeping the sensor across the forehead and just behind the ear (Figure 30-5). After scanning is complete, a reading appears on the display unit. Temporal artery temperature is a reliable noninvasive measure of core temperature.

The greatest advantages of electronic thermometers are that their readings appear within seconds and they are easy to read. The plastic sheath is unbreakable and ideal for children. Their expense is a major disadvantage. Maintaining cleanliness of the probes is an important consideration. For example, if not properly cleaned between patients, gastrointestinal contamination of the rectal probe causes disease transmission. Wipe the thermometer daily with alcohol and the thermometer probe with an alcohol swab after each patient, paying particular attention to the ridges where the probe cover is secured to the probe.

Chemical Dot Thermometers. Single-use or reusable chemical dot thermometers (Figure 30-6) are thin strips of plastic with a temperature sensor at one end. The sensor consists of a matrix of chemically impregnated dots that change color at different temperatures. In the Celsius version there are 50 dots, each representing a temperature increment of 0.1°C, over a range of 35.5°C to 40.4°C. The Fahrenheit version has 45 dots with increments of 0.2°F and a range of 96°F to 104.8°F. Chemical dots on the thermometer change color to reflect temperature reading, usually within 60 seconds. Most are for single use. In one reusable brand for a single patient the chemical dots return to the original color within a few seconds. Chemical dot thermometers are usually for oral temperatures. You also use them for rectal temperatures when covered by a plastic sheath and placed for 3 minutes. Chemical dot thermometers are useful for screening temperatures, especially in infants, young children, and patients who are intubated.

BOX 30-4 Advantages and Disadvantages of Select Temperature Measurement Sites

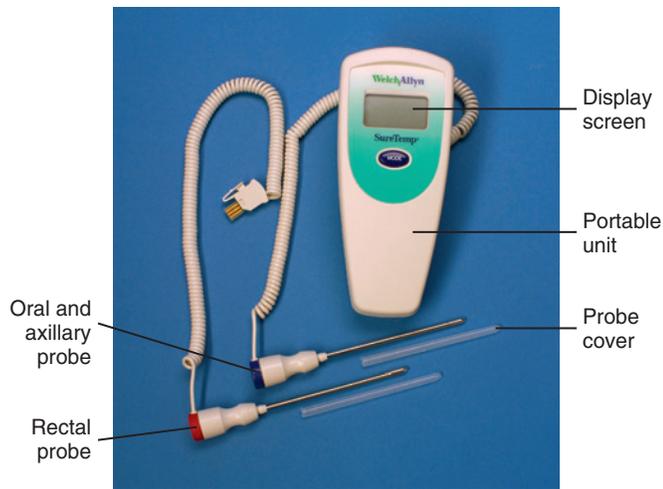
Site Advantages	Site Limitations
Oral	
Easily accessible—requires no position change	Causes delay in measurement if patient recently ingested hot/cold fluids or foods, smoked, or is receiving oxygen by mask/cannula
Comfortable for patient	
Provides accurate surface temperature reading	Not for patients who had oral surgery, trauma, history of epilepsy, or shaking chills
Reflects rapid change in core temperature	
Reliable route to measure temperature in patients who are intubated	Not for infants, small children, or patients who are confused, unconscious, or uncooperative
	Risk of body fluid exposure
Tympanic Membrane	
Easily accessible site	More variability of measurement than with other core temperature devices
Minimal patient repositioning required	Requires removal of hearing aids before measurement
Obtained without disturbing, waking, or repositioning patients	Requires disposable sensor cover with only one size available
Used for patients with tachypnea without affecting breathing	Otitis media and cerumen impaction distorts readings
Sensitive to core temperature changes	Not used in patients who have had surgery of the ear or tympanic membrane
Very rapid measurement (2 to 5 seconds)	Does not accurately measure core temperature changes during and after exercise
Unaffected by oral intake of food or fluids or smoking	Does not obtain continuous measurement
Used in newborns to reduce infant handling and heat loss (Ozdemir et al., 2011)	Affected by ambient temperature devices such as incubators, radiant warmers, and facial fans
Not influenced by environmental temperatures (Schey et al., 2010)	When used in neonates, infants, and children under 3 years old, use care to position device correctly because anatomy of ear canal makes it difficult to position
	Inaccuracies reported caused by incorrect positioning of handheld unit
Rectal	
Argued to be more reliable when oral temperature is difficult or impossible to obtain	Lags behind core temperature during rapid temperature changes
	Not for patients with diarrhea, rectal disorders, or bleeding tendencies or those who had rectal surgery
	Requires positioning and is often source of patient embarrassment and anxiety
	Risk of body fluid exposure and injury to rectal lining
	Requires lubrication
	Not for routine vital signs in newborns
	Readings influenced by impacted stool
Skin	
Inexpensive	Measurement lags behind other sites during temperature changes, especially during hyperthermia
Provides continuous reading	
Safe and noninvasive	Adhesion impaired by diaphoresis or sweat
Used for neonates	Reading affected by environmental temperature
	Cannot be used for patients with allergy to adhesives
Temporal Artery	
Easy to access without position change	Inaccurate with head covering or hair on forehead
Very rapid measurement	Affected by skin moisture such as diaphoresis or sweating
Comfortable with no risk of injury to patient or nurse	
Eliminates need to disrobe or be unbundled	
Comfortable for patient	
Used in premature infants, newborns, and children (Reynolds et al., 2014)	
Reflects rapid change in core temperature	
Sensor cover not required	
Axillary	
Safe and inexpensive	Long measurement time
Reliable in stable term and preterm infants (Charafeddine et al., 2014)	Requires continuous positioning
	Measurement lags behind core temperature during rapid temperature changes
	Not recommended for detecting fever
	Requires exposure of thorax that can result in temperature loss, especially in newborns
	Affected by exposure to environment, including time to place the thermometer
	Underestimates core temperature


FIGURE 30-4 Electronic thermometer. Blue probe is for oral use. Red probe is for rectal use.

FIGURE 30-5 Temporal artery thermometer scanning child's forehead.

BOX 30-5   Nursing Diagnostic Process

Ineffective Thermoregulation Related to Aging and Inability to Adapt to Environmental Temperature

Assessment Activities	Defining Characteristics
Obtain vital signs, including temperature, pulse (see Skill 30-2), respirations (see Skill 30-3), SpO₂ (see Skill 30-4).	Increased body temperature above usual range Tachycardia Tachypnea Hypoxemia
Palpate skin.	Warm, dry skin
Observe patient's appearance and behavior while talking and resting.	Restlessness Confusion Flushed appearance
Review medical history.	Found in unventilated apartment during heat wave; 85 years old with history of dementia

Because they often underestimate oral temperature by 0.4°C (0.7°F) or more, use electronic thermometers to confirm measurements made with a chemical dot thermometer when treatment decisions are involved. Chemical dot thermometers are useful when caring for patients on protective isolation to avoid the need to take electronic instruments into patient rooms (see Chapter 29).

Another disposable thermometer useful for screening temperature is a temperature-sensitive patch or tape. Applied to the forehead or abdomen, chemical sensitive areas of the patch change color at different temperatures. This type of thermometer can also be affected by environmental temperatures.

◆ Nursing Diagnosis

After concluding your assessment, cluster defining characteristics to form a nursing diagnosis (Box 30-5). For example, an increase in body temperature, flushed skin, skin warm to touch, and tachycardia indicate the diagnosis of *hyperthermia*. State a nursing diagnosis as either an at-risk or problem-focused temperature alteration. Implement actions to minimize or eliminate the risk factors if the patient has an at-risk diagnosis. Examples of nursing diagnoses for patients with body temperature alterations include the following:

- *Risk for Imbalanced Body Temperature*
- *Hyperthermia*
- *Hypothermia*
- *Ineffective Thermoregulation*
- *Risk for Hypothermia*

Once you determine a diagnosis, accurately select the related factor for problem-focused diagnoses. The related factor allows you to develop/set appropriate patient goals and select appropriate nursing interventions. In the example of hyperthermia, a related factor of *vigorous activity* results in much different interventions than a related factor of *decreased ability to perspire.*

◎ NURSING CARE PLAN

Hyperthermia

ASSESSMENT

Mr. Coburn is a 56-year-old school teacher who arrives at the outpatient clinic with malaise. His medical history includes a past urinary tract infection. Several of his students have been out of school lately with colds. He has been feeling poorly for the past 3 days.

Assessment Activities	*Findings/Defining Characteristics**
Palpate skin.	Mr. Coburn's skin is **warm and dry** to touch.
Observe patient's behavior while talking and resting.	Mr. Coburn's breathing is labored; he's using his neck accessory muscles. His face is **flushed.**
Obtain vital signs.	Blood pressure right arm 116/62 mm Hg, left arm 114/64 mm Hg; right radial pulse **128 beats/min,** regular and bounding; respiratory rate **26 breaths/min, breaths deep and regular;** SpO$_2$ 98% on room air; oral temperature **39.2° C** (102.6° F).
Review medical history.	He admits to smoking one pack of cigarettes per day and recently began expectorating **yellow-green sputum.** He has been **tired** for the past 3 days and on rising in the morning has been dizzy.

***Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Hyperthermia related to infectious process

PLANNING

Goals	*Expected Outcomes (NOC)†*
	Thermoregulation
Mr. Coburn will regain normal range of body temperature within next 24 hours.	Body temperature declines at least 1° C (1.8° F) within next 8 hours.
Mr. Coburn will state a sense of comfort and rest within next 48 hours.	Patient verbalizes increased satisfaction with rest and sleep pattern.
	Patient reports increase in energy level within next 3 days.
Mr. Coburn's fluid and electrolyte balance will be maintained during next 3 days.	Intake equals output within next 24 hours.
	No evidence of postural hypotension during ambulation.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 5, St Louis, 2013, Mosby.

INTERVENTIONS (NIC)‡	**RATIONALE**
Fever Treatment	
Instruct Mr. Coburn to reduce external coverings and keep clothing and bed linen dry.	Promotes heat loss through conduction and convection.
Instruct Mr. Coburn to use ordered antipyretic medications safely when needed for comfort.	Antipyretics reduce set point (Lehne, 2013).
Instruct Mr. Coburn to limit physical activity and increase to two rest periods per day over next 2 days.	Activity and stress increase metabolic rate, contributing to heat production.
Instruct Mr. Coburn to increase oral fluids of choice to 8 to 10 8-oz glasses of fluid daily.	Increased metabolic rate and diaphoresis associated with fever cause loss of body fluids.

‡Intervention classification labels from Bulechek GM et al: *Nursing interventions classification (NIC),* ed 6, St Louis, 2013, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Obtain body temperature measurement.	Body temperature is 37.8° C (100.0° F).	Body temperature within normal limits
Obtain orthostatic blood pressure measurements.	Blood pressure measurements lying, sitting, and standing are within 5 mm Hg of each other.	No evidence of postural hypotension
Ask Mr. Coburn if his energy level has changed since the last visit.	He responds, "I'm sleeping much better and have returned to work with a lot more energy."	Improved rest and sleep pattern and increased energy level

◆ **Planning**

During planning integrate the knowledge gathered from assessment and the patient history to develop an individualized plan of care (see the Nursing Care Plan). Match the patient's needs with interventions that are supported and recommended in the clinical research literature.

Goals and Outcomes. The plan of care for a patient with alteration in temperature includes realistic and individualized goals along with relevant outcomes. This requires collaboration with the patient and family in setting goals and outcomes and selecting nursing interventions. Establish expected outcomes to gauge progress toward returning the body temperature to an acceptable range. In cases in

which the temperature alteration requires helping patients modify their environment, goals may be long term (e.g., obtaining appropriate clothing to wear in cold weather). Short-term goals such as regaining normal range of body temperature improve patient health. In the example of a patient who has an elevated fever and excessive diaphoresis, the goal of care is attaining fluid and electrolyte balance. The outcome is that patient intake and output are balanced for the next 24 hours.

Setting Priorities.   Set priorities of care with regard to the extent that the temperature alteration affects a patient. The severity of a temperature alteration and its effects, together with the patient's general health status, influence your priorities in his or her care. Safety is a top priority. Often other medical problems complicate the care plan. For instance, body temperature imbalance affects body requirements for fluids. Patients with heart problems often have difficulty tolerating required fluid replacement therapy.

Teamwork and Collaboration.   Patients at risk for imbalanced body temperature require an individualized care plan directed at maintaining normothermia and reducing risk factors. For example, it is important to establish the outcome that the patient can explain appropriate actions to take and available community resources to use (e.g., cooling stations) during a heat wave. Teach the patient and caregiver the importance of thermoregulation and actions to take during excessive environmental heat. Education is particularly important for parents, who need to know how to take action at home and whom to call (e.g., health care provider's office, home care nurse) when an infant or child develops a temperature imbalance.

◆ **Implementation**

Health Promotion.   By maintaining balance between heat production and heat loss you promote the health of patients at risk for imbalanced body temperature. Consider patient activity, temperature of the environment, and clothing. Teach patients to avoid strenuous exercise in hot, humid weather; drink fluids such as water or clear fruity juices before, during, and after exercise; and wear light, loose-fitting, light-colored clothes. Also teach patients to avoid exercising in areas with poor ventilation, wear a protective covering over the head when outdoors, and expose themselves to hot climates gradually.

Prevention is key for patients at risk for hypothermia. It involves educating patients, family members, and friends. Patients at risk include the very young; the very old; and people debilitated by trauma, stroke, diabetes, drug or alcohol intoxication, and sepsis. Patients who are mentally ill or handicapped sometimes fall victim to hypothermia because they are unaware of the dangers of cold conditions. People without adequate home heating, shelter, diet, or clothing are also at risk. Fatigue, dark skin color, malnutrition, and hypoxemia also contribute to the risk of frostbite.

Acute Care

Fever.   When an elevated body temperature develops, initiate interventions to treat fever. The objective of therapy is to increase heat loss, reduce heat production, and prevent complications. The choice of interventions depends on the cause; adverse effects; and the strength, intensity, and duration of the temperature elevation. Nurses are essential in assessing and implementing temperature-reducing strategies (Box 30-6). The health care provider attempts to determine the cause of the elevated temperature by isolating the causative pyrogen. Sometimes it is necessary to obtain culture specimens for laboratory analysis such as urine, blood, sputum, and wound sites (see Chapter 29). Some antibiotic medications are ordered to be given after

---

BOX 30-6   Nursing Interventions for Patients with a Fever

Interventions (Unless Contraindicated)

- Obtain blood cultures (before beginning antibiotics) if ordered. Obtain blood specimens to coincide with temperature spikes when the antigen-producing organism is most prevalent.
- Minimize heat production: reduce frequency of activities that increase oxygen demand such as excessive turning and ambulation; allow rest periods; limit physical activity.
- Maximize heat loss: reduce external covering on patient's body without causing shivering; keep patient, clothing, and bed linen dry.
- Satisfy requirements for increased metabolic rate: provide supplemental oxygen therapy as ordered to improve oxygen delivery to body cells; provide measures to stimulate appetite and offer well-balanced meals; provide fluids (at least 8-to-10 8-oz glasses for patients with normal cardiac and renal function) to replace fluids lost through insensible water loss and sweating.
- Promote patient comfort: encourage oral hygiene because oral mucous membranes dry easily from dehydration; control temperature of the environment without inducing shivering; apply damp cloth to patient's forehead.
- Identify onset and duration of febrile episode phases: examine previous temperature measurements for trends.
- Initiate health teaching as indicated.
- Control environmental temperature to 21° to 27° C (70° to 80° F).

---

the cultures have been obtained. Administering antibiotics destroys pyrogenic bacteria and eliminates body stimulus for the elevated temperature.

Most fevers in children are of a viral origin, last only briefly, and have limited effects. However, children still have immature temperature-control mechanisms, and temperatures can rise rapidly. Dehydration and febrile seizures occur during rising temperatures of children between 6 months and 3 years of age. Febrile seizures are unusual in children more than 5 years of age. The extent of the temperature, often exceeding 38.8° C (101.8° F), seems to be a more important factor than the rapidity of the temperature increase. Children are at particular risk for fluid volume deficit because they can quickly lose large amounts of fluids in proportion to their body weight. It is important to maintain accurate intake and output records, weigh the patient daily, encourage fluids, and provide regular mouth/oral care.

Sometimes a fever is a hypersensitivity response to a drug. Drug fevers are often accompanied by other allergy symptoms such as rash or pruritus (itching). Treatment involves withdrawing the medication, treating any skin integrity impairment, and educating the patient and family about the allergy.

Antipyretics are medications that reduce fever. Acetaminophen and nonsteroidal antiinflammatory drugs such as ibuprofen, salicylates, and indomethacin reduce fever by increasing heat loss. Although not used to treat fever, corticosteroids reduce heat production by interfering with the hypothalamic response. It is important to remember that steroids mask signs and symptoms of infection by suppressing the immune system. Therefore patients who are prescribed steroids need to be monitored closely, especially if they are at risk for infection.

Nonpharmacological therapy for fever uses methods that increase heat loss by evaporation, conduction, convection, or radiation. Make sure that nursing measures to enhance body cooling do not stimulate

shivering. Shivering is counterproductive and increases energy expenditure up to 400%. Tepid sponge baths, bathing with alcohol-water solutions, applying ice packs to axillae and groin areas, and cooling fans were previously used to reduce fever; however, avoid these therapies because they lead to shivering. There is no advantage of these methods over antipyretic medications.

Blankets cooled by circulating water delivered by motorized units increase conductive heat loss. Follow manufacturer instructions for applying these hypothermia blankets because of the risk for skin breakdown and "freeze burns." Placing a bath blanket between the patient and the hypothermia blanket and wrapping distal extremities (fingers, toes, and genitalia) reduces the risk of injury to the skin and tissue from hypothermia therapy. Wrapping the patient's extremities reduces the incidence and intensity of shivering. Medications such as meperidine or butorphanol reduce shivering.

Heatstroke. Heatstroke is an emergency situation. First aid treatment includes moving the patient to a cooler environment; removing excess body clothing; placing cool, wet towels over the skin; and using oscillating fans to increase convective heat loss. Emergency medical treatment includes intravenous (IV) fluids, irrigating the stomach and lower bowel with cool solutions, and hypothermia blankets.

Hypothermia. The priority treatment for hypothermia is to prevent a further decrease in body temperature. Removing wet clothes, replacing them with dry ones, and wrapping patients in blankets are key nursing interventions. In emergencies away from a health care setting, have the patient lie under blankets next to a warm person. A conscious patient benefits from drinking hot liquids such as soup and avoiding alcohol and caffeinated fluids. It is also helpful to keep the head covered, place the patient near a fire or in a warm room, or place heating pads next to areas of the body (head and neck) that lose heat the quickest.

Restorative and Continuing Care. Educate the patient with a fever about the importance of taking and continuing any antibiotics as directed until the course of treatment is completed. Children and older adults are at risk for deficient fluid volume because they can quickly lose large amounts of fluids in proportion to their body weight. Identifying preferred fluids and encouraging oral fluid intake are important ongoing nursing interventions.

◆ **Evaluation**

Through the Patient's Eyes. Evaluate your patient's perspectives about the care provided. Is he or she satisfied with the outcomes of care or does the care plan need to be modified? Including the patient in the evaluation demonstrates that you value his or her perspective and contributes to patient safety.

Patient Outcomes. Evaluate all nursing interventions by comparing the patient's actual response to the expected outcomes of the care plan. Determine if goals of care were met and make revisions to the care plan when necessary. After an intervention, measure the patient's temperature to evaluate for change. In addition, use other evaluative measures such as palpating the skin and assessing pulse and respirations. If therapies are effective, body temperature returns to an acceptable range, other vital signs stabilize, and the patient reports a sense of comfort.

PULSE

The pulse is the palpable bounding of blood flow in a peripheral artery. Blood flows through the body in a continuous circuit. The pulse is an indirect indicator of circulatory status.

Physiology and Regulation

Electrical impulses originating from the sinoatrial (SA) node travel through heart muscle to stimulate cardiac contraction. Approximately 60 to 70 mL of blood enters the aorta with each ventricular contraction (stroke volume [SV]). With each SV ejection, the walls of the aorta distend, creating a pulse wave that travels rapidly toward the distal ends of the arteries. The pulse wave moves 15 times faster through the aorta and 100 times faster through the small arteries than the ejected volume of blood. When a pulse wave reaches a peripheral artery, you can feel it by palpating the artery lightly against underlying bone or muscle. The number of pulsing sensations occurring in 1 minute is the pulse rate.

The volume of blood pumped by the heart during 1 minute is the **cardiac output,** the product of HR and the SV of the ventricle. In an adult the heart normally pumps 5000 mL of blood per minute. A change in HR or SV does not always change the output of the heart or the amount of blood in the arteries. For example, if a person's HR is 70 beats/min and the SV is 70 mL, the cardiac output is 4900 mL/min (70 beats/min × 70 mL/beat). If the HR drops to 60 beats/min and the SV rises to 85 mL/beat, the cardiac output increases to 5100 mL or 5.1 L/min (60 beats/min × 85 mL/beat).

Mechanical, neural, and chemical factors regulate the strength of ventricular contraction and its SV. But when these factors are unable to alter SV, a change in HR causes a change in cardiac output, which affects BP. As HR increases, there is less time for the ventricular chambers of the heart to fill. As HR increases without a change in SV, BP decreases. As HR slows, filling time is increased, and BP increases. The inability of BP to respond to increases or decreases in HR indicates a possible health problem. Report this to the health care provider.

An abnormally slow, rapid, or irregular pulse alters cardiac output. Assess the ability of the heart to meet the demands of body tissue for nutrients by palpating a peripheral pulse or using a stethoscope to listen to heart sounds (apical rate).

Assessment of Pulse

You can assess any artery for pulse rate, but you typically use the radial artery because it is easy to palpate. When a patient's condition suddenly worsens, the carotid site is recommended for quickly finding and assessing the pulse. The heart continues delivering blood through the carotid artery to the brain as long as possible. When cardiac output declines significantly, peripheral pulses weaken and are difficult to palpate.

The radial and apical locations are the most common sites for pulse rate assessment. Use the radial pulse to teach patients how to monitor their own HRs (e.g., athletes, people taking heart medications, and patients starting a prescribed exercise regimen). If the radial pulse is abnormal or intermittent resulting from dysrhythmias or if it is inaccessible because of a dressing or cast, assess the apical pulse. When a patient takes medication that affects the HR, the apical pulse provides a more accurate assessment of heart function. The brachial or apical pulse is the best site for assessing an infant's or a young child's pulse because other peripheral pulses are deep and difficult to palpate accurately.

Assessment of other peripheral pulse sites such as the brachial or femoral artery is unnecessary when routinely obtaining vital signs. You assess other peripheral pulses when conducting a complete physical, when surgery or treatment has impaired blood flow to a body part, or when there are clinical indications of impaired peripheral blood flow (see Chapter 31). Table 30-2 summarizes pulse sites and criteria for measurement. Skill 30-2 on pp. 517-521 outlines pulse rate assessment.

TABLE 30-2 Pulse Sites

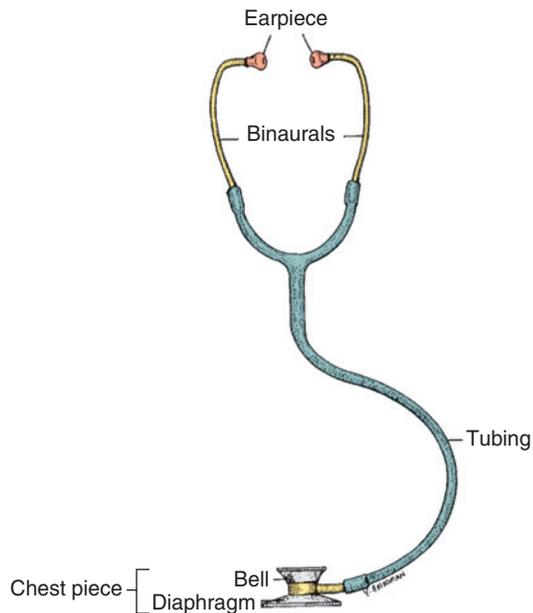
Site	Location	Assessment Criteria
Temporal	Over temporal bone of head, above and lateral to eye	Easily accessible site used to assess pulse in children
Carotid	Along medial edge of sternocleidomastoid muscle in neck	Easily accessible site used during physiological shock or cardiac arrest when other sites are not palpable
Apical	Fourth to fifth intercostal space at left midclavicular line	Site used to auscultate for apical pulse
Brachial	Groove between biceps and triceps muscles at antecubital fossa	Site used to assess status of circulation to lower arm and auscultate blood pressure
Radial	Radial or thumb side of forearm at wrist	Common site used to assess character of pulse peripherally and status of circulation to hand
Ulnar	Ulnar or little finger side of forearm at wrist	Site used to assess status of circulation to hand; also used to perform an Allen's test
Femoral	Below inguinal ligament, midway between symphysis pubis and anterior superior iliac spine	Site used to assess character of pulse during physiological shock or cardiac arrest when other pulses are not palpable; used to assess status of circulation to leg
Popliteal	Behind knee in popliteal fossa	Site used to assess status of circulation to lower leg
Posterior tibial	Inner side of ankle, below medial malleolus	Site used to assess status of circulation to foot
Dorsalis pedis	Along top of foot, between extension tendons of great and first toe	Site used to assess status of circulation to foot


FIGURE 30-7 Parts of stethoscope.

FIGURE 30-8 Positioning diaphragm of stethoscope firmly and securely when auscultating high-pitched heart sounds.

Use of a Stethoscope. Assessing the apical rate requires a stethoscope. The five major parts of the stethoscope are the earpieces, binaurals, tubing, bell chest piece, and diaphragm chest piece (Figure 30-7).

The plastic or rubber earpieces should fit snugly and comfortably in your ears. The binaurals should be angled and strong enough so the earpieces stay firmly in the ears without causing discomfort. To ensure the best reception of sound, the earpieces follow the contour of the ear canal pointing toward the face when the stethoscope is in place.

The polyvinyl tubing is flexible and 30 to 40 cm (12 to 18 inches) in length. Longer tubing decreases the transmission of sound waves. Thick-walled and moderately rigid tubing eliminates transmission of environmental noise and prevents the tubing from kinking,

which distorts sound-wave transmission. Stethoscopes have single or dual tubes.

The chest piece consists of a bell and a diaphragm that you rotate into position. The diaphragm or bell needs to be in proper position during use to hear sounds through the stethoscope. With the earpieces in your ears, tap lightly on the diaphragm to determine which side of the chest piece is functioning. The diaphragm is the circular, flat portion of the chest piece covered with a thin plastic disk. It transmits high-pitched sounds created by the high-velocity movement of air and blood. Auscultate bowel, lung, and heart sounds with the diaphragm. Always place the stethoscope directly on the skin because clothing obscures the sound. Position the diaphragm to make a tight seal and press firmly against the patient's skin (Figure 30-8). Do not use your thumb to hold the diaphragm in place because you may hear the pulse being transmitted through it.

The bell is the bowl-shaped chest piece usually surrounded by a rubber ring. The ring avoids chilling patients with cold metal when placed on the skin. The bell transmits low-pitched sounds created by the low-velocity movement of blood. Auscultate heart and vascular sounds with the bell. Apply the bell lightly, resting the chest piece on the skin (Figure 30-9).

TABLE 30-3 Acceptable Ranges of Heart Rate	
Age	**Heart Rate (beats/min)**
Infant	120-160
Toddler	90-140
Preschooler	80-110
School-age child	75-100
Adolescent	60-90
Adult	60-100

TABLE 30-4 Factors Influencing Pulse Rate		
Factor	**Increases Pulse Rate**	**Decreases Pulse Rate**
Exercise	Short-term exercise	Heart conditioned by long-term exercise, resulting in lower resting pulse and quicker return to resting level after exercise
Temperature	Fever and heat	Hypothermia
Emotions	Sympathetic stimulation increased by acute pain and anxiety, affecting heart rate; effect of chronic pain on heart rate varies	Parasympathetic stimulation increased by unrelieved severe pain affecting heart rate; relaxation
Medications	Positive chronotropic drugs such as epinephrine	Negative chronotropic drugs such as digitalis; beta-adrenergic and calcium channel blockers
Hemorrhage	Sympathetic stimulation increased by loss of blood	
Postural changes	Standing or sitting	Lying down
Pulmonary conditions	Diseases causing poor oxygenation such as asthma, chronic obstructive pulmonary disease (COPD)	

FIGURE 30-9 Positioning bell of stethoscope lightly on skin to hear low-pitched heart sounds.

Compressing the bell against the skin reduces low-pitched sound amplification and creates a "diaphragm of skin." Some stethoscopes have one chest piece that combines features of the bell and diaphragm. When you use light pressure, the chest piece is a bell; exerting more pressure converts the bell into a diaphragm.

The stethoscope is a delicate instrument and requires proper care for optimal function. Remove the earpieces regularly and clean them of cerumen (earwax). Clean the bell and diaphragm between patients with an antiseptic swab to remove microorganisms. Clean the tubing regularly with mild soap and water.

Character of the Pulse

Assessment of the radial pulse includes measuring the rate, rhythm, strength, and equality. When auscultating an apical pulse, assess rate and rhythm only.

Rate. Before measuring a pulse, review the patient's baseline rate for comparison (Table 30-3). Some practitioners prefer to make baseline measurements of the pulse rate as a patient assumes a sitting, standing, and lying position. Postural changes affect the pulse rate because of alterations in blood volume and sympathetic activity. The HR temporarily increases when a person changes from a lying to a sitting or standing position.

When assessing the pulse, consider the variety of factors influencing the pulse rate (Table 30-4). A single factor or a combination of these factors often causes significant changes. If you detect an abnormal rate while palpating a peripheral pulse, the next step is to assess the apical rate. The apical rate requires auscultation of heart sounds, which provides a more accurate assessment of cardiac contraction.

Assess the apical rate by listening to heart sounds (see Chapter 31). Identify the first and second heart sounds (S_1 and S_2). At normal slow rates S_1 is low pitched and dull, sounding like a "lub." S_2 is higher pitched and shorter, creating the sound "dub." Count each set of "lub-dub" as one heartbeat. Using the diaphragm or bell of the stethoscope, count the number of lub-dubs occurring in 1 minute.

Peripheral and apical pulse rate assessment often reveals variations in HR. Two common abnormalities in pulse rate are tachycardia and bradycardia. **Tachycardia** is an abnormally elevated HR, above 100 beats/min in adults. **Bradycardia** is a slow rate, below 60 beats/min in adults.

An inefficient contraction of the heart that fails to transmit a pulse wave to the peripheral pulse site creates a **pulse deficit**. To assess a pulse deficit you and a colleague assess radial and apical rates simultaneously and then compare rates. The difference between the apical and radial pulse rates is the pulse deficit. For example, an apical rate of 92 with a radial rate of 78 leaves a pulse deficit of 14 beats. Pulse deficits are often associated with abnormal rhythms.

Rhythm. Normally a regular interval occurs between each pulse or heartbeat. An interval interrupted by an early or late beat or a missed beat indicates an abnormal rhythm or **dysrhythmia.** A dysrhythmia threatens the ability of the heart to provide adequate cardiac output, particularly if it occurs repetitively. You identify a dysrhythmia by palpating an interruption in successive pulse waves or auscultating an interruption between heart sounds. If a dysrhythmia is present, assess the regularity of its occurrence and auscultate the apical rate (see Chapter 31). Dysrhythmias are described as regularly irregular or irregularly irregular.

To document a dysrhythmia, the health care provider often orders an electrocardiogram (ECG), Holter monitor, or telemetry monitor. An ECG records the electrical activity of the heart for a 12-second

interval. This test requires placement of electrodes across a patient's chest followed by recording of the heart rhythm. A patient wears the Holter monitor, which records and stores 24 hours of electrical activity. Access to the information recorded is not available until after the 24 hours have passed and the data are reviewed. Cardiac telemetry provides continuous monitoring of the electrical activity of the heart transmitted to a stationary monitor. Telemetry permits continuous observation of heart rhythm during all of a patient's daily activities and thus allows for immediate treatment if the rhythm becomes erratic or unstable.

Children often have a sinus dysrhythmia, which is an irregular heartbeat that speeds up with inspiration and slows with expiration. This is a normal finding that you can verify by having the child hold his or her breath; the HR usually becomes regular.

Strength. The strength or amplitude of a pulse reflects the volume of blood ejected against the arterial wall with each heart contraction and the condition of the arterial vascular system leading to the pulse site. Normally the pulse strength remains the same with each heartbeat. Document the pulse strength as bounding (4); full or strong (3); normal and expected (2); diminished or barely palpable (1); or absent (0). Include assessment of pulse strength in the assessment of the vascular system (see Chapter 31).

Equality. Assess radial pulses on both sides of the peripheral vascular system, comparing the characteristics of each. A pulse in one extremity is sometimes unequal in strength or absent in many disease states (e.g., thrombus [clot] formation, aberrant blood vessels, cervical rib syndrome, or aortic dissection). Assess all symmetrical pulses simultaneously except for the carotid pulse. Never measure the carotid pulses simultaneously because excessive pressure occludes blood supply to the brain.

Nursing Process and Pulse Determination

Pulse assessment determines the general state of cardiovascular health and the response of the body to other system imbalances. Tachycardia, bradycardia, and dysrhythmias are defining characteristics of many nursing diagnoses, including the following:

- *Activity Intolerance*
- *Anxiety*
- *Decreased Cardiac Output*
- *Deficient/Excess Fluid Volume*
- *Impaired Gas Exchange*
- *Acute Pain*
- *Ineffective Peripheral Tissue Perfusion*

The nursing care plan includes interventions based on the nursing diagnosis identified and the related factors. For example, the defining characteristics of an abnormal HR, exertional dyspnea, and a patient's verbal report of fatigue lead to a diagnosis of *Activity Intolerance.* When the related factor is *inactivity following a prolonged illness,* interventions focus on increasing the patient's daily exercise routine. Once the plan is implemented, evaluate patient outcomes, including assessment of his or her pulse.

RESPIRATION

Human survival depends on the ability of oxygen (O_2) to reach body cells and carbon dioxide (CO_2) to be removed from the cells. Respiration is the mechanism the body uses to exchange gases between the atmosphere and the blood and the blood and the cells. Respiration involves **ventilation** (the movement of gases in and out of the lungs), **diffusion** (the movement of oxygen and carbon dioxide between the alveoli and the red blood cells), and **perfusion** (the distribution of red blood cells to and from the pulmonary capillaries). Analyzing respiratory efficiency requires integrating assessment data from all three processes. Assess ventilation by determining respiratory rate, depth, rhythm and end-tidal carbon dioxide ($ETCO_2$) value. Assess diffusion and perfusion by determining oxygen saturation.

Physiological Control

Breathing generally is a passive process. Normally a person thinks little about it. The respiratory center in the brainstem regulates the involuntary control of respirations. Adults normally breathe in a smooth, uninterrupted pattern 12 to 20 times a minute.

The body regulates ventilation using levels of CO_2, O_2, and hydrogen ion concentration (pH) in the arterial blood. The most important factor in the control of ventilation is the level of CO_2 in the arterial blood. An elevation in the CO_2 level causes the respiratory control system in the brain to increase the rate and depth of breathing. The increased ventilatory effort removes excess CO_2 (hypercarbia) by increasing exhalation. However, patients with chronic lung disease have ongoing hypercarbia. For these patients chemoreceptors in the carotid artery and aorta become sensitive to **hypoxemia,** or low levels of arterial O_2. If arterial oxygen levels fall, these receptors signal the brain to increase the rate and depth of ventilation. Hypoxemia helps to control ventilation in patients with chronic lung disease. Because low levels of arterial O_2 provide the stimulus that allows a patient to breathe, administration of high oxygen levels is fatal for patients with chronic lung disease.

Mechanics of Breathing

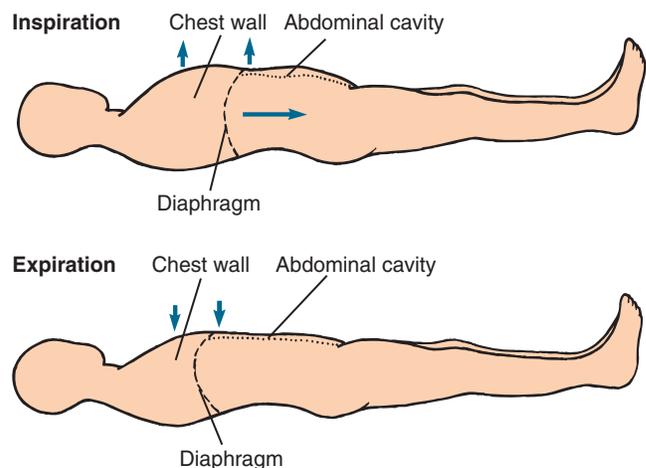
Although breathing is normally passive, muscular work is involved in moving the lungs and chest wall. Inspiration is an active process. During inspiration the respiratory center sends impulses along the phrenic nerve, causing the diaphragm to contract. Abdominal organs move downward and forward, increasing the length of the chest cavity to move air into the lungs. The diaphragm moves approximately 1 cm ($\frac{4}{10}$ inch), and the ribs retract upward from the midline of the body approximately 1.2 to 2.5 cm ($\frac{1}{2}$ to 1 inch). During a normal, relaxed breath, a person inhales 500 mL of air. This amount is referred to as the tidal volume. During expiration the diaphragm relaxes, and the abdominal organs return to their original positions. The lung and chest wall return to a relaxed position (Figure 30-10). Expiration is a passive process. Sighing interrupts the normal rate and depth of ventilation, **eupnea.** The sigh, a prolonged deeper breath, is a protective


FIGURE 30-10 Illustration of diaphragmatic and chest wall movement during inspiration and expiration.

physiological mechanism for expanding small airways and alveoli not ventilated during a normal breath.

The accurate assessment of respirations depends on the recognition of normal thoracic and abdominal movements. During quiet breathing the chest wall gently rises and falls. Contraction of the intercostal muscles between the ribs or contraction of the muscles in the neck and shoulders (the accessory muscles of breathing) is not visible. During normal quiet breathing diaphragmatic movement causes the abdominal cavity to rise and fall slowly.

Assessment of Ventilation

Respirations are the easiest of all vital signs to assess, but they are often the most haphazardly measured. Do not estimate respirations. Accurate measurement requires observation and palpation of chest wall movement.

A sudden change in the character of respirations is important. Because respiration is tied to the function of numerous body systems, consider all variables when changes occur (Box 30-7). For example, a drop in respirations occurring in a patient after head trauma often

---

BOX 30-7   Factors Influencing Character of Respirations

Exercise
- Exercise increases rate and depth to meet the need of the body for additional oxygen and to rid the body of CO_2.

Acute Pain
- Pain alters rate and rhythm of respirations; breathing becomes shallow.
- Patient inhibits or splints chest wall movement when pain is in area of chest or abdomen.

Anxiety
- Anxiety increases respiration rate and depth as a result of sympathetic stimulation.

Smoking
- Chronic smoking changes pulmonary airways, resulting in increased rate of respirations at rest when not smoking.

Body Position
- A straight, erect posture promotes full chest expansion.
- A stooped or slumped position impairs ventilatory movement.
- Lying flat prevents full chest expansion.

Medications
- Opioid analgesics, general anesthetics, and sedative hypnotics depress rate and depth.
- Amphetamines and cocaine sometimes increase rate and depth.
- Bronchodilators slow rate by causing airway dilation.

Neurological Injury
- Injury to brainstem impairs respiratory center and inhibits respiratory rate and rhythm.

Hemoglobin Function
- Decreased hemoglobin levels (anemia) reduce oxygen-carrying capacity of the blood, which increases respiratory rate.
- Increased altitude lowers amount of saturated hemoglobin, which increases respiratory rate and depth.
- Abnormal blood cell function (e.g., sickle cell disease) reduces ability of hemoglobin to carry oxygen, which increases respiratory rate and depth.

---

signifies injury to the brainstem. Abdominal trauma injures the phrenic nerve, which is responsible for diaphragmatic contraction.

Do not let a patient know that you are assessing respirations. A patient aware of the assessment can alter the rate and depth of breathing. Assess respirations immediately after measuring pulse rate, with your hand still on the patient's wrist as it rests over the chest or abdomen. When assessing a patient's respirations, keep in mind the patient's usual ventilatory rate and pattern, the influence any disease or illness has on respiratory function, the relationship between respiratory and cardiovascular function, and the influence of therapies on respirations. The objective measurements of respiratory status include the rate and depth of breathing and the rhythm of ventilatory movements (see Skill 30-3 on pp. 521-523).

Capnography is the measurement of exhaled carbon dioxide throughout exhalation. At the end of exhalation, the ETCO$_2$ measurement approximates the PaCo$_2$ in a healthy patient, normally 35 to 45 mm Hg. In nonintubated patients ETCO$_2$ can be obtained from a special nasal cannula connected to a monitor that detects the percentage of carbon dioxide exhaled at the end of respiratory cycle. The ETCO$_2$ can be used to evaluate respiratory and cardiac status, whereas interpretation of a continuous recording, or capnogram, can detect changes in ventilation.

Respiratory Rate.   Observe a full inspiration and expiration when counting ventilation or respiration rate. The usual respiratory rate varies with age (Table 30-5). The usual range of respiratory rate declines throughout life. A respiratory rate above 27 breaths/min is an important risk factor for cardiac arrest (Parkes, 2011)

The apnea monitor is a device that aids respiratory rate assessment. This device uses leads attached to a patient's chest wall; the leads sense movement. The absence of chest wall movement triggers the apnea alarm. Apnea monitoring is used often with infants in the hospital and at home to observe the risk for prolonged apneic events.

Ventilatory Depth.   Assess the depth of respirations by observing the degree of excursion or movement in the chest wall. Describe ventilatory movements as deep or shallow, normal or labored. A deep respiration involves a full expansion of the lungs with full exhalation. Respirations are shallow when only a small quantity of air passes through the lungs and ventilatory movement is difficult to see. Use more objective techniques if you observe that chest excursion is unusually shallow (see Chapter 31). Table 30-6 summarizes types of breathing patterns.

Ventilatory Rhythm.   Determine breathing pattern by observing the chest or the abdomen. Diaphragmatic breathing results from the contraction and relaxation of the diaphragm, and you observe it best

---

TABLE 30-5   Acceptable Ranges of Respiratory Rate

Age	Rate (breaths/min)
Newborn	30-60
Infant (6 months)	30-50
Toddler (2 years)	25-32
Child	20-30
Adolescent	16-20
Adult	12-20

TABLE 30-6 Alterations in Breathing Pattern

Alteration	Description
Bradypnea	Rate of breathing is regular but abnormally slow (less than 12 breaths/min).
Tachypnea	Rate of breathing is regular but abnormally rapid (greater than 20 breaths/min).
Hyperpnea	Respirations are labored, increased in depth, and increased in rate (greater than 20 breaths/min) (occurs normally during exercise).
Apnea	Respirations cease for several seconds. Persistent cessation results in respiratory arrest.
Hyperventilation	Rate and depth of respirations increase. Hypocarbia sometimes occurs.
Hypoventilation	Respiratory rate is abnormally low, and depth of ventilation is depressed. Hypercarbia sometimes occurs.
Cheyne-Stokes respiration	Respiratory rate and depth are irregular, characterized by alternating periods of apnea and hyperventilation. Respiratory cycle begins with slow, shallow breaths that gradually increase to abnormal rate and depth. The pattern reverses; breathing slows and becomes shallow, concluding as apnea before respiration resumes.
Kussmaul's respiration	Respirations are abnormally deep, regular, and increased in rate.
Biot's respiration	Respirations are abnormally shallow for two to three breaths, followed by irregular period of apnea.

by watching abdominal movements. Healthy men and children usually demonstrate diaphragmatic breathing. Women tend to use thoracic muscles to breathe, assessed by observing movements in the upper chest. Labored respirations usually involve the accessory muscles of respiration visible in the neck. When something such as a foreign body interferes with the movement of air in and out of the lungs, the intercostal spaces retract during inspiration. A longer expiration phase is evident when the outward flow of air is obstructed (e.g., asthma, chronic obstructive lung disease (COPD).

With normal breathing a regular interval occurs after each respiratory cycle. Infants tend to breathe less regularly. The young child often breathes slowly for a few seconds and then suddenly breathes more rapidly. While assessing respirations, estimate the time interval after each respiratory cycle. Respiration is regular or irregular in rhythm.

Assessment of Diffusion and Perfusion

Evaluate the respiratory processes of diffusion and perfusion by measuring the oxygen saturation of the blood. Blood flow through the pulmonary capillaries delivers red blood cells for oxygen attachment. After oxygen diffuses from the alveoli into the pulmonary blood, most of the oxygen attaches to hemoglobin molecules in red blood cells. Red blood cells carry the oxygenated hemoglobin molecules through the left side of the heart and out to the peripheral capillaries, where the oxygen detaches, depending on the needs of the tissues.

The percent of hemoglobin that is bound with oxygen in the arteries is the percent of saturation of hemoglobin (or SaO_2). It is usually between 95% and 100%. It is affected by factors that interfere with ventilation, perfusion, or diffusion (see Chapter 41). The saturation of venous blood (SvO_2) is lower because the tissues have removed some of the oxygen from the hemoglobin molecules. Factors that interfere with or increase tissue oxygen demand affect the usual value for SvO_2, which is 70%.

Measurement of Arterial Oxygen Saturation. A pulse oximeter permits the indirect measurement of **oxygen saturation** (see Skill 30-4 on pp. 523-535). The pulse oximeter is a probe with a light-emitting diode (LED) connected by cable to an oximeter (Figure 30-11). The LED emits light wavelengths that the oxygenated and deoxygenated hemoglobin molecules absorb differently. A photodetector in the probe detects the amount of oxygen bound to hemoglobin molecules, and the oximeter calculates the pulse saturation (SpO_2).

FIGURE 30-11 Portable pulse oximeter with digit probe.

SpO_2 is a reliable estimate of SaO_2 when the SaO_2 is over 70%. A saturation of less than 90% is a clinical emergency (WHO, 2011). Values obtained with pulse oximetry are less accurate at saturations less than 70%.

The photodetector is in the oximeter probe. Selecting the appropriate probe is important to reduce measurement error. Digit probes are spring loaded and conform to various sizes. Earlobe probes have greater accuracy at lower saturations and are least affected by peripheral vasoconstriction. You can apply disposable sensor pads to a variety of sites, including the forehead, the bridge of an adult's nose, or the sole of an infant's foot. Oxygen saturation measurement using a forehead probe is quicker than finger probes (Yont et al., 2011) and more accurate in conditions that decrease blood flow (Nesseler et al., 2012). Factors that affect light transmission or peripheral arterial pulsations affect the ability of the photodetector to measure SpO_2 correctly (Box 30-8). An awareness of these factors allows accurate interpretation of abnormal SpO_2 measurements.

Nursing Process and Respiratory Vital Signs

Measurement of respiratory rate, pattern, and depth, along with SpO_2, assesses ventilation, diffusion, and perfusion. You also conduct other assessments to measure respiratory status (see Chapter 31). Use assessment data to determine the nature of a patient's problem. Respiratory

---

BOX 30-8 Factors Affecting Determination of Pulse Oxygen Saturation (SpO₂)

Interference with Light Transmission
- Outside light sources interfere with ability of oximeter to process reflected light.
- Carbon monoxide (caused by smoke inhalation or poisoning) artificially elevates SpO_2 by absorbing light similar to oxygen.
- Patient motion interferes with ability of oximeter to process reflected light.
- Jaundice interferes with ability of oximeter to process reflected light.
- Intravascular dyes (methylene blue) absorb light similar to deoxyhemoglobin and artificially lower saturation.
- Black or brown nail polish or metal studs in nails and thickened nails can interfere with light absorption and the ability of the oximeter to process reflected light (Chan et al., 2013).
- Dark skin pigment sometimes results in signal loss or overestimation of saturation.

Interference with Arterial Pulsations
- Peripheral vascular disease (atherosclerosis) reduces pulse volume.
- Hypothermia at assessment site decreases peripheral blood flow.
- Pharmacological vasoconstrictors (e.g., epinephrine) decrease peripheral pulse volume.
- Low cardiac output and hypotension decrease blood flow to peripheral arteries.
- Peripheral edema obscures arterial pulsation.
- Tight probe records venous pulsations in finger that compete with arterial pulsations.

---

assessment data are defining characteristics of many nursing diagnoses, including the following:

- *Activity Intolerance*
- *Ineffective Airway Clearance*
- *Anxiety*
- *Ineffective Breathing Pattern*
- *Impaired Gas Exchange*
- *Acute Pain*
- *Ineffective Peripheral Tissue Perfusion*
- *Dysfunctional Ventilatory Weaning Response*

The nursing care plan includes interventions based on the nursing diagnosis identified and the related factors. For example, the defining characteristics of tachycardia, changes in depth of respirations, dyspnea, and a decline in CO_2 level lead to a diagnosis of *Impaired Gas Exchange*. Related factors could include *alveolar capillary membrane changes from infection or a ventilator-perfusion imbalance*. You select interventions on the basis of the related factor. After intervening, evaluate patient outcomes by assessing the respiratory rate, ventilatory depth, rhythm, and SpO_2.

BLOOD PRESSURE

Blood pressure is the force exerted on the walls of an artery by the pulsing blood under pressure from the heart. Blood flows throughout the circulatory system because of pressure changes. It moves from an area of high pressure to one of low pressure. Systemic or arterial BP, the BP in the system of arteries in the body, is a good indicator of cardiovascular health. The contraction of the heart forces the blood under high pressure into the aorta. The peak of maximum pressure when ejection occurs is the **systolic pressure.** When the ventricles relax, the blood remaining in the arteries exerts a minimum or

diastolic pressure. Diastolic pressure is the minimal pressure exerted against the arterial walls at all times.

The standard unit for measuring BP is millimeters of mercury (mm Hg). The measurement indicates the height to which the BP raises a column of mercury. Record BP with the systolic reading before the diastolic reading (e.g., 120/80). The difference between systolic and diastolic pressure is the **pulse pressure.** For example, for a BP of 120/80, the pulse pressure is 40.

Physiology of Arterial Blood Pressure

Blood pressure reflects the interrelationships of cardiac output, peripheral vascular resistance, blood volume, blood viscosity, and artery elasticity. Your knowledge of these hemodynamic variables helps in the assessment of BP alterations.

Cardiac Output. The BP depends on the cardiac output. When volume increases in an enclosed space such as a blood vessel, the pressure in that space rises. Thus as cardiac output increases, more blood is pumped against arterial walls, causing the BP to rise. Cardiac output increases as a result of an increase in HR, greater heart muscle contractility, or an increase in blood volume. Changes in HR occur faster than changes in heart muscle contractility or blood volume. A rapid or significant increase in HR decreases the filling time of the heart. As a result BP decreases.

Peripheral Resistance. The BP depends on peripheral vascular resistance. Blood circulates through a network of arteries, arterioles, capillaries, venules, and veins. Arteries and arterioles are surrounded by smooth muscle that contracts or relaxes to change the size of the lumen. The size of arteries and arterioles changes to adjust blood flow to the needs of local tissues. For example, when a major organ needs more blood, the peripheral arteries constrict, decreasing their supply of blood. More blood becomes available to the major organ because of the resistance change in the periphery. Normally arteries and arterioles remain partially constricted to maintain a constant flow of blood. Peripheral vascular resistance is the resistance to blood flow determined by the tone of vascular musculature and diameter of blood vessels. The smaller the lumen of a vessel, the greater is the peripheral vascular resistance to blood flow. As resistance rises, arterial BP rises. As vessels dilate and resistance falls, BP drops.

Blood Volume. The volume of blood circulating within the vascular system affects BP. Most adults have a circulating blood volume of 5000 mL. Normally the blood volume remains constant. However, an increase in volume exerts more pressure against arterial walls. For example, the rapid, uncontrolled infusion of IV fluids elevates BP. When a person's circulating blood volume falls, as in the case of hemorrhage or dehydration, the BP falls.

Viscosity. The thickness or viscosity of blood affects the ease with which blood flows through small vessels. The **hematocrit,** or percentage of red blood cells in the blood, determines blood viscosity. When the hematocrit rises and blood flow slows, arterial BP increases. The heart contracts more forcefully to move the viscous blood through the circulatory system.

Elasticity. Normally the walls of an artery are elastic and easily distensible. As pressure within the arteries increases, the diameter of vessel walls increases to accommodate the pressure change. Arterial distensibility prevents wide fluctuations in BP. However, in certain diseases such as arteriosclerosis, the vessel walls lose their elasticity and are replaced by fibrous tissue that cannot stretch well. Reduced

TABLE 30-7 Average Optimal Blood Pressure for Age	
Age	**Blood Pressure (mm Hg)**
Newborn (3000 g [6.6 lb])	40 (mean)
1 month	85/54
1 year	95/65
6 years*	105/65
10-13 years*	110/65
14-17 years*	119/75
18 years and older	<120/<80

*In children and adolescents hypertension is defined as blood pressure that on repeated measurement is at the 95th percentile or greater adjusted for age, height, and gender (NHBPEP, 2003).

TABLE 30-8 Classification of Blood Pressure for Adults Ages 18 and Older			
Category	**Systolic (mm Hg)***		**Diastolic (mm Hg)***
Normal	<120		<80
Prehypertension†	120-139	Or	80-89
Stage 1 hypertension	≥140	Or	≥90
Stage 2 hypertension	≥160	Or	≥90

Data from James PA, et al: 2014 evidence-based guideline for the management of high blood pressure in adults: report by the panel appointed to the Eighth Joint National Committee (JNC 8), *JAMA* 31:507, 2014.
*Treatment based on highest category.
†Based on the average of two or more readings taken at each of two or more visits after an initial screening. Patient should not be taking antihypertensive drugs or be acutely ill. When systolic and diastolic blood pressures fall into different categories, select the higher category to classify the individual's blood pressure status. For example, classify 160/92 mm Hg as stage 2 hypertension.

elasticity results in greater resistance to blood flow. As a result, when the left ventricle ejects its SV, the vessels no longer yield to pressure. Instead a given volume of blood is forced through the rigid arterial walls, and the systemic pressure rises. Systolic pressure is more significantly elevated than diastolic pressure as a result of reduced arterial elasticity.

Each hemodynamic factor significantly affects the others. For example, as arterial elasticity declines, peripheral vascular resistance increases. The complex control of the cardiovascular system normally prevents any single factor from permanently changing the BP. For example, if the blood volume falls, the body compensates with an increased vascular resistance.

Factors Influencing Blood Pressure

BP is not constant. Many factors continually influence it. One measurement cannot adequately reflect a patient's usual BP. Even under the best conditions, it changes from heartbeat to heartbeat. BP trends, not individual measurements, guide nursing interventions. Understanding these factors ensures a more accurate interpretation of BP readings.

Age. Normal BP levels vary throughout life (Table 30-7). BP increases during childhood. Evaluate the level of a child's or adolescent's BP with respect to body size and age. An infant's BP ranges from 65 to 115/42 to 80 mm Hg. The normal BP for a 7-year-old is 87 to 117/48 to 64 mm Hg. Larger children (heavier and/or taller) have higher BPs than smaller children of the same age. During adolescence BP continues to vary according to body size.

An adult's BP tends to rise with advancing age. The optimal BP for a healthy, middle-age adult is less than 120/80 mm Hg. Values of 120 to 139 systolic and 80 to 89 diastolic mm Hg are considered prehypertension (James et al., 2014) (Table 30-8). Older adults often have a rise in systolic pressure related to decreased vessel elasticity; however, BP greater than 140/90 mm Hg is defined as hypertension and increases the risk for hypertension-related illness.

Stress. Anxiety, fear, pain, and emotional stress result in sympathetic stimulation, which increases HR, cardiac output, and vascular resistance. The effect of sympathetic stimulation increases BP. Anxiety raises BP as much as 30 mm Hg.

Ethnicity. The incidence of hypertension (high BP) is higher in African-Americans than in European Americans. African-Americans tend to develop more severe hypertension at an earlier age and have twice the risk for complications such as stroke and heart attack. Genetic and environmental factors are often contributing factors. Hypertension-related deaths are also higher among African-Americans.

Gender. There is no clinically significant difference in BP levels between boys and girls. After puberty males tend to have higher BP readings. After menopause women tend to have higher BP levels than men of similar age.

Daily Variation. Blood pressure varies throughout the day, with lower BP during sleep between midnight and 3:00 AM. Between 3:00 AM and 6:00 AM there is a slow and steady rise in BP. When a patient awakens, there is an early-morning surge. It is highest during the day between 10:00 AM and 6 PM. No two people have the same pattern or degree of variation.

Medications. Some medications directly or indirectly affect BP. Before BP assessment ask whether the patient is receiving antihypertensive, diuretic, or other cardiac medications, which lower BP (Table 30-9). Another class of medications affecting BP is opioid analgesics, which can also lower it. Vasoconstrictors and an excess volume of IV fluids increase it.

Activity and Weight. A period of exercise can reduce BP for several hours afterwards. An increase in oxygen demand by the body during activity increases BP. Inadequate exercise frequently contributes to weight gain, and obesity is a factor in the development of hypertension.

Smoking. Smoking results in vasoconstriction, a narrowing of blood vessels. BP rises when a person smokes and returns to baseline about 15 minutes after stopping smoking.

Hypertension

The most common alteration in BP is **hypertension**. Hypertension is often asymptomatic. Prehypertension is diagnosed in adults when an

TABLE 30-9 Antihypertensive Medications

Medication Type	Example	Action
Diuretics	Furosemide (Lasix), spironolactone (Aldactone), metolazone, polythiazide, hydrochlorothiazide	Lowers blood pressure by reducing resorption of sodium and water by the kidneys, thus lowering circulating fluid volume
Beta-adrenergic blockers	Atenolol (Tenormin), nadolol (Corgard), timolol maleate (Blocadren), metoprolol (Lopressor)	Combines with beta-adrenergic receptors in the heart, arteries, and arterioles to block response to sympathetic nerve impulses; reduces heart rate and thus cardiac output
Vasodilators	Hydralazine hydrochloride (Apresoline), minoxidil (Loniten)	Acts on arteriolar smooth muscle to cause relaxation and reduce peripheral vascular resistance
Calcium channel blockers	Diltiazem (Cardizem, Dilacor XR), verapamil hydrochloride (Calan SR), nifedipine (Procardia), nicardipine (Cardene)	Reduces peripheral vascular resistance by systemic vasodilation
Angiotensin-converting enzyme (ACE) inhibitors	Captopril (Capoten), enalapril (Vasotec), lisinopril (Prinivil, Zestril), benazepril (Lotensin)	Lowers blood pressure by blocking the conversion of angiotensin I to angiotensin II, preventing vasoconstriction; reduces aldosterone production and fluid retention, lowering circulating fluid volume
Angiotensin-II receptor blockers (ARBs)	Losartan (Cozaar), olmesartan (Benicar)	Lowers blood pressure by blocking the binding of angiotensin II, which prevents vasoconstriction

TABLE 30-10 Recommendations for Blood Pressure Follow-Up

Initial Blood Pressure	Follow-up Recommended*
Normal	Recheck in 2 years.
Prehypertension	Recheck in 1 year.†
Stage 1 hypertension	Evaluate therapy within 1 month (James et al., 2014).†
Stage 2 hypertension	Evaluate therapy within 1 month (James et al., 2014). For those with higher pressure (e.g., >180/110 mm Hg), evaluate and treat immediately or within 1 week, depending on clinical situation and complications.

Data from James PA et al. 2014 evidence-based guideline for the management of high blood pressure in adults: report by the panel appointed to the Eighth Joint National Committee (JNC 8), *JAMA* 31:507, 2014.
*Modify the scheduling of follow-up according to reliable information about past blood pressure measurements, other cardiovascular risk factors, or target organ damage.
†Provide advice about lifestyle modifications.

average of two or more readings on at least two subsequent visits is between 120 and 139 mm Hg systolic and 80 and 89 mm Hg diastolic. Diastolic readings greater than 90 mm Hg and systolic readings greater than 140 mm Hg define hypertension (James et al., 2014). Categories of hypertension have been developed (Table 30-10) and determine medical intervention. One elevated BP measurement does not qualify as a diagnosis of hypertension. However, if a high reading during the first BP measurement (e.g., 150/90 mm Hg) is obtained, the patient is encouraged to return for another checkup within 2 months.

Hypertension is associated with thickening and loss of elasticity in the arterial walls. Peripheral vascular resistance increases within thick and inelastic vessels. The heart continually pumps against greater resistance. As a result blood flow to vital organs such as the heart, brain, and kidney decreases.

People with a family history of hypertension are at significant risk. Modifiable risk factors include obesity, cigarette smoking, heavy alcohol consumption, and high sodium (salt) intake. Sedentary lifestyle and continued exposure to stress are also linked to hypertension. The incidence of hypertension is greater in patients with diabetes, older adults, and African-Americans. It is a major factor underlying deaths from strokes and is a contributing factor to myocardial infarctions (heart attacks). When patients are diagnosed with hypertension, educate them about BP values, long-term follow-up care and therapy, the usual lack of symptoms (the fact that it may not be "felt"), the ability of therapy to control but not cure it, and a consistently followed treatment plan that ensures a relatively normal lifestyle (James et al., 2014).

Hypotension

Hypotension is present when the systolic BP falls to 90 mm Hg or below. Although some adults have a low BP normally, for most people low BP is an abnormal finding associated with illness.

Hypotension occurs because of the dilation of the arteries in the vascular bed, the loss of a substantial amount of blood volume (e.g., hemorrhage), or the failure of the heart muscle to pump adequately (e.g., myocardial infarction). Hypotension associated with pallor, skin mottling, clamminess, confusion, increased HR, or decreased urine output is life threatening and is reported to a health care provider immediately.

Orthostatic hypotension, also referred to as **postural hypotension,** occurs when a normotensive person develops symptoms and a drop in systolic pressure by at least 20 mm Hg or a drop in diastolic pressure by at least 20 mm Hg within 3 minutes of rising to an upright position (Shibao et al., 2013). When a healthy individual changes from a lying–to sitting–to standing position, the peripheral blood vessels in the legs constrict. When standing, the lower-extremity vessels constrict, preventing the pooling of blood in the legs caused by gravity. Thus an individual normally does not feel any symptoms when standing. In contrast, when patients have a decreased blood volume, their blood vessels are already constricted. When a patient with volume depletion stands, there is a significant drop in BP with an increase in HR to compensate for the drop in cardiac output. Patients who are dehydrated, anemic, or have

FIGURE 30-12 Wall-mounted aneroid sphygmomanometer.

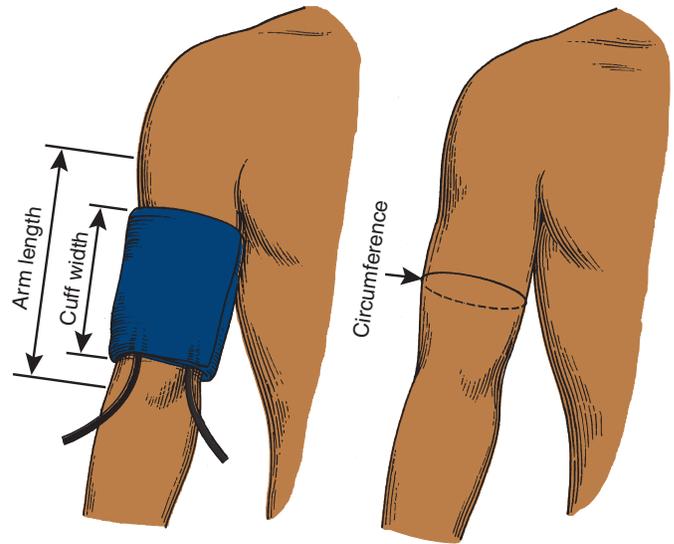
FIGURE 30-13 Guidelines for proper blood pressure cuff size. Cuff width 20% more than upper-arm diameter or 40% of circumference and two thirds of arm length.

experienced prolonged bed rest or recent blood loss are at risk for orthostatic hypotension, particularly in the morning (Shibao et al., 2013). Some medications cause orthostatic hypotension if misused, especially in older adults or young patients. Always measure BP before administering such medications.

Assess for orthostatic hypotension during measurements of vital signs by obtaining BP and pulse in sequence with the patient supine, sitting, and standing. Obtain BP readings within 3 minutes after the patient changes position. In most cases orthostatic hypotension is detected within a minute of standing. If it occurs, help the patient to a lying position and notify the health care provider or nurse in charge. While obtaining orthostatic measurements, observe for other symptoms of hypotension such as fainting, weakness, blurred vision, or light-headedness. Orthostatic hypotension is a risk factor for falls, especially among elderly patients with hypertension (Angelousi et al., 2014). When recording orthostatic BP measurements, record the patient's position in addition to the BP measurement (e.g., 140/80 mm Hg supine, 132/72 mm Hg sitting, 108/60 mm Hg standing). The skill of orthostatic measurements requires critical thinking and ongoing nursing judgment when determining a patient's response to repositioning. Do not delegate this procedure.

Measurement of Blood Pressure

Arterial BP measurements are obtained either directly (invasively) or indirectly (noninvasively). The direct method requires the insertion of a thin catheter into an artery. Tubing connects the catheter with electronic hemodynamic monitoring equipment. The monitor displays a constant arterial pressure waveform and reading. Because of the risk of sudden blood loss from an artery, invasive BP monitoring is used only in intensive care settings. The common indirect method requires a sphygmomanometer and stethoscope. Auscultation or palpation with auscultation is the most widely used technique (see Skill 30-5 on pp. 525-529).

Blood Pressure Equipment. Before assessing BP, make sure that you are comfortable using a sphygmomanometer and stethoscope. A **sphygmomanometer** includes a pressure manometer, an occlusive cuff that encloses an inflatable rubber bladder, and a pressure bulb with a release valve that inflates the bladder (Figure 30-12). The aneroid


manometer has a glass-enclosed circular gauge containing a needle that registers millimeter calibrations. Before using the aneroid model, make sure that the needle points to zero and that the manometer is correctly calibrated. Aneroid sphygmomanometers require biomedical calibration every 6 months to verify their accuracy.

The occlusive cuff comes in different sizes. The size selected is proportional to the circumference of the limb being assessed (Figure 30-13). Ideally the width of the cuff is 40% of the circumference (or 20% wider than the diameter) of the midpoint of the limb on which the cuff is used to measure BP. The inflatable bladder, contained in the occlusive cuff, encircles at least 80% of the upper arm of an adult and the entire arm of a child (James et al., 2014). Place the lower edge of the cuff above the antecubital fossa, allowing room for positioning the stethoscope bell or diaphragm. Many adults require a large adult cuff. Using the forearm when a larger cuff is not readily available is not recommended and can result in an overestimate of systolic blood pressure up to 20 mm Hg (Schimanski et al, 2014). An improperly fitting cuff causes inaccurate BP measurements (Table 30-11).

The release valve of the sphygmomanometer needs to be clean and freely movable in either direction. A closed valve holds the pressure constant. A sticky valve makes pressure cuff deflation hard to regulate.

Auscultation. The best environment for BP measurement by auscultation is a quiet room at a comfortable temperature. Although the patient may lie or stand, sitting is the preferred position. In most cases BP readings obtained with the patient in the supine, sitting, and standing positions are similar.

The patient's position during routine BP determination needs to be the same during each measurement to permit a meaningful comparison of values. Before obtaining the patient's BP, attempt to control factors responsible for artificially high readings such as pain, anxiety, or exertion. The patient's perception that the physical or interpersonal environment is stressful affects the BP measurement. BP measurements taken at the patient's place of employment or in a health care provider's office are often higher than those taken at the patient's home.

During the initial assessment obtain and record the BP in both arms. Normally there is a difference of 5 to 10 mm Hg between the arms. In subsequent assessments measure the BP in the arm with the higher pressure. Pressure differences greater than 10 mm Hg indicate

TABLE 30-11 Common Errors in Blood Pressure Assessment

Error	Effect
Bladder or cuff too wide	False-low reading
Bladder or cuff too narrow or too short	False-high reading
Cuff wrapped too loosely or unevenly	False-high reading
Deflating cuff too slowly	False-high diastolic reading
Deflating cuff too quickly	False-low systolic and false-high diastolic reading
Arm below heart level	False-high reading
Arm above heart level	False-low reading
Arm not supported	False-high reading
Stethoscope that fits poorly or impairment of examiner's hearing, causing sounds to be muffled	False-low systolic and false-high diastolic reading
Stethoscope applied too firmly against antecubital fossa	False-low diastolic reading
Inflating too slowly	False-high diastolic reading
Repeating assessments too quickly	False-high systolic reading
Inadequate inflation level	False-low systolic reading
Multiple examiners using different sounds for diastolic readings	False-high systolic and false-low diastolic reading

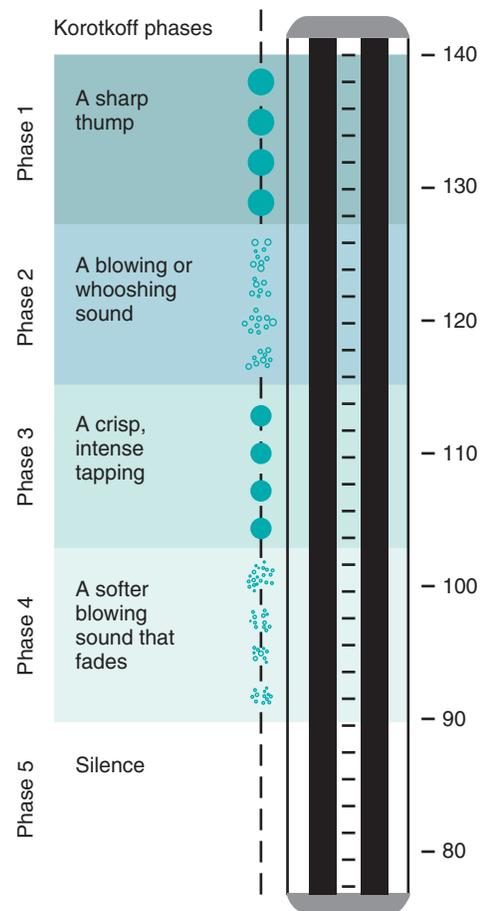
FIGURE 30-14 The sounds auscultated during blood pressure measurement can be differentiated into five phases. In this example blood pressure is 140/90 mm Hg.

vascular problems and are reported to the health care provider or nurse in charge.

Ask the patient to state his or her usual BP. If the patient does not know, inform him or her after measuring and recording it. This is a good opportunity to educate a patient about optimal values of BP, risk factors for developing hypertension, and dangers of hypertension.

Indirect measurement of arterial BP works on a basic principle of pressure. Blood flows freely through an artery until an inflated cuff applies pressure to tissues and causes the artery to collapse. After release of the cuff pressure, the point at which blood flow returns and sound appears through auscultation is the systolic pressure.

In 1905 Korotkoff, a Russian surgeon, first described the sounds heard over an artery distal to the BP cuff when the cuff was deflated. The first sound is a clear rhythmical tapping corresponding to the pulse rate that gradually increases in intensity. *Onset of the sound corresponds to the systolic pressure.* A blowing or swishing sound occurs as the cuff continues to deflate, resulting in the second sound. As the artery distends there is turbulence in blood flow. The third sound is a crisper and more intense tapping. The fourth sound becomes muffled and low pitched as the cuff is further deflated. At this point the cuff pressure has fallen below the pressure within the vessel walls; *this sound is the diastolic pressure in infants and children.* The fifth sound marks the disappearance of sound. *In adolescents and adults the fifth sound corresponds with the diastolic pressure* (Figure 30-14). In some patients the sounds are clear and distinct. In others only the beginning and ending sounds are clear.

The American Heart Association recommends recording two numbers for a BP measurement: the point on the manometer when you hear the first sound for systolic and the point on the manometer when you hear the fifth sound for diastolic. Some institutions recommend recording the point when you hear the fourth sound as well, especially for patients with hypertension. Divide the numbers by


slashed lines (e.g., 120/70 or 120/100/70). Note the arm used to measure the BP (e.g., right arm [RA] 130/70) and the patient's position (e.g., sitting).

BP assessment results in many medical decisions and nursing interventions. Obtaining an accurate measurement is essential. There are several sources for error (see Table 30-11). When you are unsure of a reading, have a colleague reassess the BP.

Assessment in Children. All children 3 years of age through adolescence need to have BP checked at least annually. BP in children changes with growth and development. Help parents understand the importance of this routine screening to detect children who are at risk for hypertension. The measurement of BP in infants and children is difficult for several reasons:

- Different arm size requires careful and appropriate cuff size selection. Do not choose a cuff on the basis of the name of the cuff. An "infant" cuff is often too small for some infants.
- Readings are difficult to obtain in restless or anxious infants and children. Allow at least 15 minutes for children to recover from recent activities and become less apprehensive. The child's cooperation is increased when you or the parent have prepared him or her for the unusual sensation of the BP cuff. Most children understand the analogy of a "tight hug on your arm."
- Placing the stethoscope too firmly on the antecubital fossa causes errors in auscultation. Sounds are difficult to hear in children because of low frequency and amplitude. A pediatric stethoscope bell is often helpful.

BOX 30-9   PROCEDURAL GUIDELINES

Palpating Systolic Blood Pressure

Delegation Considerations
The skill of palpation of blood pressure (BP) cannot be delegated to nursing assistive personnel.

Equipment
Sphygmomanometer

Steps
1. Identify patient using two identifiers (e.g., name and birth date or name and medical record number) according to agency policy (TJC, 2016).
2. Perform hand hygiene.
3. Apply BP cuff to extremity selected for measurement.
4. Continually palpate pulse of brachial, radial, or popliteal artery with fingertips of one hand.
5. Inflate BP cuff 30 mm Hg above point at which you no longer can palpate the pulse.
6. Slowly release valve and deflate cuff, allowing manometer needle mercury to fall 2 mm Hg per second.
7. Note point on manometer when pulse is again palpable; this is the systolic BP.
8. Deflate cuff rapidly and completely. Remove cuff from patient extremity unless you need to repeat the measurement.
9. Perform hand hygiene.
10. Record BP as systolic/-, palpated (e.g., BP 108/-, palpated, location) on vital sign flow sheet, in nurses' notes, or electronic medical record. Report abnormal findings to nurse in charge or health care provider.

FIGURE 30-15 Lower-extremity blood pressure cuff positioned above popliteal artery at midthigh with knee flexed.

FIGURE 30-16 Automatic blood pressure monitor.

Ultrasonic Stethoscope. When you are unable to auscultate sounds because of a weakened arterial pulse, you can use an ultrasonic stethoscope (see Chapter 31). This stethoscope allows you to hear low-frequency systolic sounds. You frequently use this device when measuring the BP of infants and children and low BP in adults.

Palpation. Indirect measurement of BP by palpation is useful for patients whose arterial pulsations are too weak to create sounds. Severe blood loss and decreased heart contractility are examples of conditions that result in BPs too low to auscultate accurately. In these cases you can assess the systolic BP by palpation (Box 30-9). The diastolic BP is difficult to determine by palpation. When using the palpation technique, record the systolic value and how you measured it (e.g., RA 90/-, palpated, supine).

You can use the palpation technique along with auscultation. In some patients with hypertension the sounds usually heard over the brachial artery when the cuff pressure is high disappear as pressure is reduced and then reappear at a lower level. This temporary disappearance of sound is the **auscultatory gap.** It typically occurs between the first and second sounds. The gap in sound covers a range of 40 mm Hg and thus causes an underestimation of systolic pressure or overestimation of diastolic pressure. The examiner needs to be certain to inflate the cuff high enough to hear the true systolic pressure before the auscultatory gap. Palpation of the radial artery helps to determine how high to inflate the cuff. The examiner inflates the cuff 30 mm Hg above the pressure at which the radial pulse was palpated. Record the range of pressures in which the auscultatory gap occurs (e.g., BP RA 180/94 mm Hg with an auscultatory gap from 180 to 160 mm Hg, sitting).

Lower-Extremity Blood Pressure. Dressings, casts, IV catheters, or arteriovenous fistulas or shunts make the upper extremities

inaccessible for BP measurement. You then need to obtain the BP in a lower extremity. Comparing upper-extremity BP with that in the legs is also necessary for patients with certain cardiac and BP abnormalities. The popliteal artery, palpable behind the knee in the popliteal space, is the site for auscultation. The cuff needs to be wide and long enough to allow for the larger girth of the thigh. Placing the patient in a prone position is best. If such a position is impossible, ask the patient to flex the knee slightly for easier access to the artery. Position the cuff 2.5 cm (1 inch) above the popliteal artery, with the bladder over the posterior aspect of the midthigh (Figure 30-15). The procedure is identical to brachial artery auscultation. Systolic pressure in the legs is usually higher by 10 to 40 mm Hg than in the brachial artery, but the diastolic pressure is the same (Frese et al., 2011).

Electronic Blood Pressure Devices. Many different styles of electronic BP machines are available to determine BP automatically (Figure 30-16). Electronic BP machines rely on an electronic sensor to

BOX 30-10 PROCEDURAL GUIDELINES

Electronic Blood Pressure Measurement

Delegation Considerations

The skill of obtaining an electronic blood pressure (BP) measurement can be delegated to nursing assistive personnel (NAP). However, the nurse must first verify that the patient is stable and does not need to be monitored closely for evaluating response to medications or other therapies. Instruct the NAP to:

- Obtain BP at appropriate times as determined by agency policy, health care provider's order, or patient's condition such as frequent postoperative measurements.
- Consider patient-specific factors that affect patient's usual values.
- Obtain the BP on the appropriate limb using the correct size cuff considering the patient's history such as presence of intravenous (IV) sites.
- Immediately report significant BP changes as specified by the nurse.

Equipment

Electronic BP machine, BP cuff of appropriate size as recommended by manufacturer

Steps

1. Identify patient using two identifiers (e.g., name and birth date or name and medical record number) according to agency policy (TJC, 2016).
2. Determine appropriateness of using electronic BP measurement. Patients with irregular heart rate, peripheral vascular disease, seizures, tremors, and shivering are not candidates for this device (Suokhrie et al., 2013).
3. Determine best site for cuff placement (see Skill 30-5).
4. Perform hand hygiene. Help patient to comfortable position, either lying or sitting. Plug in device and place it near patient, ensuring that connector hose between cuff and machine will reach.
5. Locate on/off switch and turn machine on to enable device to self-test computer systems.
6. Select appropriate cuff size for patient extremity (see Table 30-11) and appropriate cuff for machine. Electronic BP cuff and machine are matched by the manufacturer and are not interchangeable.
7. Prepare BP cuff by manually squeezing all the air out of cuff and attaching cuff to connector hose.
8. Remove any constricting clothing to ensure proper cuff application. BP cuff may be placed over a light shirt sleeve (Pinar et al., 2010).
9. Wrap flattened cuff snugly around extremity, verifying that only one finger fits between cuff and patient's skin. Make sure that "artery" arrow marked

on outside of cuff is placed correctly (see illustration for Skill 30-5, Step 4).
10. Verify that connector hose between cuff and machine is not kinked. Kinking prevents proper inflation and deflation of cuff.
11. Following manufacturer directions, set frequency control of automatic or manual and press start button. The first BP measurement pumps cuff to pressure of approximately 180 mm Hg. After this pressure is reached, the machine begins a deflation sequence that determines BP. The first reading determines peak pressure inflation for additional measurements.

CLINICAL DECISION: If unable to obtain BP with electronic device, verify machine connections (e.g., plugged into working electrical outlet, hose-cuff connections tight, machine on, correct cuff). Wait at least 1 minute but not more than 2 minutes to repeat electronic BP; if unable to obtain, use auscultatory technique (see Skill 30-5).

12. When deflation is complete, digital display provides most recent values and flashes time in minutes that have elapsed since measurement occurred.
13. Set frequency of BP measurements and upper and lower alarm limits for systolic, diastolic, and mean BP readings. Intervals between BP measurements are set from 1 to 90 minutes.
14. Determine measurement frequency and alarm limits on the basis of patient's acceptable range of BP, nursing judgment, and health care provider order.
15. Obtain additional readings at any time by pressing start button. (Sometimes you need additional readings for unstable patients.) Pressing cancel button immediately deflates cuff.
16. If frequent BP determinations are necessary, leave cuff in place. Remove cuff at least every 2 hours to assess underlying skin integrity and, if possible, alternate BP sites. Patients with abnormal bleeding tendencies are at risk for microvascular rupture from repeated inflations. When you are finished using the electronic BP machine, clean BP cuff according to agency policy to reduce transmission of microorganisms.
17. Compare electronic BP readings with auscultatory BP to verify accuracy of electronic BP measurement.
18. Record BP and site assessed on vital sign flow sheet, in nurses' notes, or electronic medical record (per agency policy). Record any signs of BP alterations in nurses' notes.
19. Report abnormal findings to nurse in charge or health care provider.

---

detect the vibrations caused by the rush of blood through an artery (Box 30-10). Use electronic devices when frequent BP assessment is necessary such as in patients who are critically ill or unstable, during or after invasive procedures, or when therapies require frequent monitoring (e.g., IV heart and BP medications). Box 30-11 lists conditions that are not appropriate for automatic BP devices.

The advantages of automatic devices are the ease of use and efficiency when repeated or frequent measurements are indicated. The ability to use a stethoscope is not necessary. However, automatic devices are not recommended for hypertensive patients, patients with irregular heart rates, or those who have experienced trauma (Skirton et al., 2011). Most electronic BP devices are unable to process sounds or vibrations of low BP. The range of device sophistication also makes BP measurement comparisons difficult.

Self-Measurement of Blood Pressure. Improved technology in electronic monitoring devices allows individuals to measure their own BPs in their home with the push of a button. The portable home

BOX 30-11 Patient Conditions Not Appropriate for Electronic Blood Pressure Measurement

- Irregular heart rate
- Peripheral vascular obstruction (e.g., clots, narrowed vessels)
- Shivering
- Seizures
- Excessive tremors
- Inability to cooperate
- Blood pressure less than 90 mm Hg systolic

devices include the aneroid sphygmomanometer and electronic digital readout devices that do not require use of a stethoscope. The electronic devices are easier to manipulate but require frequent recalibration, more than once a year. Because of their sensitivity, improper cuff placement or movement of the arm causes electronic devices to give incorrect readings.

Stationary automatic BP devices are often found in public places such as grocery stores, fitness clubs, airports, or work sites. Users simply rest their arms within the inflatable cuff of the machine, which contains a pressure sensor. A visual display tells users their BP within 60 to 90 seconds. The reliability of the stationary machines is limited. BP values vary by 5 to 10 mm Hg or more (for both systolic and diastolic values) compared with pressures taken with a manual sphygmomanometer.

Self-measurement of BP has several benefits. Sometimes elevated BP is detected in people previously unaware of a problem. People with prehypertension provide information about the pattern of BP values to their health care provider. Patients with hypertension benefit from participating actively in their treatment through self-monitoring, which helps adherence with treatment. The disadvantages of self-measurement include improper use of the device and risk of inaccurate readings. Some patients are needlessly alarmed with one elevated reading. Some patients with hypertension become overly conscious of their BP and inappropriately self-adjust medications.

Consumers can learn to use self-measurement devices if they have the information needed to perform the procedure correctly and if they know when to seek medical attention. Advise patients of possible inaccuracies in the BP devices, help them understand the meaning and implications of readings, and teach them proper measurement techniques. Encourage them to record the date of their BP readings to assess BP over time and share findings with their health care provider.

Nursing Process and Blood Pressure Determination

The assessment of BP along with pulse assessment evaluates the general state of cardiovascular health and responses to other system imbalances. Hypotension, hypertension, orthostatic hypotension, and narrow or wide pulse pressures are defining characteristics of certain nursing diagnoses, including the following:

- *Activity Intolerance*
- *Anxiety*
- *Decreased Cardiac Output*
- *Deficient/Excess Fluid Volume*
- *Risk for Injury*
- *Acute Pain*
- *Ineffective Peripheral Tissue Perfusion*

The nursing care plan includes interventions based on the nursing diagnosis identified and the related factors. For example, the defining characteristics of hypotension, dizziness, pulse deficit, and dysrhythmia lead to a diagnosis of *Decreased Cardiac Output.* Related factors might include *poor oral intake, excessive heat exposure,* and a *history of valvular heart disease.* The related factor guides the choice of nursing interventions. Evaluate patient outcomes by assessing the BP following each intervention.

HEALTH PROMOTION AND VITAL SIGNS

The emphasis on health promotion and maintenance and discharge from hospital settings has resulted in an increase in the need for patients and their families to monitor vital signs in the home. Teaching

---

BOX 30-12   PATIENT TEACHING
Health Promotion

Objective
- Patient identifies measures to promote health.

Teaching Strategies
- Instruct patient about the importance of diet, exercise, and remaining tobacco free.
- Instruct patient on risk factors for hypothermia, frostbite, and heat stroke.
- Demonstrate self-assessment of heart rate using the carotid pulse. Patients taking certain prescribed cardiac medications need to learn to assess their own pulse rate to detect side effects of medications. Patients undergoing cardiac rehabilitation need to learn to assess their own pulse rate to determine their response to exercise.
- Instruct patient about normal blood pressure values, risk factors for hypertension, and usual lack of hypertension symptoms.
- Demonstrate how to obtain blood pressure to the patient's family caregiver using an appropriate-size blood pressure cuff for home use at the same time each day, after patient has had a brief rest, and in the same position and arm each time pressure is taken.

Evaluation
- Ask patient to state three activities to promote health.
- Observe patient obtaining carotid pulse rate.
- Observe family caregiver's measurement of blood pressure.

---

considerations affect all vital sign measurements. Incorporate them within the patient's plan of care (Box 30-12).

When considering how to teach patients and their families about vital sign measurements and their importance and significance, a patient's age is an important factor. With an increase in the older-adult population there is a greater need for family caregivers to be aware of changes that are unique to older adults. Box 30-13 identifies some of these variations.

RECORDING VITAL SIGNS

Special electronic and paper graphic flow sheets exist for recording vital signs (see Chapter 26). Identify institution procedure for documenting on a graphic. In addition to the actual vital sign values, record in the nurses' notes any accompanying or precipitating symptoms such as chest pain and dizziness with abnormal BP, shortness of breath with abnormal respirations, cyanosis with hypoxemia, or flushing and diaphoresis with elevated temperature. Document any interventions initiated as a result of vital sign measurement such as administration of oxygen therapy, hydration, or an antihypertensive medication.

Patients being managed on critical paths often have vital sign values listed as outcomes. If a vital sign value is above or below the anticipated outcomes, write a variance note to explain the nature of the variance and the nursing course of action. For example, a path for a patient who has undergone lung surgery often has an outcome during the postoperative period of "afebrile." If the patient has a fever, the nurse's variance note addresses possible sources of fever (e.g., retained pulmonary secretions) and nursing interventions (e.g., increased suctioning, postural drainage, or hydration).

BOX 30-13 FOCUS ON OLDER ADULTS

Factors Affecting Vital Signs of Older Adults

Temperature
- The temperature of older adults is at the lower end of the normal temperature range, 36° to 36.8°C (96.8° to 98.3°F) orally and 36.6° to 37.2°C (98° to 99°F) rectally. Therefore temperatures considered within normal range sometimes reflect a fever in an older adult. In an older adult fever is present when a single oral temperature is over 37.8°C (100°F); repeated oral temperatures are over 37.2°C (99°F); rectal temperatures are over 37.5°C (99.5°F); or temperature has increased more than 1°C (2°F) over baseline.
- Older adults are very sensitive to slight changes in environmental temperature because their thermoregulatory systems are not as efficient.
- A decrease in sweat gland reactivity in the older adult results in a higher threshold for sweating at high temperatures, which leads to hyperthermia and heatstroke.
- Be especially attentive to subtle temperature changes and other manifestations of fever in this population such as tachypnea, anorexia, falls, delirium, and overall functional decline.
- Older adults without teeth or with poor muscle control may be unable to close their mouths tightly to obtain accurate oral temperature readings.

Pulse Rate
- If it is difficult to palpate the pulse of an obese older adult, a Doppler device provides a more accurate reading.
- Pedal pulses are often difficult to palpate in older adults.
- The older adult has a decreased heart rate at rest.
- It takes longer for the heart rate to rise in the older adult to meet sudden increased demands that result from stress, illness, or excitement. Once elevated, the pulse rate takes longer to return to normal resting rate.
- Heart sounds are sometimes muffled or difficult to hear in older adults because of an increase in air space in the lungs.

Blood Pressure
- Older adults who have lost upper arm mass, especially the frail elderly, require special attention to selection of a smaller size blood pressure cuff.
- Older adults sometimes have an increase in systolic pressure related to decreased vessel elasticity, whereas the diastolic pressure remains the same, resulting in a wider pulse pressure.
- Instruct older adults to change position slowly and wait after each change to avoid postural hypotension and prevent injuries.
- Skin of older adults is more fragile and susceptible to cuff pressure during frequent measurements. More frequent assessment of skin under the cuff or rotating blood pressure sites is recommended.

Respirations
- Aging causes ossification of costal cartilage and downward slant of ribs, resulting in a more rigid rib cage, which reduces chest wall expansion. Kyphosis and scoliosis that occur in older adults also restrict chest expansion and decrease tidal volume.
- Older adults depend more on accessory abdominal muscles during respiration than on weaker thoracic muscles.
- The respiratory system matures by the time a person reaches 20 years of age and begins to decline in healthy people after the age of 25. Despite this decline older adults are able to breathe effortlessly as long as they are healthy. However, sudden events that require an increased demand for oxygen (e.g., exercise, stress, illness) create shortness of breath in the older adult.
- Identifying an acceptable pulse oximeter probe site is difficult with older adults because of the likelihood of peripheral vascular disease, decreased cardiac output, cold-induced vasoconstriction, and anemia.

QSEN QSEN: BUILDING COMPETENCY IN INFORMATICS. The team leader notifies you that your patient has achieved a critical Early Warning Score, a computer-generated value that reflects a patient's condition on the basis of the vital signs entered by the nursing assistive personnel within the past 15 minutes. After completing a focused assessment of the patient, you review the vital signs and compare the most recent with baseline readings. Which vital signs that are included in the Early Warning Score indicate a potential change in the patient's condition? Which actions should you take next?

Baseline Vital Signs	Vital Signs During the Past 15 Minutes
Heart rate 86 and regular	Heart rate 92 and regular
Blood pressure 120/84 in right arm via electronic blood pressure machine	Blood pressure 92/76 in right arm via electronic blood pressure machine
Oxygen saturation 95% on 2 L nasal cannula	Oxygen saturation 89% on 2 L nasal cannula
Respiratory rate 16, regular and deep	Respiratory rate 22, regular and deep
Temperature 37.2°C via temporal artery	Temperature 37.6°C via temporal artery

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with the members of the health care team, assess and incorporate the patient's priorities of care and preferences and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient-centered care.

- Devices for measuring vital signs are often shared among patients. Cleaning each device carefully between patients decreases patients' risk of infection.
- Blood pressure cuffs and pulse oximetry sensors can apply excessive pressure on fragile skin. Rotating sites during repeated measurements decreases risk for skin breakdown.
- Analyze the trends for measuring vital signs and report abnormal findings to the health care provider.
- Determine frequency of measuring vital signs on the basis of the patient's condition.

SKILL 30-1	MEASURING BODY TEMPERATURE

DELEGATION CONSIDERATIONS

The skill of temperature measurement can be delegated to nursing assistive personnel (NAP). Instruct the NAP about:

- Using the appropriate route, device, and frequency for temperature measurement.
- Implementing appropriate precautions when positioning the patient for rectal temperature measurement.
- Considering specific patient-related factors that falsely raise or lower temperature.
- Obtaining temperature measurements at appropriate times as determined by agency policy, health care provider's orders, or patient condition such as when a patient is shivering or feels warm.
- Knowing the usual temperature values for patient.
- Immediately reporting abnormalities to the nurse for further assessment.

EQUIPMENT

- Appropriate thermometer (see Box 30-4)
- Soft tissue or wipe
- Alcohol wipe
- Lubricant (for rectal measurements only)
- Pen, vital sign flow sheet or record, or patient's electronic medical record
- Clean gloves, plastic thermometer sleeve, disposable probe or sensor cover
- Towel

STEP	RATIONALE

ASSESSMENT

1. Assess for signs and symptoms of temperature alterations and factors that accompany body temperature alterations.

Hyperthermia: Decreased skin turgor; tachycardia; hypotension; concentrated urine

Heatstroke: Hot, dry skin; tachycardia; hypotension; excessive thirst; muscle cramps; visual disturbances; confusion or delirium

Hypothermia: Pale skin; skin cool or cold to touch; bradycardia and dysrhythmias; uncontrolled shivering; reduced level of consciousness; shallow respirations

Physical signs and symptoms indicate abnormal temperature. Enables you to accurately assess the nature of variations.

2. Determine previous activity that interferes with accuracy of temperature measurement. When taking oral temperature, wait 20 to 30 minutes before measuring temperature if patient has smoked or ingested hot or cold liquids or foods.

Smoking, mouth breathing, and oral intake cause false oral temperature readings (Lu et al., 2010).

3. Assess pertinent laboratory values, including complete blood count (CBC).

A white blood cell count (WBC) greater than 12,000/mm^3 in a nonpregnant adult suggests the presence of infection, which can lead to hyperthermia; a WBC count less than 5000/mm^3 suggests that the ability to fight an infection is compromised, which can lead to ineffective thermoregulation.

4. Identify any medications or treatments that may influence body temperature.

Antiinflammatory medications, steroids, and warming or cooling blankets affect body temperature.

5. Determine appropriate temperature site and device for patient.

Site is chosen on the basis of advantages and disadvantages of each site (see Box 30-4). Use disposable single-use thermometer for patient on isolation precautions.

6. Obtain previous baseline temperature and measurement site from patient's medical record.

Allows for assessment of change in patient's condition with future measurements.

PLANNING

1. Identify patient using two identifiers (e.g., name and birth date or name and medical record number) according to agency policy.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).

2. Explain route by which temperature will be taken and importance of maintaining proper position until reading is complete.

Patients often are curious about such measurements and need to be cautioned against prematurely removing thermometer to read results.

IMPLEMENTATION

1. Perform hand hygiene.

Reduces transmission of microorganisms.

2. Help patient assume comfortable position that provides easy access to temperature measurement site.

Ensures comfort and accuracy of temperature reading.

3. Obtain temperature reading.

   a. Oral temperature measurement with electronic thermometer

      (1) Apply clean gloves (optional) when there are respiratory secretions or facial or mouth wound drainage.

Use of oral probe cover, which you can remove without physical contact, minimizes need to wear gloves.

      (2) Remove thermometer pack from charging unit. Attach oral thermometer probe stem (blue tip) to thermometer unit. Grasp top of probe stem, being careful not to apply pressure on ejection button.

Charging provides battery power. Ejection button releases plastic probe cover from probe stem.

      (3) Slide disposable plastic probe cover over thermometer probe stem until cover locks in place (see illustrations).

Soft plastic cover will not break in patient's mouth and prevents transmission of microorganisms between patients.

STEP	RATIONALE
(4) Ask patient to open mouth; gently place thermometer probe under tongue in posterior sublingual pocket lateral to center of lower jaw (see illustration).	Heat from superficial blood vessels in sublingual pocket produces temperature reading. With electronic thermometer, temperatures in right and left posterior sublingual pocket are significantly higher than in area under front of tongue.
(5) Ask patient to hold thermometer probe with lips closed.	Closed lips maintain proper position of thermometer during recording.
(6) Leave thermometer probe in place until audible signal indicates completion and temperate reading appears on digital display; remove thermometer probe from under patient's tongue.	Probe needs to stay in place until signal occurs to ensure accurate reading.
(7) Push ejection button on thermometer probe stem to discard plastic probe cover into appropriate receptacle.	Reduces transmission of microorganisms.
(8) Return thermometer probe stem to storage position of recording unit.	Storage position protects probe stem. Returning probe stem automatically causes digital reading to disappear.
(9) If gloves are worn, remove and dispose in appropriate receptacle. Perform hand hygiene.	Hand hygiene reduces transmission of microorganisms.
(10) Return thermometer to charger.	Charger maintains battery charge.
b. Rectal temperature measurement with electronic thermometer	
(1) Draw curtain around bed and/or close room door. Help patient to Sims' position with upper leg flexed. Move aside bed linen to expose only anal area. Keep patient's upper body and lower extremities covered with sheet or blanket.	Maintains patient's privacy, minimizes embarrassment, and promotes comfort. Exposes anal area for correct thermometer placement.

STEP 3a(3) Disposable plastic cover is placed over probe.

STEP 3a(4) Probe under tongue in posterior sublingual pocket.

SKILL 30-1	MEASURING BODY TEMPERATURE—cont'd

STEP	RATIONALE
(2) Apply clean gloves. Cleanse anal region when feces and/or secretions are present. Remove soiled gloves and reapply clean gloves.	Maintains standard precautions when exposed to items soiled with body fluids (e.g., feces).
(3) Remove thermometer pack from charging unit. Attach rectal probe stem (red tip) to thermometer unit. Grasp top of probe stem, being careful not to apply pressure ejection button.	Charging provides battery power. Ejection button releases plastic cover from probe stem.
(4) Slide disposable plastic probe cover over thermometer probe stem until cover locks in place.	Soft plastic probe cover prevents transmission of microorganisms between patients.
(5) Squeeze liberal portion of lubricant on tissue. Dip end of probe cover into lubricant, covering 2.5 to 3.5 cm (1 to 1½ inches) for adult.	Lubrication minimizes trauma to rectal mucosa during insertion. Tissue avoids contamination of remaining lubricant in container.
(6) With nondominant hand separate patient's buttocks to expose anus. Ask patient to breathe slowly and relax.	Fully exposes anus for thermometer insertion. Relaxes anal sphincter for easier thermometer insertion.
(7) Gently insert thermometer probe into anus in direction of umbilicus 2.5 to 3.5 cm (1 to 1½ inches) for adult. Do not force thermometer.	Ensures adequate exposure against blood vessels in rectal wall.

CLINICAL DECISION: *If you cannot adequately insert thermometer into rectum, remove it and consider alternative method for obtaining temperature.*

STEP	RATIONALE
(8) Once positioned, hold thermometer probe in place (see illustration) until audible signal indicates completion and patient's temperature appears on digital display; remove thermometer probe from anus.	Probe needs to stay in place until signal occurs to ensure accurate reading. Holding probe in place prevents movement.
(9) Push ejection button on thermometer stem to discard plastic probe cover into appropriate receptacle. Wipe probe stem with alcohol swab, paying particular attention to ridges where probe stem cover connects to probe.	Reduces transmission of microorganisms.
(10) Return thermometer probe stem to storage position of recording unit.	Protects probe stem from damage. Returning probe stem automatically causes digital reading to disappear.
(11) Wipe patient's anal area with soft tissue to remove lubricant or feces and discard tissue. Help patient assume a comfortable position.	Provides for comfort and hygiene.
(12) Remove and dispose of gloves in appropriate receptacle. Perform hand hygiene.	Reduces transmission of microorganisms.
(13) Return thermometer to charger. Verify that charger and probes are wiped with alcohol daily.	Maintains battery charge of thermometer unit. Reduces transmission of microorganisms.
c. Tympanic membrane temperature with electronic infrared thermometer	
(1) Help patient assume comfortable position with head turned toward side away from you. If patient has been lying on one side, use upper ear.	Ensures comfort and exposes auditory canal for accurate temperature measurement. Heat trapped in lower ear causes false-high temperature readings.
(2) Note if there is obvious earwax in patient's ear canal.	Earwax on lens cover blocks a clear optical pathway. It can lower tympanic temperature by 0.3° C (0.6° F). Switch to other ear or select alternative measurement site if needed.

STEP 3b(8) Probe positioned in anus. (Copyright © Mosby's Clinical Skills: Essentials Collection.)

STEP	RATIONALE
(3) Remove thermometer handheld unit from charging base.	Base provides battery power. Removal of handheld unit from base prepares it to measure temperature.
(4) Slide clean disposable speculum cover over otoscope-like lens tip until it locks into place. Be careful not to apply pressure to ejection button and not to touch lens cover.	Soft plastic probe cover prevents transmission of microorganisms between patients. Ejection button releases plastic probe cover from thermometer tip. Lens cover needs to be free of dust, fingerprints, or earwax to ensure clear optical pathway.
(5) Insert infrared speculum into ear canal following manufacturer instructions for tympanic probe positioning:	Ear tug straightens external auditory canal, allowing maximum exposure of tympanic membrane to correctly position speculum (Hockenberry and Wilson, 2015).
(a) Pull ear pinna backward, up, and out for an adult. For children 3 years and younger, point covered probe toward midpoint between eyebrow and side burns. For children older than 3 years, pull pinna up and back (Hockenberry and Wilson, 2015).	Correctly positioning speculum tip with respect to ear canal ensures accurate readings.
(b) Move thermometer in a figure-eight pattern (see manufacturer directions).	Some manufacturers recommend movement of the speculum tip in a figure-eight pattern, which allows the sensor to detect maximum tympanic membrane heat radiation.
(c) Fit speculum tip snugly into canal and do not move (see illustration), pointing speculum tip toward nose.	Gentle pressure seals ear canal from ambient temperature, which alters readings as much as 2.8° C (5° F). Operator error leads to false-low temperatures.
(6) Once positioned, press scan button on handheld unit. Leave speculum in place until audible signal indicates completion and patient's temperature appears on digital display.	Pressing scan button causes detection of infrared energy. Speculum probe tip needs to stay in place until device has detected infrared energy noted by audible signal.
(7) Carefully remove speculum from auditory meatus.	Prevents rubbing of sensitive outer ear lining.
(8) Push ejection button on handheld unit to discard speculum cover into appropriate receptacle.	Reduces transmission of microorganisms. Automatically causes digital reading to disappear.
(9) If temperature is abnormal or a second reading is necessary, replace speculum cover and wait 2 to 3 minutes before repeating measurement in same ear. Repeat measurement in other ear or try an alternative temperature site or instrument.	Time allows ear canal to regain usual temperature.
(10) Return handheld unit to charging base.	Protects sensor tip from damage.
(11) Help patient get into a comfortable position.	Restores comfort and sense of well-being.
(12) Perform hand hygiene.	Reduces transmission of microorganisms.
d. **Temporal artery temperature measurement with electronic infrared thermometer**	
(1) Ensure that forehead is dry; wipe with towel if needed.	Moist skin interferes with thermometer sensor.
(2) Place sensor flush on patient's forehead above eyebrow (see illustration).	Contact avoids measurement of ambient temperature.
(3) Press red scan button with your thumb. Slowly slide thermometer straight across forehead while keeping sensor flush on skin.	Scanning for highest temperature continues until you release scan button.
(4) Keeping scan button pressed, lift sensor from forehead and touch sensor to skin on neck, just behind earlobe. Peak temperature occurs when clicking sound during scanning stops (see illustration). Release scan button and note reading.	Sensor confirms highest temperature behind earlobe.

STEP 3c(5)(c) Tympanic thermometer with probe cover inserted into auditory canal.

SKILL 30-1   MEASURING BODY TEMPERATURE—cont'd

STEP	RATIONALE
(5) Clean sensor with alcohol swab.	Prevents transmission of microorganisms.
(6) Return thermometer to charger or thermometer base.	Maintains battery charge of thermometer unit.
e. Axillary temperature measurement with electronic thermometer	
(1) Draw curtain around bed or close room door. Help patient to supine or sitting position. Move clothing or gown away from shoulder and arm.	Maintains patient's privacy, minimizes embarrassment, and promotes comfort. Exposes axilla for correct thermometer probe placement.
(2) Remove thermometer pack from charging unit. Attach oral thermometer probe stem (blue tip) to thermometer unit. Grasp top of thermometer probe stem, being careful not to apply pressure on ejection button.	Ejection button releases plastic cover from probe.
(3) Slide disposable plastic probe cover over thermometer stem until cover locks in place.	Probe cover prevents transmission of microorganisms between patients.
(4) Raise patient's arm away from torso. Inspect for skin lesions and excessive perspiration. Insert thermometer probe into center of axilla (see illustration). Lower arm over probe and place arm across patient's chest.	Do not use axillar if skin lesions are present because local skin temperature may be altered or area may be painful to touch. Axillary temperature is not reliable in adults but can be used in infants.

STEP 3d(2) Scanning the forehead. (Copyright © Mosby's Clinical Skills: Essentials Collection.)

STEP 3d(4) Digital reading shown on display unit. (Copyright © Mosby's Clinical Skills: Essentials Collection.)

STEP 3e(4) Place thermometer in axilla.

STEP	RATIONALE
(5) Once positioned, hold thermometer probe in place until audible signal indicates completion and patient's temperature appears on digital display. Remove thermometer probe from axilla.	Thermometer probe needs to stay in place until signal sounds to ensure accurate reading.
(6) Push ejection button on thermometer stem to discard plastic probe cover into appropriate receptacle.	Reduces transmission of microorganisms.
(7) Return thermometer stem to storage position/charger of recording unit.	Returning thermometer stem to storage unit position automatically causes digital reading to disappear. Storage position protects stem.
4. Discuss findings with patient and explain significance.	Promotes participation in care and understanding of health status.

EVALUATION

1. If temperature is assessed for first time, establish temperature as baseline if it is within normal range.	Used to compare future temperature measurements.
2. Compare temperature reading with patient's previous baseline and acceptable temperature range for his or her age-group.	Body temperature fluctuates within narrow range; comparison reveals presence of abnormality. Improper placement or movement of thermometer causes inaccuracies. Second measurement confirms initial findings of abnormal body temperature.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Temperature 1°C (1.8°F) above usual range
- Assess possible sites (e.g., central line catheter, wounds) for localized infection and related data suggesting a systemic infection.
- Follow interventions listed in Box 30-7.

2. Fever persists or reaches unacceptable level as defined by health care provider.
- Notify health care provider and administer antipyretics and antibiotics as ordered.

3. Temperature 1°C (1.8°F) below usual range
- Remove any drafts, wet clothing, or linen.
- Apply extra blankets and, unless contraindicated, offer warm liquids.
- Monitor apical pulse rate and rhythm because hypothermia causes bradycardia and dysrhythmias.

RECORDING AND REPORTING

- Record temperature in nurses' notes or vital sign flow sheet or EHR. Document measurement of temperature after administration of specific therapies in narrative form in nurses' notes.
- Report abnormal findings to nurse in charge or health care provider.

HOME CARE CONSIDERATIONS

- Assess temperature and ventilation of patient's environment to determine existence of any environmental condition that influences patient's temperature.

SKILL 30-2	ASSESSING RADIAL AND APICAL PULSES	

DELEGATION CONSIDERATIONS

The skill of pulse measurement can be delegated to nursing assistive personnel (NAP) if the patient is stable and not at high risk for acute or serious cardiac problems. The nurse instructs the NAP to:
- Consider factors related to patient's history, usual values, and risk for abnormally slow or irregular pulse.
- Obtain appropriate pulse measurement frequency at appropriate times as determined by agency policy, health care provider's order, or patient condition such as presence of chest pain or dizziness.
- Immediately report significant changes or abnormalities to nurse for further assessment.

EQUIPMENT
- Stethoscope (apical pulse only)
- Wristwatch with second hand or digital display
- Pen, vital sign flow sheet, or patient's electronic health record
- Alcohol swab

STEP	RATIONALE

ASSESSMENT

1. Determine need to assess radial or apical pulse:	Nurse uses clinical judgment to determine need for assessment.
a. Assess for any risk factors for pulse alterations.	These conditions place patients at risk for pulse alterations. A history of peripheral vascular disease often alters pulse rate and quality.
• History of heart disease	
• Cardiac dysrhythmias	
• Onset of sudden chest pain or acute pain from any site	
• Invasive cardiovascular diagnostic tests	
• Surgery	
• Sudden infusion of large volume of intravenous (IV) fluid	
• Internal or external hemorrhage, dehydration	
• Administration of medications that alter cardiac function	

SKILL 30-2	ASSESSING RADIAL AND APICAL PULSES—cont'd

STEP	RATIONALE
b. Assess for signs and symptoms of altered stroke volume and cardiac output such as dyspnea, fatigue, chest pain, orthopnea, syncope, palpitations (person's unpleasant awareness of heartbeat), jugular venous distention, edema of dependent body parts, cyanosis, or pallor of skin (see Chapter 41).	Physical signs and symptoms indicate alteration in cardiac function.
c. Assess for signs and symptoms of peripheral vascular disease such as pale, cool extremities; thin, shiny skin with decreased hair growth; thickened nails.	Physical signs and symptoms indicate alteration in local arterial blood flow.
2. Assess for factors that influence pulse rate and rhythm: age, exercise, position changes, fluid balance, medications, temperature, and sympathetic stimulation.	Allows for accurate assessment of presence and significance of pulse alterations. Acceptable range of pulse rate changes with age (see Table 30-3).
3. Assess pertinent laboratory values, including serum potassium and complete blood count (CBC).	Elevated or decreased potassium levels can cause dysrhythmias. Low values for hemoglobin are associated with reduced oxygen transport, which can increase pulse rate.
4. Determine patient's previous baseline pulse rate if available in his or her medical record.	Allows for accurate assessment of change in condition and provides comparison with future apical pulse measurements.
5. Determine if patient has latex allergy.	If patient has latex allergy, verify that stethoscope is latex free.

PLANNING

1. Identify patient using two identifiers (e.g., name and birth date or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).
2. Explain that you will assess pulse or heart rate. Encourage patient to relax and not speak. If patient was active, wait 5 to 10 minutes before assessing pulse.	Activity and anxiety elevate heart rate. Patient's voice interferes with your ability to hear sound when assessing apical rate. Obtaining pulse rates at rest allows for objective comparison of values.

IMPLEMENTATION

1. Perform hand hygiene.	Reduces transmission of microorganisms.
2. Draw curtain around bed and/or close door.	Maintains privacy.
3. Obtain pulse measurement.	
a. Radial pulse	
(1) Help patient get into supine or sitting position.	Provides easy access to pulse sites.
(2) If supine, place patient's forearm straight alongside body or across lower chest or upper abdomen with wrist extended straight (see illustration). If sitting, bend patient's elbow 90 degrees and support lower arm on chair or on your arm.	Relaxed position of lower arm and slight flexion of wrist promote exposure of artery to palpation without restriction.
(3) Place tips of first two or middle three fingers of hand over groove along radial or thumb side of patient's inner wrist. Slightly extend or flex wrist with palm down until you note strongest pulse (see illustration).	Fingertips are most sensitive parts of hand to palpate arterial pulsation. Your thumb has a pulsation that interferes with accuracy.
(4) Lightly compress pulse against radius, losing pulse initially, and then relax pressure so pulse becomes easily palpable.	Pulse is assessed more accurately with moderate pressure. Too much pressure occludes pulse and impairs blood flow.
(5) Determine strength of pulse. Note whether thrust of vessel against fingertips is bounding (4), full/strong (3), normal or expected (2), diminished or barely palpable (1), or absent (0).	Strength reflects volume of blood ejected against arterial wall with each heart contraction. Accurate description of strength improves communication among nurses and other health care providers.

STEP 3a(2) Pulse check with patient's forearm at side with wrist flexed.

STEP 3a(3) Hand placement for pulse checks.

STEP	RATIONALE
(6) After feeling a regular pulse, look at second hand of a watch and begin to count rate: count the first beat after the second hand hits the number on the dial; count as one, then two, and so on.	Determine rate only after knowing that you can palpate pulse. Timing begins with zero. Count of one is first beat palpated after timing begins.
(7) If pulse is regular, count rate for 30 seconds and multiply total by 2.	A 30-second count is accurate for rapid, slow, or regular pulse rates.
(8) If pulse is irregular, count rate for 1 minute (60 seconds). Assess frequency and pattern of irregularity. Compare radial pulses bilaterally.	Inefficient contraction of heart fails to transmit pulse wave, interfering with cardiac output, resulting in irregular pulse. Longer time ensures accurate count.

> **CLINICAL DECISION:** *If pulse is irregular, do an apical/radial pulse assessment to detect a pulse deficit. Count apical pulse (see Step 3b) while a colleague counts radial pulse. Begin apical pulse count out loud to simultaneously assess pulses. If pulse count differs by more than 2, a pulse deficit exists, which sometimes indicates alterations in cardiac output.*

b. Apical pulse

(1) Clean earpieces and diaphragm of stethoscope with alcohol swab. Perform hand hygiene.

Reduces transmission of microorganisms.

(2) Draw curtain around bed and/or close door.

Provides privacy and minimizes embarrassment.

(3) Help patient to supine or sitting position. Move aside bed linen and gown to expose sternum and left side of chest.

Exposes portion of chest wall for selection of auscultatory site. Stethoscope diaphragm must touch skin to best hear sounds.

(4) Locate anatomical landmarks to identify point of maximal impulse (PMI), also called *apical impulse* (see illustrations A-D). Heart is located behind and to left of sternum with base at top and apex at bottom. Find angle of Louis just below suprasternal notch between sternal body and manubrium; feels like bony prominence (illustration A). Slip fingers down each side of angle to find second intercostal space (ICS) (illustration B). Carefully move fingers down left side of sternum to fifth ICS (illustration C) and laterally to left midclavicular line (MCL) (illustration D). A light tap felt within an area 1 to 2 cm ($\frac{1}{2}$ to 1 inch) of PMI is reflected from apex of heart.

Use of anatomical landmarks allows correct placement of stethoscope over apex of heart, enhancing ability to hear heart sounds clearly. If unable to palpate PMI, reposition patient on left side. In presence of serious heart disease, PMI is located to left of MCL or at sixth ICS.

STEP 3b(4) **A,** Locating angle of Louis. **B,** Locating second intercostal space (ICS). **C,** Locating fifth ICS. **D,** Identifying midclavicular line (MCL).

SKILL 30-2	ASSESSING RADIAL AND APICAL PULSES—cont'd

STEP	RATIONALE

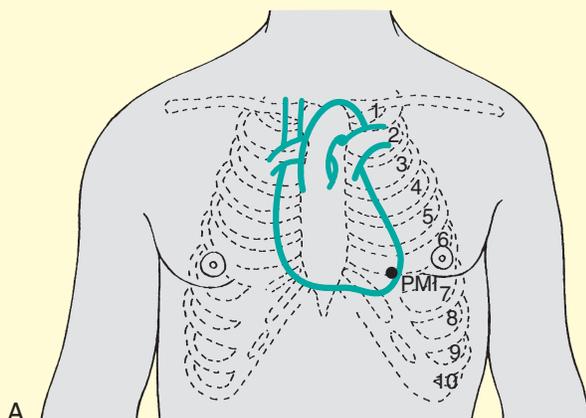
CLINICAL DECISION: *When assessing the apical rate of an older woman, lift the breast tissue gently, and place the stethoscope at the fifth intercostal space (ICS) or the lower edge of the breast.*

STEP	RATIONALE
(5) Place diaphragm of stethoscope in palm of hand for 5 to 10 seconds.	Warming of metal or plastic diaphragm prevents patient from being startled and promotes comfort.
(6) Place diaphragm of stethoscope over PMI at fifth ICS at left MCL and auscultate for normal S_1 and S_2 heart sounds (heard as "lub-dub") (see illustrations).	Allow stethoscope tubing to extend straight without kinks that would distort sound transmission. Normal sounds S_1 and S_2 are high pitched and best heard with the diaphragm.
(7) When you hear S_1 and S_2 with regularity, use second hand of watch and begin to count rate; when sweep hand hits number 12 on dial, start counting with zero, then one, two, and so on.	Determine apical rate accurately only after you are able to auscultate sounds clearly. Timing begins with zero. Count of one is first sound auscultated after timing begins.
(8) If apical rate is regular, count for 30 seconds and multiply by 2.	Regular rate is accurate when measured for 30 seconds.

CLINICAL DECISION: *If heart rate is irregular or patient is receiving cardiovascular medication, count for 1 minute (60 seconds). Irregular rate is assessed more accurately when measured over a longer interval.*

STEP	RATIONALE
(9) Note if heart rate is irregular and describe pattern or irregularity (S_1 and S_2 occurring early or later after previous sequence of sounds [e.g., every third or every fourth beat is skipped]).	Irregular heart rate indicates dysrhythmia. Regular occurrence of dysrhythmia within 1 minute indicates inefficient contraction of heart and alteration in cardiac output.
(10) Replace patient's gown and bed linen; help patient return to comfortable position.	Restores comfort and promotes sense of well-being.
(11) Perform hand hygiene.	Reduces transmission of microorganisms.
(12) Clean earpieces and diaphragm of stethoscope with alcohol swab routinely after each use.	Prevents transmission of microorganisms.
4. Discuss findings with patient as needed.	Promotes participation in care and understanding of health status.

EVALUATION

1. Compare readings with previous baseline and/or acceptable range of heart rate for patient's age (see Table 30-3).	Evaluates for change in condition and alterations.
2. Compare peripheral pulse rate with apical rate and note discrepancy.	Differences between measurements indicate pulse deficit and warn of cardiovascular compromise. Abnormalities often require therapy.
3. Compare radial pulse equality and note discrepancy.	Differences between radial arteries indicate compromised peripheral vascular system.
4. Correlate pulse rate with data obtained from blood pressure and related signs and symptoms (palpitations, dizziness).	Pulse rate and blood pressure are interrelated.


STEP 3b(6) A, Location of point of maximal impulse (PMI) in adult. **B,** Stethoscope diaphragm over PMI.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Radial pulse is less than expected value, weak, thready, or difficult to palpate.
- Assess both radial pulses and compare findings. Local obstruction to one extremity (e.g., clot, edema) decreases peripheral blood flow.
- Assess for swelling in surrounding tissues or other reason causing decreased peripheral blood flow (e.g., dressing, cast).
- Perform complete assessment of all peripheral pulses (see Chapter 31).
- Observe for symptoms associated with decreased tissue perfusion, including pallor and cool skin temperature of tissue distal to the weak pulse.
- Measure apical and radial pulse simultaneously to determine presence of pulse deficit.
- Have a second nurse assess pulses.

2. Apical pulse is greater than expected normal value (e.g., rate greater than 100 beats/min [tachycardia] in an adult; see Table 30-3).
- Identify related data, including fever, anxiety, pain, recent exercise, hypotension, decreased oxygenation, or dehydration.
- Observe for signs and symptoms of inadequate cardiac output, including fatigue, chest pain, orthopnea, cyanosis, and dizziness.

3. Apical pulse is less than expected normal value (e.g., rate less than 60 beats/min [bradycardia] in an adult; see Table 30-3).
- Assess for factors that alter heart rate such as beta-blockers and antidysrhythmic medications.
- Observe for signs and symptoms of inadequate cardiac output, including fatigue, chest pain, orthopnea, cyanosis, dizziness.

RECORDING AND REPORTING

- Record pulse rate with assessment site in nurses' notes or vital signs flow sheet. Document pulse rate after administration of specific therapies in narrative form in nurses' notes.
- Report abnormal findings to nurse in charge or health care provider immediately.

HOME CARE CONSIDERATIONS

- Assess home environment to determine room that affords quiet environment for auscultating apical rate.

SKILL 30-3	**ASSESSING RESPIRATIONS**

DELEGATION CONSIDERATIONS
The skill of respiration measurement can be delegated to nursing assistive personnel (NAP) unless the patient is considered unstable. The nurse instructs the NAP to:
- Obtain the appropriate frequency of respirations as determined by patient history and risk for respiratory rate, rhythm, or depth alternations.
- Consider specific patient factors related to history or risk for increased or decreased respiratory rate or irregular respirations.
- Immediately report significant changes or abnormalities to the nurse immediately for further assessment.

EQUIPMENT
- Wristwatch with second hand or digital display
- Pen, vital sign flow sheet or record, or electronic health record

---

STEP	**RATIONALE**

ASSESSMENT

1. Determine need to assess patient's respirations:

  a. Identify risk factors for respiratory alterations, including:
- Fever, pain, anxiety
- Diseases of chest wall or muscles
- Constrictive chest or abdominal dressings
- Gastric distention
- Pulmonary disease (emphysema, bronchitis, asthma, pneumonia, acute bronchitis)
- Traumatic injury to chest wall with or without collapse of underlying lung tissue; thoracic or abdominal surgery
- Presence of chest tube
- Pulmonary edema and emboli
- Head injury with damage to brainstem
- Anemia

  b. Assess for signs and symptoms of respiratory alterations such as bluish or cyanotic appearance of nail beds, lips, mucous membranes, and skin; restlessness, irritability, confusion, reduced level of consciousness; pain during inspiration; labored or difficult breathing; adventitious breath sounds (see Chapter 31) or inability to breathe spontaneously; thick, frothy, blood-tinged, or copious sputum produced on coughing.

Rationale column:

Nurse uses clinical judgment to determine need for assessment.
Conditions that place patient at risk for ventilatory and respiratory alterations are detected by changes in respiratory rate, depth, and rhythm.

Physical signs and symptoms indicate alterations in respiratory status.

SKILL 30-3	ASSESSING RESPIRATIONS—cont'd

STEP	RATIONALE

2. Assess pertinent laboratory values:
   a. Arterial blood gases (ABGs): Normal ABGs (values vary slightly among institutions):
     • pH: 7.35-7.45
     • $PaCO_2$: 35-45 mm Hg
     • PaO_2: 80-100 mm Hg
     • SaO_2: 95%-100%
	ABGs measure arterial blood pH; partial pressure of O_2 and CO_2; and arterial O_2 saturation, which reflects patient's oxygenation status.

b. Pulse oximetry (SpO_2): Acceptable SpO_2 ranges from 95% to 100%; a value of less than 90% is considered hypoxemia; however, values below 90% may be acceptable for certain chronic disease conditions (see Skill 30-4).	SpO_2 less than 90% is often accompanied by changes in respiratory rate, depth, and rhythm.

c. Complete blood count (CBC): Normal CBC for adults (values vary among institutions):
     • *Hemoglobin:* 14 to 18 g/100 mL, males; 12 to 16 g/100 mL, females
     • *Hematocrit:* 42% to 52%, males; 37% to 47%, females
     • *Red blood cell count:* 4.7 to 6.1 million/mm^3, males; 4.2 to 5.4 million/mm^3, females (Pagana and Pagana, 2015)
	Complete blood count measures red blood cell count; volume of red blood cells; and concentration of hemoglobin, which reflects patient's capacity to carry O_2.

3. Assess for factors that influence respirations (see Box 30-7).	Allows you to control for factors that can affect measurement.
4. Determine previous baseline respiratory rate (if available) from patient's record.	Allows you to assess for change in condition. Provides comparison with future respiratory measurements.

PLANNING

1. Identify patient using two identifiers (e.g., name and birth date or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).
2. Plan to assess respirations after measuring pulse in an adult.	Inconspicuous assessment of respirations immediately after pulse assessment prevents patient from consciously or unintentionally altering rate and depth of breathing.

IMPLEMENTATION

1. Perform hand hygiene. Draw curtain around bed and/or close door.	Prevents transmission of microorganisms. Maintains privacy.
2. Be sure that patient is in comfortable position, preferably sitting or lying with head of bed elevated 45 to 60 degrees. Be sure that patient's chest is visible. If necessary, move bed linen or gown.	Sitting erect promotes full ventilatory movement. Ensures clear view of chest wall and abdominal movements.
3. Place patient's arm in relaxed position across abdomen or lower chest or place your hand directly over patient's upper abdomen.	A similar position used during pulse assessment allows respiratory rate assessment to be inconspicuous. Patient's hand or your hand rises and falls during respiratory cycle.
4. Observe complete respiratory cycle (one inspiration and one expiration).	Rate is accurately determined only after you have observed a respiratory cycle.
5. After observing a cycle, look at second hand of watch and begin to count rate; when sweep hand hits number on dial, begin time frame, counting one with first full respiratory cycle.	Timing begins with count of one. Respirations occur more slowly than pulse; thus timing does not begin with zero.
6. If rhythm is regular, count number of respirations in 30 seconds and multiply by 2. If rhythm is irregular, less than 12, or greater than 20, count for 1 full minute.	Respiratory rate is equivalent to number of respirations per minute. Suspected irregularities require assessment for at least 1 minute (see Table 30-6).
7. Note depth of respirations subjectively assessed by observing degree of chest wall movement while counting rate. You also objectively assess depth by palpating chest wall excursion or auscultating posterior thorax after rate has been counted (see Chapter 31). Describe depth as shallow, normal, or deep.	Character of ventilatory movement reveals specific disease states that restrict volume of air from moving into and out of the lungs.
8. Note rhythm of ventilatory cycle. Normal breathing is regular and uninterrupted. Do not confuse sighing with abnormal rhythm.	Character of ventilations reveals specific types of alterations. Periodically people unconsciously take single deep breaths or sighs to expand small airways prone to collapse.
9. Observe for any increased effort to inhale and exhale. Ask patient to describe subjective experience of breathing compared with usual breathing pattern.	Patients with chronic lung disease may experience difficulty breathing all the time and can best describe their own discomfort from shortness of breath.

CLINICAL DECISION: *An irregular respiratory pattern or occurrence of periods of apnea (cessation of respiration for several seconds) is a symptom of underlying disease in the adult and must be reported to the nurse in charge or health care provider. The patient requires further assessment (see Chapter 31) and needs immediate intervention. An irregular respiratory rate and short apneic spells are normal for newborns.*

10. Replace bed linen and patient's gown.	Restores comfort and promotes sense of well-being.
11. Perform hand hygiene.	Reduces transmission of microorganisms.
12. Discuss findings with patient as needed.	Promotes participation in care and understanding of health status.

STEP	RATIONALE

EVALUATION

1. If assessing respirations for first time, establish rate, rhythm, and depth as baseline if within normal range.

Used to compare future respiratory assessment.

2. Compare respirations with patient's previous baseline and normal rate, rhythm, and depth.

Allows nurse to assess for changes in patient's condition and presence of respiratory alterations.

3. Correlate respiratory rate, depth, and rhythm with data obtained from pulse oximetry and ABG measurements if available.

Ventilation, perfusion, and diffusion are interrelated.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Patient has respiratory rate that is outside of expected normal values (e.g., less than 12 (bradypnea) or above 20 (tachypnea) breaths/min in an adult; see Table 30-5). Breathing pattern is irregular. Depth of respirations increases or decreases: patient complains of dyspnea.
   - Observe for related factors such as obstructed airway; assess for abnormal breath sounds, productive cough, restlessness, irritability, anxiety, confusion (see Chapter 31).
   - Help patient to supported sitting position (semi- or high-Fowler's) unless contraindicated, which improves ventilation.
   - Provide oxygen as ordered (see Chapter 31).
   - Assess for environmental factors that influence patient's respiratory rate such as secondhand smoke and poor room ventilation and make corrections.

RECORDING AND REPORTING

- Record respiratory rate and character in nurses' notes or vital sign flow sheet.
- Record abnormal depth and rhythm in narrative form in nurses' notes.
- Document measurement of respiratory rate after administration of specific therapies in narrative form in nurses' notes.
- Indicate type and amount of oxygen therapy if used by patient during assessment. Document respiratory assessment after administration of specific therapies in narrative form in nurses' notes.
- Report abnormal findings to nurse in charge or health care provider immediately.

HOME CARE CONSIDERATIONS

- Assess for environmental factors in the home that influence patient's respiratory rate such as secondhand smoke, poor ventilation, gas or fireplace fumes, dust, and pets.

SKILL 30-4   MEASURING OXYGEN SATURATION (PULSE OXIMETRY) ▶

DELEGATION CONSIDERATIONS

The skill of oxygen saturation measurement can be delegated to nursing assistive personnel (NAP) unless patient is unstable. The nurse instructs the NAP about:

- The frequency, probe location, and patient position for oxygen saturation measurement based on patient condition such as onset of dyspnea, labored breathing, or cyanosis.
- The appropriate sensor site, probe, and patient position for measurement of oxygen saturation.
- Refraining from using pulse oximetry as an assessment of heart rate because oximeter will not detect an irregular pulse.
- Need to immediately report any significant changes or abnormalities and any SpO_2 reading lower than 90% to nurse immediately.

EQUIPMENT

- Oximeter
- Oximeter probe appropriate for patient and recommended by manufacturer
- Acetone or nail polish remover if needed
- Pen, vital sign flow sheet or record form, or patient's electronic medical record

STEP	RATIONALE

ASSESSMENT

1. Determine need to measure patient's oxygen saturation:

Clinical judgment determines need for assessment.

   a. Identify risk factors of decreased oxygen saturation, including acute or chronic compromised respiratory function, recovery from general anesthesia or conscious sedation, traumatic injury to chest wall with or without collapse of underlying lung tissue, ventilator dependence, changes in supplemental oxygen therapy.

Certain conditions place patients at risk for decreased oxygen saturation.

   b. Assess for signs and symptoms of alterations in oxygen saturation such as altered respiratory rate, depth, or rhythm; adventitious breath sounds (see Chapter 31); cyanotic appearance of nail beds, lips, mucous membranes, and skin; restlessness, irritability, confusion; reduced level of consciousness; labored or difficult breathing.

Physical signs and symptoms often indicate abnormal oxygen saturation.

2. Assess for factors that normally influence measurement of SpO_2 (see Box 30-8) in addition to oxygen therapy, hemoglobin level, body temperature, and medications such as bronchodilators.

Allows you to accurately assess oxygen saturation variations.

SKILL 30-4	MEASURING OXYGEN SATURATION (PULSE OXIMETRY)—cont'd

STEP	RATIONALE
3. Determine previous baseline SpO_2 (if available) from patient's record.	Baseline information provides basis for comparison and helps in assessment of current status and evaluation of interventions.
4. Determine most appropriate patient-specific site (e.g., finger, earlobe, forehead) for sensor probe placement by measuring capillary refill (see Chapter 31). If capillary refill is greater than 2 seconds, select alternate site.	Sensor requires pulsating vascular bed to identify hemoglobin molecules that absorb emitted light. Changes in SpO_2 are reflected in circulation of finger capillary bed within 30 seconds and capillary bed of earlobe within 5-10 seconds. Forehead sensors are preferred for critically ill patients requiring vasopressors (Nesseler et al., 2012).
a. Site must have adequate local circulation and be free of moisture.	Moisture prevents sensor from detecting SpO_2 levels.
b. Place probe on finger free of polish or artificial nail.	Black or brown nail polish color alters readings (Chan et al., 2013).
c. If tremors are present, use earlobe as site.	Motion artifact is most common cause of inaccurate readings (Chan et al., 2013).
d. If patient is obese, clip-on probe may not fit properly; obtain single-use (tape-on) probe.	
5. **Determine if patient has latex allergy.**	Do not use adhesive sensors if patient has latex allergy.

PLANNING

1. Identify patient using two identifiers (e.g., name and birth date or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).
2. Explain purpose of procedure and how you measure oxygen saturation to patient. Instruct patient to breathe normally.	Promotes patient cooperation and increases compliance. Prevents large fluctuations in minute ventilation and possible error in SpO_2 readings.

IMPLEMENTATION

1. Perform hand hygiene.	Reduces transmission of microorganisms.
2. Position patient comfortably. When using finger as monitoring site, support lower arm.	Ensures probe positioning and decreases motion artifact that interferes with SpO_2 determination.
3. Instruct patient to breathe normally.	Prevents large fluctuations in respiratory rate and depth and possible changes in SpO_2.
4. When using finger as monitoring site, remove fingernail polish on one finger with acetone or polish remover. Acrylic nails without polish do not interfere with SpO_2 determination.	Ensures accurate readings. Nail polish may falsely alter saturation (Chan et al., 2013).
5. Attach sensor probe to monitoring site. Instruct patient that clip-on probe feels like a clothespin on finger but will not hurt.	Pressure spring tension of sensor probe on peripheral digit or earlobe is unexpected.

CLINICAL DECISION: *Do not attach probe to finger, ear, forehead, or bridge of nose if area is edematous or skin integrity is compromised. Do not attach probe to fingers that are hypothermic. Select forehead, ear, or bridge of nose if adult patient has history of peripheral vascular disease. Do not use earlobe and bridge of nose sensors for infants and toddlers because of skin fragility. Do not use disposable adhesive probes if patient has latex allergy. Do not place sensor on same extremity as electronic blood pressure cuff because blood flow to finger is interrupted temporarily when cuff inflates and causes inaccurate readings that trigger alarms.*

6. Once sensor is in place, turn on oximeter by activating power. Observe pulse waveform/intensity display and audible beep. Correlate oximeter pulse rate with patient's radial pulse. Differences require reevaluation of oximeter probe placement and may require reassessment of pulse rates.	Pulse waveform/intensity display enables detection of valid pulse or presence of interfering signal. Pitch of audible beep is proportional to SpO_2 value. Double-checking pulse rate ensures oximeter accuracy. Oximeter pulse rate, patient's radial pulse, and apical pulse rate should be the same. Any difference requires reevaluation of oximeter sensor probe placement and reassessment of pulse rates.
7. Leave probe in place until oximeter readout reaches constant value and pulse display reaches full strength during each cardiac cycle. Inform patient that oximeter will alarm if probe falls off or patient moves probe. Read SpO_2 on digital display.	Reading takes 10-30 seconds, depending on site selected.
8. If continuous SpO_2 monitoring is necessary, verify SpO_2 alarm limits and volume, which are preset by manufacturer at low of 85% and high of 100%. Determine limits for SpO_2 and pulse rate alarms on basis of each patient's condition. Verify that alarms are on. Assess skin integrity every 2 hours under sensor probe. Relocate sensor probe at least every 24 hours or more frequently if skin integrity is altered or tissue perfusion compromised.	Alarms are set at appropriate limits and volumes to avoid frightening patients and visitors. Sensor probe tension and sensitivity to disposable sensor probe adhesive cause skin irritation and lead to disruption of skin integrity.
9. Help patient return to comfortable position.	Restores comfort and promotes sense of well-being.
10. Perform hand hygiene.	Reduces transmission of microorganisms.
11. Discuss findings with patient as needed.	Promotes participation in care and understanding of health status.
12. If planning intermittent or spot-checking SpO_2 measurements, remove probe and turn oximeter power off. Store probe in appropriate location.	Batteries will run out if oximeter is left on. Sensor probes are expensive and vulnerable to damage.

STEP	RATIONALE

EVALUATION

1. Compare SpO_2 readings with patient baseline and acceptable values. Note use of oxygen therapy, which can affect SpO_2.

   Comparison reveals presence of abnormality.

2. Correlate SpO_2 with SaO_2 obtained from ABG measurements (see Chapter 42) if available.

   Documents reliability of noninvasive assessment.

3. Correlate SpO_2 reading with data obtained from respiratory rate, depth, and rhythm assessment (see Skill 30-3).

   Measurements assessing ventilation, perfusion, and diffusion are interrelated.

4. During continuous monitoring assess skin integrity underneath probe at least every 2 hours on basis of patient's peripheral circulation.

   Prevents tissue ischemia.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. SpO_2 is less than 90%.
   - Verify that oximeter probe is intact and outside light transmission does not influence measurement.
   - Observe for signs and symptoms of decreased oxygenation: anxiety, restlessness, tachycardia, cyanosis.
   - Verify that supplemental oxygen delivery system is delivered as ordered and functioning properly.
   - Observe for and minimize factors that decrease SpO_2 such as lung secretions, increased activity, and hyperthermia.
   - Help patient to a position that maximizes ventilatory effort (e.g., place obese patient in high-Fowler's position).
   - Notify nurse in charge or health care provider immediately.
2. Pulse rate indicated on the oximeter is less than patient's radial or apical pulse.
   - Reposition sensor probe to an alternative site with increased blood flow.
   - Assess patient for signs of altered cardiac output (e.g., decreased blood pressure, cool skin, confusion).

RECORDING AND REPORTING

- Record SpO_2 value on nurses' notes or vital sign flow sheet.
- Indicate type and amount of oxygen therapy used by patient during assessment.
- Record signs and symptoms of oxygen desaturation in nurses' notes.
- Report abnormal findings to nurse in charge or health care provider immediately.
- Document oxygen saturation after administration of specific therapies in narrative form in nurses' notes.
- Record in nurses' notes patient's use of continuous or intermittent pulse oximetry (documents use of equipment for third-party payers).

HOME CARE CONSIDERATIONS

- Pulse oximetry is used in home care to noninvasively monitor oxygen therapy or changes in oxygen therapy.
- Instruct family caregivers to examine oximeter site before applying sensor.
- Instruct family caregivers on procedure to implement when oxygen saturation is not within acceptable values.

SKILL 30-5   MEASURING BLOOD PRESSURE

DELEGATION CONSIDERATIONS

The skill of blood pressure (BP) measurement can be delegated to nursing assistive personnel (NAP) unless the patient is considered unstable. The nurse instructs the NAP about:

- The appropriate times to obtain BP measurements as determined by agency policy, health care provider's order, or patient condition.
- The patient-specific factors related to the patient's history that may alter BP, such as previous surgery or risk for orthostatic hypotension.
- The appropriate limb to use for BP measurement.
- The appropriate size BP cuff to use for designated limb and equipment (electronic or manual).
- When to report any significant changes or abnormalities to the nurse for further assessment.

EQUIPMENT

- Aneroid sphygmomanometer
- Cloth or disposable vinyl pressure cuff of appropriate size for patient's extremity
- Stethoscope
- Alcohol swab
- Pen, vital sign flow sheet or record form, or electronic medical record

STEP	RATIONALE

ASSESSMENT

1. Determine need to assess patient's BP:

   Use clinical judgment to determine need for assessment.

   a. Identify risk factors, including:

   Conditions place patients at risk for BP alteration.

   - History of cardiovascular, cerebrovascular or renal disease, diabetes
   - Circulatory shock (hypovolemic, septic, cardiogenic, or neurogenic)
   - Acute or chronic pain
   - Rapid intravenous infusion of fluids or blood products
   - Increased intracranial pressure
   - Toxemia of pregnancy

SKILL 30-5	MEASURING BLOOD PRESSURE—cont'd

STEP	RATIONALE
b. Observe for signs and symptoms of BP alterations:	Physical signs and symptoms often indicate alterations in BP.
(1) High BP (hypertension): headache (usually occipital), flushing of face, nosebleed, and fatigue in older adults	High BP is often asymptomatic until pressure is very high.
(2) Low BP (hypotension): dizziness, mental confusion; restlessness; pale, dusky, or cyanotic skin and mucous membranes; cool, mottled skin over extremities	
2. Assess for factors that affect BP (see Table 30-11).	Allows you to ensure that BP measurement is accurate.
3. Determine best site for BP assessment. Avoid applying cuff to an extremity where intravenous fluids are infusing, a peripherally inserted central catheter (PICC) line has been inserted, an arteriovenous shunt or fistula is present, breast or axillary surgery has been performed on that side, or extremity has been traumatized or diseased or requires a cast or bulky bandage. Use lower extremities when brachial arteries are inaccessible.	Inappropriate site selection results in poor amplification of sounds, causing inaccurate readings. Application of pressure from inflated cuff temporarily restricts blood flow and further compromises circulation in extremity that already has impaired blood flow.
4. Determine previous baseline BP (if available) from patient's record.	Allows you to assess for change in condition. Provides comparison with future BP measurements.
5. Determine if patient has latex allergy.	Verify that stethoscope and BP cuff are latex free if patient has latex allergy.

PLANNING

1. Identify patient using two identifiers (e.g., name and birth date or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).
2. Explain to patient that you will assess BP. Have patient rest at least 5 minutes before measuring BP sitting or lying down; wait 1 minute if patient is standing. When possible, have patient sit in a chair with legs uncrossed (James et al., 2014; NHBPEP, 2003). Ask patient not to speak while measuring BP and breathe normally.	Allows patient to relax and helps to avoid falsely elevated readings. When assessed at rest, BP readings taken at different times are comparable. Talking increases BP readings (Zheng et al., 2012). Deep breath lowers blood pressure.
3. Be sure that patient has not ingested caffeine or smoked 20 to 30 minutes before BP measurement.	Caffeine or nicotine causes false BP elevations. Smoking immediately increases BP and lasts up to 15 minutes; caffeine increases BP up to 3 hours.
4. Help patient to sitting position with legs uncrossed at knees (Adiyaman, 2007) if appropriate. Be sure that room is warm, quiet, and relaxing.	Maintains patient comfort during measurement. Sitting is preferred to lying. Diastolic pressure measured with sitting is approximately 5 mm Hg higher than when measured supine. Patient perceptions of stressful environment affect BP measurement. Talking and background noise result in inaccurate measurements.
5. Select appropriate cuff size.	Improper cuff size results in inaccurate readings (see Table 30-11). If cuff is too small, it tends to come loose when being inflated or results in false-high readings. If cuff is too large, you may obtain false-low readings (Mourad et al., 2013).

IMPLEMENTATION

1. Perform hand hygiene and clean stethoscope earpieces and diaphragm with alcohol swab.	Reduces transmission of microorganisms.
2. Position patient.	
a. Arm: Position patient sitting or lying; position his or her forearm at heart level (see illustration). Turn palm up. If sitting, instruct patient to keep feet flat on floor without crossing legs.	If arm is extended and not supported, patient performs isometric exercise that increases diastolic pressure. Placing arm above level of heart causes false-low reading 2 mm Hg for each inch above heart level. Leg crossing falsely increases systolic BP. Even in the supine position a diastolic pressure increases BP up to 3-4 mm Hg for each 5-cm (1.97-in) change in heart level.
b. Thigh: Position patient lying with thigh flat (provide support as needed). Have knee slightly flexed.	
3. Expose extremity (arm or leg) fully by removing constricting clothing. Cuff may be placed over shirt sleeve as long as stethoscope rests on skin of antecubital space (Box 30-14).	Ensures proper cuff application. Tight clothing causes congestion of blood and can falsely elevate BP readings.

STEP 2a Patient's forearm supported in bed. (Copyright © Mosby's Clinical Skills: Essentials Collection.)

STEP	RATIONALE

4. Palpate brachial artery (arm) (see illustration) or popliteal artery (leg). With cuff fully deflated, apply bladder of cuff above artery by centering arrows marked on cuff over artery. If there are no center arrows on cuff, estimate center of bladder and place it over artery. Position cuff 2.5 cm (1 inch) above site of pulsation (antecubital or popliteal space). Wrap cuff evenly and snugly around extremity (see illustrations).

Inflating bladder directly over artery ensures that proper pressure is applied during inflation. Loose-fitting cuff causes false-high readings.

5. Position manometer gauge vertically at eye level and no farther than 1 m (approximately 1 yard) away.

Looking up or down at scale results in inaccurate readings.

6. Measure BP.

a. Two-step method

(1) Relocate brachial or popliteal pulse. Palpate artery distal to cuff with fingertips of nondominant hand while inflating cuff rapidly to pressure 30 mm Hg above point at which pulse disappears. Slowly deflate cuff and note point when pulse reappears. Deflate cuff fully and wait 30 seconds.

Estimating systolic pressure prevents false-low readings. Determine maximal inflation point for accurate reading by palpation. If unable to palpate artery because of weakened pulse, use an ultrasonic stethoscope (see Chapter 31). Completely deflating cuff prevents venous congestion and false-high readings.

(2) Place stethoscope earpieces in ears and be sure that sounds are clear, not muffled.

Each earpiece follows angle of ear canal to facilitate hearing.

(3) Relocate brachial or popliteal artery and place bell or diaphragm chest piece of stethoscope over it. Do not allow chest piece to touch cuff or clothing (see illustration).

Proper stethoscope placement ensures best sound reception. Stethoscope improperly positioned causes muffled sounds that often result in false-low systolic and false-high diastolic readings.

(4) Close valve of pressure bulb clockwise until tight.

Tightening valve prevents air leak during inflation.

(5) Quickly inflate cuff to 30 mm Hg above palpated systolic pressure (patient's estimated systolic pressure) (see illustration).

Rapid inflation ensures accurate measurement of systolic pressure.

(6) Slowly release pressure bulb valve and allow needle of manometer gauge to fall at rate of 2-3 mm Hg/sec. Make sure that there are no extraneous sounds.

Too-rapid or too-slow decline in pressure causes inaccurate readings (Zheng et al., 2011). Noise interferes with precise assessment of sounds.

(7) Note point on manometer when you hear first clear sound. Sound slowly increases in intensity.

First sound reflects systolic BP.

BOX 30-14 EVIDENCE-BASED PRACTICE

Effect of Clothes on Blood Pressure Measurements

PICO Question: Does placing the blood pressure cuff over clothes compared to a bare arm effect blood pressure measurement?

Evidence Summary

Obtaining blood pressure measurements has traditionally required exposing a bare upper arm either by rolling up the shirt sleeve or removing upper garments. Sleeve rolling has the potential to constrict the underlying vessels. Some patients may be uncomfortable disrobing, which lacks dignity and privacy and can infringe on religious beliefs. Most cotton shirts are less than 2 mm thick and provide little resistance to the pressure generated by an inflated blood pressure cuff. A study obtained two manual auscultatory blood pressure readings on a nonsleeved arm, sleeved arm, and again on a nonsleeved arm of 258 hypertensive patients (Pinar et al., 2010). There was no significant difference

among the six measurements. A similar study (Ki et al., 2013) compared sleeved, rolled sleeve, and bare arm blood pressure measurements using an automatic oscillometric sphygmomanometer on 141 clinic patients. There was no difference among the groups in systolic or diastolic measurements.

Application to Nursing Practice

- Blood pressure cuffs applied over sleeves will save time during routine blood pressure screenings and disasters.
- Allowing the patient to remain robed can provide culturally congruent care in some settings.
- Consider patient privacy and cultural beliefs when repositioning clothing for blood pressure measurement.

SKILL 30-5 MEASURING BLOOD PRESSURE—cont'd

STEP	RATIONALE
(8) Continue to deflate cuff, noting point at which muffled or dampened sound appears.	Fourth sound involves distinct muffling of sounds and is an indicator of diastolic pressure in children (Kaplan et al., 2014).
(9) Continue to deflate cuff gradually, noting point at which sound disappears in adults. Listen for 10-20 mm Hg after last sound and allow remaining air to escape quickly.	Beginning of fifth sound is indicator of diastolic pressure in adults (Kaplan et al., 2014). Continuous cuff inflation causes arterial occlusion, resulting in numbness and tingling of patient's arm.
b. One-step method	
(1) Place stethoscope earpieces in ears and be sure that sounds are clear, not muffled.	Each earpiece follows angle of ear canal to facilitate hearing.
(2) Relocate brachial or popliteal artery and place bell or diaphragm chest piece of stethoscope over it. Do not allow chest piece to touch cuff or clothing.	Proper stethoscope placement ensures optimal sound reception. Stethoscope improperly positioned causes muffled sounds that result in false-low systolic and false-high diastolic readings.
(3) Close valve of pressure bulb clockwise until tight.	Tightening of valve prevents air leak during inflation.
(4) Quickly inflate cuff to 30 mm Hg above patient's usual systolic pressure.	Inflation above systolic level ensures accurate measurement of systolic BP.
(5) Slowly release pressure bulb valve and allow needle of manometer gauge to fall at rate of 2 to 3 mm Hg/sec.	Too-rapid or too-slow decline in pressure causes inaccurate readings (Zheng et al., 2011).
(6) Note point on manometer when you hear first clear sound. Sound slowly increases in intensity.	First sound reflects systolic pressure.
(7) Continue to deflate cuff, noting point at which muffled or dampened sound appears.	In children fourth sound involves distinct muffling of sounds and indicates diastolic pressure (Hockenberry and Wilson, 2015).
(8) While gradually deflating cuff, note point at which sound disappears in adults. Listen for 10 to 20 mm Hg after last sound and allow remaining air to escape quickly.	Beginning of last or fifth sound indicates diastolic pressure in adults. Continuous cuff inflation causes arterial occlusion, resulting in numbness and tingling of patient's arm.
7. American Heart Association recommends average of two sets of BP measurement, 2 minutes apart. Use second set of BP measurements as baseline. If readings are different by more than 5 mm Hg, additional readings are necessary.	Two sets of BP measurements help to prevent false-positives based on patient's sympathetic response (alert reaction). Averaging minimizes effect of anxiety, which often causes first reading to be higher than subsequent measurements (Kaplan et al., 2014).
8. Remove cuff from extremity unless you need to repeat measurement. If this is first assessment of patient, repeat BP assessment on other extremity.	Comparison of BP in both extremities detects circulation problems. (Normal difference of 5-10 mm Hg exists between extremities.) Use arm with higher pressure for repeated measurements (Frese et al., 2011).
9. Help patient return to comfortable position and cover upper arm if previously clothed.	Restores comfort and promotes sense of well-being.
10. Discuss findings with patient as needed.	Promotes participation in care and understanding of health status.
11. Perform hand hygiene. Wipe cuff with facility-approved cleaning agent if used between patients.	Reduces transmission of microorganisms.

EVALUATION

1. Compare reading with previous baseline and/or acceptable value of BP for patient's age.	Evaluates for change in condition and cardiovascular alterations.
2. Compare BP in both arms or both legs.	If using upper extremities, use arm with higher pressure for subsequent assessments unless contraindicated.
3. Correlate BP with data obtained from pulse assessment and related cardiovascular signs and symptoms.	BP and heart rate are interrelated.

STEP 6a(3) Stethoscope over brachial artery to measure BP. (Copyright © Mosby's Clinical Skills: Essentials Collection.)

STEP 6a(5) Inflating BP cuff. (Copyright © Mosby's Clinical Skills: Essentials Collection.)

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Unable to obtain BP reading
- Determine that no immediate crisis is present by obtaining pulse and respiratory rate.
- Assess for signs of decreased cardiac output; if present, notify nurse in charge or health care provider immediately.
- Use alternative sites or procedures to obtain BP: auscultate BP in lower extremity, use a Doppler ultrasonic instrument, implement palpation method to obtain systolic BP.
- Repeat BP measurement with sphygmomanometer. Electronic BP devices are less accurate in low–blood flow conditions.

2. BP is not sufficient for adequate perfusion and oxygenation of tissues.
- Compare BP value to baseline. A systolic reading of 90 mm Hg is an acceptable value for some patients.
- Position patient in supine position to enhance circulation and restrict activity if it is decreasing BP.
- Assess for signs and symptoms of hypotension such as tachycardia; weak, thready pulse; weakness, dizziness, confusion; cool, pale, dusky or cyanotic skin.
- Notify nurse in charge or health care provider immediately.
- Increase rate of intravenous infusion or administer vasoconstricting drugs if ordered.

3. BP is above acceptable range.
- Repeat BP measurement in other arm and compare findings. Verify correct size and placement of cuff.
- Ask nurse colleague to repeat measurement in 1 to 2 minutes.
- Observe for related symptoms, although symptoms are sometimes not apparent until BP is extremely elevated.
- Report elevated BP to nurse in charge or health care provider to initiate appropriate evaluation and treatment.
- Administer antihypertensive medications as ordered.

4. Patient has a difference of more than 20 mm Hg systolic or diastolic when comparing BP measurements on upper extremities.
- Report abnormal findings to nurse in charge or health care provider.

RECORDING AND REPORTING

- Record BP in nurses' notes or vital sign flow sheet. BP measurement after administration of specific therapies needs to be documented in narrative form in nurses' notes.
- Record any signs or symptoms of BP alterations in narrative form in nurses' notes.
- Document measurement of BP after administration of specific therapies in narrative form in nurses' notes.
- Report abnormal findings to nurse in charge or health care provider immediately.

HOME CARE CONSIDERATIONS

- Assess home noise level to determine room that provides most quiet environment for assessing BP.
- Consider electronic BP cuff for home if patient has hearing difficulties, sufficient financial resources, and adequate dexterity.

KEY POINTS

- Measurement of vital signs includes the physiological measurement of temperature, pulse, BP, respirations, and oxygen saturation.
- Nurses measure vital signs as part of a complete physical examination or in a review of a patient's condition.
- Nurses assess changes in vital signs with other physical assessment findings, using clinical judgment to determine measurement frequency.
- Knowledge of the factors influencing vital signs helps to determine and evaluate abnormal values.
- Vital signs provide a basis for evaluating response to nursing interventions.
- Measure vital signs when the patient is inactive and the environment is controlled for comfort.
- Nurses help patients maintain body temperature by initiating interventions that promote heat loss, production, or conservation.
- A fever is one of the normal defense mechanisms of the body.
- Measurement of temperature using the temporal artery is the least invasive, most accurate method of obtaining core temperature.
- Respiratory assessment includes determining the effectiveness of ventilation, perfusion, and diffusion.
- Assessment of respiration involves observing ventilatory movements through the respiratory cycle.
- Variables affecting ventilation, perfusion, and diffusion influence oxygen saturation.
- To assess cardiac function, it is easy to measure pulse rate and rhythm using the radial or apical pulses.
- Hypertension is diagnosed only after an average of readings made during two or more subsequent visits reveals an elevated BP.
- Improper selection and application of the BP measurement cuff result in errors in BP measurement.
- Changes in one vital sign often influence characteristics of the other vital signs.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mr. Coburn, the 56-year-old school teacher who was seen earlier in the week for hyperthermia, arrives at the walk-in health center complaining of feeling dizzy and nauseated. You immediately note that he appears to be having some difficulty catching his breath during coughing spells. A new graduate nurse takes Mr. Coburn's admitting vital

signs as: pulse 122 and regular, RR 22 and easy, BP 88/50 RA, tympanic temperature 38°C (100.4°F), SpO$_2$ 92%. As you enter Mr. Coburn's room, the electronic blood pressure (BP) machine alarm is sounding with cuff on right arm. You note that it is flashing "72 systolic" with no diastolic reading. Mr. Coburn is turned on his right side, and his eyes are closed. His respirations appear labored.

1. List in order of priority your first five interventions.
2. Which vital signs should you reassess and which methods should you use?
3. Which hourly vital signs should you delegate to a nursing assistive personnel (NAP)?

▌ REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A 52-year-old woman is admitted with dyspnea and discomfort in her left chest with deep breaths. She has smoked for 35 years and recently lost over 10 lbs. Her vital signs on admission are: HR 112, BP 138/82, RR 22, tympanic temperature 36.8°C (98.2°F), and oxygen saturation 94%. She is receiving oxygen at 2 L via a nasal cannula. Which vital sign reflects a positive outcome of the oxygen therapy?
   1. Temperature: 37°C (98.6°F)
   2. Radial pulse: 112
   3. Respiratory rate: 24
   4. Oxygen saturation: 96%
   5. Blood pressure: 134/78

2. The licensed practical nurse (LPN) provides you with the change-of-shift vital signs on four of your patients. Which patient do you need to assess first?
   1. 84-year-old man recently admitted with pneumonia, RR 28, SpO$_2$ 89%
   2. 54-year-old woman admitted after surgery for fractured arm, BP 160/86 mm Hg, HR 72
   3. 63-year-old man with venous ulcers from diabetes, temperature 37.3°C (99.1°F), HR 84
   4. 77-year-old woman with left mastectomy 2 days ago, RR 22, BP 148/62

3. A 55-year-old female patient was in a motor vehicle accident and is admitted to a surgical unit after repair of a fractured left arm and left leg. She also has a laceration on her forehead. An intravenous (IV) line is infusing in the right antecubital fossa, and pneumatic compression stockings are on the right lower leg. She is receiving oxygen via a simple face mask. Which sites do you instruct the nursing assistant to use for obtaining the patient's blood pressure and temperature?
   1. Right antecubital and tympanic membrane
   2. Right popliteal and rectal
   3. Left antecubital and oral
   4. Left popliteal and temporal artery

4. The nurse observes a nursing student taking a blood pressure (BP) on a patient. The nurse notes that the student very slowly deflates the cuff in an attempt to hear the sounds. The patient's BP range over the past 24 hours is 132/64 to 126/72 mm Hg. Which of the following BP readings made by the student is most likely caused by an incorrect technique?
   1. 96/40 mm Hg
   2. 110/66 mm Hg
   3. 130/90 mm Hg
   4. 156/82 mm Hg

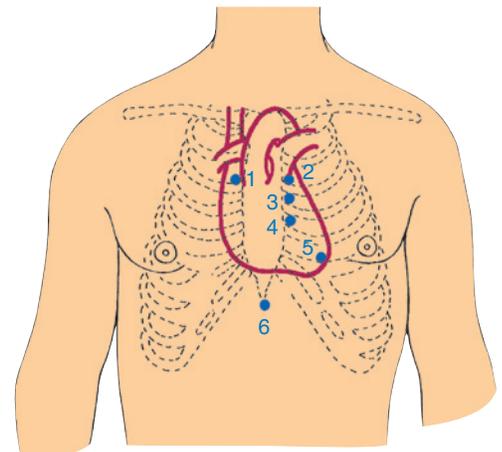
5. As you are obtaining the oxygen saturation on a 19-year-old college student with severe asthma, you note that she has black nail polish on her nails. You remove the polish from one nail, and she asks you why her nail polish had to be removed. What is the best response?
   1. Nail polish attracts microorganisms and contaminates the finger sensor.
   2. Nail polish increases oxygen saturation.
   3. Nail polish interferes with sensor function.
   4. Nail polish creates excessive heat in sensor probe.

6. A patient has been hospitalized for the past 48 hours with a fever of unknown origin. His medical record indicates tympanic temperatures of 38.7°C (101.6°F) (0400), 36.6°C (97.9°F) (0800), 36.9°C (98.4°F) (1200), 37.6°C (99.6°F) (1600), and 38.3°C (100.9°F) (2000). How would you describe this pattern of temperature measurements?
   1. Usual range of circadian rhythm measurements
   2. Sustained fever pattern
   3. Intermittent fever pattern
   4. Resolving fever pattern

7. A patient presents in the clinic with dizziness and fatigue. The nursing assistant reports a slow but regular radial pulse of 44. What is your priority intervention?
   1. Request that the nursing assistant repeat the pulse check
   2. Call for a stat electrocardiogram (ECG)
   3. Assess the patient's apical pulse and evidence of a pulse deficit
   4. Prepare to administer cardiac-stimulating medications

8. Which patient is at highest risk for tachycardia?
   1. A healthy basketball player during warmup exercises
   2. A patient admitted with hypothermia
   3. A patient with a fever of 39.4°C (103°F)
   4. A 90-year-old male taking beta blockers

9. Which of the following patients are at most risk for tachypnea? (Select all that apply.)
   1. Patient just admitted with four rib fractures
   2. Woman who is 9 months' pregnant
   3. Adult who has consumed alcoholic beverages
   4. Adolescent waking from sleep
   5. Three-pack–per-day smoker with pneumonia

10. Which number marks the location where you would auscultate the point of maximal impulse (PMI)?
    1. 1
    2. 2
    3. 3
    4. 4
    5. 5
    6. 6


11. A patient has been admitted for a cerebrovascular accident (stroke). She cannot move her right arm, and she has a right-sided facial droop. She is able to eat with her dentures in place and

swallow safely. The nursing assistive personnel (NAP) reports to you that the patient will not keep the oral thermometer probe in her mouth. What direction do you provide to the NAP?
1. Direct the NAP to hold the thermometer in place with her gloved hand
2. Direct the NAP to switch the thermometer probe to the left sublingual pocket
3. Direct the NAP to obtain a right tympanic temperature
4. Direct the NAP to use a temporal artery thermometer from right to left

12. The nursing assistive personnel (NAP) reports to you that the blood pressure (BP) of the patient in Question 11 is 140/76 on the left arm and 128/72 on the right arm. What actions do you take on the basis of this information? (Select all that apply.)
1. Notify the health care provider immediately
2. Repeat the measurements on both arms using a stethoscope
3. Ask the patient if she has taken her blood pressure medications recently
4. Obtain blood pressure measurements on lower extremities
5. Verify that the correct cuff size was used during the measurements
6. Review the patient's record for her baseline vital signs
7. Compare right and left radial pulses for strength

13. The nursing assistive personnel (NAP) informs you that the electronic blood pressure machine on the patient who has recently returned from surgery following removal of her gallbladder is flashing a blood pressure of 65/46 and alarming. Place your care activities in priority order.
1. Press the start button of the electronic blood pressure machine to obtain a new reading.
2. Obtain a manual blood pressure with a stethoscope.
3. Check the patient's pulse distal to the blood pressure cuff.
4. Assess the patient's mental status.
5. Remind the patient not to bend her arm with the blood pressure cuff.

14. A healthy adult patient tells the nurse that he obtained his blood pressure in "one of those quick machines in the mall" and was alarmed that it was 152/72 when his normal value ranges from 114/72 to 118/78. The nurse obtains a blood pressure of 116/76. What would account for the blood pressure of 152/92? (Select all that apply.)
1. Cuff too small
2. Arm positioned above heart level
3. Slow inflation of the cuff by the machine
4. Patient did not remove his long-sleeved shirt
5. Insufficient time between measurements

15. A patient is admitted for dehydration caused by pneumonia and shortness of breath. He has a history of heart disease and cardiac dysrhythmias. The nursing assistant reports his admitting vital signs to the nurse. Which measurements should the nurse reassess? (Select all that apply.)
1. Right arm BP: 118/72
2. Radial pulse rate: 72 and irregular
3. Temporal temperature: 37.4°C (99.3°F)
4. Respiratory rate: 28
5. Oxygen saturation: 99%

Answers: 1. 4; **2.** 1; **3.** 1; **4.** 3; **5.** 3; **6.** 3; **7.** 3; **8.** 3; **9.** 1, 2, 5; **10.** 5; **11.** 4; **12.** 2, 6; **13.** 4, 1, 3, 2, 5; **14.** 1, 5; **15.** 2, 4, 5.

Health Assessment and Physical Examination

OBJECTIVES

- Discuss the purposes of physical assessment.
- Discuss how cultural diversity influences a nurse's approach to and findings from a health assessment.
- List techniques for preparing a patient physically and psychologically before and during an examination.
- Describe interview techniques used to enhance communication during history taking.
- Make environmental preparations before an examination.
- Identify data to collect from the nursing history before an examination.
- Demonstrate the techniques used with each physical assessment skill.
- Discuss normal physical findings in a young, middle-age, and older adult.
- Discuss ways to incorporate health promotion and health teaching into an examination.
- Identify ways to use physical assessment skills during routine nursing care.
- Describe physical measurements made in assessing each body system.
- Identify self-screening examinations commonly performed by patients.
- Identify preventive screenings and the appropriate age(s) for each screening to occur.

The health assessment and physical examination are important steps toward providing safe and competent nursing care. As a nurse, you are in a unique position to determine each patient's current health status, distinguish variations from the norm, and recognize improvements or deterioration in his or her condition. As a nurse you must be able to recognize and interpret each patient's behavioral and physical presentation. By performing health assessments and physical examinations, you identify health patterns and evaluate each patient's response to treatments and therapies.

Nurses gather assessment data about patients' past and current health conditions in a variety of ways, using a comprehensive or focused approach, depending on the patient situation. Assessments are

performed at health fairs, at screening clinics, in a health provider's office, in acute care agencies, or in patients' homes. Depending on the outcome of an assessment, a nurse considers evidence-based recommendations for care on the basis of a patient's values, the health provider's clinical expertise, or own personal experience.

A complete health assessment involves a nursing history (see Chapter 16) and behavioral and physical examination. Through the health history interview you gather subjective data about a patient's condition. You obtain objective data while observing a patient's behavior and overall presentation. You identify additional objective data through a head-to-toe body system review during the physical examination. Your clinical judgments are made on the basis of all of the gathered data to create a plan of care for each situation. With accurate data you create a patient-centered care plan, identifying the nursing diagnoses, desired patient outcomes, and nursing interventions. Continuity in health care improves when you evaluate a patient by making ongoing, objective, and comprehensive assessments.

PURPOSES OF THE PHYSICAL EXAMINATION

A physical examination is conducted as an initial evaluation in triage for emergency care; for routine screening to promote wellness behaviors and preventive health care measures; to determine eligibility for health insurance, military service, or a new job; or to admit a patient to a hospital or long-term care facility. After considering a patient's current condition, a nurse selects a focused physical examination on a specific system or area. For example, when a patient is having a severe asthma episode, the nurse first focuses on the pulmonary and cardiovascular systems so treatments can begin immediately. When the patient is no longer at risk for a bad outcome or injury, the nurse performs a more comprehensive examination of other body systems.

For patients who are hospitalized, a nurse integrates the collection of physical assessment data during routine patient care, validating findings with what is known about the patient's health history. For example, on entering a patient's room a nurse may notice behavioral patient cues that indicate comfort, anxiety, or sadness; assess the skin during the bed bath; or assess physical movements and swallowing abilities while administering medications. Use physical examination to do the following:

- Gather baseline data about the patient's health status.
- Supplement, confirm, or refute subjective data obtained in the nursing history.
- Identify and confirm nursing diagnoses.
- Make clinical decisions about a patient's changing health status and management.
- Evaluate the outcomes of care.

Cultural Sensitivity

Respect the cultural differences among patients from a variety of backgrounds when completing an examination. It is important to remember that cultural differences influence patient behaviors. Consider the patient's health beliefs, use of alternative therapies, nutrition habits, relationships with family, and comfort with physical closeness during the examination and history. These factors will affect both your approach and the type of findings you might expect.

Be culturally aware and avoid stereotyping on the basis of gender, race, education or other cultural factors. There is a difference between cultural and physical characteristics. Learn to recognize common characteristics and disorders among members of ethnic populations within the community. It is equally important to recognize variations in physical characteristics such as in the skin and musculoskeletal system,

which are related to racial variables. Consider the patient's cultural beliefs as you assess how the person receives, processes, and understands health care information and how he or she makes health care decisions (Ingram, 2012). By recognizing cultural diversity, you show respect for each patient's uniqueness, leading to higher-quality care and improved clinical outcomes (see Chapter 9).

PREPARATION FOR EXAMINATION

Physical examination is a routine part of a nurse's patient assessment. In many care settings a head-to-toe physical assessment is required daily. You perform a reassessment when a patient's condition changes as it improves or worsens. In some health care settings such as during a home health visit a focused physical examination is preferred. Proper preparation of the environment, equipment, and patient ensures a smooth physical examination with few interruptions. A disorganized approach causes errors and incomplete findings. Safety for confused patients should be a priority; never leave a confused or combative patient alone during an examination.

Infection Control

Some patients present with open skin lesions, infected wounds, or other communicable diseases. Use standard precautions throughout an examination (see Chapter 29). When an open sore or microorganism is present, wear gloves to reduce contact with contaminants. If a patient has excessive drainage or there is a risk of splattering from a wound, additional personal protective equipment such as an isolation gown or eye shield should be used. Follow agency hand hygiene policies before initiating and after completing a physical assessment.

Although most health care agencies make nonlatex gloves available, it is your responsibility to identify latex allergies in patients and use equipment items that are latex free. By recognizing risk factors for latex allergies, patients remain free of a natural rubber latex (NRL) allergy response. Two types of allergic responses appear with NRL. The most immediate is an immunological reaction type 1 response, for which the body develops antibodies known as *immunoglobulin E* that can lead to an anaphylactic response. Atopy occurs when there is an increased tendency for the body to form antibodies as a result of the immune response. The second is the allergic contact dermatitis type 4 response, which causes a delayed reaction that appears 12 to 48 hours after exposure (Huether and McCance, 2012). Both require prior exposure to the substance to which the body reacts. The severity of the response varies among individuals. Table 31-1 provides a short list of products that contain latex and suggests available alternatives.

Environment

A respectful, considerate physical examination requires privacy. In the acute setting nurses perform assessments in a patient's room. Examination rooms are used in clinics or office settings. In the home the examination is performed in a space where privacy can be established such as the patient's bedroom.

Examination spaces need to be well equipped for any procedures. Adequate lighting is necessary to properly illuminate body parts. The hospital patient room can be secured for privacy so patients are comfortable discussing their condition. Eliminate extra noise and take precautions to prevent interruptions from others. The room must be warm enough to maintain comfort.

Depending on the body part being assessed, it may be difficult to perform a selected assessment skill when a patient is in bed or on a stretcher. Special examination tables make positioning easier and body areas more easily accessible. By helping patients on and off

TABLE 31-1 Products Containing Latex and Nonlatex Substitutes*

Products Containing Latex	Nonlatex Substitutes
Medical Equipment	
Disposable gloves	Vinyl, nitrile, or neoprene gloves
Blood pressure cuffs	Covered cuffs
Stethoscope tubing	Covered tubing
Intravenous injection ports	Needleless system, stopcocks, covered latex ports
Tourniquets	Latex-free or cloth-covered tourniquets
Syringes	Glass syringes
Adhesive tape	Nonlatex tapes
Oral and nasal airways	Nonlatex tubes
Endotracheal tubes	Hard plastic tubes
Catheters	Silicone catheters
Eye goggles	Silicone eye goggles
Anesthesia masks	Silicone masks
Respirators	Nonlatex respirators
Rubber aprons	Cloth-covered aprons
Wound drains	Silicone drains
Medication vial stoppers	Stoppers removed
Household Items	
Rubber bands	String; latex-free bands
Erasers	Silicone erasers
Motorcycle and bicycle handgrips	Handgrips removed or covered
Carpeting	Other types of flooring
Swimming goggles	Silicone construction
Shoe soles	Leather shoes
Expandable fabric (e.g., waistbands)	Fabric removed or covered
Dishwashing gloves	Vinyl gloves
Condoms	Nonlatex condoms
Diaphragms	Synthetic rubber diaphragms
Balloons	Mylar balloons
Pacifiers and baby bottle nipples	Silicone, plastic, or nonlatex pacifiers and nipples

Modified from American Latex Allergy Association: *Literature review on latex-food cross-reactivity, 1991-2006*, 2011, http://latexallergyresources.org/sites/default/files/attachments/Latex-food%20cross-reactivity%20review.pdf. Accessed November 13, 2014; and Seidel HM et al: *Mosby's guide to physical examination*, ed 8, St Louis, 2015, Mosby;
*This list is intended to provide examples of products and alternatives. It is not complete.

examination tables, injury can be avoided, and falls prevented. Examination tables can be uncomfortable; elevate the head of the table about 30 degrees. A small pillow helps with head and neck comfort. If the examination is completed in the patient room, raise the patient's bed to be able to reach him or her more easily.

BOX 31-1 Equipment and Supplies for Physical Assessment

- Cervical brush or broom devices (if needed)
- Cotton applicators
- Disposable pad/paper towels
- Drapes/cover
- Eye chart (e.g., Snellen chart)
- Flashlight and spotlight
- Forms (e.g., physical, laboratory)
- Nonlatex gloves (clean)
- Gown for patient
- Ophthalmoscope
- Otoscope
- Papanicolaou (Pap) liquid preparation (if needed)
- Percussion (reflex) hammer
- Pulse oximeter
- Ruler
- Scale with height measurement rod
- Specimen containers, slides, wooden or plastic spatula, and cytological fixative (if needed)
- Sphygmomanometer and cuff
- Sterile swabs
- Stethoscope
- Tape measure
- Thermometer
- Tissues
- Tongue depressors
- Tuning fork
- Vaginal speculum (if needed)
- Water-soluble lubricant
- Watch with second hand or digital display

Equipment

Perform hand hygiene thoroughly before handling equipment and starting an examination. Arrange any necessary equipment so it is readily available and easy to use. Prepare equipment as appropriate (e.g., warm the diaphragm of the stethoscope between the hands before applying it to the skin). Be sure that equipment functions properly before using it (e.g., ensure that the ophthalmoscope and otoscope have good batteries and light bulbs). Box 31-1 lists typical equipment used during a physical examination.

Physical Preparation of the Patient

To show respect for a patient, ensure that physical comfort needs are met. Before starting, ask if the patient needs to use the restroom. An empty bladder and bowel facilitate examination of the abdomen, genitalia, and rectum. You will collect urine or fecal specimens at this time if needed.

Physical preparation involves making certain that patient privacy is maintained with proper dress and draping. The patient in the hospital likely is wearing only a simple gown. In the clinic or health care provider's office the patient needs to undress and usually is provided a disposable paper cover or paper gown. If the examination is limited to certain body systems, it is not always necessary for the patient to undress completely. Provide the patient privacy and plenty of time to undress to avoid embarrassment. After changing into the recommended gown or cover, the patient sits or lies down on the examination table with a light drape over the lap or lower trunk. Make sure that he or she stays warm by eliminating drafts, controlling room temperature, and providing warm blankets. Routinely ask if he or she is comfortable.

Positioning. During the examination ask the patient to assume proper positions so body parts are accessible and he or she stays comfortable. Table 31-2 lists the preferred positions for each part of the examination and contains figures illustrating the positions. Patients' abilities to assume positions depend on their physical strength, mobility, ease of breathing, age, and degree of wellness. After explaining a position, help the patient to assume it correctly. Take care to maintain respect and show consideration by adjusting the drapes so only the area examined is accessible. During the examination a patient may need to assume more than one position. To decrease the number of

TABLE 31-2 Positions for Examination

Position	Areas Assessed	Rationale	Limitations
Sitting	Head and neck, back, posterior thorax and lungs, anterior thorax and lungs, breasts, axillae, heart, vital signs, and upper extremities	Sitting upright provides full expansion of lungs and better visualization of symmetry of upper body parts.	Physically weakened patient sometimes is unable to sit. Use supine position with head of bed elevated instead.
Supine	Head and neck, anterior thorax and lungs, breasts, axillae, heart, abdomen, extremities, pulses	This is most normally relaxed position. It provides easy access to pulse sites.	If patient becomes short of breath easily, raise head of bed.
Dorsal recumbent	Head and neck, anterior thorax and lungs, breasts, axillae, heart, abdomen	Position is for abdominal assessment because it promotes relaxation of abdominal muscles.	Patients with painful disorders are more comfortable with knees flexed.
Lithotomy*	Female genitalia and genital tract	Position provides maximal exposure of female genitalia and facilitates insertion of vaginal speculum.	Lithotomy position is embarrassing and uncomfortable; thus examiner minimizes time that patient spends in it. Keep patient well draped.
Sims'	Rectum and vagina	Flexion of hip and knee improves exposure of rectal area.	Joint deformities hinder patient's ability to bend hip and knee.
Prone	Musculoskeletal system	Position is only for assessing extension of hip joint, skin, and buttocks.	Patients with respiratory difficulties do not tolerate this position well.
Lateral recumbent	Heart	Position aids in detecting murmurs.	Patients with respiratory difficulties do not tolerate this position well.
Knee-chest*	Rectum	Position provides maximal exposure of rectal area.	This position is embarrassing and uncomfortable.

*Some patients with arthritis or other joint deformities are unable to assume this position.

position changes, organize the examination so all techniques requiring a sitting position are completed first, followed by those that require a supine position next, and so forth. Use extra care when positioning older adults with disabilities and limitations.

Psychological Preparation of a Patient

Many patients find an examination stressful or tiring, or they experience anxiety about possible findings. A thorough explanation of the purpose and steps of each assessment lets a patient know what to expect and how to cooperate. Adapt explanations to the patient's level of understanding and encourage him or her to ask questions and comment on any discomfort. Convey an open, professional approach while remaining relaxed. A quiet, formal demeanor inhibits a patient's ability to communicate, but a style that is too casual may cause him or her to doubt an examiner's competence (Ball et al., 2015).

Consider cultural or social norms when performing an examination on a person of the opposite gender. When this situation occurs, another person of the patient's gender or a culturally approved family member needs to be in the room. By taking this step you demonstrate cultural awareness for a patient's individual needs. As a side benefit, the second person acts as a witness to the conduct of the examiner and the patient should any question arise.

During the examination watch the patient's emotional responses by observing whether his or her facial expressions show fear or concern or if body movements indicate anxiety. When you remain calm, the patient is more likely to relax. Especially if the patient is weak or elderly, it is necessary to pace the examination, pausing at intervals to ask how he or she is tolerating the assessment. If the patient feels alright, the examination can proceed. However, do not force the patient to cooperate based on your schedule. Postponing the examination is advantageous because the findings may be more accurate when the patient can cooperate and relax.

Assessment of Age-Groups

It is necessary to use different interview styles and approaches to physical examination for patients of different age-groups. Your approach will vary with each group. When assessing children, show sensitivity and anticipate the child's perception of the examination as a strange and unfamiliar experience. Routine pediatric examinations focus on health promotion and illness prevention, particularly for well children who receive competent parenting and have no serious health problems (Hockenberry and Wilson, 2015). This examination focuses on growth and development, sensory screening, dental examination, and behavioral assessment. Children who are chronically ill or disabled and foster, foreign-born, or adopted children sometimes require additional examination visits. When examining children, the following tips help in data collection:

- Gather all or part of the history on infants and children from parents or guardians. Use open-ended questions to allow parents to share more information and describe more of the children's problems. This also allows observation of parent-child interactions. You can interview older children, who often provide details about their health history and severity of symptoms.
- Gain a child's trust before doing any type of an examination. Perform the examination in a nonthreatening area. Talk and play with the child first. Do the visual parts of the examination before actually touching the child. Start the examination from the periphery and then move to the center (e.g., start with the extremities before moving to the chest).
- Because parents sometimes think the examiner is testing them, offer support during the examination and do not pass judgment.

- Call children by their first name and address the parents as "Mr., Mrs., or Ms." rather than by their first name unless instructed differently.
- Treat adolescents as adults and individuals because they tend to respond best when treated as such. Remember that adolescents have the right to confidentiality. After talking with parents about historical information, speak alone with adolescents.

A comprehensive health assessment and examination of older adults includes physical data; developmental stage; family relationships; religious and occupational pursuits; and a review of the patient's cognitive, affective, and social level. An important aspect is to assess the patient's ability to perform basic activities of daily living (e.g., bathing, grooming) and complex instrumental activities of daily living (e.g., making phone call).

Throughout an examination recognize that with advancing age the body does not demonstrate obvious injury or disease as vigorously as younger patients and older adults do not always exhibit the expected signs and symptoms (Touhy and Jett, 2014). Characteristically older adults present with subtle or atypical signs and symptoms. Principles to follow during examination of an older adult include the following:

- Do not stereotype about aging patients' level of cognition. Most older adults are able to adapt to change and learn about their health. Similarly most are reliable historians.
- Recognize that some older adults have sensory or physical limitations that affect how quickly they can be interviewed and examinations can be conducted. It might be necessary to plan for more than one examination session. Sometimes it helps to give patients an initial health questionnaire before they come to a clinic or office.
- Perform the examination with adequate space; this is especially important for patients with mobility aids such as a cane or walker.
- During the examination use patience, allow for pauses, and observe for details. Recognize normal physiological and behavioral changes that are characteristic of later life.
- Certain types of health information are stressful for older patients to give. Some view illness as a threat to independence and a step toward institutionalization.
- Be aware of the location of the closest bathroom facility in case the patient has an urgent need to eliminate.
- Be alert to signs of increasing fatigue such as sighing, grimacing, irritability, leaning against objects for support, and drooping head and shoulders.

ORGANIZATION OF THE EXAMINATION

You conduct a physical examination by assessing each body system. Use judgment to ensure that an examination is relevant and includes the correct assessments. Patients with focused symptoms or needs require only parts of an examination; thus, when a patient comes to a clinic with symptoms of a severe chest cold, a neurological assessment should not be required. A patient entering the emergency department with acute abdominal symptoms requires assessment of the body systems most at risk for being abnormal. However, when a patient is admitted to the hospital, you perform a complete examination at the time of admission and at least once each day to maintain and monitor the patient's baseline. Agency guidelines may define the components of a complete examination (see agency policy). A patient in the community seeks screening for specific conditions, often dependent on his or her age or health risks listed in Table 31-3.

TABLE 31-3	Recommended Preventive Screenings	
Disease/Condition	**Age-Group**	**Screening Measures**
Breast cancer* (Women at average risk)	Ages 40-44	Should have the choice to start annual breast cancer screening with mammograms if they wish to do so. The risks of screening as well as the potential benefits should be considered. Monthly BSE dependent on health care provider recommendations (not recommended by ACS)
	Ages 45-54	Monthly BSE dependent upon health care provider recommendations (not recommended by ACS) Should get mammogram every year
	Ages 55 and older	Should switch to mammograms every 2 years or have the choice to continue yearly screening.
	Women with a personal history of breast cancer, a family history of breast cancer, a genetic mutation known to increase the risk of breast cancer (such as *BRCA*), and women who have had radiation therapy to the chest before the age of 30 are at a higher risk for breast cancer, not average risk. These women require earlier and more extensive screening.	
Colon/rectal cancer**	Ages 50 and up	Men and women need to have one of the following: fecal occult blood test (FOBT) or fecal immunochemical test (FIT) annually or flexible sigmoidoscopy (FSIG) every 5 years; the combination of FOBT or FIT annually and an FSIG every 5 years is preferred over either of the previous options; or double-contrast barium enema every 5 years; or colonoscopy every 10 years. They also need a digital rectal examination at the same time. Earlier screening is necessary if risk factors exist.
Ear disorders	All ages	Periodic hearing checks as needed
	Over age 65	Regular hearing checks
Eye disorders	Age 40 and under	Complete eye examination every 3 to 5 years (more if positive history for eye disease [e.g., diabetes])
	Ages 40 to 64	Complete eye examination every 2 years to screen for conditions that may go unnoticed (e.g., glaucoma) Annual eye examinations if patient has diabetes
	Age 65 and up	Complete eye examination every year
Heart/vascular disorders	Men age 45 to 65 Women age 45 to 65	Regular measurement of total blood cholesterol levels, lipids, and triglycerides; blood pressure screenings (If patient has risk factors for coronary artery disease [CAD], blood pressure screening needs to begin at age 20-35 for men, 20-45 for women.)
Obesity	All ages	Periodic height and weight measurements
Oral cavity/pharyngeal disorders/cancer	All ages (children, adults, older adults)	Regular dental examinations every 6 months
Ovarian cancer**	Age 18 and up or on becoming sexually active	Annual pelvic examinations by health care provider (This screening occasionally detects ovarian cancer in its advanced stage. Those at high risk need to have a thorough pelvic examination, a transvaginal ultrasound, and a blood test [tumor marker CA 125].)
Prostate cancer**	Ages 50 and up	Men who have at least a 10-year life expectancy need to have a digital rectal examination (DRE) and prostate-specific antigen (PSA) blood test annually. Men at high risk require earlier screening.
Skin cancer**	Ages 20 to 40	See specialist every 3 years
	Over 40	Annual skin checkups with biopsy of suspicious lesions
Testicular cancer**	Age 15 and up	Monthly testicular self-examination (TSE)
Uterine cancer**	Screening begins 3 years after having vaginal intercourse but not later than age 21	Annual pelvic examination by health care provider plus annual Papanicolaou (Pap) test
Cervical cancer	An **annual** Pap test is no longer recommended by the United States Preventive Services Task Force (USPSTF) (2012) and the American Cancer Society (ACS).	
	Ages 21-29	Pelvic examination by health care provider plus Pap test with cytology every 3 years; human papillomavirus (HPV) needed only if Pap test is abnormal (USPSTF, 2012; ACS, 2012)
	Ages 30-65	Pap test with cytology every 3 years. Women who want to lengthen the screening interval: pelvic exam with a combination of cytology and HPV testing every 5 years (USPSTF, 2012; ACS, 2012)
	Over 65	No testing needed if previous regular testing was normal and not otherwise at high risk for cervical cancer (USPSTF, 2012; ACS, 2012). Women diagnosed with cervical precancer should continue to be screened
Endometrial cancer	Same as for cervical cancer	Endometrial biopsy at age 35 for high-risk patients (those with or at risk for hereditary nonpolyposis colon cancer [HNPCC]) (At menopause women at average and high risk need to be informed about signs and symptoms to report.)

*Data from American Cancer Society (ACS): American Cancer Society recommendations for early breast cancer detection in women without breast symptoms, http://www.cancer.org/cancer/breastcancer/moreinformation/breastcancerearlydetection/breast-cancer-early-detection-acs-recs. Accessed October 26, 2015.

**Data from American Cancer Society (ACS): *American Cancer Society guidelines for the early detection of cancer,* 2014, http://www.cancer .org/healthy/findcancerearly/cancerscreeningguidelines/american-cancer-society-guidelines-for-the-early-detection-of-cancer. Any physical examination should follow a systematic routine to avoid missing important findings. A head-to-toe approach includes all body systems, and the examiner recalls and performs each step in a predetermined order. For an adult the examination begins with an assessment of the head and neck and progresses methodically down the body to incorporate all body systems. The following tips help keep an examination well organized:

- Compare both sides of the body for symmetry. A degree of asymmetry is normal (e.g., the biceps muscles in the dominant arm are sometimes more developed than the same muscles in the nondominant arm).
- If the patient is seriously ill, first assess the systems of the body most at risk for being abnormal. For example, a patient with chest pain first undergoes a cardiovascular assessment.
- If the patient becomes fatigued, offer rest periods between assessments.
- Perform painful procedures near the end of an examination.
- Record assessments in specific terms in the electronic or paper record. A standard form allows for recording information in the same sequence that it is gathered.
- Use common and accepted medical terms and abbreviations to keep notes accurate, brief, and concise.
- Record quick notes during the examination to avoid delays. Complete any larger documentation notes at the end of the examination.

TECHNIQUES OF PHYSICAL ASSESSMENT

The four techniques used in a physical examination are inspection, palpation, percussion, and auscultation.

Inspection

To inspect, carefully look, listen, and smell to distinguish normal from abnormal findings. To do so, you must be aware of any personal visual, hearing, or olfactory deficits. It is important to deliberately practice this skill and learn to recognize all of the possible pieces of data that can be gathered through inspection alone. **Inspection** occurs when interacting with a patient, watching for nonverbal expressions of emotional and mental status. Physical movements and structural components can also be identified in such an informal way. Most important, be deliberate and pay attention to detail. Follow these guidelines to achieve the best results during inspection:

- Make sure that adequate lighting is available, either direct or tangential.
- Use a direct lighting source (e.g., a penlight or lamp) to inspect body cavities.
- Inspect each area for size, shape, color, symmetry, position, and abnormality.
- Position and expose body parts as needed so all surfaces can be viewed but privacy can be maintained.
- When possible, check for side-to-side symmetry by comparing each area with its match on the opposite side of the body.
- Validate findings with the patient.

While assessing a patient, recognize the nature and source of body odors (Table 31-4). An unusual odor often indicates an underlying pathology. **Olfaction** helps to detect abnormalities that cannot be recognized by any other means. For example, when a patient's breath has a sweet, fruity odor, assess for signs of diabetes. Continue to inspect various parts of the body during the physical examination. Palpation may be used concurrently with inspection, or it may follow in a more deliberate fashion.

TABLE 31-4 Assessment of Characteristic Odors

Odor	Site or Source	Potential Causes
Alcohol	Oral cavity	Ingestion of alcohol, diabetes
Ammonia	Urine	Urinary tract infection, renal failure
Body odor	Skin, particularly in areas where body parts rub together (e.g., underarms and under breasts)	Poor hygiene, excess perspiration (hyperhidrosis), foul-smelling perspiration (bromhidrosis)
	Wound site	Wound abscess
	Vomitus	Abdominal irritation, contaminated food
Feces	Vomitus/oral cavity (fecal odor)	Bowel obstruction
	Rectal area	Fecal incontinence
Foul-smelling stools in infant	Stool	Malabsorption syndrome
Halitosis	Oral cavity	Poor dental and oral hygiene, gum disease
Sweet, fruity ketones	Oral cavity	Diabetic acidosis
Stale urine	Skin	Uremic acidosis
Sweet, heavy, thick odor	Draining wound	*Pseudomonas* (bacterial) infection
Musty odor	Casted body part	Infection inside cast
Fetid, sweet odor	Tracheostomy or mucus secretions	Infection of bronchial tree (*Pseudomonas* bacteria)

Palpation

Palpation involves using the sense of touch to gather information. Through touch you make judgments about expected and unexpected findings of the skin or underlying tissue, muscle, and bones. For example, you palpate the skin for temperature, moisture, texture, turgor, tenderness, and thickness and the abdomen for tenderness, distention, or masses. Use different parts of the hand to detect different characteristics (Table 31-5). The palmar surface of the hand and finger pads is more sensitive than the fingertips and should be used to determine position, texture, size, consistency, masses, fluid, and crepitus (Figure 31-1, *A*). Assess body temperature by using the dorsal surface or back of the hand (Figure 31-1, *B*). The palmar surface of the hand and fingers (Figure 31-1, *C*) is more sensitive to vibration. Measure position, consistency, and turgor by lightly grasping the body part with the fingertips.

Touching a patient is a personal experience for both you and the patient. Display respect and concern throughout an examination. Before palpating consider the patient's condition and ability to tolerate the assessment techniques, paying close attention to areas that are painful or tender. In addition, always be conscious of the environment and any threats to the patient's safety.

Prepare for palpation by warming hands, keeping fingernails short, and using a gentle approach. Palpation proceeds slowly, gently, and deliberately. The patient needs to be guided to relax and feel comfortable since tense muscles make assessment more difficult. To promote

FIGURE 31-1 A, Radial pulse is detected with pads of fingertips, the most sensitive part of the hand. **B,** Dorsum of hand detects temperature variations in skin. **C,** Bony part of palm at base of fingers detects vibrations.

TABLE 31-5	**Examples of Characteristics Measured by Palpation**	
Area Examined	**Criteria Measured**	**Portion of Hand to Use**
Skin	Temperature	Dorsum of hand/fingers
	Moisture	Palmar surface
	Texture	Palmar surface
	Turgor and elasticity	Grasping with fingertips
	Tenderness	Finger pads/palmar surface of fingers
	Thickness	Palmar surface
Organs (e.g., liver and intestine)	Size	Entire palmar surface of hand or palmar surface of fingers
	Shape	
	Tenderness	
	Absence of masses	
Glands (e.g., thyroid and lymph)	Swelling	Pads of fingertips
	Symmetry and mobility	
Blood vessels (e.g., carotid or femoral artery)	Pulse amplitude	Palmar surface/pads of fingertips
	Elasticity	
	Rate	
	Rhythm	
Thorax	Excursion	Palmar surface
	Tenderness	Finger pads/palmar surface of fingers
	Fremitus	Palmar or ulnar surface of entire hand

FIGURE 31-2 A, During light palpation gentle pressure against underlying skin and tissues can detect areas of irregularity and tenderness. **B,** During deep palpation depress tissue to assess condition of underlying organs.

sensing hand. The lower hand does not exert pressure directly and thus remains sensitive to detect organ characteristics. For safety deep palpation should be observed by your clinical instructor when you first attempt the procedure.

Percussion

Percussion involves tapping the skin with the fingertips to vibrate underlying tissues and organs. The vibration travels through body tissues, and the character of the resulting sound reflects the density of the underlying tissue. The denser the tissue, the quieter is the sound. By knowing how various densities influence sound, it is possible to locate organs or masses, map their edges, and determine their size. An abnormal sound suggests a mass or substance such as air or fluid within an organ or body cavity. The skill of percussion is used more often by advanced practice nurses than by nurses in daily practice at the bedside.

Auscultation

Auscultation involves listening to sounds the body makes to detect variations from normal. Some sounds such as speech and coughing can be heard without additional equipment, but a stethoscope is necessary to hear internal body sounds.

relaxation, have him or her take slow, deep breaths and place both arms along the sides of the body. Ask the patient to point to more sensitive areas, watching for nonverbal signs of discomfort. *Palpate tender areas last.*

Two types of palpation are used for physical examination, light and deep. Perform light palpation by placing the hand on the body part being examined; it also involves pressing inward about 1 cm (½ inch). Light, superficial palpation of structures such as the abdomen gives the patient the chance to identify areas of tenderness (Figure 31-2, *A*). Inquire about areas of tenderness and assess them further for potentially serious pathologies. Use deep palpation to examine the condition of organs such as those in the abdomen (Figure 31-2, *B*). Depress the area under examination approximately 4 cm (2 inches) (Ball et al., 2015), using one or both hands (bimanually). When using bimanual palpation, relax one hand (sensing hand) and place it lightly over the patient's skin. The other hand (active hand) helps apply pressure to the

Internal body sounds are created by blood, air, or gastric contents as they move against the body structures. For example, normal heart sounds are created when the heart valves close, moving blood to the next part of the cardiovascular system. Normal sounds for each body system are discussed later in this chapter. Learn to recognize abnormal sounds after learning normal variations. Becoming more proficient in auscultation occurs by knowing the types of sounds each body structure makes and the location in which the sounds are heard best.

To auscultate internal sounds you need to hear well, have a good stethoscope, and know how to use it properly. Nurses with hearing disorders can obtain stethoscopes with extra sound amplification. Chapter 30 describes the parts of the stethoscope and its general use. The bell is best for hearing low-pitched sounds such as vascular and certain heart sounds, and the diaphragm is best for listening to high-pitched sounds such as bowel and lung sounds.

By practicing with the stethoscope, you become proficient at using it and realize when sounds are clear and when there are extraneous sounds. Extraneous sounds created by rubbing against the tubing or chest piece interfere with auscultation of body organ sounds. By deliberately producing these sounds, you learn to recognize and disregard them during the actual examination. Box 31-2 contains ways to practice using and techniques for caring for the stethoscope. Describe any sound you hear using the following characteristics:

- Frequency indicates the number of sound wave cycles generated per second by a vibrating object. The higher the frequency, the higher the pitch of a sound and vice versa.
- Loudness refers to the amplitude of a sound wave. Auscultated sounds range from soft to loud.
- Quality refers to sounds of similar frequency and loudness from different sources. Terms such as *blowing* or *gurgling* describe the quality of sound.
- Duration means the length of time that sound vibrations last. The duration of sound is short, medium, or long. Layers of soft tissue dampen the duration of sounds from deep internal organs.

Auscultation requires concentration and practice. While listening, know which sounds are expected in certain parts of the body and what causes the sounds. Expected sounds are discussed in each body system section of this chapter. After understanding the cause and character of normal auscultated sounds, it becomes easier to recognize abnormal sounds and their origins.

GENERAL SURVEY

When a patient first enters an examination room, observe his or her walk and general appearance and be attentive to his or her behavior and dress. A general survey, or appraisal, of the patient's presentation and behavior provides information about characteristics of an illness, the patient's ability to function independently, body image, emotional state, recent changes in weight, and developmental status. If there are abnormalities or problems, assess the affected body system more closely during the full examination.

General Appearance and Behavior

Assess appearance and behavior while preparing the patient for the examination. For this review include:

- *Gender and race:* A person's gender affects the type of examination performed and the order of the assessments. Different physical features are related to gender and race. Certain illnesses are more likely to affect a specific gender or race (e.g., the incidence of skin cancer is more common in whites than in blacks, prostate cancer is higher in black men than in white

---

BOX 31-2   Use and Care of the Stethoscope

- Ensure that the earpiece follows the contour of the ear canals. Learn which fit is best for you by comparing amplification of sounds with the earpieces in both directions.
- Place the earpieces in your ears with the tips turned toward the face. *Lightly* blow into the diaphragm. Again place the earpieces in your ears, this time with the ends turned toward the back of the head. *Lightly* blow into the diaphragm. You will find that you hear clearer sounds with the earpiece turned toward the face. After you have learned the right fit for the loudest amplification, wear the stethoscope the same way each time.
- Put on the stethoscope and *lightly* blow into the diaphragm. If the sound is barely audible, *lightly* blow into the bell. Sound is carried through only one part of the chest piece at a time. If the sound is greatly amplified through the diaphragm, the diaphragm is in position for use. If the sound is barely audible through the diaphragm, the bell is in position for use. Rotation of the diaphragm and bell places the chest piece in the desired position. Leave the diaphragm in position for the next exercise.
- Place the diaphragm over the anterior part of your chest. Ask a friend to speak in a normal conversational tone. Environmental noise seriously detracts from hearing the noise created by body organs. When using a stethoscope, the patient and the examiner need to remain quiet.
- Put on the stethoscope and gently tap the tubing. It is often difficult to avoid stretching or moving the stethoscope tubing. The examiner is in a position so the tubing hangs free. Moving or touching the tubing creates extraneous sounds.
- *Care of the stethoscope:* Remove earpieces regularly and clean; remove cerumen (earwax). Keep the bell and diaphragm free of dust, lint, and body oils. Keep the tubing away from any body oils. Avoid draping the stethoscope around the neck next to the skin. Clean daily or after soiling by wiping the entire stethoscope (e.g., diaphragm, tubing) with alcohol. Be sure to dry all parts thoroughly. Follow manufacturer recommendations.
- *Infection control:* Harmful bacteria such as gram-positive bacilli, methicillin-resistant *Staphylococcus aureus* (MRSA), nonaureus *Staphylococcus, Enterobacter cloacae,* and methicillin-sensitive *S. aureus* can be transferred from patient to patient when using portable equipment such as stethoscopes. Clean the stethoscope (diaphragm/bell) *before* reuse on another patient. Using a disinfectant such as isopropyl alcohol (with or without chlorhexidine), benzalkonium, or sodium hypochlorite is effective in reducing the number of bacterial colonies. Hand foam serves this purpose well. Earpieces of stethoscopes are sources of transferable bacteria. When you inadvertently touch your ears and care for the patient, potential pathogens could contaminate the earpieces. Using hand hygiene before and after patient contact decreases the risk of transmitting microorganisms from your ear to your patient. Follow institution infection control guidelines, especially contact precautions, to decrease this risk.

---

men, and cancer of the bladder is higher in men than women) (ACS, 2015a).

- *Age:* Age influences normal physical characteristics and a person's ability to participate in some parts of the examination.
- *Signs of distress:* Sometimes obvious signs or symptoms indicate pain (grimacing, splinting painful area), difficulty breathing (shortness of breath, sternal retractions), or anxiety. Set priorities and examine the related physical areas first.
- *Body type:* Observe if the patient appears trim and muscular, obese, or excessively thin. Body type reflects the level of health, age, and lifestyle.
- *Posture:* Normal standing posture shows an upright stance with parallel alignment of the hips and shoulders. Normal sitting

posture involves some degree of rounding of the shoulders. Observe whether the patient has a slumped, erect, or bent posture, which reflects mood or pain. Changes in older adult physiology often result in a stooped, forward-bent posture, with the hips and knees somewhat flexed and the arms bent at the elbows.

- *Gait:* Observe as the patient walks into the room or stands at the bedside (if the patient is ambulatory). Note whether movements are coordinated or uncoordinated. A person normally walks smoothly, with the arms swinging freely at the sides and the head and face leading the body.
- *Body movements:* Observe whether movements are purposeful, noting any tremors involving the extremities. Determine if any body parts are immobile.
- *Hygiene and grooming:* Note the patient's level of cleanliness by observing the appearance of the hair, skin, and fingernails. Determine if his or her clothes are clean. Grooming depends on the patient's cognitive and emotional function, daily or social activities, and occupation. Observe for excessive use of cosmetics or colognes that could indicate a change in self-perception.
- *Dress:* Culture, lifestyle, socioeconomic level, and personal preference affect the selection and wearing of clothing. However, you should assess whether or not the clothing is appropriate for the temperature, weather conditions, or setting. Depressed or mentally ill people may not be able to select proper clothing, and an older adult might tend to wear extra clothing because of sensitivity to cold.
- *Body odor:* An unpleasant body odor can result from physical exercise, poor hygiene, or certain disease states. Validate any odors that might indicate a health problem.
- *Affect and mood:* Affect is how a person appears to others. Patients express mood or emotional state verbally and nonverbally. Determine whether or not verbal expressions match nonverbal behavior and if the mood is appropriate for the situation. By maintaining eye contact you can observe facial expressions while asking questions.
- *Speech:* Normal speech is understandable and moderately paced and shows an association with the person's thoughts. However, emotions or neurological impairment sometimes causes rapid or slowed speech. Observe whether the patient speaks in a normal tone with clear inflection of words.
- *Signs of patient abuse:* During the examination observe if the patient fears his or her spouse or partner, a caregiver, a parent, or an adult child. Abuse of children, women, and older adults is a growing health problem. Consider any obvious physical injury or neglect as signs of possible abuse (e.g., evidence of malnutrition or presence of bruising on the extremities or trunk) (WHO, 2015). Abuse occurs in many forms: physical, mental or emotional, sexual, social, and financial or economic. Observe the behavior of the individual for any signs of frustration, explanations that do not fit his or her physical presentation, or signs of injury. Most states mandate a report to a social service center when abuse or neglect is suspected (Box 31-3). It is difficult to detect abuse because victims often do not complain or report that they are in abusive situations. If abuse is suspected, find a way to interview the patient in private; patients are more likely to reveal any problems when the suspected abuser is absent from the room. It is imperative that you help the patient find safe housing or seek protection from the abuser since the risk for further abuse is high once the victim has reported it or tries to leave the abusive situation.

- *Substance abuse:* Unusual or inconsistent behavior may be an indicator of substance abuse, which can affect all socioeconomic groups. Although a single patient visit to a clinic does not always reveal the problem, unusual behaviors should be investigated further to reveal behaviors that should be confirmed with a well-focused history and physical examination. Always approach the patient in a caring and nonjudgmental way; substance abuse involves both emotional and lifestyle issues. Box 31-4 lists characteristics of patients who should be further assessed for potential substance abuse. If you suspect abuse or addiction in people 18 years of age or older, a tool such as the NIDA Quick Screen V1.0 helps to identify the level or risks associated with substance abuse (NIDA, 2012). If you suspect that alcohol abuse is a major problem, the CAGE questionnaire provides a useful set of questions to guide assessment. CAGE is an acronym for the following:
  - Have you ever felt the need to **Cut down** on your drinking or drug use?
  - Have people **Annoyed** you by criticizing your drinking or drug use?
  - Have you ever felt bad or **Guilty** about your drinking or drug use?
  - Have you ever used or had a drink first thing in the morning as an **Eye-opener** to steady your nerves or feel normal?

Among older adults risk factors for development of alcohol-related problems include chronic medical disorders, sleep disorders, social isolation, loneliness, bereavement, and acute or chronic pain. When assessing adolescents use the T-ACE modification to assess a patient's degree of tolerance (e.g., how many drinks does it take to make you feel high?) (Burns et al., 2010).

Vital Signs

After completing the general survey, measure the patient's vital signs (see Chapter 30). Measurement of vital signs is more accurate if completed before beginning positional changes or movements. If there is a chance that the vital signs are skewed when first measured, recheck them later during the rest of the examination. Pain, considered the fifth vital sign, should also be assessed.

Height and Weight

The relationship of height and weight reflects a person's general health status. Assess every patient to identify if he or she is at a healthy weight, overweight, or obese. Weight is routinely measured during health screenings, visits to physicians' offices or clinics, and on admission to the hospital. Infants and children are measured for both height and weight at each health care visit to assess for healthy growth and development. If older adults are underweight, difficulty with feeding and other functional activities is a possibility. Measuring height and weight of older adults, along with obtaining a dietary history (Box 31-5), shows risk factors for chronic diseases.

Assess trends in weight changes compared with height for signs of poor health. Assessments screen for abnormal weight changes. A patient's weight normally varies daily because of fluid loss or retention. However, a downward trend in a frail older adult indicates that there is a serious reduction in nutritional reserves. The nursing history helps to focus on possible causes for a change in weight (Table 31-6). Ask the patient to report current height and weight, along with a history of any substantial weight gain or loss. A weight gain of 5 lbs (2.3 kg) in 1 day indicates fluid-retention problems. A weight loss is considered significant if the patient has lost more than 5% of body weight in a month or 10% in 6 months.

BOX 31-3   Clinical Indicators of Abuse

Physical Findings	Behavioral Findings
Child Abuse	
Vaginal or penile discharge	Problem sleeping or eating, anxiety, depression
Blood on underclothing	Fear of certain people or places
Pain, itching, or unusual odor in genital area	Play activities recreate the abuse situation
Genital injuries	Regressed behavior
Difficulty sitting or walking	Sexual acting out
Pain while urinating; recurrent urinary tract infections	Knowledge of explicit sexual matters
Foreign bodies in rectum, urethra, or vagina	Preoccupation with others' or own genitals
Sexually transmitted infections	Profound and rapid personality changes
Pregnancy in young adolescent	Rapidly declining school performance
	Poor relationship with peers
Intimate Partner Violence	
Injuries and trauma inconsistent with reported cause	Overuse of health services
Multiple injuries involving head, face, neck, breasts, abdomen, and genitalia (black eyes, orbital fractures, broken nose, fractured skull, lip lacerations, broken teeth, vaginal tears)	Thoughts of or attempted suicide
	Eating or sleeping disorders
	Anxiety and panic attacks
X-ray films showing old and new fractures in different stages of healing	Pattern of substance abuse (follows physical abuse)
Abrasions, lacerations, bruises/welts	Low self-esteem
Burns from cigarettes or other	Depression, problems with eating or sleeping
Human bites	Sense of helplessness
Unexplained injuries (e.g., bruises, fractures, and welts)	Guilt
Strangulation marks on neck from rope burns or bruises; throat pain, voice changes, trouble swallowing; damage to hyoid bone	Smoking
	Stress-related complaints (headache, anxiety)
	Financial dependence on abuser
Stress-related disorders such as irritable bowel syndrome, exacerbation of asthma, or chronic pain	Isolation from others
	Unsafe sexual behaviors
Older-Adult Abuse	
Injuries and trauma inconsistent with reported cause (scratch, bruise, or bite)	Dependent on caregiver
Hematomas, bruises at various stages of resolution	Physically and/or cognitively impaired
Unexplained bruises or welts, pattern bruises	Combative, verbally aggressive
Burns	Wandering
Bruises, chafing, excoriation on wrist or legs (restraints)	Minimal social support
Fractures inconsistent with cause described	Prolonged interval between injury and medical treatment
Dried blood	Life circumstances do not match size of patient's estate
Overmedication or undermedication	Uncommunicative or isolated
Exposure to severe weather, cold or hot	
Torn, bloody underwear or vaginal and anal bruises	
Sunken eyes or loss of weight	
Extreme thirst	
Bed sores	

Data from Cooper C et al: The prevalence of elder abuse and neglect: a systematic review, *Age Aging* 37(2):151, 2008; Hockenberry MJ, Wilson P: *Wong's nursing care of infants and children*, ed 10, St Louis, 2015, Mosby; World Health Organization (WHO): Intimate partner violence, 2012, http://www.who.int/reproductivehealth/publications/violence/rhr12_36/en/index.html. Accessed October 26, 2015.

When a patient is hospitalized, daily weight is measured at the same time of day, on the same scale, with approximately the same clothes (Byrd et al., 2011). This allows an objective comparison of subsequent weights. Accuracy of weight measurement is important because health care providers base medical and nursing decisions (e.g., drug dosage, medications) on changes.

Several different scales are available for use. Patients capable of bearing their own weight use a standing scale. You calibrate a standard platform scale by moving the large and small weights to zero. By adjusting the calibrating knob, the balance beam is leveled and steadied. The patient stands on the scale platform and remains still as the nurse adjusts the largest solid weight to the 50-lb or 22.5-kg increment under

the patient's weight. Next the smaller weight is moved to balance the scale at the nearest $\frac{1}{4}$ lb or 0.1 kg (Ball et al., 2015). Electronic scales are calibrated automatically each time they are used and automatically display the weight within seconds.

Bed and chair scales are available for patients who are unable to bear weight. Newer electronic hospital beds have built-in electronic scales for weighing patients who are not able to get out of bed.

You can use a basket or platform scale to weigh infants. After removing the infant's clothing, weigh him or her in dry disposable diapers. Adjust the measurement later for the weight of the diaper, ensuring an accurate reading. Keep the room warm to prevent chills. Place a light cloth or paper on the surface of the infant scale to prevent

BOX 31-4 Behaviors That are Suspicious for Substance Abuse

Among adolescents and adults: Agitation; inappropriate behavior; problems thinking clearly, remembering, and paying attention; poor coordination; seizure; respiratory depression; coma; asphyxiation; aspiration; pulmonary edema; cardiac arrhythmias; immune system impairment, self-inflicted trauma; and suicidal ideation

Red flags:

- The risk of suicide, seizures, and violent behavior is high among substance abusers.
- Intoxicated patients, particularly those with phencyclidine (PCP) or meth-amphetamine intoxication, are at significant risk for becoming agitated and violent, placing themselves and others at risk for injury.
- Observe for combinations or repetition of these behaviors:
- Frequently misses appointments
- Frequently requests written excuses for absence from school or work
- Drops out of school
- Chief complaints of insomnia, "bad nerves," or pain that does not fit a particular pattern
- Reports lost prescriptions (e.g., tranquilizers or pain medications) or asks for frequent refills
- Frequent emergency department visits
- History of changing health care providers or brings in medication bottles prescribed by several different providers
- History of gastrointestinal bleeds, peptic ulcers, pancreatitis, cellulitis, or frequent pulmonary infections
- Frequent sexually transmitted infections (STIs), complicated pregnancies, multiple abortions, or sexual dysfunction
- Complaints of chest pains or palpitations or has a history of admissions to rule out heart attacks
- History of activities that place the patient at risk for human immunodeficiency virus (HIV) infections (multiple partners, multiple rapes)
- Family history of addiction; history of childhood sexual, physical, or emotional abuse; or social and financial or marital problems
- Intimate partner violence

Data from American Psychiatric Association: *Diagnostic and statistical manual of mental disorders*, ed 4, text revision, Washington, DC, 2000, The Association; American Society of Addiction Medicine and Widlitz M, Marin D: Substance abuse in older adults: an overview, *Geriatrics* 57(12):29, 2002; and Walsh K et al: Examining the interface between substance misuse and intimate partner violence, *Substance Abuse Res Treatment* 3:25, 2009; and National Institute on Drug Abuse: *Drugs, brains and behavior: the science of addiction*, 2014, https://www.drugabuse.gov/publications/drugs-brains-behavior -science-addiction/introduction. Accessed October 26, 2015.

BOX 31-5 Dietary History for Older Adults

- Does the older adult need or have help shopping for or preparing meals?
- Is income adequate for food purchasing? Food stamps or public assistance required?
- Does the patient ever skip meals?
- Are the five primary food groups from MyPlate (fruits, grains, protein, vegetables, dairy) represented in the daily diet (see Chapter 45) (USDA, 2011)?
- Does the older adult take nutritional supplements such as multivitamins?
- Does the older adult take any medication affecting appetite or absorption of nutrients?
- Does the older adult have any religious or cultural beliefs and practices that influence diet?
- Does the older adult have a special diet, food intolerances, or allergies? Does the patient's diet contain an unusual amount of alcohol, sweets, or fried food?
- Does the older adult have problems with chewing, swallowing, or salivation?
- Does the older adult have gastrointestinal problems that interfere with food intake?

Data from Meiner SE: *Gerontologic nursing,* ed 4, St Louis, 2011, Mosby; and US Department of Agriculture and US Department of Health and Human Services: *Dietary guidelines for Americans, 2010*, ed 7, Washington, DC, 2010, US Government Printing Office.

FIGURE 31-3 Measurement of infant length. (From Murray SS, McKinney ES: *Foundations of maternal-newborn and women's health nursing,* ed 5, St Louis, 2010, Saunders.)

cross-infection from urine or feces. When placing an infant in a basket or on a platform, hold a hand lightly above him or her to detect movements and prevent accidental falls. Measure an infant's weight in both ounces and grams.

In patients who are able to stand, measure height by having them remove their shoes. The standing surface should be clean. Use a measuring rod attached vertically to a weight scale, or use a tape ruler on the wall. As the patient stands erect, place a flat surface on his or her head that is even with the vertical measure. Then read the number on the scale or ruler that indicates his or her height in centimeters or inches.

Remove the shoes of a non–weight-bearing patient and position the patient (such as an infant) supine on a firm surface. When measuring an infant, hold his or her head and make sure that his or her legs are straight at the knees. After positioning the infant, use a tape measure to measure length from the head to the bottom of the feet (Figure 31-3). Record the infant's length to the nearest 0.5 cm or $\frac{1}{4}$ inch.

SKIN, HAIR, AND NAILS

The **integumentary system** refers to the skin, hair, scalp, and nails. To assess the integument, you first gather a health history to guide your examination and use the techniques of inspection and palpation.

Skin

Begin an assessment of the skin by focusing on the health history questions found in Table 31-7. The physical examination begins with an inspection of all visible skin surfaces; the less visible surfaces are assessed when you examine other body systems. Use the senses of

TABLE 31-6 Nursing History for Weight Assessment

Assessment	Rationale
Ask about total weight lost or gained; compare with usual weight; note time period for loss and whether it was planned (e.g., gradual, sudden, desired, or undesired).	Assessment determines severity of problem and reveals if weight change is related to disease process, change in eating pattern, or pregnancy.
If weight loss desired, ask about eating habits, diet plan followed, food preparation, calorie intake, appetite, exercise pattern, support group participation, weight goal.	Assessment helps to determine appropriateness of diet plan followed.
If weight loss undesired, ask about anorexia; vomiting; diarrhea; thirst; frequent urination; and change in lifestyle, activity, and stress levels.	Assessment focuses on problems that cause weight loss (e.g., gastrointestinal problems).
Assess if patient has noted changes in social aspects of eating: more meals in restaurants, rushing to eat meals, stress at work, or skipping meals.	Lifestyle changes sometimes contribute to weight changes.
Assess if patient takes chemotherapy, diuretics, insulin, fluoxetine, prescription and nonprescription appetite suppressants, laxatives, oral hypoglycemics, or herbal supplements (weight loss); steroids, oral contraceptives, antidepressants, insulin (weight gain).	Weight gain or loss is a side effect of these medications.
Assess for preoccupation with body weight or body shape such as fasting, never feeling thin enough, unusually strict caloric intake or restrictions, laxative abuse, induced vomiting, amenorrhea, excessive exercise, alcohol intake.	Excesses indicate an eating disorder.

TABLE 31-7 Nursing History for Skin Assessment

Assessment	Rationale
Ask patient about history of changes in skin: dryness, pruritus, sores, rashes, lumps, color, texture, odor, and lesion that does not heal.	Patient is best source to recognize change. Usually skin cancer is first noticed as a localized change in skin color.
Consider if patient has the following history: fair, freckled, ruddy complexion; light-colored hair or eyes; tendency to burn easily.	Characteristics are risk factors for skin cancer.
Determine whether patient works or spends excessive time outside. If so, ask whether patient wears sunscreen and the level of protection.	Exposed areas such as face and arms are more pigmented than rest of body. The American Cancer Society (2015a) recommends sun safety and use of sunscreen and lip balm with broad-spectrum protection and a sun protection factor (SPF) of 30 or higher.
Determine whether patient has noted lesions, rashes, or bruises.	Most skin changes do not develop suddenly. Change in character of lesion can indicate cancer. Bruising indicates trauma or bleeding disorder.
Question patient about frequency of bathing and type of soap used.	Excessive bathing and use of harsh soaps cause dry skin.
Ask if patient has had recent trauma to skin.	Some injuries cause bruising and changes in skin texture.
Determine whether patient has history of allergies.	Skin rashes commonly occur from allergies.
Ask if patient uses topical medications or home remedies on skin.	Incorrect use of topical agents causes inflammation or irritation.
Ask if patient goes to tanning parlors, uses sunlamps, or takes tanning pills.	Overexposure of skin to these irritants can cause skin cancer.
Ask if patient has family history of serious skin disorders such as skin cancer or psoriasis.	Family history can reveal information about patient's condition.
Determine if patient works with creosote, coal, tar, petroleum products, arsenic compounds, or radium.	Exposure to these agents creates risk for skin cancer.

sight, smell, and touch while performing inspection and palpation of the skin.

Assessment of the skin reveals the patient's health status related to oxygenation, circulation, nutrition, local tissue damage, and hydration. Check the condition of the patient's integument to determine the need for nursing care. For example, assessment findings can help determine the type of hygiene measures required to maintain integrity of the integument (see Chapter 40). For example, vigorous towel drying significantly impairs the barrier function of the skin in adults, whereas using no-rinse cleansers and cleaning cloths results in less damage to the skin (Cowdell, 2011). Adequate nutrition and hydration become

goals of therapy if there is an alteration in the integumentary status (see Chapter 45).

Every patient has a risk for skin impairment during administration of care in a hospital setting. Risk increases if there is pressure against the skin when the patient is immobile, from reactions to various medications used in treatment, and from moisture if the patient is incontinent or has wound drainage. At high risk are patients who are neurologically impaired or chronically ill or have had orthopedic or vascular injuries. Also at higher risk are patients with diminished mental status, poor tissue oxygenation, low cardiac output, or inadequate nutrition. Patients who are homebound or in nursing homes or

extended care facilities are often at risk for pressure ulcers, depending on their level of mobility and the presence of chronic illness. Routinely assess the skin of all at-risk patients to look for primary or initial lesions that develop. Without proper care primary lesions can deteriorate to become secondary lesions that require more extensive nursing care. For example, the development of a pressure ulcer lengthens a hospital stay unless it is prevented or discovered and treated early (see Chapter 48).

Adequate lighting is required when assessing the skin. Daylight is the best choice to identify variations in skin color, especially for detecting skin changes in dark-skinned patients. When sunlight is not available, fluorescent lighting is the next best choice. Room temperature also affects skin assessment. A room that is too warm causes superficial vasodilation, resulting in increased redness of the skin. A cool environment causes the sensitive patient to develop cyanosis around the lips and nail beds (Ball et al., 2015).

Although you inspect the skin over each part of the body during an examination, it is helpful to make a brief but careful overall visual sweep of the entire body. This approach provides a good idea of the distribution and extent of any lesions and the overall symmetry of skin color. Inspect all skin surfaces, making a point to do so when examining other body systems. Often overlooked, inspection of the feet is absolutely essential for patients with poor circulation or diabetes. If any abnormalities are found during an examination, palpate the involved areas. Use disposable gloves for palpation if open, moist, or draining lesions are present.

Throughout the examination remain alert for skin odors. White and black adolescents and adults ordinarily have body odor because they have a greater number of functioning apocrine glands. In contrast, Asians and Native Americans/American Indians often do not (Ball et al., 2015). Figure 31-4 illustrates a normal cross-section of the skin.

Color. Skin color varies from body part to body part and from person to person. Despite individual variations, it is usually uniform over the body. Table 31-8 lists common variations. Normal skin pigmentation ranges in tone from ivory or light pink to ruddy pink in light skin and from light to deep brown or olive in dark skin. In older adults **pigmentation** increases unevenly, causing discolored skin. While inspecting the skin be aware that cosmetics or tanning agents sometimes mask normal skin color.

The assessment of color first involves areas of the skin not exposed to the sun such as the palms of the hands. Note if the skin is unusually pale or dark. Areas exposed to the sun such as the face and arms are darker. It is more difficult to note changes such as pallor or cyanosis in patients with dark skin. Usually color hues are most evident in the palms, soles of the feet, lips, tongue, and nail beds. Areas of increased (hyperpigmentation) and decreased (hypopigmentation) color are common. Skin creases and folds are darker than the rest of the body in the dark-skinned patient.

Inspect sites where abnormalities are more easily identified. For example, pallor is more evident in the face, buccal (mouth) mucosa, conjunctiva, and nail beds. Observe for **cyanosis** (bluish discoloration) in the lips, nail beds, palpebral conjunctivae, and palms. In recognizing pallor in the dark-skinned patient, observe that normal brown skin appears to be yellow-brown and normal black skin appears to be ashen gray. Also assess the lips, nail beds, and mucous membranes for generalized pallor; if pallor is present, the mucous membranes are ashen gray. Assessment of cyanosis in the dark-skinned patient requires observing areas where pigmentation occurs the least (conjunctiva, sclera, buccal mucosa, tongue, lips, nail beds, and palms and soles). In addition, verify these findings with clinical manifestations (Ball et al., 2015).

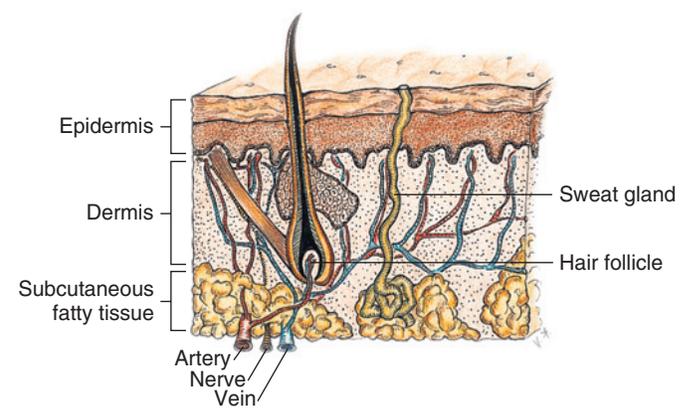
The best site to inspect for **jaundice** (yellow-orange discoloration) is on the patient's sclera. You can see normal reactive hyperemia, or redness, most often in regions exposed to pressure such as the sacrum, heels, and greater trochanter. Inspect for any patches or areas


FIGURE 31-4 Cross-section of skin reveals three layers: epidermis, dermis, and subcutaneous fatty tissues.

TABLE 31-8	**Skin Color Variations**		
Color	**Condition**	**Causes**	**Assessment Locations**
Bluish (cyanosis)	Increased amount of deoxygenated hemoglobin (associated with hypoxia)	Heart or lung disease, cold environment	Nail beds, lips, mouth, skin (severe cases)
Pallor (decrease in color)	Reduced amount of oxyhemoglobin Reduced visibility of oxyhemoglobin resulting from decreased blood flow	Anemia Shock	Face, conjunctivae, nail beds, palms of hands Skin, nail beds, conjunctivae, lips
Loss of pigmentation	Vitiligo	Congenital or autoimmune condition causing lack of pigment	Patchy areas on skin over face, hands, arms
Yellow-orange (jaundice)	Increased deposit of bilirubin in tissues	Liver disease, destruction of red blood cells	Sclera, mucous membranes, skin
Red (erythema)	Increased visibility of oxyhemoglobin caused by dilation or increased blood flow	Fever, direct trauma, blushing, alcohol intake	Face, area of trauma, sacrum, shoulders, other common sites for pressure ulcers
Tan-brown	Increased amount of melanin	Suntan, pregnancy	Areas exposed to sun: face, arms, areolas, nipples

TABLE 31-9 Physical Findings of the Skin Indicative of Substance Abuse

Skin Finding	Commonly Associated Drug
Diaphoresis	Sedative hypnotic (including alcohol)
Spider angiomas	Alcohol, stimulants
Burns (especially fingers)	Alcohol
Needle marks	Opioids
Contusion, abrasions, cuts, scars	Alcohol, other sedative hypnotics, intravenous (IV) opioids
"Homemade" tattoos	Cocaine, IV opioids (prevents detection of injection sites)
Vasculitis	Cocaine
Red, dry skin	Phencyclidine (PCP)

Modified from Lehne RA: *Pharmacology for nursing care*, ed 8, St Louis, 2013, Saunders; Ries R, Wilford B: *Principles of addiction medicine*, ed 4, Chevy Chase, MD, 2009, Lippincott Williams & Wilkins.

of skin color variation. Localized skin changes such as pallor or **erythema** (red discoloration) indicate circulatory changes. For example, an area of erythema is caused by localized vasodilation resulting from a sunburn, inflammation, or fever. It is difficult to observe erythema in the dark-skinned patient; thus palpate the area for heat and warmth to note the presence of skin inflammation. Compare the area with a different part of the skin to detect a difference in temperature. An area of an extremity that appears unusually pale results from arterial occlusion or edema. Be sure to ask if the patient has noticed any changes in skin coloring.

There is also a pattern of findings associated with patients who are chemically dependent or intravenous (IV) drug abusers (Table 31-9). It is sometimes difficult to recognize signs and symptoms through an isolated examination. A patient who takes repeated IV injections has edematous, reddened, and warm areas along the arms and legs. This pattern suggests recent injections. Evidence of old injection sites appears as hyperpigmented and shiny or scarred areas.

Moisture. The hydration of skin and mucous membranes helps to reveal body fluid imbalances, changes in the environment of the skin, and regulation of body temperature. Moisture refers to wetness and oiliness. The skin is normally smooth and dry. Skinfolds such as the axillae are normally moist. Minimal perspiration or oiliness is often present (Ball et al., 2015). Increased perspiration can be associated with activity, exposure to warm environments, obesity, anxiety, or excitement. Use ungloved fingertips to palpate skin surfaces. Observe for dullness, dryness, crusting, and flaking that resembles dandruff when the skin surface is lightly rubbed. Excessively dry skin is common in older adults and people who use excessive amounts of soap during bathing (Cowdell, 2011). Other factors causing dry skin include lack of humidity, exposure to sun, smoking, stress, excessive perspiration, and dehydration. Excessive dryness worsens existing skin conditions such as eczema and dermatitis. Patients with large abdominal skinfolds are at high risk for moisture within the skinfolds. This moisture promotes the growth of bacteria and fungi, which contribute to rashes and infection (Rush and Muir, 2012). Excessive moisture may cause maceration of the skin or softening of the tissues, resulting in an increased risk for breakdown (see Chapter 48).

Temperature. The temperature of the skin depends on the amount of blood circulating through the dermis. Increased or decreased skin temperature indicates an increase or decrease in blood flow. An increase in skin temperature often accompanies localized erythema or redness of the skin. A reduction in skin temperature often accompanies pallor and reflects a decrease in blood flow. It is important to remember that a cold or excessively warm examination room can cause changes in the patient's skin temperature and color.

Accurately assess temperature by palpating the skin with the dorsum or back of the hand. Compare symmetrical body parts. Normally the skin temperature is warm. Sometimes it is the same throughout the body, and other times it varies in one area. Always assess skin temperature for patients at risk of having impaired circulation such as after a cast application or vascular surgery. You can identify a stage I pressure ulcer early by noting warmth over an area of erythema on the skin (see Chapter 48).

Texture. Texture refers to the character of the surface of the skin and how the deeper layers feel. By palpating lightly with the fingertips, you determine whether the patient's skin is smooth or rough, thin or thick, tight or supple, and **indurated** (hardened) or soft. The texture of the skin is normally smooth, soft, even, and flexible in children and adults. However, the texture is usually not uniform throughout, with thicker texture over the palms of the hand and soles of the feet. In older adults the skin becomes wrinkled and leathery because of a decrease in collagen, subcutaneous fat, and sweat glands.

Localized skin changes result from trauma, surgical wounds, or lesions. When there are irregularities in texture such as scars or indurations, ask the patient about recent injury to the skin. Deeper palpation sometimes reveals irregularities such as tenderness or localized areas of induration, which can be caused by repeated injections.

Turgor. **Turgor** refers to the elasticity of the skin. Normally the skin loses its elasticity with age, but fluid balance can also affect skin turgor. Edema or dehydration diminishes turgor. To assess skin turgor, grasp a fold of skin on the back of the forearm or sternal area with the fingertips and release (Figure 31-5). Since the skin on the back of the hand is normally loose and thin, turgor is not assessed reliably at that site (Ball et al., 2015). Normally the skin lifts easily and falls immediately back to its resting position. When turgor is poor, it stays pinched and shows tenting. Evaluate the ease with which the skin moves and the speed at which it returns to its resting state. Failure of the skin to reassume its normal contour or shape indicates dehydration. The patient with poor skin turgor does not have resilience to the normal wear and tear on the skin, and a decrease in turgor predisposes him or her to skin breakdown.

Vascularity. The circulation of the skin affects color in localized areas and leads to the appearance of superficial blood vessels. Vascularity occurs in localized pressure areas when patients remain in one position. Vascularity appears reddened, pink, or pale (see Chapter 48). With aging capillaries become fragile and more easily injured. **Petechiae** are nonblanching, pinpoint-size, red or purple spots on the skin caused by small hemorrhages in the skin layers. Many petechiae have no known cause; but some may indicate serious blood-clotting disorders, drug reactions, or liver disease.

Edema. Areas of the skin become swollen or edematous from a buildup of fluid in the tissues. Direct trauma and impairment of venous return are two common causes of **edema**. Inspect edematous areas for location, color, and shape. The formation of edema separates the surface of the skin from the pigmented and vascular layers, masking

skin color. Edematous skin also appears stretched and shiny. Palpate edematous areas to determine mobility, consistency, and tenderness. When pressure from the examiner's fingers leaves an indentation in the edematous area, it is called *pitting edema*. To assess the degree of pitting edema, press the edematous area firmly with the thumb for several seconds and release. The depth of pitting, recorded in millimeters, determines the degree of edema (Ball et al., 2015). For example, 1+ edema equals a 2-mm depth, 2+ edema equals a 4-mm depth, 3+ equals 6 mm, and 4+ equals 8 mm (Figure 31-6).

Lesions. The term *lesion* refers broadly to any unusual finding of the skin surface. Normally the skin is free of lesions, except for common freckles or age-related changes such as skin tags, senile keratosis (thickening of skin), cherry angiomas (ruby red papules), and atrophic warts. Lesions that are primary occur as an initial spontaneous sign of a pathological process such as with an insect bite. Secondary lesions result from later formation or trauma to a primary lesion such as occurs with a pressure ulcer. When you find a lesion, collect standard information about its color, location, texture, size, shape, type, grouping (clustered or linear), and distribution (localized or generalized). Next observe for any exudate, odor, amount, and consistency. Measure the size of the lesion in centimeters by using a small, clear, flexible ruler. Measure each lesion for height, width, and depth.

Palpation helps determine the mobility, contour (flat, raised, or depressed), and consistency (soft or indurated) of a lesion. Certain types of lesions present characteristic patterns. For example, a tumor is usually an elevated, solid lesion larger than 2 cm (1 inch). Primary lesions such as macules and nodules come from some stimulus to the skin (Box 31-6). Secondary lesions such as ulcers occur as alterations in primary lesions. After you identify a lesion, closely inspect it in good lighting. Palpate gently, covering the entire area of the lesion. If it is moist or draining fluid, wear gloves during palpation and pay attention to whether or not the patient identifies any areas of tenderness.

Skin (cutaneous) malignancies are the most common neoplasms in patients. For this reason the examiner should incorporate a thorough skin assessment on all patients. Cancerous lesions have distinct features and over time undergo changes in color and size (Box 31-7). Basal cell carcinoma is most common in sun-exposed areas and frequently occurs with a history of sun-damaged skin; it almost never spreads to other parts of the body. Squamous cell carcinoma is more serious than basal cell and develops on the outer layers of sun-exposed skin; these cells may travel to lymph nodes and throughout the body. Malignant melanoma, a skin cancer that develops from melanocytes, begins as a mole or other area that has changed in appearance and is usually located on normal skin (**NOTE:** melanoma also can originate in noncutaneous primary sites including mucosal epithelium (GI tract), retinas, and leptomeninges). In African-Americans (more than in other races) it can also appear under fingernails or on the palms of the hands and soles of the feet. Use the *ABCD* mnemonic to assess the skin for any type of carcinoma (ACS, 2015a):

- *A*symmetry—Look for an uneven shape. One half of mole does not match other half.
- *B*order irregularity—Look for edges that are blurred, notched, or ragged.
- *C*olor—Look for pigmentation that is not uniform; variegated areas of blue, black, and brown and areas of pink, white, gray, blue, or red are abnormal.
- *D*iameter—Look for areas greater than 6 mm (about the size of a typical pencil eraser).

Report abnormal lesions to the health care provider for further examination. Since ultraviolet light of the sun or tanning beds increase the risk for development of skin cancers, teach patients about the risks that exist. They should be taught how to perform a skin self-examination, using the best-quality teaching materials.

Hair and Scalp

Two types of hair cover the body: soft, fine, vellus hair, which covers the body; and coarse, long, thick terminal hair, which is easily visible on the scalp, axillae, and pubic areas and in the facial beard on men. First obtain health history information listed in Table 31-10. Prepare to inspect the condition and distribution of hair and the integrity of the scalp by first obtaining a good light source. In addition, hair assessment occurs during all parts of the examination.

Inspection. During inspection explain that it is necessary to separate parts of the hair to detect abnormalities. Wear a pair of clean gloves if open lesions or lice are noted.

First inspect the color, distribution, quantity, thickness, texture, and lubrication of body hair. Scalp hair is coarse or fine and curly or straight; and it should be shiny, smooth, and pliant. While separating

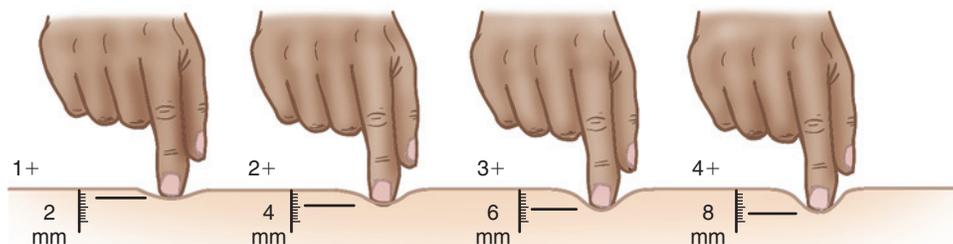
FIGURE 31-5 Assessment for skin turgor. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)


FIGURE 31-6 Assessing for pitting edema. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

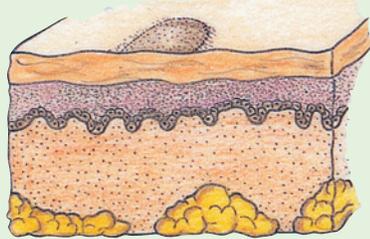
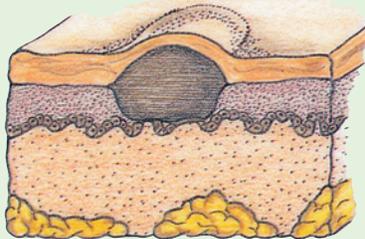
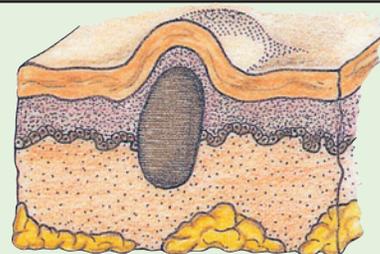
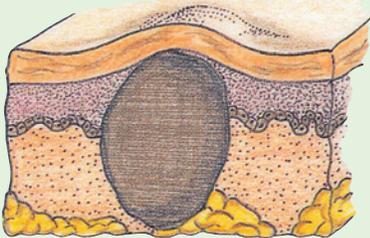
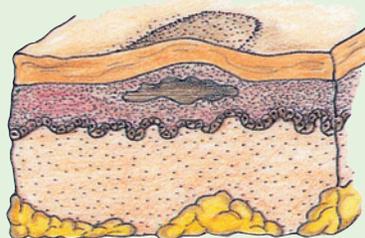
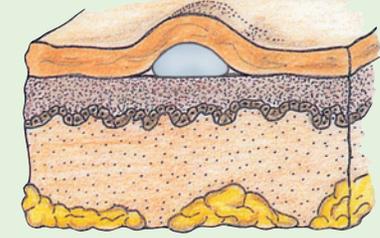
BOX 31-6 Types of Primary Skin Lesions


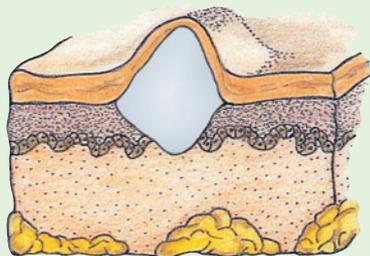
Macule: Flat, nonpalpable change in skin color; smaller than 1 cm (e.g., freckle, petechiae)


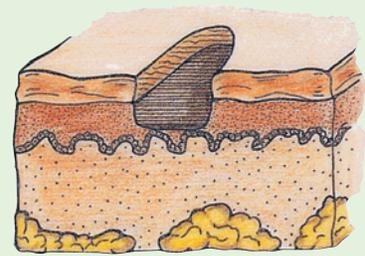
Papule: Palpable, circumscribed, solid elevation in skin; smaller than 1 cm (e.g., elevated nevus)


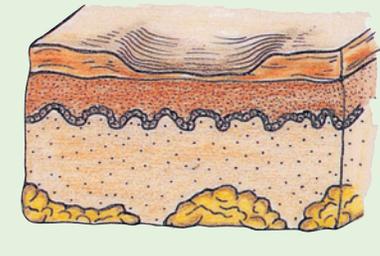
Nodule: Elevated solid mass, deeper and firmer than papule; 1-2 cm (e.g., wart)


Tumor: Solid mass that extends deep through subcutaneous tissue; larger than 1-2 cm (e.g., epithelioma)


Wheal: Irregularly shaped, elevated area or superficial localized edema; varies in size (e.g., hive, mosquito bite)


Vesicle: Circumscribed elevation of skin filled with serous fluid, smaller than 1 cm (e.g., herpes simplex, chickenpox)


Pustule: Circumscribed elevation of skin similar to vesicle but filled with pus; varies in size (e.g., acne, staphylococcal infection)


Ulcer: Deep loss of skin surface that extends to dermis and frequently bleeds and scars; varies in size (e.g., venous stasis ulcer)


Atrophy: Thinning of skin with loss of normal skin furrow, with skin appearing shiny and translucent; varies in size (e.g., arterial insufficiency)

sections of scalp hair, observe characteristics of color and coarseness. Color varies from very light blond to black to gray and is sometimes altered by rinses or dyes. In older adults the hair becomes dull gray, white, or yellow.

Be aware of the normal distribution of hair growth in a man and a woman. At puberty an increase in the amount and distribution of hair occurs for both genders. During the aging process the hair may thin over the scalp, axillae, and pubic areas. Facial hair of older men decreases. A woman with hirsutism has hair growth on the upper lip, chin, and cheeks, with vellus hair becoming coarser over the body. This may be related to an endocrine disorder. For some a change in hair growth negatively affects body image and emotional well-being. The amount of hair covering the extremities is sometimes reduced as a result of aging, or it could result from arterial insufficiency that could reduce hair growth over the lower extremities. In the United States and some other cultures, women commonly shave their legs and axilla, although shaving remains a matter of personal preference among women from all cultures.

Assess for causes of changes in the thickness, texture, and lubrication of scalp hair. At times these are a result of febrile illnesses or scalp diseases that result in hair loss. Conditions such as thyroid disease alter the condition of the hair, making it fine and brittle. Hair loss (**alopecia**) or thinning of the hair is usually related to genetic tendencies or endocrine disorders such as diabetes, thyroiditis, and even menopause. Poor nutrition causes stringy, dull, dry, and thin hair. The oil of sebaceous glands lubricates the hair, but excessively oily hair is associated with androgen hormone stimulation. Dry, brittle hair occurs with aging and excessive use of chemical agents.

Normally the scalp is smooth and inelastic with even coloration. Carefully separate strands of hair and thoroughly inspect the scalp for lesions, which are not easy to notice in thick hair. Note the characteristics of any scalp lesion. For lumps or bruises, ask if the patient has experienced recent head trauma. Moles on the scalp are common, but they can bleed as a result of vigorous combing or brushing. Dandruff or psoriasis frequently causes scaliness or dryness of the scalp.

Careful inspection of hair follicles on the scalp and pubic areas can reveal lice or other parasites. The three types of lice are *Pediculus humanus capitis* (head lice), *Pediculus humanus corporis* (body lice), and *Pediculus pubis* (crab lice). The presence of lice does not mean that a person practices poor hygiene. Lice spread easily, especially among children who play closely together. Head and crab lice attach their eggs to hair. The tiny eggs look like oval particles of dandruff, although the

BOX 31-7 Skin Malignancies

Basal Cell Carcinoma

0.5- to 1-cm crusted lesion that is flat or raised and has a rolled, somewhat scaly border

Frequently appearance of underlying, widely dilated blood vessels within the lesion

Squamous Cell Carcinoma

Occurs more often on mucosal surfaces and nonexposed areas of skin than basal cell

0.5- to 1.5-cm scaly lesion sometimes ulcerated or crusted; appears frequently and grows more rapidly than basal cell

Melanoma

0.5- to 1-cm brown, flat lesion; appears on sun-exposed or nonexposed skin; variegated pigmentation, irregular borders, and indistinct margins

Ulceration, recent growth, or recent changes in long-standing mole are ominous signs

Illustrations from Belcher AE: *Cancer nursing,* St Louis, 1992, Mosby; Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy,* ed 3, St Louis, 1996, Mosby; and Zitelli BJ, McIntyre SC, Nowalk AJ: *Zitelli and Davis' atlas of pediatric physical diagnosis,* ed 6, St Louis, 2012, Saunders.

lice themselves are difficult to see (Figure 31-7). Head and body lice are very small with grayish-white bodies, whereas crab lice have red legs. To better identify infestations, observe for small, red, pustular eruptions in the hair follicles and areas where skin surfaces meet, such as behind the ears and in the groin. A person often has intense itching of the scalp, especially on the back of the head or neck. Combing with

TABLE 31-10 Nursing History for Hair and Scalp Assessment

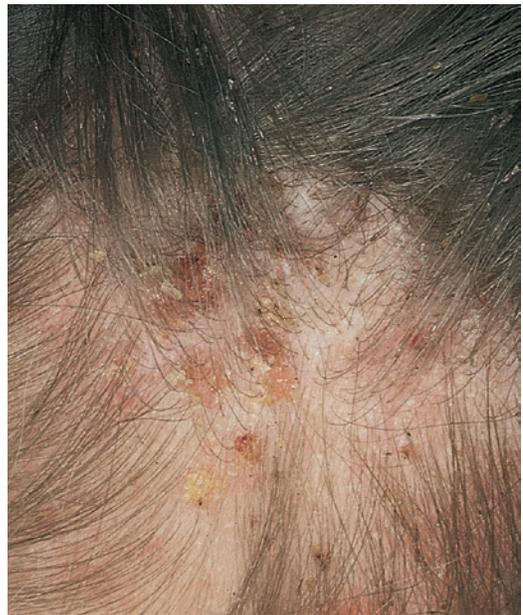
Assessment	Rationale
Ask patient if he or she is wearing a wig or hairpiece and ask him or her to remove it.	Wigs or hairpieces interfere with inspection of hair and scalp. (Patient sometimes requests to omit this part of examination.)
Determine if patient has noted change in growth, loss of hair, or change in texture or color.	Change often occurs slowly over time.
Identify type of hair-care products used for grooming.	Excessive use of chemical agents and burning of hair causes drying and brittleness.
Determine if patient has had chemotherapy (drugs that cause hair loss) recently or taken a vasodilator (minoxidil) for hair growth.	Chemotherapeutic agents kill cells that rapidly multiply such as tumor and normal hair cells. Minoxidil causes excessive hair growth.
Has patient noted changes in diet or appetite?	Nutrition influences condition of hair.


FIGURE 31-7 Head lice infestation. (From Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy,* ed 4, Philadelphia, 2004, Mosby.)

a fine-tooth comb reveals the small oval-shaped lice; discovery of lice requires immediate treatment. Teach the patient to perform best hair and scalp hygiene practices (Box 31-8).

Nails

The condition of the nails reflects a person's general health, state of nutrition, occupation, and habits of self-care. Before assessing the nails, gather a brief history (Table 31-11). The most visible part of the nail is the nail plate, the transparent layer of epithelial cells covering the nail bed (Figure 31-8). The vascularity of the nail bed creates the underlying color of the nail. The semilunar whitish area at the base of the nail bed is called the *lunula,* from which the nail plate grows.

BOX 31-8   PATIENT TEACHING

Hair and Scalp Assessment

Objective
- Patient will perform proper hygiene practices for care of hair and scalp.

Teaching Strategies
- Instruct patient about basic hygiene practices for hair and scalp care.
- Instruct patients who have head lice to shampoo thoroughly with pediculicide (shampoo available at drugstores) in cold water at a basin or sink. Do not use a tub or shower, where the medication can reach other body parts. Comb thoroughly with a fine-tooth comb (following product directions) and discard comb. *Caution: Do not use products containing Lindane, a toxic ingredient known to cause adverse reactions*. Repeat shampoo treatment 12 to 24 hours later.
- After shampooing, remove any detectable nits or nit cases with tweezers or a metal nit comb. A dilute solution of vinegar and water helps loosen nits.
- Instruct patients and parents about ways to reduce transmission of lice:
  - Do not share hair brushes, combs, hairpieces, hats, bedding, towels, or clothing with someone who has head lice.
  - Vacuum all rugs, car seats, pillows, furniture, and flooring thoroughly and discard vacuum bag.
  - Seal nonwashable items in plastic bags for 14 days if unable to dry-clean or vacuum.
  - Use thorough hand hygiene practices.
  - Launder all clothing, linen, and bedding in hot water and detergent; then dry in a hot dryer for at least 31 minutes. Dry-clean nonwashable items.
  - Do not use insecticide.
  - Instruct patient to notify his or her partner if lice were sexually transmitted.
  - Avoid physical contact with infested individuals and their belongings, especially clothing and bedding.
  - Soak any comb or brush used to remove lice for 15 minutes in very hot ammonia water (1 tsp ammonia to 2 cups hot water) or boiling water for 10 minutes.

Evaluation
- Have patient describe methods used to care for hair and scalp.
- Have patient explain the steps to take to reduce lice transmission in the home.

TABLE 31-11   Nursing History for Nail Assessment

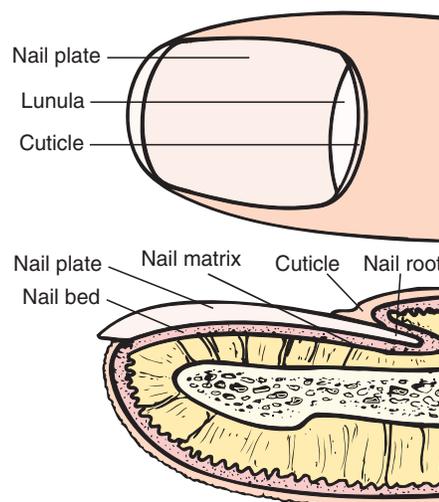
Assessment	Rationale
Ask if patient has experienced recent trauma or changes in nails (splitting, breaking, discoloration, thickening).	Trauma changes shape and growth of nail. Systemic conditions cause changes in color, growth, and shape.
Has patient had other symptoms of pain, swelling, presence of systemic disease with fever, or psychological or physical stress?	Alterations sometimes occur slowly over time.
Question patient's nail care practices. Determine if patient has acrylic nails or silk wraps.	Change in nails can be caused by local or systemic problem. Acrylic nails and silk wraps are areas for fungal growth.
Determine if patient has risks for nail or foot problems (e.g., diabetes, peripheral vascular disease, older adulthood, obesity).	Chemical agents cause drying of nails. Improper care damages nails and cuticles. Vascular changes associated with diabetes and peripheral vascular disease reduce blood flow to peripheral tissues; foot lesions and thickened nails are common. Some older adults have trouble performing foot and nail care because of poor vision, lack of coordination, or inability to bend over. Obese patients have difficulty bending.


FIGURE 31-8 Components of nail unit. (From Lewis SL et al: *Medical-surgical nursing,* ed 9, St Louis, 2014, Mosby.)

Inspection and Palpation. Inspect the nail bed for color, length, symmetry, cleanliness, and configuration. The shape and condition of the nails can give clues to pathophysiological problems. Assess the thickness and shape of the nail, its texture, the angle between the nail and the nail bed, and the condition of the lateral and proximal nail folds around the nail. When inspecting the nails you gather a sense of the patient's hygiene practices. The nails are normally transparent, smooth, well rounded, and convex, with a nail bed angle of about 160 degrees (Box 31-9). A larger angle and softening of the nail bed indicate chronic oxygenation problems. The surrounding cuticles are smooth, intact, and without inflammation. When you assess for basic care of the nails, you recognize that nail biting, stains, and jagged edges either represent poor nail care or are caused by habits or occupational exposure to grease or dirt. Jagged, bitten, or broken nail edges or cuticles predispose a patient to localized infection.

When palpating, expect to find a firm nail base and check for any abnormalities such as erythema or swelling. For patients with impaired circulation, especially observe for early signs of infection or open lesions. To palpate, gently grasp the patient's finger and observe the color of the nail bed. The nail bed and nails appear pink with white nail tips in white patients. In darker-skinned patients the nail beds are darkly pigmented with a blue or reddish hue. A brown or black pigmentation is normal with longitudinal streaks (Figure 31-9). Trauma, cirrhosis, diabetes mellitus, and hypertension cause splinter hemorrhages. Vitamin, protein, and electrolyte changes cause various lines or bands to form on the nail beds.

Nails normally grow at a constant rate, but direct injury or generalized disease changes growth patterns. With aging the nails of the fingers and toes become harder and thicker. Longitudinal striations develop, and the rate of nail growth slows. Nails become more brittle, dull, and

BOX 31-9   Abnormalities of the Nail Bed

160 degrees

Normal nail: Approximately 160-degree angle between nail plate and nail

180 degrees

Clubbing: Change in angle between nail and nail base (eventually larger than 180 degrees); nail bed softening with nail flattening; often enlargement of fingertips
Causes: Chronic lack of oxygen: heart or pulmonary disease

>180 degrees

Beau's lines: Transverse depressions in nails indicating temporary disturbance of nail growth (nail grows out over several months).
Causes: Systemic illness such as severe infection; nail injury

Koilonychia (spoon nail): Concave curves
Causes: Iron deficiency anemia, syphilis, use of strong detergents

Splinter hemorrhages: Red or brown linear streaks in nail bed
Causes: Minor trauma, subacute bacterial endocarditis, trichinosis

Paronychia: Inflammation of skin at base of nail
Causes: Local infection, trauma

BOX 31-10   PATIENT TEACHING

Nail Assessment

Objective
- Patient will properly care for fingernails, feet, and toenails.

Teaching Strategies
- Instruct patient to cut nails only after soaking them about 10 minutes in warm water. (*Exception:* Patients with diabetes or peripheral vascular disease are warned against soaking nails because this can cause maceration of the skin, leading to infection. Long-term soaking also dries out the hands and feet; dry, cracked skin leads to infection.)
- Caution patient against over-the-counter preparations to treat corns, calluses, or ingrown toenails.
- Instruct patient to cut nails straight across and even with tops of fingers or toes. If patient has diabetes, tell him or her to file rather than cut nails (see Chapter 40).
- Instruct patient to shape nails with a file or emery board.
- If patient has diabetes:
  - Wash feet daily in warm water and carefully dry them, especially between toes. Inspect feet each day in good lighting, looking for dry places and cracks in skin. Soften dry feet by applying a cream or lotion such as Nivea, Eucerin, or Alpha Keri.
  - Do not put lotion between toes; moisture between toes allows microorganisms to grow, leading to infections.
  - Caution patient against using sharp objects to poke or dig under toenail or around the cuticle.
  - Have patient see a podiatrist for treatment of ingrown toenails and nails that are thick or tend to split.

Evaluation
- Inspect nails during the next home visit.
- Have patient explain steps to take to avoid injury.

opaque and turn yellow in older adults with insufficient calcium. In addition, the cuticle becomes less thick and wide.

Calluses and corns commonly are found on the toes or fingers. A callus is flat and painless, resulting from a thickening of the epidermis. Friction and pressure from shoes cause corns, usually over bony prominences. During the examination instruct the patient in proper nail care (Box 31-10).

HEAD AND NECK

An examination of the head and neck includes assessment of the head, eyes, ears, nose, mouth, pharynx, and neck (lymph nodes, carotid arteries, thyroid gland, and trachea). During assessment of peripheral arteries also assess the carotid arteries. Assessment of the head and neck uses inspection, palpation, and auscultation, with inspection and palpation often used simultaneously.

Head

Inspection and Palpation.   The nursing history screens for intracranial injury and local or congenital deformities (Table 31-12). Inspect the patient's head, noting the position, size, shape, and contour. The head is normally held upright and midline to the trunk. Holding it tilted to one side acts as a behavioral indicator of a potential unilateral hearing or visual loss or is a physical indicator of muscle weakness in the neck. A horizontal jerking or bobbing indicates a tremor.

Note the patient's facial features, looking at the eyelids, eyebrows, nasolabial folds, and mouth for shape and symmetry. It is normal for

FIGURE 31-9 Pigmented bands in nail of patient with dark skin. (From Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy,* ed 5, St Louis, 2010, Mosby.)

slight asymmetry to exist. If there is facial asymmetry, note if all features on one side of the face are affected or if only a part of the face is involved. Various neurological disorders (e.g., facial nerve paralysis) affect different nerves that innervate muscles of the face.

Examine the size, shape, and contour of the skull. The skull is generally round with prominences in the frontal area anteriorly and the occipital area posteriorly. Trauma typically causes local skull deformities. In infants a large head results from congenital anomaly or the buildup of cerebrospinal fluid in the ventricles (hydrocephalus). Some adults have enlarged jaws and facial bones resulting from acromegaly,

a disorder caused by excessive secretion of growth hormone. Palpate the skull for nodules or masses. Gently rotate the fingertips down the midline of the scalp and along the sides of the head to identify abnormalities. Palpate the temporomandibular joint (TMJ) space bilaterally. Place the fingertips just anterior to the tragus of each ear. The fingertips should slip into the joint space as the patient's mouth opens to gently palpate the joint spaces. Normally the movements should be smooth, although it is not unusual to hear or feel a clicking, grating or snapping in the TMJ, indicating degenerative joint disease (Ball et al., 2015).

Eyes

Examination of the eyes includes assessment of visual acuity, visual fields, extraocular movements, and external and internal eye structures. Figure 31-10 shows a cross-section of the eye. The eye assessment detects visual alterations and determines the general level of assistance that patients require when ambulating or performing self-care activities. Some patients with visual problems also need special aids for reading educational materials or instructions (e.g., medication labels). Table 31-13 reviews the nursing history for an eye examination. Box 31-11 describes common types of visual problems.

TABLE 31-12 Nursing History for Head Assessment

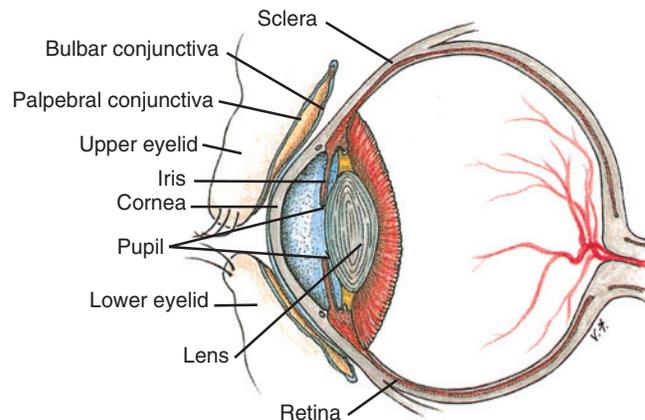
Assessment	Rationale
Determine if patient experienced recent head trauma. If so, assess state of consciousness after injury (immediately on return and 5 minutes later), duration of unconsciousness, and predisposing factors (e.g., seizure, poor vision, blackout).	Trauma is major cause for lumps, bumps, cuts, bruises, or deformities of scalp or skull. Loss of consciousness following head injury indicates possible brain injury.
Ask if patient has history of headache; note onset, duration, character, pattern, and associated symptoms.	Character of headache helps to reveal causative factors such as sinus infection, migraine, or neurological disorders.
Determine length of time patient has experienced neurological symptoms.	Duration of signs or symptoms reveals severity of problem.
Review patient's occupational history for use of safety helmets.	Nature of some occupations creates a risk for head injury.
Ask if patient participates in contact sports, cycling, rollerblading, or skateboarding.	These activities require use of safety helmets.


FIGURE 31-10 Cross-section of eye.

TABLE 31-13 Nursing History for Eye Assessment

Assessment	Rationale
Determine if patient has history of eye disease (e.g., glaucoma, retinopathy, cataracts), eye trauma, diabetes, hypertension, or eye surgery.	Some diseases or trauma cause risk for partial or complete visual loss. Patient may have had surgery for a visual disorder.
Determine problems that prompted patient to seek health care. Ask patient about eye pain, photophobia (sensitivity to light), burning or itching, excess tearing or crusting, diplopia (double vision) or blurred vision, awareness of a "film" or "curtain" over field of vision, floaters (small, black spots that seem to float across field of vision), flashing lights, or halos around lights.	Common symptoms of eye disease indicate need for health care provider.
Determine whether there is family history of eye disorders or diseases.	Certain eye problems such as glaucoma or retinitis pigmentosa are inherited.
Review patient's occupational history and recreational hobbies. Are safety glasses worn?	Performance of close, intricate work causes eye fatigue. Working with computers causes eye strain. Certain occupational tasks (e.g., working with chemicals) and recreational activities (e.g., fencing, motorcycle riding) place people at risk for eye injury unless they take precautions.
Ask patient if he or she wears glasses or contacts and, if so, how often.	Patients need to wear glasses or contacts during certain parts of examination for accurate assessment.
Determine when patient last visited ophthalmologist or optometrist.	Date of last eye examination reveals level of preventive care patient takes.
Assess medications patient is taking, including eyedrops or ointment.	Determines need to assess patient's knowledge of medications. Certain medications cause visual symptoms.

BOX 31-11   Common Eye and Vision Problems

Hyperopia
Hyperopia is farsightedness, a refractive error in which rays of light enter the eye and focus behind the retina. People are able to clearly see distant objects but not close objects.

Myopia
Myopia is nearsightedness, a refractive error in which rays of light enter the eye and focus in front of the retina. People are able to clearly see close objects but not distant objects.

Presbyopia
Presbyopia is impaired near vision in middle-age and older adults caused by loss of elasticity of the lens and associated with the aging process.

Retinopathy
Retinopathy is a noninflammatory eye disorder resulting from changes in retinal blood vessels. It is a leading cause of blindness.

Strabismus
Strabismus is a (congenital) condition in which both eyes do not focus on an object simultaneously; these eyes appear crossed. Impairment of the extra-ocular muscles or their nerve supply causes strabismus.

Cataracts
A cataract is an increased opacity of the lens, which blocks light rays from entering the eye. Cataracts sometimes develop slowly and progressively after age 35 or suddenly after trauma. They are one of the most common eye dis-orders. Most older adults (65 years old and older) have some evidence of visual impairment from cataracts.

Glaucoma
Glaucoma is intraocular structural damage resulting from elevated intraocular pressure. Obstruction of the outflow of aqueous humor causes this. Without treatment the disorder leads to blindness.

Macular Degeneration
Macular degeneration is associated with aging and results in damaging sharp and central vision. There are two types of macular degeneration: wet and dry. Wet AMD occurs when abnormal blood vessels behind the retina start to grow under the macula, ultimately leading to blood and fluid leakage. Dry AMD occurs when the macula thins over time as part of the aging process, gradually blurring central vision (CDC, 2013). Macular degeneration is one of the leading causes of blindness and low vision in the United States (CDC, 2013). There is no cure.

BOX 31-12   PATIENT TEACHING

Eye Assessment

Objective
- Patient will follow recommendations for regular eye examinations and prevention of injury.

Teaching Strategies
- Explain recommended frequency for eye testing with a Snellen chart and examination (see Table 31-3).
- Describe the typical symptoms of eye disease.
- Instruct older adult to take the following precautions because of normal vision changes: avoid or use caution while driving at night, increase lighting in the home to reduce risk of falls, and paint the first and last steps of a staircase and the edge of each of the other steps a bright color to aid depth perception.
- Remind patient that wearing protective eyewear prevents injury from debris and splashes.

Evaluation
- Ask patient or family member to report on patient's most recent visit to an ophthalmologist.
- Have patient describe when to have an eye examination.
- Ask patient to describe common symptoms of eye disease.
- Observe the home environment of a patient with visual deficits.

Modified from Agency for Healthcare Research and Quality: *Guide to clinical preventive services,* AHRQ Publication No. 14-05158, 2014, Rockville, MD, http://www.ahrq.gov/professionals/clinicians-providers/guidelines-recommendations/guide/cpsguide.pdf. Accessed November 13, 2014.

line for which the patient is able to read all of the letters correctly and record the visual acuity for that line. Repeat the test with the patient wearing corrective lenses. Complete the test rapidly enough so the patient does not memorize the chart (Ball et al., 2015). If a patient is unable to read, use an *E* chart or one with pictures of familiar objects. Instead of reading letters, patients tell which direction each *E* is pointing or the name of the object.

The Snellen chart has standardized numbers at the end of each line of the chart. The numerator is the number 20, or the distance the patient stands from the chart. The denominator is the distance from which the normal eye is able to read the chart. Normal visual acuity is 20/20. The larger the denominator, the poorer the patient's visual acuity. For example, a value of 20/40 means that the patient, standing 20 feet away, can read a line that a person with normal vision can read from 40 feet away. Record visual acuity for each eye and both eyes and record whether the test was performed with or without correction (including glasses or contact lenses).

If patients cannot read even the largest letters or figures of a Snellen chart, test their ability to count upraised fingers or distinguish light. Hold a hand 31 cm (1 foot) from the patient's face and have him or her count the upraised fingers. To check light perception shine a pen-light into the eye and turn off the light. If the patient notes when the light is turned on or off, light perception is intact.

Assess near vision by asking the patient to read a handheld card containing a vision screening chart. The patient holds the card a comfortable distance (5 to 6 cm [about $12\frac{1}{2}$ to 14 inches]) from the eyes and reads the smallest line possible. This part of the examina-tion is a good time to discuss the need for routine eye examinations (Box 31-12).

Visual Acuity. The assessment of visual acuity (i.e., the ability to see small details) tests central vision. The easiest way to assess near vision is to ask patients to read printed material under adequate light-ing. If patients wear glasses, make sure that they wear them during the assessment. Determine the language the patient speaks and his or her reading ability. Asking patients to read aloud helps to determine lit-eracy. If the patient has difficulty reading, move to the next step.

Assessment of distant vision requires using a Snellen chart (paper chart or projection screen). The chart should be well lit. Test vision without corrective lenses first. Have the patient sit or stand 6.1 m (20 feet) away from the chart and try to read all of the letters beginning at any line with both eyes open. Then have the patient read the line with each eye separately (patient covers the opposite eye with an index card or eye cover to avoid applying pressure to the eye). Note the smallest

FIGURE 31-11 Six directions of gaze. Direct patient to follow finger movement through each gaze. *CN,* Cranial nerve.

Extraocular Movements. Six small muscles guide the movement of each eye. Both eyes move parallel to one another in each of the six directions of gaze (Figure 31-11). To assess extraocular movements, a patient sits or stands, and the nurse faces the patient from 60 cm (2 feet) away. The nurse holds a finger at a comfortable distance (15 to 31 cm [6 to 12 inches]) from the patient's eyes. While the patient maintains his or her head in a fixed position facing forward, the nurse directs him or her to follow with the eyes only as the nurse's finger moves to the right, left, and diagonally up and down to the left and right. The nurse moves the finger smoothly and slowly within the normal field of vision.

As the patient gazes in each direction, observe for parallel eye movement, the position of the upper eyelid in relation to the iris, and the presence of abnormal movements. As the eyes move through each direction of gaze, the upper eyelid covers the iris only slightly. **Nystagmus**, an involuntary, rhythmical oscillation of the eyes, occurs as a result of local injury to eye muscles and supporting structures or a disorder of the cranial nerves innervating the muscles. Initiate nystagmus in patients with normal eye movements by having them gaze to the far left or right.

Visual Fields. As a person looks straight ahead, he or she normally is able to see all objects in the periphery. To assess visual fields direct the patient to stand or sit 60 cm (2 feet) away at eye level. The patient gently closes or covers one eye (e.g., the left) and looks at your eye directly opposite. You close your opposite eye (in this case the right) so the field of vision is superimposed on that of the patient. Next move a finger equidistant between you and the patient outside the field of vision and slowly bring it back into the visual field. The patient reports when he or she is able to see the finger. If you see the finger before the patient does, a part of the patient's visual field is reduced. To test temporal field vision, hold an object or your finger slightly behind the patient. Repeat the procedure for each field of vision for the other eye. Patients with visual field problems are at risk for injury because they cannot see all of the objects in front of them. Older adults commonly have loss of peripheral vision caused by changes in the lens.

External Eye Structures. To inspect external eye structures, stand directly in front of the patient at eye level and ask him or her to look at your face.

Position and Alignment. Assess the position of the eyes in relation to one another. Normally they are parallel to one another. Bulging eyes (exophthalmos) usually indicate hyperthyroidism. Crossed eyes (strabismus) result from neuromuscular injury or inherited abnormalities. Tumors or inflammation of the orbit often cause abnormal eye protrusion.

For the remainder of the eye examination have the patient remove contact lenses.

Eyebrows. Inspect the eyebrows for size, extension, texture of hair, alignment, and movement. Normally the eyebrows are symmetrical. Coarseness of hair and failure to extend beyond the temporal canthus possibly reveals hypothyroidism. Thin brows may be a result of waxing or plucking. Aging causes loss of the lateral third of the eyebrows. To assess movement, ask the patient to raise and lower the eyebrows. The brows normally raise and lower symmetrically. An inability to move them indicates a facial nerve paralysis (cranial nerve VII).

Eyelids. Inspect the eyelids for position; color; condition of the surface; condition and direction of the eyelashes; and the patient's ability to open, close, and blink. When the eyes are open in a normal position, the lids cover the sclera above the iris but not the pupil. The lids are also close to the eyeball. An abnormal drooping of the lid over the pupil is called **ptosis** (pronounced "toe-sis"), caused by edema or impairment of the third cranial nerve. In the older adult ptosis results from a loss of elasticity that accompanies aging. You observe for defects in the position of the lid margins. An older adult frequently has lid margins that turn out (**ectropion**) or in (**entropion**). Entropion sometimes leads to the lashes of the lid irritating the conjunctiva and cornea, increasing the risk of infection. Normally the eyelashes are distributed evenly and curved outward away from the eye. An erythematous or yellow lump (hordeolum or sty) on the follicle of an eyelash indicates an acute suppurative inflammation.

To inspect the surface of the upper lids ask the patient to close his or her eyes while observing for lid tremors. Normally the lids are smooth and the same color as the surrounding skin. Redness indicates inflammation or infection. Lid edema is sometimes caused by allergies or heart or kidney failure. Edema of the eyelids prevents them from closing. Inspect any lesions for typical characteristics and discomfort or drainage. Wear clean gloves if drainage is present.

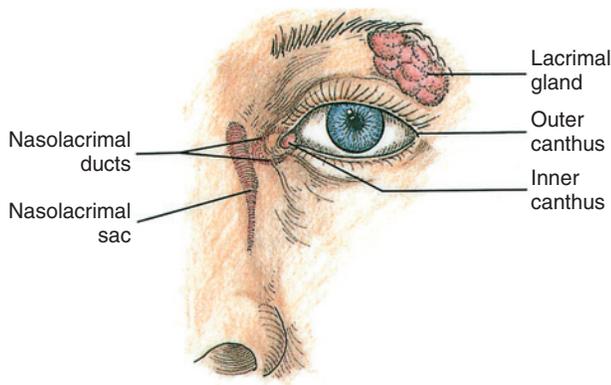
The lids normally close symmetrically. Their failure to close exposes the cornea to drying. This condition is common in unconscious patients or those with facial nerve paralysis. To inspect the lower lids, ask the patient to open the eyes again while you look for the same characteristics noted for the upper lids. Normally a patient blinks involuntarily and bilaterally up to 20 times a minute. The blink reflex


FIGURE 31-12 The lacrimal apparatus secretes and drains tears, which moisten and lubricate eye structures.

FIGURE 31-13 Chart depicting pupillary size in millimeters.

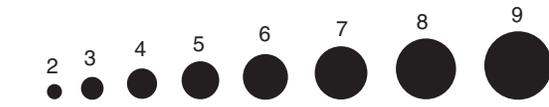
lubricates the cornea. Report absent, infrequent, rapid, or monocular (one-eyed) blinking.

Lacrimal Apparatus. The lacrimal gland (Figure 31-12), located in the upper outer wall of the anterior part of the orbit, is responsible for tear production. Tears flow from the gland across the surface of the eye to the lacrimal duct, which is in the nasal corner or inner canthus of the eye. The lacrimal gland is sometimes the site of tumors or infections and should be inspected for edema and redness. Palpate the gland gently to detect tenderness; normally tenderness cannot be felt.

The nasolacrimal duct sometimes becomes obstructed, blocking the flow of tears. Observe for evidence of edema in the inner canthus. Gentle palpation of the duct at the lower eyelid just inside the lower orbital rim causes a regurgitation of tears.

Conjunctivae and Sclerae. The bulbar conjunctiva covers the exposed surface of the eyeball up to the outer edge of the cornea. Observe the sclera under the bulbar conjunctiva; normally it has the color of white porcelain in light-skinned patients and is light yellow in dark-skinned patients. Sclerae become pigmented and appear either yellow or green if liver disease is present.

Take care when inspecting the conjunctivae. For adequate exposure of the bulbar conjunctiva, retract the eyelids without placing pressure directly on the eyeball. Gently retract both lids, with the thumb and index finger pressed against the lower and upper bony orbits. Ask the patient to look up, down, and from side to side. Many patients begin to blink, making the examination difficult. Inspect for color, texture, and the presence of edema or lesions. Normally the conjunctivae are free of erythema. The presence of redness indicates an allergic or infectious **conjunctivitis**. Bright red blood in a localized area surrounded by normal-appearing conjunctiva usually indicates subconjunctival hemorrhage. Conjunctivitis is a highly contagious infection. It is easy to spread the crusty drainage that collects on eyelid margins from one eye to the other. Wear clean gloves during the examination. Performing proper hand hygiene is necessary before and after the examination.

Corneas. The cornea is the transparent, colorless part of the eye covering the pupil and iris. From a side view it looks like the crystal of a wristwatch. While the patient looks straight ahead, inspect the cornea for clarity and texture while shining a penlight obliquely across its entire surface. The cornea is normally shiny, transparent, and smooth. In older adults it loses its luster. Any irregularity in the surface indicates an abrasion or tear that requires further examination by a health care provider. Both conditions are very painful. Note the color and details of the underlying iris. In an older adult the iris becomes faded. A thin white ring along the margin of the iris, called an **arcus senilis**, is common with aging but is abnormal in anyone under age 40. To test


for the corneal blink reflex, see the cranial nerve test section of this chapter.

Pupils and Irises. Observe the pupils for size, shape, equality, accommodation, and reaction to light. They are normally black, round, regular, and equal in size (3 to 7 mm in diameter) (Figure 31-13). The iris should be clearly visible.

Cloudy pupils indicate cataracts. Dilated pupils result from glaucoma, trauma, neurological disorders, eye medications (e.g., atropine), or withdrawal from opioids. Inflammation of the iris or use of drugs (e.g., pilocarpine, morphine, or cocaine) causes constricted pupils. Pinpoint pupils are a common sign of opioid intoxication. Shining a beam of light through the pupil and onto the retina stimulates the third cranial nerve, causing the muscles of the iris to constrict. Any abnormality along the nerve pathways from the retina to the iris alters the ability of the pupils to react to light. Changes in intracranial pressure, lesions along the nerve pathways, locally applied ophthalmic medications, and direct trauma to the eye alter pupillary reaction.

Test pupillary reflexes (to light and accommodation) in a dimly lit room. Instruct the patient to avoid looking directly at the light. While the patient looks straight ahead, bring a penlight from the side of his or her face, directing the light onto the pupil (Figure 31-14). A directly illuminated pupil constricts, and the opposite pupil constricts consensually. Observe the quickness and equality of the reflex. Repeat the examination for the opposite eye.

To test for accommodation, ask the patient to gaze at a distant object (the far wall) and then at a test object (finger or pencil) held approximately 10 cm (4 inches) from the bridge of his or her nose. The pupils normally converge and accommodate by constricting when looking at close objects. The pupillary responses are equal. Testing for accommodation is only important if the patient has a defect in the pupillary response to light (Ball et al., 2015). If assessment of pupillary reaction is normal in all tests, record the abbreviation **PERRLA** (pupils equal, round, reactive to light, and accommodation).

Internal Eye Structures. The examination of the internal eye structures through the use of an ophthalmoscope is beyond the scope of new graduate nurses' practice. Advanced nurse practitioners use the ophthalmoscope to inspect the fundus (Figure 31-15), which includes the retina, choroid, optic nerve disc, macula, fovea centralis, and retinal vessels. Patients in greatest need of an examination are those with diabetes, hypertension, and intracranial disorders.

Ears

The ear assessment determines the integrity of ear structures and hearing acuity. The three parts of the ear are the external, middle, and inner ear (Figure 31-16). Inspect and palpate external ear structures, which consist of the auricle, outer ear canal, and tympanic membrane (eardrum). The ear canal is normally curved and approximately 2.5 cm (1 inch) long in an adult. It is lined with skin containing fine hairs, nerve endings, and glands secreting cerumen. The middle ear is inspected with an otoscope. It is an air-filled cavity containing the three bony ossicles (malleus, incus, and stapes). The eustachian tube connects the middle ear to the nasopharynx. Pressure between the outer atmosphere and the middle ear is stabilized through this tube. Finally the inner ear is tested by measuring a patient's hearing acuity. The inner ear contains the cochlea, vestibule, and semicircular canals.

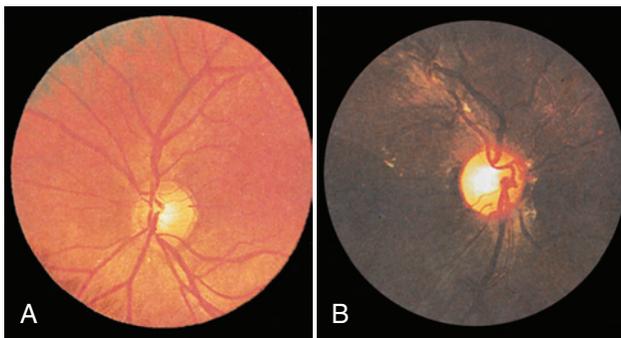
FIGURE 31-14 A, To check pupillary reflexes the nurse first holds penlight to side of patient's face. **B,** Illumination of pupil causes pupillary constriction.


FIGURE 31-15 Fundus of white patient **(A)** and black patient **(B).** (Courtesy MEDCOM, Cypress, CA.)

Assessing the ears determines the integrity of ear structures and the condition of hearing. Use nursing history data to identify patients' risks for hearing disorders (Table 31-14).

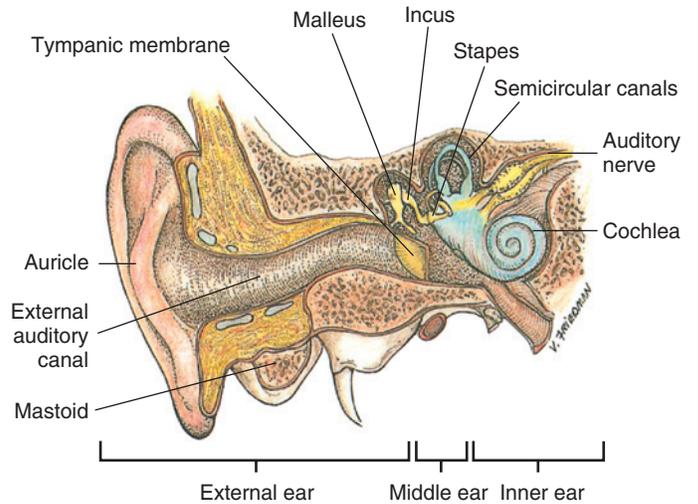
Understanding the mechanisms for sound transmission helps identify the nature of hearing disorders. Sound travels through the ear by air and bone conduction. Nerve impulses from the cochlea travel to the auditory nerve (eighth cranial nerve) and the cerebral cortex. Disorders of the ear result from several types of problems, including mechanical dysfunction (blockage by cerumen or foreign body),


FIGURE 31-16 Structures of external, middle, and inner ear.
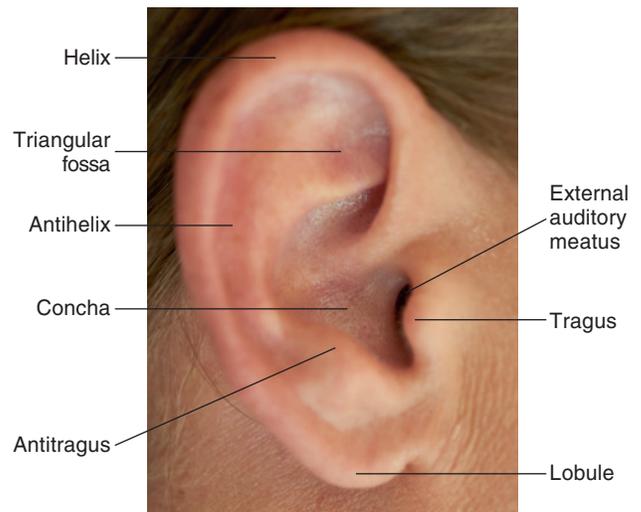

FIGURE 31-17 Anatomical structures of auricle.

trauma (foreign bodies or noise exposure), neurological disorders (auditory nerve damage), acute illnesses (viral infection), and toxic effects of medications.

Auricles. With the patient sitting comfortably, inspect the size, shape, symmetry, landmarks, position, and color of the auricle (Figure 31-17). The auricles are normally of equal size and level with one another. The upper point of attachment is in a straight line with the lateral canthus, or corner of the eye. The position of the auricle is almost vertical. Ears that are low set or at an unusual angle are a sign of chromosome abnormality such as Down syndrome. Ear color is usually the same as that of the face, without moles, cysts, deformities, or nodules. Redness is a sign of inflammation or fever. Extreme pallor indicates frostbite.

Palpate the auricles for texture, tenderness, and skin lesions. Auricles are normally smooth and without lesions. If a patient complains of pain, gently pull the auricle, press on the tragus, and palpate behind the ear over the mastoid process. If palpating the external ear increases the pain, an external ear infection is likely. If palpating the auricle and tragus does not influence the pain, the patient can have a middle ear infection. Tenderness in the mastoid area indicates mastoiditis.

TABLE 31-14 Nursing History for Ear Assessment

Assessment	Rationale
Ask if patient has experienced ear pain, itching, discharge, vertigo, tinnitus (ringing in ears), or change in hearing.	These signs and symptoms indicate infection or hearing loss.
Assess risks for hearing problem. *Infants/children:* Hypoxia at birth, meningitis, birth weight less than 1500 g, family history of hearing loss, congenital anomalies of skull or face, nonbacterial intrauterine infections (rubella, herpes), maternal drug use, excessively high bilirubin, head trauma *Adolescents:* Frequent exposure to loud music from concerts, car radios, and cell phone or iPods while wearing headphone, earbuds, or other devices *Adults:* Exposure to industrial or recreational noise, genetic disease (Ménière's disease), neurodegenerative disorder	Risk factors predispose patient to permanent hearing loss. It is difficult to assess infant's hearing status with examination only.
Determine patient's exposure to loud noises at work and availability of protective devices.	Prolonged noise exposure causes temporary or permanent hearing loss.
Note behaviors indicative of hearing loss such as failure to respond when spoken to, requests to repeat comments, leaning forward to hear, and child's inattentiveness or use of monotonous voice tone.	People with hearing loss cope with sensory deficit through a variety of behavioral cues.
Assess if patient takes large doses of aspirin or other ototoxic drugs (e.g., aminoglycosides, furosemide, streptomycin, cisplatin, ethacrynic acid).	Medications have side effects of hearing loss.
Determine whether patient uses hearing aid.	Determination allows you to assess patient's ability to care for device and adjust voice tone to communicate.
If patient had recent hearing problem, note onset, contributing factors, affected ear, and effect on activities of daily living.	Helps determine nature and severity of hearing problem.
Determine whether patient has repeated history of cerumen buildup in ear.	Cerumen impaction is common cause for conduction deafness.

Inspect the opening of the ear canal for size and presence of discharge. If discharge is present, wear clean gloves. A swollen or occluded meatus is not normal. A yellow, waxy substance called **cerumen** is common. Yellow or green, foul-smelling discharge indicates infection or a foreign body.

Ear Canals and Eardrums. Observe the deeper structures of the external and middle ear with the use of an otoscope. A special ear speculum attaches to the handle of the ophthalmoscope. For best visualization select the largest speculum that fits comfortably in the patient's ear. Before inserting the speculum, check for foreign bodies in the opening of the auditory canal.

Make sure that the patient avoids moving the head during the examination to avoid damage to the canal and tympanic membrane. Infants and young children might need to be held securely to prevent movement. Lay infants supine with head turned to one side and arms held securely at the sides. Have young children sit on their parents' laps with their legs held between the parents' knees.

Turn on the otoscope by rotating the dial at the top of the handle. To insert the speculum properly, ask the patient to tip the head slightly toward the opposite shoulder. Hold the handle of the otoscope in the space between the thumb and index finger, supported on the middle finger. This leaves the ulnar side of the hand to rest against the patient's head, stabilizing the otoscope as you insert it into the canal (Ball et al., 2015). There are two ways to grip the otoscope: (1) hold the handle along the patient's face with the fingers against the face or neck; and (2) lightly brace the inverted otoscope against the side of the patient's head or cheek. This latter grip, used with children, prevents accidental movement of the otoscope deeper into the ear canal. Insert the scope while pulling the auricle upward and backward in the adult and older child (Figure 31-18). This maneuver straightens the ear canal. For infants the auricle should be pulled down and back.

FIGURE 31-18 Otoscopic examination. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

Insert the speculum slightly down and forward 1 to 1.5 cm ($\frac{1}{2}$ inch) into the ear canal. Take care not to scrape the sensitive lining, which is painful. The ear canal normally has little cerumen and is uniformly pink with tiny hairs in the outer third of the canal. Observe for color, discharge, scaling, lesions, foreign bodies, and cerumen. Normally cerumen is dry (light brown to gray and flaky) or moist (dark yellow or brown) and sticky. Dry cerumen is common in Asians and Native Americans (Ball et al., 2015). A reddened canal with discharge is a sign of inflammation or infection. In other adults accumulated cerumen is a common problem; buildup creates a mild hearing loss. During the examination ask the patient about methods he or she uses to clean the ear canal (Box 31-13).

Ear Assessment

Objective
- Patient will follow preventive guidelines for screening of hearing loss and proper cleaning technique for the ears.

Teaching Strategies
- Explain that noise-induced hearing loss can lead to communication difficulties, learning difficulties, pain or ringing in the ears (tinnitus), distorted or muffled hearing, and an inability to hear some environmental sounds and warning signals.
- Apply cultural sensitivity in encouraging patients to adopt behaviors to protect their hearing (CDC, 2015a):
  - Avoid or limit exposure to excessively loud sounds
  - Turn down the volume of music systems
  - Move away from the source of loud sounds when possible
  - Use hearing protection devices when it is not feasible to avoid exposure to loud sounds or to reduce them to a safe levels
- Instruct patient in the proper way to clean the outer ear (see Chapter 40), avoiding use of cotton-tipped applicators and sharp objects such as hairpins, which cause impaction of cerumen deep in the ear canal or trauma.
- Tell patient to avoid inserting pointed objects into the ear canal.
- Encourage patients over age 65 to have regular hearing checks. Explain that a reduction in hearing is a normal part of aging (see Chapter 49).
- Instruct family members of patients with hearing loss to avoid shouting; speak in slower, low tones; and be sure that patient is able to see the speaker's face.

Evaluation
- Have patient describe ways he or she can protect hearing at home.
- Ask patient to explain the proper technique for cleaning the ears.
- In a follow-up visit question patient about frequency of hearing checks.
- Observe patient with hearing loss interacting with family members.

FIGURE 31-19 Normal right tympanic membrane. (Courtesy Dr. Richard A. Buckingham, Abraham Lincoln School of Medicine, University of Illinois, Chicago.)

The light from the otoscope allows visualization of the tympanic membrane. Know the common anatomical landmarks and their appearances (Figure 31-19). Gently move the otoscope so the entire tympanic membrane and its periphery are visible. Because the tympanic membrane is angled away from the ear canal, the light from the otoscope appears as a cone shape rather than a circle. A ring of fibrous cartilage surrounds the oval membrane. The umbo is near the center of the membrane, behind which is the attachment of the malleus. The underlying short process of the malleus creates a knoblike structure at the top of the drum. Check carefully to make sure that there are no tears or breaks in the membrane. The normal tympanic membrane is translucent, shiny, and pearly gray. It is free from tears or breaks. A pink or red bulging membrane indicates inflammation. A white color reveals pus behind it. The membrane is taut, except for the small triangular pars flaccida near the top. If cerumen is blocking the tympanic membrane, warm water irrigation safely removes the wax.

Hearing Acuity. A patient with a hearing loss often fails to respond to conversation. The three types of hearing loss are conduction, sensorineural, and mixed. A conduction loss interrupts sound waves as they travel from the outer ear to the cochlea of the inner ear because the sound waves are not transmitted through the outer and middle ear structures. For example, causes of a conduction loss include swelling of the auditory canal and tears in the tympanic membrane. A sensorineural loss involves the inner ear, auditory nerve, or hearing center of the brain. Sound is conducted through the outer and middle ear structures, but the continued transmission of sound becomes interrupted at some point beyond the bony ossicles. A mixed loss involves a combination of conduction and sensorineural loss. Patients working or living around loud noises and those who listen to loud music are at risk for hearing loss. According to the CDC (2015a) an estimated 12.5% of children and adolescents 6 to 19 years of age (approximately 5.2 million) and 17% of adults 20 to 69 years of age (approximately 26 million) have suffered permanent damage to their hearing from excessive exposure to noise.

Older adults experience an inability to hear high-frequency sounds and consonants (e.g., *S, Z, T,* and *G)*. Deterioration of the cochlea and thickening of the tympanic membrane cause older adults to gradually lose hearing acuity. They are especially at risk for hearing loss caused by **ototoxicity** (injury to auditory nerve) resulting from high maintenance doses of antibiotics (e.g., aminoglycosides).

To conduct a hearing assessment, have the patient remove any hearing aid if worn. Note his or her response to questions. Normally he or she responds without excessive requests to have the questions repeated. If a hearing loss is suspected, check the patient's response to the whispered voice. Test one ear at a time while the patient occludes the other ear with a finger. Ask him or her to gently move the finger up and down during the test in response to the whispered sound. While standing 31 to 60 cm (1 to 2 feet) from the testing ear, speak while covering the mouth so the patient is unable to read lips. After exhaling fully, whisper softly toward the unoccluded ear, reciting random numbers with equally accented syllables such as *nine-four-ten.* If necessary, gradually increase voice intensity until the patient correctly repeats the numbers. Then test the other ear for comparison. Ball et al. (2015) report that patients normally hear numbers clearly when whispered, responding correctly at least 50% of the time.

If a hearing loss is present, test the hearing using a tuning fork. A tuning fork of 256 to 512 hertz (Hz) is most commonly used. The tuning fork allows for comparison of hearing by bone conduction with that of air conduction. Hold the base of the tuning fork with one hand without touching the tines. Tap the fork lightly against the palm of the other hand to set it in vibration (Table 31-15).

Nose and Sinuses

Use inspection and palpation to assess the integrity of the nose and sinuses. The patient sits during the examination. A penlight allows for gross examination of each naris. A more detailed examination requires use of a nasal speculum to inspect the deeper nasal turbinates. Do not use a speculum unless a qualified practitioner such as a nurse educator or an advanced practice nurse is present. Table 31-16 lists components of the nursing history.

TABLE 31-15 Tuning Fork Tests

Tests and Steps	Rationale
Weber's Test (Lateralization of Sound) Hold fork at its base and tap it lightly against heel of palm. Place base of vibrating fork on midline vertex of patient's head or middle of forehead (see illustration *A*). Ask patient if he or she hears the sound equally in both ears or better in one ear (lateralization).	Patient with normal hearing hears sound equally in both ears. In conduction deafness sound is heard best in impaired ear. In sensorineural hearing loss, sound is heard better in normal ear.
Rinne Test (Comparison of Air and Bone Conduction) Place stem of vibrating tuning fork against patient's mastoid process (see illustration *B*). Begin counting the interval with your watch. Ask patient to tell you when he or she no longer hears the sound; note number of seconds. Quickly place still-vibrating tines 1 to 2 cm (½ to 1 inch) from ear canal and ask patient to tell you when he or she no longer hears the sound (see illustration *C*). Continue counting time the sound is heard by air conduction. Compare number of seconds the sound is heard by bone conduction versus air conduction.	Patient should hear air-conducted sound twice as long as bone-conducted sound (2:1 ratio). For example, if patient hears bone-conducted sound for 10 seconds, he or she should hear air-conducted sound for an additional 10 seconds. In conduction deafness patient hears bone conduction longer than air conduction in affected ear. In sensorineural loss patient hears air conduction longer than bone conduction in affected ear, but at less than a 2:1 ratio (Ball et al., 2015).

Nose. When inspecting the external nose, observe for shape, size, skin, color, and the presence of deformity or inflammation. The nose is normally smooth and symmetrical with the same skin color as the face. Recent trauma sometimes causes edema and discoloration. If swelling or deformities exist, gently palpate the ridge and soft tissue of the nose by placing one finger on each side of the nasal arch and gently moving the fingers from the nasal bridge to the tip. Note any tenderness, masses, or underlying deviations. Nasal structures are usually firm and stable.

Air normally passes freely through the nose when a person breathes. To assess patency of the nares, place a finger on the side of the patient's nose and occlude one naris. Ask the patient to breathe with the mouth closed. Repeat the procedure for the other naris.

While illuminating the anterior nares, inspect the mucosa for color, lesions, discharge, swelling, and evidence of bleeding. If discharge is present, apply gloves. Normal mucosa is pink and moist without lesions. Pale mucosa with clear discharge indicates allergy. A mucoid discharge indicates rhinitis. A sinus infection results in yellowish or

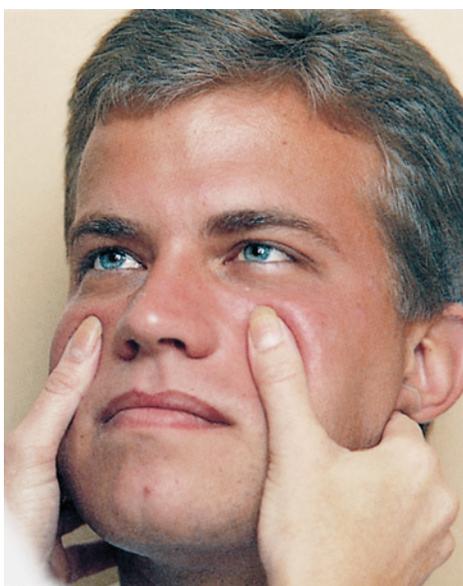
TABLE 31-16 **Nursing History for Nose and Sinus Assessment**	
Assessment	**Rationale**
Ask if patient has had trauma to nose.	Trauma causes septal deviation and asymmetry of external nose.
Ask if patient has history of allergies, nasal discharge, epistaxis (nosebleeds), or postnasal drip.	History is useful in determining source or nature of nasal and sinus drainage.
If there is history of nasal discharge, assess color, amount, odor, duration, and associated symptoms (e.g., sneezing, nasal congestion, obstruction, or mouth breathing).	Aids in ruling out presence of infection, allergy, or drug use.
Assess for history of nosebleed, including site, frequency, amount of bleeding, treatment, and difficulty stopping bleeding.	Characteristics sometimes reveal trauma, medication use, or excessive dryness as causative factors.
Ask if patient uses nasal spray or drops, including amount, frequency, and duration of use.	Overuse of over-the-counter nasal preparations causes physical change in mucosa.
Ask if patient snores at night or has difficulty breathing.	Difficulty breathing or snoring indicates septal deviation or obstruction.


FIGURE 31-20 Palpation of maxillary sinuses.

greenish discharge. Habitual use of intranasal cocaine and opioids causes puffiness and increased vascularity of the nasal mucosa. For the patient with a nasogastric tube, routinely check for local skin breakdown (**excoriation**) of the naris, characterized by redness and skin sloughing.

To view the septum and turbinates, have the patient tip the head back slightly to provide a clear view. Illuminate the septum and observe for alignment, perforation, or bleeding. Normally the septum is close to the midline and thicker anteriorly than posteriorly. The turbinates are covered with mucous membranes that warm and moisten inspired air. Normal mucosa is pink and moist, without lesions. A deviated septum obstructs breathing and interferes with passage of a nasogastric tube. Perforation of the septum often occurs after repeated use of intranasal cocaine. Note any **polyps** (tumorlike growths) or purulent drainage.

Sinuses. Examination of the sinuses involves palpation. In cases of allergies or infection, the interior of the sinuses becomes inflamed and swollen. The most effective way to assess for tenderness is by externally palpating the frontal and maxillary facial areas (Figure 31-20). Palpate the frontal sinus by exerting pressure with the thumb

---

BOX 31-14 **PATIENT TEACHING**

Nose and Sinus Assessment

Objective
- Patient will explain self-care measures to address and minimize loss of olfaction.

Teaching Strategies
- Caution patient against overuse of over-the-counter nasal sprays, which leads to "rebound" effect, causing excess nasal congestion.
- Instruct parents in care of a child with nosebleeds: have child sit up and lean forward to avoid aspiration of blood, apply pressure to the anterior nose with the thumb and forefinger as the child breathes through the mouth, and apply ice or a cold cloth to the bridge of the nose if pressure fails to stop bleeding.
- Instruct older adults with loss of olfaction to follow safety precautions:
  - Install smoke detectors on each floor of their home.
  - Ask others to advise them when food smells pungent.
- Instruct older adults to always check dated labels on food to ensure against spoilage.

Evaluation
- Have patient explain proper use of over-the-counter nasal sprays.
- Have parents demonstrate and describe technique for stopping a nosebleed.
- Inspect patient's home during visit and look for smoke detectors. Ask to check some food items in the refrigerator.

up and under the patient's eyebrow. Gentle, upward pressure elicits tenderness easily if sinus irritation is present. Do not apply pressure to the eyes. If sinus tenderness is present, the sinuses may be transilluminated. However, this procedure requires advanced experience. Box 31-14 describes teaching guidelines during nose and sinus assessment.

Mouth and Pharynx

Assess the mouth and pharynx to detect signs of overall health. Determine the patient's oral hygiene needs and therapies needed if he or she has dehydration, restricted intake, oral trauma, or oral airway obstruction. To assess the oral cavity use a penlight and tongue depressor or gauze square. Wear clean gloves during the examination. Have the patient sit or lie down. Assess the oral cavity also while

TABLE 31-17 Nursing History for Mouth and Pharyngeal Assessment

Assessment	Rationale
Determine if patient wears dentures or retainers and if they are comfortable.	Patient needs to remove dentures to visualize and palpate gums. Ill-fitting dentures chronically irritate mucosa and gums.
Determine if patient has had recent change in appetite or weight.	Symptoms result from painful mouth conditions or poor hygiene.
Determine if patient uses tobacco products: • Smoking cigarette, cigar, or pipe; smokeless tobacco; chewing tobacco and snuff • E-Cigarettes or vapor cigarettes	Tobacco use in any form (smoked and smokeless) increases the risk for oral-pharyngeal cancer (ACS, 2015a). Long-term snuff users have an increased risk for cancer of the gums and cheeks (ACS, 2015a). Exposure to addictive nicotine effects; unknown effects of inhalants on the oral cavity (Cancer Net, 2015)
Review history for alcohol consumption.	Oral and pharyngeal cancers are more common in alcohol users than nonalcohol users. Combine tobacco with heavy use of alcohol, and the risk is significantly increased because the two act synergistically (ACS, 2015a). Those who both smoke and drink have a 15 times greater risk of developing oral cancer than others (Oral Cancer Foundation, 2014). Effects of alcohol are also independent of tobacco use.
Assess dental hygiene practices, including use of fluoride toothpaste, frequency of brushing and flossing, and frequency of dental visits.	Assessment reveals patient's need for education and/or financial support. Periodontal disease has a higher prevalence in older adults who have history of high plaque buildup, use tobacco, and visit the dentist infrequently.
Ask if patient has pain from chewing or eating. If so, ask if mouth lesions are present, including duration and associated symptoms.	Pain is often associated with broken tooth, teeth grinding, or temporomandibular joint problems. Extra care is needed during oral hygiene administration.
Review the patient's medical history for a previous diagnosis of the human papilloma virus (HPV).	HPV, particularly HPV16, has been definitively implicated as a risk for oral cancers, particularly those that occur in the back of the mouth (oropharynx, base of tongue, tonsillar pillars and crypt, and the tonsils themselves) (Oral Cancer Foundation, 2014; ACS, 2015a).

FIGURE 31-21 Lips are normally pink, symmetrical, smooth, and moist.

administering oral hygiene (see Chapter 40). Table 31-17 describes the nursing history for assessment of the mouth and pharynx.

Lips. Inspect the lips for color, texture, hydration, contour, and lesions. With the patient's mouth closed, view the lips from end to end. Normally they are pink, moist, symmetrical, and smooth (Figure 31-21). Lip color in the dark-skinned patient varies from pink to plum. Have female patients remove their lipstick before the examination. Anemia causes pallor of the lips, with cyanosis caused by respiratory or cardiovascular problems. Cherry-colored lips indicate carbon monoxide poisoning. When you inspect any lesion, consider the potential of it being an infection, irritation, or skin cancer.

Buccal Mucosa, Gums, and Teeth. Ask the patient to clench the teeth and smile to observe teeth occlusion. The upper molars

BOX 31-15 PATIENT TEACHING

Mouth and Pharyngeal Assessment

Objective
• Patient will practice proper oral hygiene/dental care measures and identify symptoms of oral cancer.

Teaching Strategies
• Discuss proper techniques for oral hygiene, including brushing and flossing (see Chapter 40).
• Explain the early warning signs of oral cavity and pharynx cancer that should be checked by a health care professional, including a mouth sore that bleeds easily and does not heal, a lump or thickening in the cheek, a white or red patch on the mucosa that persists, a sore throat or a feeling that something is caught in the throat, numbness of the tongue or other area of the mouth, or a swelling of the jaw that causes dentures to not fit (Oral Cancer Foundation, 2014).
• Late symptoms of oral cancer are difficulty chewing, swallowing, or moving the tongue or jaw (ACS, 2015a).
• Encourage regular dental examination every 6 months for children, adults, and older adults.

Evaluation
• Ask patient to demonstrate brushing.
• Have patient identify when to have regular dental checkups.
• Have patient identify the warning signs of oral cavity and pharynx cancer that require further evaluation by a health care provider.

normally rest directly on the lower molars, and the upper incisors slightly override the lower incisors. A symmetrical smile reveals normal facial nerve function.

Inspect the teeth to determine the quality of dental hygiene (Box 31-15). Note the position and alignment of the teeth. To examine the

FIGURE 31-22 Inspection of inner oral mucosa of lower lip.

FIGURE 31-23 Retraction of buccal mucosa allows for clear visualization.

FIGURE 31-24 Undersurface of tongue is highly vascular.

posterior surface of the teeth, have the patient open the mouth with the lips relaxed. Use a tongue depressor to retract the lips and cheeks, especially when viewing the molars. Note the color of teeth and presence of dental caries (cavities), tartar, and extraction sites. Normal, healthy teeth are smooth, white, and shiny. A chalky white discoloration of the enamel is an early indication of caries formation. Brown or black discolorations indicate the formation of caries. A stained yellow color is from tobacco use; coffee, tea, and colas cause a brown stain. In the older adult loose or missing teeth are common because bone resorption increases. An older adult's teeth often feel rough when tooth enamel calcifies. Yellow or darkened teeth are also common in the older adult because of the general wear and tear that exposes the darker underlying dentin.

To view the mucosa and gums, ask the patient to first remove any dental appliance. View the inner oral mucosa by having the patient open and relax the mouth slightly and then gently retract his or her lower lip away from the teeth (Figure 31-22). Repeat this process for the upper lip. Inspect the mucosa for color; hydration; texture; and lesions such as ulcers, abrasions, or cysts. Normally the mucosa is glistening, pink, smooth, and moist. Some common small, yellow-white raised lesions on the buccal mucosa and lips are Fordyce spots, or ectopic sebaceous glands (Ball et al., 2015). If lesions are present, palpate them gently with a gloved hand for tenderness, size, and consistency.

To inspect the buccal mucosa, ask the patient to open the mouth and then gently retract the cheeks with a tongue depressor (Figure 31-23). View the surface of the mucosa from right to left and top to bottom. A penlight illuminates the most posterior part of the mucosa. Normal mucosa is glistening, pink, soft, moist, and smooth. Varying shades of hyperpigmentation are normal in 10% of whites after age 50 and as many as 90% of blacks by the same age. For patients with normal pigmentation, the buccal mucosa is a good site to inspect for jaundice and pallor. In older adults the mucosa is normally dry because of reduced salivation. Thick white patches (leukoplakia) are often a precancerous lesion seen in heavy smokers and alcoholics. Palpate for any buccal lesions by placing the index finger within the buccal cavity and the thumb on the outer surface of the cheek. Patients who smoke cigarettes, cigars, or pipes and those who use smokeless tobacco have an increased risk of oral, pharyngeal, laryngeal, and esophageal cancer. These individuals may have leukoplakia or other lesions anywhere in their oral cavity (e.g., lips, gums, or tongue) at an early age.

Inspect the gums (gingivae) for color, edema, retraction, bleeding, and lesions while retracting the cheeks. Healthy gums are pink, smooth, and moist and fit tightly around each tooth. Dark-skinned patients often have patchy pigmentation. In older adults the gums are usually pale. Using clean gloves, palpate the gums to assess for lesions, thickening, or masses. Normally there is no tenderness. Spongy gums that bleed easily indicate periodontal disease and vitamin C deficiency. If a patient has loose or mobile teeth, swollen gums, or pockets containing debris at the tooth margins, a dental referral is necessary to check for periodontal disease or gingivitis.

Tongue and Floor of Mouth. Carefully inspect the tongue on all sides and the floor of the mouth. Have the patient relax the mouth and stick the tongue out halfway. Note any deviation, tremor, or limitation in movement. This tests hypoglossal nerve function. If a patient protrudes the tongue too far, it elicits the gag reflex. When the tongue protrudes, it lays midline. To test for tongue mobility, ask the patient to raise it up and move it from side to side. It should move freely.

Using a penlight for illumination, examine the tongue for color, size, position, texture, and coatings or lesions. A normal tongue is medium or dull red in color, moist, slightly rough on the top surface, and smooth along the lateral margins. The undersurface of the tongue and the floor of the mouth are highly vascular (Figure 31-24). Take extra care to inspect this area, a common site for oral cancer lesions. The patient lifts the tongue by placing its tip on the palate behind the upper incisors. Inspect for color, swelling, and lesions such as nodules or cysts. The ventral surface of the tongue is pink and smooth, with large veins between the frenulum folds. To palpate the tongue, explain the procedure and ask the patient to protrude it. Grasp the tip with a gauze square and gently pull it to one side. With a gloved hand palpate the full length of the tongue and the base for any areas of hardening

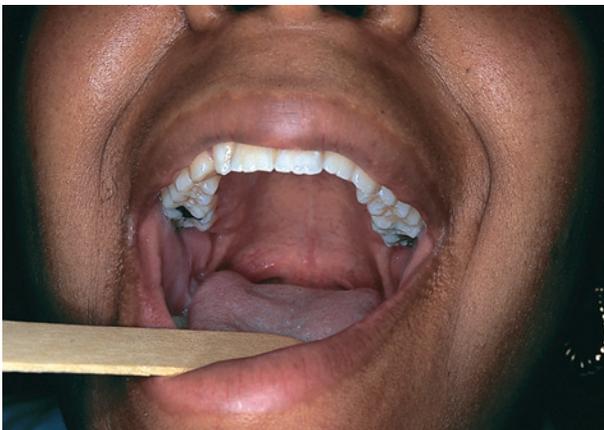
FIGURE 31-25 Hard palate is located anteriorly in roof of mouth.


FIGURE 31-26 Penlight and tongue depressor allow visualization of uvula and posterior soft palate.

or ulceration. Varicosities (swollen, tortuous veins) are common in the older adult and rarely cause problems.

Palate. Have the patient extend the head backward, holding the mouth open to inspect the hard and soft palates. The hard palate, or roof of the mouth, is located anteriorly. The whitish hard palate is dome shaped. The soft palate extends posteriorly toward the pharynx. It is normally light pink and smooth. Observe the palates for color, shape, texture, and extra bony prominences or defects (Figure 31-25). A bony growth, or exostosis, between the two palates is common.

Pharynx. Perform an examination of pharyngeal structures to rule out infection, inflammation, or lesions. Have the patient tip the head back slightly, open the mouth wide, and say "ah" while you place the tip of a tongue depressor on the middle third of the tongue. Take care not to press the lower lip against the teeth. By placing the tongue depressor too far anteriorly, the posterior part of the tongue mounds up, obstructing the view. Placing the tongue depressor on the posterior tongue elicits the gag reflex.

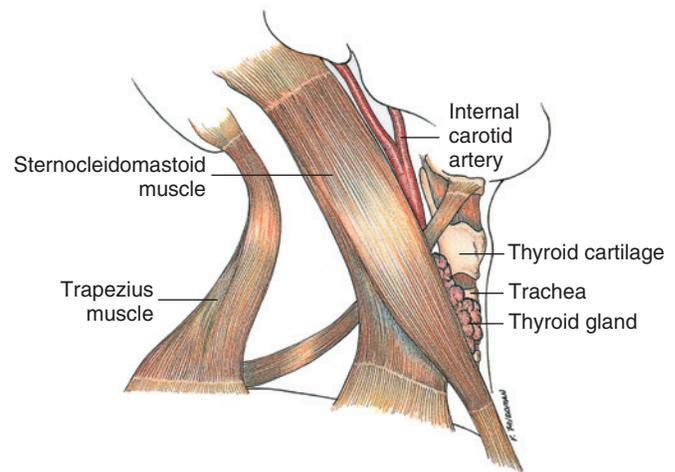
With a penlight first inspect the uvula and soft palate (Figure 31-26). Both structures, which are innervated by the tenth cranial (vagus) nerve, should rise centrally as the patient says "ah." Examine the anterior and posterior pillars, soft palate, and uvula. View the tonsils in the cavities between the anterior and posterior pillars and note the presence or absence of tissue. The posterior pharynx is behind the pillars. Normally pharyngeal tissues are pink and smooth and well


FIGURE 31-27 Anatomical position of major neck structures. Note triangles formed by sternocleidomastoid muscle, lower jaw, and anterior neck anteriorly and sternocleidomastoid muscle, trapezius muscle, and lower neck posteriorly.

hydrated. Small irregular spots of lymphatic tissue and small blood vessels are normal. Note edema, petechiae (small hemorrhages), lesions, or exudate. The back of the pharynx is a common site for oral cancer (Oral Cancer Foundation, 2014). Patients with chronic sinus problems frequently exhibit a clear exudate that drains along the wall of the posterior pharynx. Yellow or green exudate indicates infection. A patient with a typical sore throat has a red and edematous uvula and tonsillar pillars with possible presence of yellow exudate.

Neck

Assessment of the neck includes assessing the neck muscles, lymph nodes of the head and neck, carotid arteries, jugular veins, thyroid gland, and trachea (Figure 31-27). You may postpone the examination of the jugular veins and carotid arteries until the vascular system assessment. Inspect and palpate the neck to determine the integrity of its structures and examine the lymphatic system. An abnormality of superficial lymph nodes sometimes reveals the presence of an infection or **malignancy**. Examine the lymphatic system region by region during the assessment of other body systems (head and neck, breast, genitalia, and extremities). Examination of the thyroid gland and trachea also aids in ruling out malignancies. Perform this examination with the patient sitting. The sternocleidomastoid and trapezius muscles outline the areas of the neck, dividing each side of the neck into two triangles. The anterior triangle contains the trachea, thyroid gland, carotid artery, and anterior cervical lymph nodes. The posterior triangle contains the posterior lymph nodes. Table 31-18 reviews the nursing history for the head and neck examination.

Neck Muscles. First inspect the neck in the usual anatomical position, with slight hyperextension. Observe for symmetry of the neck muscles. Ask the patient to flex the neck with the chin to the chest, hyperextend the neck backward, and move the head laterally to each side and then sideways with the ear moving toward the shoulder. This tests the sternocleidomastoid and trapezius muscles. The neck normally moves without discomfort. Perform other tests for muscle strength and function during assessment of the musculoskeletal system.

Lymph Nodes. An extensive system of lymph nodes collects lymph from the head, ears, nose, cheeks, and lips (Figure 31-28). The

TABLE 31-18 Nursing History for Neck Assessment

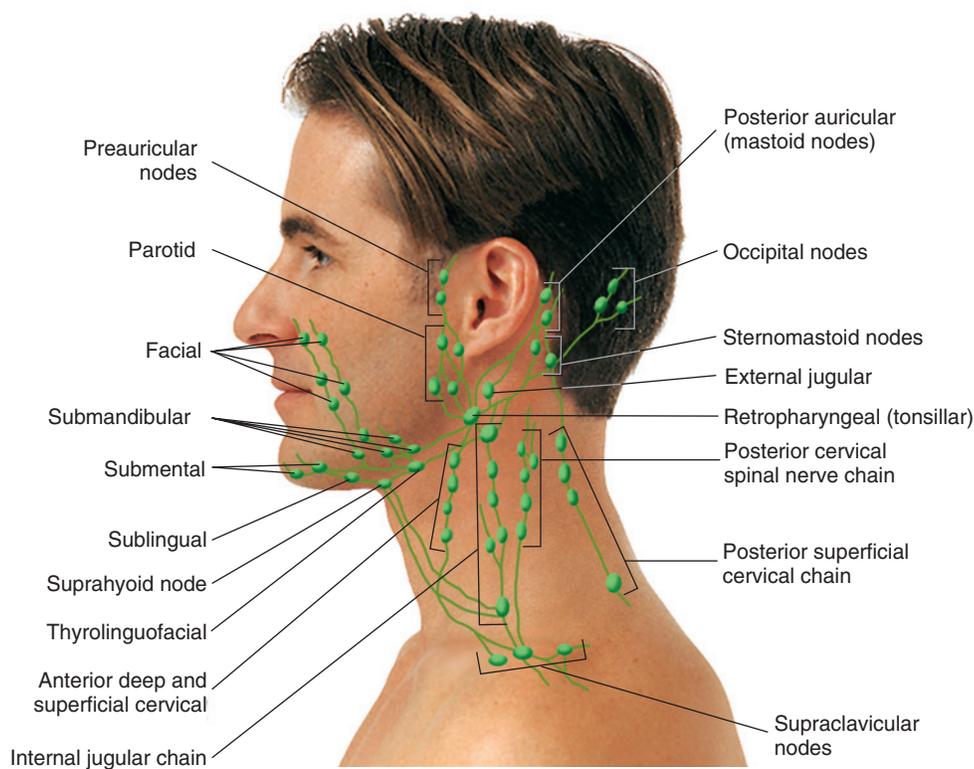
Assessment	Rationale
Assess for history of recent cold, infection, or enlarged lymph nodes or exposure to radiation or toxic chemicals.	Colds or infections cause temporary or permanent lymph node enlargement. Lymph nodes are also enlarged in various diseases such as cancer.
If there is an enlarged lymph node, consider reviewing history of intravenous drug use, hemophilia, sexual contact with people infected with human immunodeficiency virus (HIV), history of blood transfusion, multiple and indiscriminate sexual contacts, or male with homosexual or bisexual activities.	These are risk factors for HIV infection.
Ask if patient has had history of neck pain with restriction in movement.	This indicates muscle strain, head injury, local nerve injury, or enlarged or swollen lymph node.
Ask if patient has had change in temperature preference (more or less clothing); swelling in neck; change in texture of hair, skin, or nails; or change in emotional stability.	Symptoms indicate thyroid disease.
Ask if patient has history of hypothyroidism or hyperthyroidism, takes thyroid medication, or has a family history of thyroid disease.	Disease or medications influence tissue growth of gland.
Review medical history of pneumothorax (collapsed lung) or bronchial tumor.	Conditions place patient at risk for tracheal displacement or lateral deviation.


FIGURE 31-28 Palpable lymph nodes in head and neck. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

immune system protects the body from foreign antigens, removes damaged cells from the circulation, and provides a partial barrier to growth of malignant cells within the body. Assessing the lymph nodes requires competence when caring for patients with suspected immunoincompetence, which is often linked to allergies, human immunodeficiency virus (HIV) infection, autoimmune disease (e.g., lupus erythematosus), or serious infection.

With the patient's chin raised and head tilted slightly, first inspect the area where lymph nodes are distributed and compare both sides. This position stretches the skin slightly over any possible enlarged nodes. Inspect visible nodes for edema, erythema, or red streaks. Nodes normally are not visible.

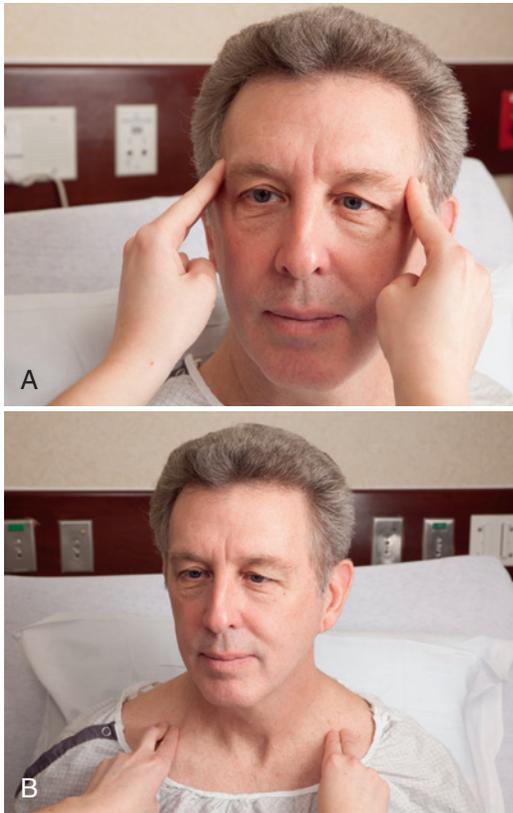
Use a methodical approach to palpate the lymph nodes to avoid overlooking any single node or chain. The patient relaxes with the neck flexed slightly forward. Inspect and palpate both sides of the neck for comparison. During palpation either face or stand to the side of the patient for easy access to all nodes. Use the pads of the middle three fingers of each hand to gently palpate in a circular motion over the nodes (Figure 31-29). Check each node methodically in the following sequence: occipital nodes at the base of the skull, postauricular nodes


FIGURE 31-29 A, Palpation of preauricular lymph nodes. **B,** Palpation of supraclavicular lymph nodes.

HIV, Human immunodeficiency virus.

over the mastoid, preauricular nodes just in front of the ear, retropharyngeal nodes at the angle of the mandible, submandibular nodes, and submental nodes in the midline behind the mandibular tip. Try to detect enlargement and note the location, size, shape, surface characteristics, consistency, mobility, tenderness, and warmth of the nodes. If the skin is mobile, move it over the area of the nodes. It is important to press underlying tissue in each area and not simply move the fingers over the skin. However, if you apply excessive pressure, you miss small nodes and destroy palpable nodes.

To palpate supraclavicular nodes, ask the patient to bend the head forward and relax the shoulders. Palpate these nodes by hooking the index and third finger over the clavicle lateral to the sternocleidomastoid muscle. Palpate the deep cervical nodes only with the fingers hooked around the sternocleidomastoid muscle.

Normally lymph nodes are not easily palpable. However, small, mobile, nontender nodes are common. Lymph nodes that are large, fixed, inflamed, or tender indicate a problem such as local infection, systemic disease, or neoplasm (Ball et al., 2015) (Box 31-16). When you find enlarged nodes, explore the adjacent areas and regions that they drain. Tenderness almost always indicates inflammation. A problem involving a lymph node of the head and neck means an abnormality in the mouth, throat, abdomen, breasts, thorax, or arms. These are the areas drained by the head and neck nodes.

Thyroid Gland. The thyroid gland lies in the anterior lower neck, in front of and to both sides of the trachea. The gland is fixed to the trachea, with the isthmus overlying the trachea and connecting the two irregular, cone-shaped lobes (Figure 31-30). Inspect the lower neck overlying the thyroid gland for obvious masses, symmetry, and any subtle fullness at the base of the neck. Ask the patient to hyperextend the neck, which helps tighten the skin for better visualization.

FIGURE 31-30 Anatomical position of thyroid gland.

Offer the patient a glass of water, and, while observing the neck, have him or her swallow. This maneuver helps to visualize an abnormally enlarged thyroid. Normally the thyroid cannot be visualized.

Advanced practice nurses examine the thyroid by palpating for more subtle masses; this technique is not discussed here.

Carotid Artery and Jugular Vein. This part of the examination is described under examination of the vascular system (see later section).

Trachea. The trachea is a part of the upper respiratory system that you directly palpate. It is normally located in the midline above the suprasternal notch. Masses in the neck or mediastinum and pulmonary abnormalities cause displacement laterally. Have the patient sit or lie down during palpation. Determine the position of the trachea by palpating at the suprasternal notch, slipping the thumb and index fingers to each side. Note if the finger and thumb shift laterally. Do not apply forceful pressure because this elicits coughing.

THORAX AND LUNGS

Accurate physical assessment of the thorax and lungs requires review of the ventilatory and respiratory functions of the lungs. If disease is affecting the lungs, it affects other body systems as well. For example, reduced oxygenation causes changes in mental alertness because of the sensitivity of the brain to lowered oxygen levels. Use data from all body systems to determine the nature of pulmonary alterations. You use inspection, palpation, and auscultation to examine the thorax and lungs. Diagnostic equipment such as x-ray films, magnetic resonance imaging (MRI), and computed tomography (CT) scans create little need for the use of percussion as an assessment measure. Risk factors for lung disease are reviewed at the time of respiratory assessment (Box 31-17).

Before assessing the thorax and lungs, be familiar with the landmarks of the chest (Figure 31-31, *A* to *C*). These landmarks help you identify findings and use assessment skills correctly. A patient's nipples, angle of Louis, suprasternal notch, costal angle, clavicles, and vertebrae are key landmarks that provide a series of imaginary lines for sign identification. Keep a mental image of the location of the lobes of the lung and the position of each rib (Figure 31-32, *A* to *C*). The proper orientation to anatomical structures ensures a thorough assessment of the anterior, lateral, and posterior thorax.

Locating the position of each rib is critical to visualizing the lobe of the lung being assessed. To begin, locate the angle of Louis at the manubriosternal junction. The angle is a visible and palpable angulation of the sternum and is the point at which the second rib articulates with the sternum. Count the ribs and intercostal spaces (between the ribs) from this point. The number of each intercostal space corresponds with that of the rib just above it. The spinous process of the third thoracic vertebra and the fourth, fifth, and sixth ribs helps to locate the lobes of the lung laterally. The lower lobes project laterally

---

BOX 31-17 PATIENT TEACHING

Lung Assessment

Objective
- Patients of all age-groups will practice preventive care measures for lung health.

Teaching Strategies
- Explain risk factors for chronic lung disease and lung cancer, including cigarette smoking, history of smoking for over 20 years; exposure to environmental pollution; and radiation exposure from occupational, medical, and environmental sources. Exposure to radon and asbestos also increases risk. Other risk factors include exposure to certain metals (e.g., arsenic, cadmium, chromium), some organic chemicals, and tuberculosis. Exposure to secondhand cigarette smoke increases risk for nonsmokers (ACS, 2015a).
- Share brochures on lung cancer, asthma, and COPD from American Cancer Society with patient and family.
- Instruct patient with asthma to identify and tell family members and friends which triggers cause asthma episodes.

- Discuss warning signs of lung cancer such as a persistent cough, sputum streaked with blood, chest pains, and recurrent attacks of pneumonia or bronchitis.
- Counsel older adult about benefits of receiving influenza and pneumonia vaccinations because of a greater susceptibility to respiratory infection.
- Instruct patient with COPD how to perform coughing and pursed-lip breathing exercises.
- Refer people at risk for tuberculosis to visit clinics or health care centers for skin testing.

Evaluation
- Have patient describe risk factors for lung disease and cancer.
- Ask patient to identify any known risks for cancer.
- Ask patient to name warning signs of lung cancer.
- In a follow-up visit review patient's immunization record.
- Observe patient performing breathing exercises and coughing.

COPD, chronic obstructive pulmonary disease.

TABLE 31-19 Nursing History for Lung Assessment

Assessment	Rationale
Assess history of tobacco or marijuana use, including type of tobacco, duration and amount (Pack-years = Number of years smoking × Number of packs per day), age started, efforts to quit, and length of time since smoking stopped.	Smoking is a risk factor for lung cancer, heart disease, cerebrovascular disease, emphysema, or chronic bronchitis. It accounts for a significant percentage of all cancer deaths. It increases the risk for 15 types of cancer (ACS, 2015a).
Ask if patient has had a *persistent cough* (productive or nonproductive), *sputum streaked with blood, voice change, chest pain,* shortness of breath, **orthopnea**, dyspnea during exertion or at rest, poor activity tolerance, or *recurrent attacks of pneumonia or bronchitis.*	Symptoms of cardiopulmonary alterations help localize objective physical findings. (Warning signals for lung cancer are in italic type.) The diaphragm of the lungs expands more easily when the individual is sitting upright, as for patients who must be in an upright position to breathe.
Determine if patient works in environment containing pollutants (e.g., asbestos, arsenic, coal dust) or requiring exposure to radiation. Does patient have exposure to secondhand smoke?	These risk factors increase chance for various lung diseases.
Review history for known or suspected human immunodeficiency virus (HIV) infection; substance abuse; low income; or being a resident or employee of nursing home or shelter, homeless, recent prison inmate, family member of tuberculosis (TB) patient, or immigrant to the United States from a country where TB is prevalent.	These are risk factors for TB.
Ask if patient has history of persistent cough, hemoptysis, unexplained weight loss, fatigue, night sweats, or fever.	These are risk factors for both TB and HIV infection.
Does patient have history of chronic hoarseness?	Hoarseness indicates laryngeal disorder or abuse of cocaine or opioids (sniffing).
Assess history of allergies to pollens, dust, or other airborne irritants and to foods, drugs, or chemical substances.	Symptoms such as choking feeling, bronchospasm with respiratory stridor, wheezes on auscultation, and dyspnea are often caused by allergic response.
Review family history for cancer, TB, allergies, or chronic obstructive pulmonary disease.	Conditions place patient at risk for lung disease.
Ask if patient has had a pneumonia or influenza vaccine and a TB test; if not, educate him or her on need to do so.	The very young, the very old, and those with chronic respiratory problems or immunosuppressive diseases are at increased risk for respiratory disease.

and anteriorly (see Figure 31-32, *B*). Posteriorly the tip or inferior margin of the scapula lies approximately at the level of the seventh rib (see Figure 31-32, *C*). After identifying the seventh rib, count upward to locate the third thoracic vertebra and align it with the inner borders of the scapula to locate the posterior lobes.

The examination requires a patient to be undressed to the waist, with good lighting. Assess patients at risk for pulmonary problems such as the patient confined to bed rest or with chest pain who cannot fully expand the lungs. The examination begins with the patient sitting

for assessment of the posterior and lateral chest. Have him or her sit or lie down for assessment of the anterior chest. Table 31-19 reviews the nursing history for lung examination.

Posterior Thorax

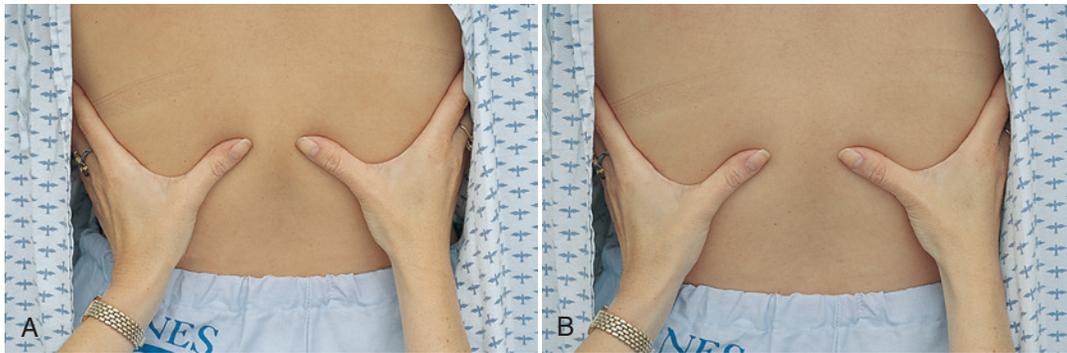
Begin examination of the posterior thorax by observing for any signs or symptoms in other body systems that indicate pulmonary problems. Reduced mental alertness, nasal flaring, somnolence, and cyanosis are examples of assessed signs that indicate oxygenation problems. Inspect


FIGURE 31-33 A, Hand position for palpation of posterior thorax excursion. **B,** As patient inhales, movement of chest excursion separates thumbs.
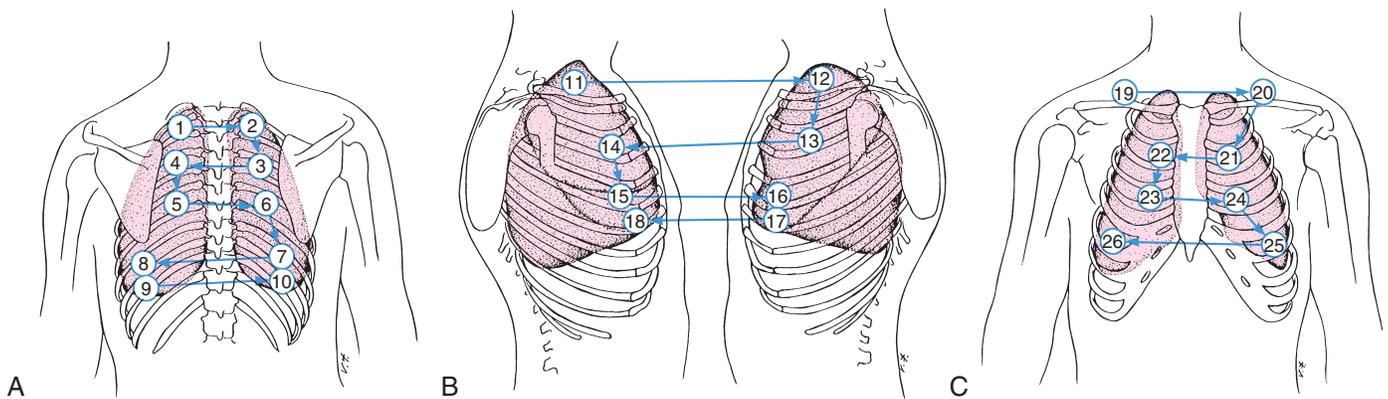

FIGURE 31-34 A to **C,** Systematic pattern (posterior-lateral-anterior) is followed when palpating and auscultating thorax.

the posterior thorax by observing the shape and symmetry of the chest from the patient's back and front. Note the anteroposterior diameter. Body shape or posture significantly impairs ventilatory movement. Normally the chest contour is symmetrical, with the anteroposterior diameter one third to one half of the transverse, or side-to-side, diameter. A barrel-shaped chest (anteroposterior diameter equals transverse diameter) characterizes aging and chronic lung disease. Infants have an almost round shape. Congenital and postural alterations cause abnormal contours. Some patients lean over a table or splint the side of the chest because of a breathing problem. Splinting or holding the chest wall because of pain causes a patient to bend toward the side affected. Such a posture impairs ventilatory movement.

Standing at a midline position behind the patient, look for deformities, position of the spine, slope of the ribs, retraction of the intercostal spaces during inspiration, and bulging of the intercostal spaces during expiration. The scapulae are normally symmetrical and closely attached to the thoracic wall. The normal spine is straight without lateral deviation. Posteriorly the ribs tend to slope across and down. The ribs and intercostal spaces are easier to see in a thin person. Normally no bulging or active movement occurs within the intercostal spaces during breathing. Bulging indicates that a patient is using great effort to breathe.

Also assess the rate and rhythm of breathing (see Chapter 30). Observe the thorax as a whole. It normally expands and relaxes regularly with equality of movement bilaterally. In healthy adults the normal respiratory rates vary from 12 to 20 respirations per minute.

Palpation of the posterior thorax provides further information about a patient's health status. Palpate the thoracic muscles and skeleton for lumps, masses, pulsations, and unusual movement. If the

patient voices pain or tenderness, avoid deep palpation. Fractured rib fragments could be displaced against vital organs. Normally the chest wall is not tender. If there is a suspicious mass or swollen area, lightly palpate it for size, shape, and the typical qualities of a lesion.

To measure chest excursion or depth of breathing, stand behind the patient and place the thumbs along the spinal processes at the tenth rib, with the palms lightly contacting the posterolateral surfaces. Place thumbs 5 cm (2 inches) apart, pointing toward the spine with fingers pointing laterally (Figure 31-33, A). Press the hands toward the spine so a small skinfold appears between the thumbs. Do not slide the hands over the skin. Instruct the patient to exhale and then take a deep breath. Note movement of the thumbs during inhalation (see Figure 31-33, B). Chest excursion is symmetrical, separating the thumbs 3 to 5 cm ($1\frac{1}{4}$ to 2 inches). Reduced chest excursion may be caused by pain, postural deformity, or fatigue. In older adults chest movement normally declines because of costal cartilage calcification and respiratory muscle atrophy.

During speech the sound created by the vocal cords is transmitted through the lungs to the chest wall. The sound waves create vibrations that you palpate externally. These vibrations are called **vocal or tactile fremitus**. The accumulation of mucus, the collapse of lung tissue, or the presence of one or more lung lesions blocks the vibrations from reaching the chest wall.

To palpate for tactile fremitus, place the palmar surfaces of the fingers or the ulnar part of the hand over symmetrical intercostal spaces, beginning at the lung apex (Figure 31-34, A) and using a firm, light touch. Ask the patient to say "ninety-nine" or "one-one-one." Palpate both sides simultaneously and symmetrically (from top to bottom) for comparison or use one hand, quickly alternating between

the two sides (Ball et al., 2015). Normally a faint vibration is present as a patient speaks. If fremitus is faint, ask the patient to speak in a louder or lower tone of voice. Normally fremitus is symmetrical. Vibrations are strongest at the top, near the level of the tracheal bifurcation. Strong vibrations through the chest wall occur in crying infants.

Auscultation assesses the movement of air through the tracheobronchial tree and detects mucus or obstructed airways. Normally air flows through the airways in an unobstructed pattern. Recognizing the sounds created by normal airflow allows you to detect sounds caused by airway obstruction. Follow the same systematic approach when listening that was used for palpation (see Figure 31-34, A).

Place the diaphragm of the stethoscope firmly on the skin, over the posterior chest wall between the ribs (Figure 31-35). Have the patient fold the arms in front of the chest and keep the head bent forward while taking slow, deep breaths with the mouth slightly open. Listen to an entire inspiration and expiration at each position of the stethoscope. If sounds are faint, as in the obese patient, ask the patient to breathe harder and faster temporarily. Breath sounds are much louder in children because of their thin chest walls. The bell works best in children because of a child's small chest. Auscultate for normal breath sounds and abnormal or **adventitious sounds** (Figure 31-36). Normal breath sounds differ in character, depending on the area you are auscultating. Bronchovesicular and vesicular sounds are normally heard over the posterior thorax (Table 31-20).

FIGURE 31-35 Use diaphragm of stethoscope to auscultate breath sounds.

Abnormal sounds result from air passing through moisture, mucus, or narrowed airways. They also result from alveoli suddenly reinflating or an inflammation between the pleural linings of the lung. Adventitious sounds often occur superimposed over normal sounds. The four types of adventitious sounds are crackles, rhonchi, wheezes, and pleural friction rub (see Figure 31-36). A specific entity causes each sound, and each has typical auditory features (Table 31-21). During auscultation note the location and characteristics of the sounds and listen for the absence of breath sounds (found in patients with collapsed or surgically removed lobes).

If there are abnormalities in tactile fremitus or auscultation, perform the vocal resonance tests (spoken and whispered voice sounds). Place the stethoscope over the same locations used to assess breath sounds and have the patient say "ninety-nine" in a normal voice tone. Normally the sound is muffled. If fluid is compressing the lung,

TABLE 31-20   Normal Breath Sounds

Description	Location	Origin
Vesicular		
Vesicular sounds are soft, breezy, and low pitched. Inspiratory phase is 3 times longer than expiratory phase.	Best heard over periphery of lung (except over scapula)	Created by air moving through smaller airways
Bronchovesicular		
Bronchovesicular sounds are blowing sounds that are medium pitched and of medium intensity. Inspiratory phase is equal to expiratory phase.	Best heard posteriorly between scapulae and anteriorly over bronchioles lateral to sternum at first and second intercostal spaces	Created by air moving through large airways
Bronchial		
Bronchial sounds are loud and high pitched with hollow quality. Expiration lasts longer than inspiration (3:2 ratio).	Heard only over trachea	Created by air moving through trachea close to chest wall

ILL
- Rhonchi: coarse, low-pitched; may clear with cough
- Wheeze: whistling, high-pitched bronchus
- Bronchial: coarse, loud; heard with consolidation
- Rub: scratchy, high-pitched
- Crackles: fine crackling, high-pitched

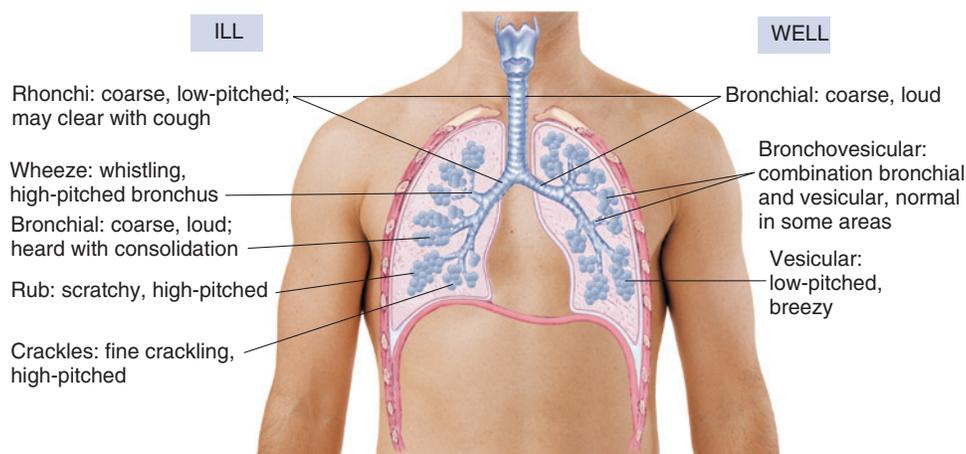
WELL
- Bronchial: coarse, loud
- Bronchovesicular: combination bronchial and vesicular, normal in some areas
- Vesicular: low-pitched, breezy


FIGURE 31-36 Schema of breath sounds in the ill and well patient. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Elsevier.)

TABLE 31-21 Adventitious Breath Sounds

Sound	Site Auscultated	Cause	Character
Crackles	Most common in dependent lobes: right and left lung bases	Random, sudden reinflation of groups of alveoli; disruptive passage of air through small airways	Fine crackles are high-pitched fine, short, interrupted crackling sounds heard during end of inspiration; usually not cleared with coughing. Medium crackles are lower, moister sounds heard during middle of inspiration; not cleared with coughing. Coarse crackles are loud, bubbly sounds heard during inspiration; not cleared with coughing.
Rhonchi (sonorous wheeze)	Primarily heard over trachea and bronchi; if loud enough, able to be heard over most lung fields	Muscular spasm, fluid, or mucus in larger airways; new growth or external pressure causing turbulence	Loud, low-pitched, rumbling, coarse sounds are heard either during inspiration or expiration; sometimes cleared by coughing.
Wheezes (sibilant wheeze)	Heard over all lung fields	High-velocity airflow through severely narrowed or obstructed airway	High-pitched, continuous musical sounds are like a squeak heard continuously during inspiration or expiration; usually louder on expiration.
Pleural friction rub	Heard over anterior lateral lung field (if patient is sitting upright)	Inflamed pleura; parietal pleura rubbing against visceral pleura	Dry, rubbing, or grating quality is heard during inspiration or expiration; does not clear with coughing; heard loudest over lower lateral anterior surface.

Data from Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.

the vibrations from the patient's voice are transmitted to the chest wall, and the sound becomes clear (bronchophony). Then ask the patient to whisper "ninety-nine." The whispered voice is usually faint and indistinct. Certain lung abnormalities cause the whispered voice to become clear and distinct (whispered pectoriloquy).

Lateral Thorax

Extend the assessment of the posterior thorax to the lateral sides of the chest. The patient sits during examination of the lateral chest. Have the patient raise the arms to improve access to lateral thoracic structures. Use inspection, palpation, and auscultation skills to examine the lateral thorax (see Figure 31-34, *B*). Do not assess excursion laterally. Normally the breath sounds you hear are vesicular.

Anterior Thorax

Inspect the anterior thorax for the same features as the posterior thorax. The patient sits or lies down with the head elevated. Observe the accessory muscles of breathing: sternocleidomastoid, trapezius, and abdominal muscles. The accessory muscles move little with normal passive breathing. However, patients who use a great deal of effort to breathe as a result of strenuous exercise or pulmonary disease (e.g., chronic obstructive pulmonary disease) rely on the accessory and abdominal muscles to contract, thereby leading to inspiration and expiration. Some patients who require great effort produce a grunting sound.

Observe the width of the costal angle. It is usually larger than 90 degrees between the two costal margins. Observe the breathing pattern. Normal breathing is quiet and barely audible near the open mouth. You most often assess respiratory rate and rhythm anteriorly (see Chapter 30). The male patient's respirations are usually diaphragmatic, whereas a female's are more costal. Accurate assessment occurs as the patient breathes passively.

Palpate the anterior thoracic muscles and skeleton for lumps, masses, tenderness, or unusual movement. The sternum and xiphoid are relatively inflexible. Place the thumbs parallel approximately along the costal margin 6 cm (2½ inches) apart with the palms touching the anterolateral chest. Push the thumbs toward the midline to create a

skinfold. As the patient inhales deeply, the thumbs normally separate approximately 3 to 5 cm (1¼ to 2 inches), with each side expanding equally.

Assess tactile fremitus over the anterior chest wall. Anterior findings differ from posterior findings because of the heart and female breast tissue. Fremitus is felt next to the sternum at the second intercostal space, at the level of the bronchial bifurcation. It decreases over the heart, lower thorax, and breast tissue.

Auscultation of the anterior thorax follows a systematic pattern (see Figure 31-34, *C*) comparing right and left sides. This is important so lung sounds in one region on one side of the body can be compared with sounds in the same region on the opposite side of the body.

If possible, have the patient sit to maximize chest expansion. Give special attention to the lower lobes, where mucus secretions commonly gather. Listen for bronchovesicular and vesicular sounds above and below the clavicles and along the lung periphery. In addition, auscultate for bronchial sounds, which are loud, high pitched, and hollow sounding, with expiration lasting longer than inspiration (3:2 ratio). This sound is normally heard over the trachea.

HEART

Compare the assessment of heart function with findings from the vascular assessment (see later section). Alterations in either system sometimes manifest as changes in the other. Some patients with signs or symptoms of heart (cardiac) problems have a life-threatening condition requiring immediate attention. In this case act quickly and conduct only the parts of the examination that are absolutely necessary. Conduct a more thorough assessment when the patient is more stable. The nursing history (Table 31-22) provides data to help interpret physical findings.

Assess cardiac function through the anterior thorax. Form a mental image of the exact location of the heart (Figure 31-37). In the adult it is located in the center of the chest (precordium), behind and to the left of the sternum, with a small section of the right atrium extending to the right of the sternum. The base of the heart is the upper part, and the apex is the bottom tip. The surface of the right ventricle

TABLE 31-22 Nursing History for Heart Assessment

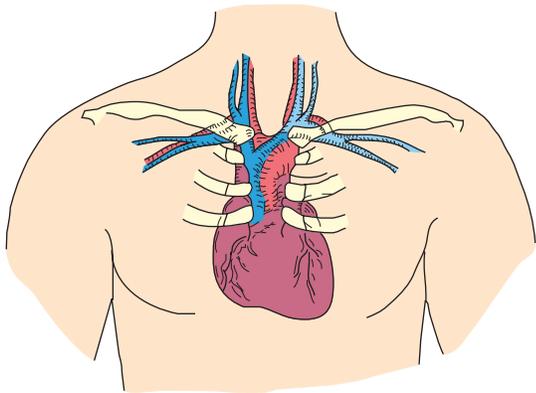
Assessment	Rationale
Determine history of smoking, alcohol intake, caffeine intake, use of prescriptive and recreational drugs, exercise habits, and dietary patterns and intake (including fat and sodium intake).	Smoking; alcohol ingestion; cocaine use; lack of regular exercise; intake of foods high in carbohydrates, fats, and cholesterol are risk factors for cardiovascular disease. Caffeine can cause heart dysrhythmias.
Determine if patient is taking medications for cardiovascular function (e.g., antidysrhythmics, antihypertensives) and if he or she knows their purpose, dosage, and side effects.	Knowledge allows nurse to assess compliance with drug therapies. Medications sometimes affect vital sign values.
Assess for chest pain or discomfort, palpitations, excess fatigue, cough, dyspnea, leg pain or cramps, edema of feet, cyanosis, fainting, and orthopnea. Ask if symptoms occur at rest or during exercise.	These are key symptoms of heart disease. Cardiovascular function is sometimes adequate during rest but not during exercise. Positions affect how well lungs can expand.
If patient reports chest pain, determine if it is cardiac in nature. Anginal pain is usually a deep pressure or ache that is substernal and diffuse, radiating to one or both arms, neck, or jaw.	Assessment determines nature of pain and need to initiate care immediately.
Determine whether patient has stressful lifestyle. Which physical demands and/or emotional stress exist?	Repeated exposure to stress increases risk for heart disease.
Assess family history for heart disease, diabetes, high cholesterol levels, hypertension, stroke, or rheumatic heart disease.	Factors increase risk for heart disease.
Ask patient about history of heart trouble (e.g., heart failure, congenital heart disease, coronary artery disease, dysrhythmias, murmurs).	Knowledge reveals patient's level of understanding of condition. Preexisting condition influences examination techniques used and findings to expect.
Determine whether patient has preexisting diabetes, lung disease, obesity, or hypertension.	These disorders alter heart function.


FIGURE 31-37 Anatomical position of heart.

FIGURE 31-38 Cardiac cycle. *AVC,* Aortic valve closes; *AVO,* aortic valve opens; *ECG,* electrocardiogram; *MVC,* mitral valve closes; *MVO,* mitral valve opens.

composes most of the anterior surface of the heart. A section of the left ventricle shapes the left anterior side of the apex. The apex actually touches the anterior chest wall at approximately the fourth to fifth intercostal space just medial to the left midclavicular line. This is the **apical impulse or point of maximal impulse (PMI).**

An infant's heart is positioned more horizontally. The apex of the heart is at the third or fourth intercostal space, just to the left of the midclavicular line. By the age of 7 a child's PMI is in the same location as the adult's. In tall, slender people the heart hangs more vertically and is positioned more centrally. In shorter or stockier individuals the heart tends to lie more to the left and horizontally (Ball et al., 2015).

To assess heart function, a clear understanding of the cardiac cycle and associated physiological events is of utmost importance (Figure 31-38). The heart normally pumps blood through its four chambers in a methodical, even sequence. Events on the left side occur just before those on the right. As blood flows through each chamber, the valves open and close, the pressures within chambers rise and fall, and the

chambers contract. Each event creates a physiological sign. Both sides of the heart function in a coordinated fashion.

There are two phases to the cardiac cycle: systole and diastole. During systole the ventricles contract and eject blood from the left ventricle into the aorta and from the right ventricle into the pulmonary artery. During diastole the ventricles relax, and the atria contract to move blood into the ventricles and fill the coronary arteries.

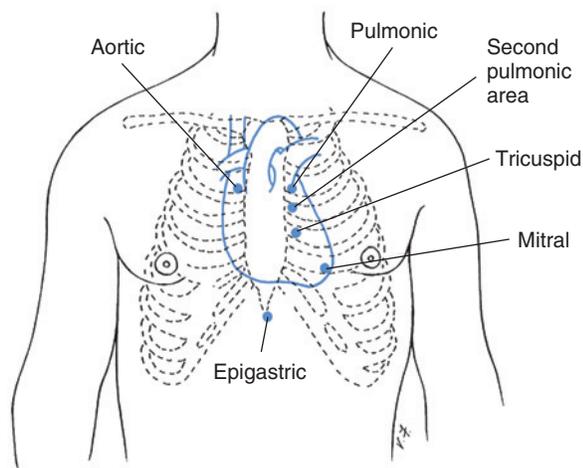
Heart sounds occur in relation to physiological events in the cardiac cycle. As systole begins, ventricular pressure rises and closes the mitral and tricuspid valves. Valve closure causes the first heart sound (S_1),


FIGURE 31-39 Anatomical sites for assessment of cardiac function.

FIGURE 31-40 Palpation of apical pulse.

often described as "lub." The ventricles then contract, and blood flows through the aorta and pulmonary circulation. After the ventricles empty, ventricular pressure falls below that in the aorta and pulmonary artery. This allows the aortic and pulmonic valves to close, causing the second heart sound (S_2), described as "dub." As ventricular pressure continues to fall, it drops below that of the atria. The mitral and tricuspid valves reopen to allow ventricular filling. When the heart attempts to fill an already distended ventricle, a third heart sound (S_3) can be heard, as with heart failure. An S_3 is considered abnormal in adults over 31 years of age but can often be heard normally in children and young adults. It can also be present among women in the late stages of pregnancy. A fourth heart sound (S_4) occurs when the atria contract to enhance ventricular filling. An S_4 is often heard in healthy older adults, children, and athletes; but it is not normal in adults. Because S_4 also indicates an abnormal condition, report it to a health care provider.

Inspection and Palpation

Make the patient relaxed and comfortable before the examination. Explain the procedure to relieve his or her anxiety. An anxious or uncomfortable patient has mild tachycardia, which leads to inaccurate findings.

Use the skills of inspection and palpation simultaneously. Begin the examination with the patient in the supine position or the upper body elevated 45 degrees because patients with heart disease frequently suffer shortness of breath while lying flat. Stand at the patient's right side. Do not let the patient talk, especially when auscultating heart sounds. Good lighting in the room is essential.

Direct your attention to the anatomical sites best suited for assessment of cardiac function. During inspection and palpation look for visible pulsations and exaggerated lifts and palpate for the apical impulse and any source of vibrations (thrills). Follow an orderly sequence, beginning with assessment of the base of the heart and moving toward the apex. First inspect the angle of Louis, which lies between the sternal body and manubrium, and feel the ridge in the sternum approximately 5 cm (2 inches) below the sternal notch. Slip the fingers along the angle on each side of the sternum to feel adjacent ribs. The intercostal spaces are just below each rib. The second intercostal space allows identification of each of the six anatomical landmarks (Figure 31-39). The second intercostal space on the right is the *aortic area,* and the left second intercostal space is the *pulmonic area.* You need to use deeper palpation to feel the spaces in obese or heavily muscled patients. After locating the pulmonic area, move the fingers

down the patient's left sternal border to the third intercostal space, called the *second pulmonic area*. The *tricuspid area* is located at the fourth or fifth intercostal space along the sternum. To find the *apical* or *mitral area*, locate the fifth intercostal space just to the left of the sternum and move the fingers laterally to the left midclavicular line. Locate the apical area with the palm of the hand or the fingertips. Normally you feel the apical impulse as a light tap in an area 1 to 2 cm ($\frac{1}{2}$ to 1 inch) in diameter at the apex (Figure 31-40). Another landmark is the epigastric area at the tip of the sternum. Palpate there if you suspect aortic abnormalities.

Locate the six anatomical landmarks of the heart and inspect and palpate each area. Look for the appearance of pulsations, viewing each area over the chest at an angle to the side. Normally pulsations are not seen, except perhaps at the PMI in thin patients or at the epigastric area as a result of abdominal aorta pulsation. Use the proximal halves of the four fingers together and alternate this with the ball of the hand to palpate for pulsations. Touch the areas gently to allow movements to lift the hand. Normally no pulsations or vibrations are felt in the second, third, or fourth intercostal spaces. Loud murmurs cause a vibration. Time palpated pulsations or vibrations and their occurrence in relation to systole or diastole by auscultating heart sounds simultaneously.

The apical impulse or PMI is felt easily. If you cannot locate it with the patient in a supine position, have him or her roll onto the left side, moving the heart closer to the chest wall. Estimate the size of the heart by noting the diameter of the PMI and its position relative to the midclavicular line. In cases of serious heart disease, the cardiac muscle enlarges, with the PMI found to the left of the midclavicular line. The PMI is sometimes difficult to find in the older adult because the chest deepens in its anteroposterior diameters. It is also difficult to find in muscular or overweight patients. An infant's PMI is located near the third or fourth intercostal space. It is easy to palpate because of the child's thin chest wall.

Auscultation

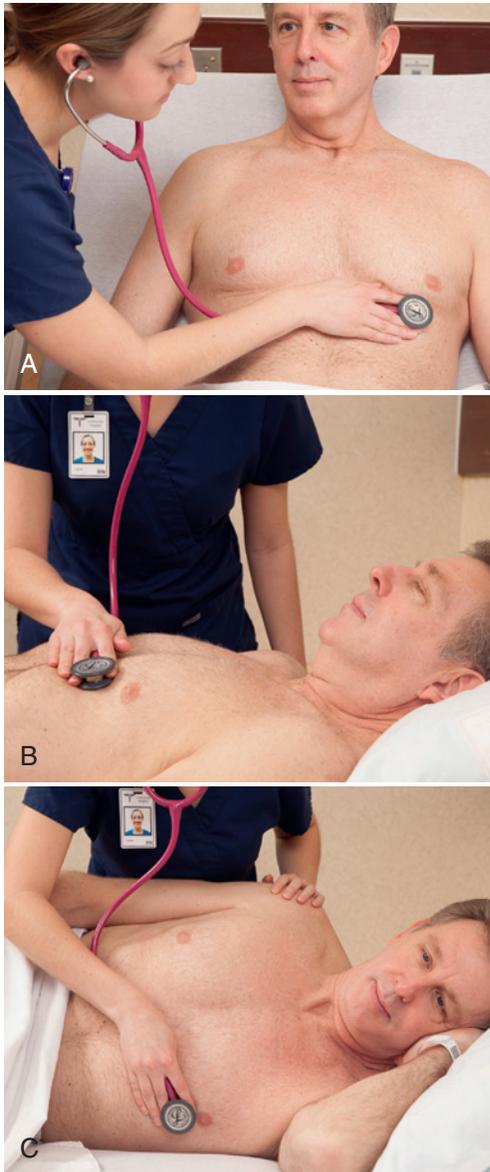
Auscultation of the heart detects normal heart sounds, extra heart sounds, and murmurs. Concentrate on detecting the normal low-intensity sounds created by valve closures. To begin auscultation eliminate all sources of room noise and explain the procedure to reduce the patient's anxiety. Follow a systematic pattern, beginning at the aortic area and inching the stethoscope across each of the anatomical sites. Listen for the complete cycle ("lub-dub") of heart sounds clearly at each location. Repeat the sequence with the bell of the stethoscope.


FIGURE 31-41 Sequence of patient positions for heart auscultation. **A,** Sitting. **B,** Supine. **C,** Left lateral recumbent.

Sometimes you will have a patient assume three different positions during the examination to hear sounds clearly (Figure 31-41, *A to C*): sitting up and leaning forward (good for all areas and to hear high-pitched murmurs), supine (good for all areas), and left lateral recumbent (good for all areas; best position to hear low-pitched sounds in diastole).

Learn to identify the first (S_1) and second (S_2) heart sounds. At normal rates S_1 occurs after the long diastolic pause and before the short systolic pause. S_1 is high pitched, dull in quality, and heard best at the apex. If it is difficult to hear S_1, time it in relation to the carotid pulsation. S_2 follows the short systolic pause and precedes the long diastolic pause; it is best heard at the aortic area.

Auscultate for rate and rhythm after hearing both sounds clearly. Each combination of S_1 and S_2 or "lub-dub" counts as one heartbeat. Count the rate for 1 minute and listen for the interval between S_1 and S_2 and then the time between S_2 and the next S_1. A regular rhythm involves regular intervals of time between each sequence of beats. There is a distinct silent pause between S_1 and S_2. Failure of the heart

to beat at regular successive intervals is a **dysrhythmia**. Some dysrhythmias are life threatening.

When assessing an irregular heart rhythm, compare apical and radial pulse rates simultaneously to determine if a pulse deficit exists. Auscultate the apical pulse first and then immediately palpate the radial pulse (one-examiner technique). Assess the apical and radial rates at the same time when two examiners are present. When a patient has a pulse deficit, the radial pulse is slower than the apical pulse because ineffective contractions fail to send pulse waves to the periphery. Report a difference in pulse rates to the health care provider immediately.

Assess for extra heart sounds at each auscultatory site. Use the bell of the stethoscope and listen for low-pitched extra heart sounds such as S_3 and S_4 gallops, clicks, and rubs. Auscultate over all anatomical areas. S_3, or a **ventricular gallop**, occurs after S_2. It is caused by a premature rush of blood into a ventricle that is stiff or dilated as a result of heart failure and hypertension. The combination of S_1, S_2, and S_3 sounds like "Ken-TUCK-y".

S_4, or an atrial gallop, occurs just before S_1 or ventricular systole. The sound of an S_4 is similar to that of "TEN-nes-see" Physiologically it is caused by an atrial contraction pushing against a ventricle that is not accepting blood because of heart failure or other alterations. You can hear extra heart sounds more easily with the patient lying on the left side and the stethoscope at the apical site.

The final part of the examination includes assessment for heart murmurs. **Murmurs** are sustained swishing or blowing sounds heard at the beginning, middle, or end of the systolic or diastolic phase. They are caused by increased blood flow through a normal valve, forward flow through a stenotic valve or into a dilated vessel or heart chamber, or backward flow through a valve that fails to close. A murmur is asymptomatic or a sign of heart disease (Box 31-18). It is common in children. Keep the following factors in mind when auscultating to detect murmurs:

- When a murmur is detected, auscultate the mitral, tricuspid, aortic, and pulmonic valve areas for placement in the cardiac cycle (timing); the place it is heard best (location); radiation; loudness; pitch; and quality.
- If a murmur occurs between S_1 and S_2, it is a systolic murmur.
- If it occurs between S_2 and the next S_1, it is a diastolic murmur.
- The location of a murmur is not necessarily directly over the valves. Experience with hearing murmurs helps with better understanding of where each type of murmur is best heard. For example, mitral murmurs are best heard at the apex of the heart.
- To assess for radiation, listen over other areas in addition to where it is heard best. Murmurs can also be heard over the neck or back.
- Intensity or loudness is related to the rate of blood flow through the heart or the amount of blood regurgitated. Feel for a thrust or intermittent palpable sensation at the auscultation site in serious murmurs. A **thrill** is a continuous palpable sensation that resembles the purring of a cat. Intensity is recorded using the following grades (Ball et al., 2015):
  - *Grade 1:* Barely audible in a quiet room
  - *Grade 2:* Quiet but clearly audible
  - *Grade 3:* Moderately loud
  - *Grade 4:* Loud, with associated thrill
  - *Grade 5:* Very loud; thrill easily palpable
  - *Grade 6:* Very loud; audible with stethoscope not in contact with chest; thrill palpable and visible
- A murmur is low, medium, or high in pitch, depending on the velocity of blood flow through the valves. A low-pitched murmur is best heard with the bell of the stethoscope. If the murmur is best heard with the diaphragm, it is high pitched.

BOX 31-18 PATIENT TEACHING

Heart Assessment

Objective
- Patient will describe risk factors for heart disease and take appropriate steps to eliminate risks from lifestyle.

Teaching Strategies
- Explain risk factors for heart disease, including high dietary intake of saturated fat or cholesterol, lack of regular aerobic exercise, smoking, excess weight, stressful lifestyle, hypertension, and family history of heart disease.
- Refer patient (if appropriate) to resources available for controlling or reducing risks (e.g., nutritional counseling, exercise class, stress-reduction programs).
- Teach patient to reduce dietary intake of cholesterol and saturated fats. Explain that approximately 70% to 75% of saturated fatty acids come from meats, poultry, fish, and dairy products. The American Heart Association (AHA) (2014) recommends a diet that includes an intake that limits total fat to less than 35% of total calories, saturated fats to less than 10% of daily calories, trans fats to less than 1% of calories, and cholesterol to less than 310 mg/day.
- Encourage patient to have total blood cholesterol levels and triglycerides measured regularly. Desirable levels are less than 200 mg/dL. You need more than one cholesterol measurement to assess the blood cholesterol level accurately. Low-density lipoprotein (LDL) cholesterol is the major component of atherosclerotic plaques. Separate measurement of LDL cholesterol is wise in a patient with high total blood cholesterol levels. In an individual with no other risk factors, an LDL cholesterol level of 160 mg/100 dL or higher is high risk (AHA, 2014).
- Encourage patient to discuss with health care provider the need for periodic C-reactive protein (CRP) testing. CRP levels assess a patient's risk for cardiovascular disease.
- Advise patient to avoid cigarette smoke because nicotine causes vasoconstriction.
- Advise patient to quit smoking to lower the risk for coronary heart disease and coronary vascular disease.
- Patients who are at risk benefit from taking a daily low dose of aspirin. Consult health care provider before starting therapy.

Evaluation
- Ask patient to identify risk factors for heart disease.
- Have patient develop a meal plan low in saturated fat and cholesterol.
- Check patient's cholesterol level during follow-up appointments at the clinic or physician's office.
- Ask patient to describe ways he or she has chosen to reduce cardiac risk factors.

TABLE 31-23 Nursing History for Vascular Assessment

Assessment	Rationale
Determine if patient experiences leg cramps; numbness or tingling in extremities; sensation of cold hands or feet; pain in legs; or swelling or cyanosis of feet, ankles, or hand.	These signs and symptoms indicate vascular disease.
If patient experiences leg pain or cramping in lower extremities, ask if walking or standing for long periods or sleeping aggravates or relieves it.	Relationship of symptoms to exercise clarifies whether problem is vascular or musculoskeletal. Pain caused by vascular condition tends to increase with activity. Musculoskeletal pain usually is not relieved when exercise ends.
Ask patients if they wear tight-fitting garters, socks, or hosiery and sit or lie in bed with legs crossed.	Tight hosiery around lower extremities and crossing legs can impair venous return.
Reconsider previous heart risk factors (e.g., smoking, exercise, nutritional problems).	These predispose patient to vascular disease.
Assess medical history for heart disease, hypertension, phlebitis, diabetes, or varicose veins.	Circulatory and vascular disorders influence findings gathered during examination.

palpating the cervical lymph nodes. Note signs and symptoms of arterial and venous insufficiency when assessing the skin.

Blood Pressure

When auscultating blood pressure, know that readings between the arms vary by as much as 10 mm Hg and tend to be higher in the right arm (Ball et al., 2015). Always record the higher reading. Repeated systolic readings that differ by 15 mm Hg or more suggest atherosclerosis or disease of the aorta.

Carotid Arteries

When the left ventricle pumps blood into the aorta, the arterial system transmits pressure waves. The carotid arteries reflect heart function better than peripheral arteries because their pressure correlates with that of the aorta. The carotid artery supplies oxygenated blood to the head and neck (Figure 31-42). The overlying sternocleidomastoid muscle protects it.

To examine the carotid arteries, have the patient sit or lie supine with the head of the bed elevated 31 degrees. Examine one carotid artery at a time. If both arteries are occluded simultaneously during palpation, the patient loses consciousness as a result of inadequate circulation to the brain. *Do not palpate or massage the carotid arteries vigorously* because the carotid sinus is located at the bifurcation of the common carotid arteries in the upper third of the neck. This sinus sends impulses along the vagus nerve. Its stimulation causes a reflex drop in heart rate and blood pressure, which causes **syncope** or circulatory arrest. This is a particular problem for older adults.

Begin inspection of the neck for obvious pulsation of the artery. Have the patient turn the head slightly away from the artery being examined. Sometimes the wave of the pulse is visible. The carotid is the only site for assessing the quality of a pulse wave. An absent pulse wave indicates arterial occlusion (blockage) or **stenosis** (narrowing).

The quality of a murmur refers to its characteristic pattern and sound. A crescendo murmur starts softly and builds in loudness. A decrescendo murmur starts loudly and becomes less intense.

VASCULAR SYSTEM

Examination of the vascular system includes measuring the blood pressure (see Chapter 30) and assessing the integrity of the peripheral vascular system. Table 31-23 reviews the nursing history data collected before the examination. Use the skills of inspection, palpation, and auscultation. Perform parts of the vascular examination during other body system assessments. For example, check the carotid pulse after

FIGURE 31-42 Anatomical position of carotid artery.

FIGURE 31-43 Palpation of internal carotid artery along margin of sternocleidomastoid muscle.

To palpate the pulse ask the patient to look straight ahead or turn the head slightly toward the side you are examining. Turning relaxes the sternocleidomastoid muscle. Slide the tips of the index and middle fingers around the medial edge of the sternocleidomastoid muscle. Gently palpate to avoid occlusion of circulation (Figure 31-43).

The normal carotid pulse is localized and strong rather than diffuse. It has a thrusting quality. As a patient breathes, no change occurs. Rotation of the neck or a shift from a sitting to a supine position does not change the quality of the carotid impulse. Both carotid arteries are normally equal in pulse rate, rhythm, and strength and are equally elastic. Diminished or unequal carotid pulsations indicate atherosclerosis or other forms of arterial disease.

The carotid is the most commonly auscultated pulse. Auscultation is especially important for middle-age or older adults or patients suspected of having cerebrovascular disease. When the lumen of a blood vessel is narrowed, it disturbs blood flow. As blood passes through the narrowed section, it creates turbulence, causing a blowing or swishing sound. The blowing sound is called a **bruit** (pronounced "brew-ee") (Figure 31-44).

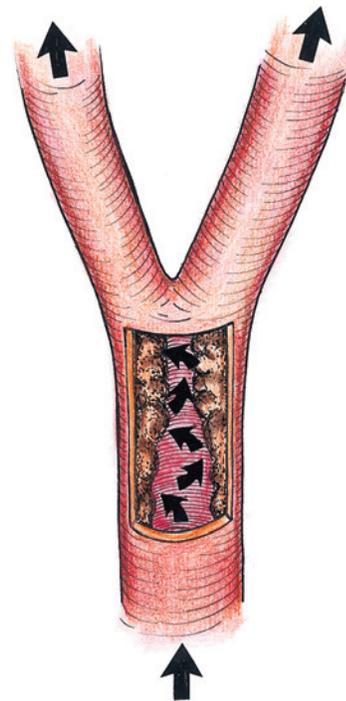
Place the bell of the stethoscope over the carotid artery at the lateral end of the clavicle and the posterior margin of the sternocleidomastoid muscle. Have the patient turn his or her head slightly away from the


FIGURE 31-44 Occlusion or narrowing of the carotid artery disrupts normal blood flow. The resultant turbulence creates a sound (bruit) that is auscultated.

FIGURE 31-45 Auscultation for carotid artery bruit. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

side being examined (Figure 31-45). Ask him or her to hold the breath for a moment so breath sounds do not obscure a bruit. Normally you do not hear any sounds during carotid auscultation. Palpate the artery lightly for a thrill (palpable bruit) if you hear a bruit.

Jugular Veins

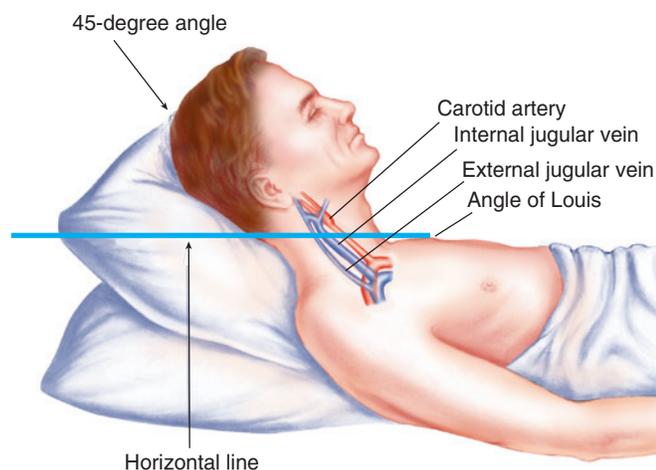
The most accessible veins for examination are the internal and external jugular veins in the neck. Both veins drain bilaterally from the head and neck into the superior vena cava. The external jugular vein lies


FIGURE 31-46 Position of patient to assess jugular vein distention. (From Thompson JM et al: *Mosby's manual of clinical nursing,* ed 5, St Louis, 2001, Mosby.)

FIGURE 31-47 Measuring jugular venous pressure. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

superficially and is just above the clavicle. The internal jugular vein lies deeper, along the carotid artery.

It is best to examine the right internal jugular vein because it follows a more direct anatomical path to the right atrium of the heart. The column of blood inside the internal jugular vein serves as a manometer, reflecting pressure in the right atrium. The higher the column, the greater is the venous pressure. Raised venous pressure reflects right-sided heart failure.

Normally, when a patient lies in the supine position, the external jugular vein distends and becomes easily visible. In contrast, the jugular veins normally flatten when the patient changes to a sitting or standing position. However, for some patients with heart disease the jugular veins remain distended when sitting.

To measure venous pressure, first inspect the jugular veins. Venous pressure is influenced by blood volume (i.e., the capacity of the right atrium to receive blood and send it to the right ventricle and the ability of the right ventricle to contract and force blood into the pulmonary artery). Any factor resulting in greater blood volume within the venous system results in elevated venous pressure. Assess venous pressure by using the following steps:

1. Ask the patient to lie supine with the head elevated 31 to 45 degrees (semi-Fowler's position).
2. Expose the neck and upper thorax. Use a pillow to align the head. Avoid neck hyperextension or flexion to ensure that the vein is not stretched or kinked (Figure 31-46).
3. Usually pulsations are not evident with the patient sitting up. As he or she slowly leans back into a supine position, the level of venous pulsations begins to rise above the level of the manubrium as much as 1 or 2 cm ($\frac{1}{2}$ to 1 inch) as the patient reaches a 45-degree angle. Measure venous pressure by measuring the vertical distance between the angle of Louis and the highest level of the visible point of the internal jugular vein pulsation.
4. Use two rulers. Line up the bottom edge of a regular ruler with the top of the area of pulsation in the jugular vein. Then take a centimeter ruler and align it perpendicular to the first ruler at the level of the sternal angle. Measure in centimeters the distance between the second ruler and the sternal angle (Figure 31-47).
5. Repeat the same measurement on the other side. Bilateral pressures higher than 2.5 cm (1 inch) are considered elevated and are a sign of right-sided heart failure. One-sided pressure elevation is caused by obstruction.

TABLE 31-24	**Indicators for Assessing Local Blood Flow**
Indicator	**Rationale**
Systemic diseases (e.g., arteriosclerosis, atherosclerosis, diabetes)	Diseases result in changes in integrity of walls of arteries and smaller blood vessels.
Coagulation disorders (e.g., thrombosis, embolus)	Blood clot causes mechanical obstruction to blood flow.
Local trauma or surgery (e.g., contusion, fracture, vascular surgery)	Direct manipulation of vessels or localized edema impairs blood flow.
Application of constricting devices (e.g., casts, dressings, elastic bandages, restraints)	Constriction causes tourniquet effect, impairing blood flow to areas below site of constriction.

Peripheral Arteries and Veins

To examine the peripheral vascular system, first assess the adequacy of blood flow to the extremities by measuring arterial pulses and inspecting the condition of the skin and nails. Next assess the integrity of the venous system. Assess the arterial pulses in the extremities to determine sufficiency of the entire arterial circulation.

Factors such as coagulation disorders, local trauma or surgery, constricting casts or bandages, and systemic diseases impair circulation to the extremities (Table 31-24). Discuss risk factors and ways to monitor for circulatory problems with the patient (Box 31-19).

Peripheral Arteries. Examine each peripheral artery using the distal pads of your second and third fingers. The thumb helps anchor the brachial and femoral artery. Apply firm pressure but avoid occluding a pulse. When a pulse is difficult to find, it helps to vary pressure and feel all around the pulse site. Be sure not to palpate your own pulse.

Routine vital signs usually include assessment of the rate and rhythm of the radial artery because it is easily accessible. Count the pulse for either 31 seconds or a full minute, depending on the character of the pulse (see Chapter 30). Always count an irregular pulse for 60 seconds. With palpation normally feel the pulse wave at regular intervals. When an interval is interrupted by an early, a late, or a missed beat, the pulse rhythm is irregular. During cardiac emergencies health care providers usually assess the carotid artery because it is accessible

BOX 31-19 PATIENT TEACHING

Vascular Assessment

Objective
- Patient with vascular insufficiency will avoid activities that worsen circulatory status.

Teaching Strategies
- Instruct patient with risk or evidence of vascular insufficiency in the lower extremities to avoid tight clothing over the lower body or legs, avoid sitting or standing for long periods, avoid sitting with legs crossed, walk regularly, and elevate feet when sitting.
- Advise patient to avoid or stop smoking cigarettes, cigars, pipes or using nicotine products (e.g., chewing tobacco, nicotine patches or gum) because nicotine causes vasoconstriction. Offer a referral to a reliable stop-smoking program.
- Instruct patient with hypertension about the benefits of regular monitoring of blood pressure (daily, weekly, or monthly). Teach patient how to use home monitoring kits.

Evaluation
- Ask patient to identify if blood pressure reading is within normal limits for age.
- Have patient with vascular insufficiency describe precautions to take to avoid further circulatory deficiency.
- Have patient demonstrate self-monitoring of blood pressure.

and most useful in evaluating heart activity. To check local circulatory status of tissues (e.g., when a leg cast is in place or following vascular surgery), palpate the peripheral arteries long enough to note that a pulse is present.

Assess each peripheral artery for elasticity of the vessel wall, strength, and equality. The arterial wall normally is elastic, making it easily palpable. After depressing the artery, it springs back to shape when the pressure is released. An abnormal artery is hard, inelastic, or calcified.

The strength of a pulse is a measurement of the force at which blood is ejected against the arterial wall. Some examiners use a scale rating from 0 to 4 for the strength of a pulse (Ball et al., 2015):

0: Absent, not palpable
1: Pulse diminished, barely palpable
2: Expected
3: Full, increased
4: Bounding, aneurysmal

Measure all peripheral pulses for equality and symmetry. Compare the left radial pulse with that of the right and so on. Lack of symmetry indicates impaired circulation such as a localized obstruction or an abnormally positioned artery.

In the upper extremities the brachial artery channels blood to the radial and ulnar arteries of the forearm and hand. If circulation in this artery becomes blocked, the hands do not receive adequate blood flow. If circulation in the radial or ulnar arteries becomes impaired, the hand still receives adequate perfusion. An interconnection between the radial and ulnar arteries guards against arterial occlusion (Figure 31-48, *A*).

To locate pulses in the arm have the patient sit or lie down. Find the radial pulse along the radial side of the forearm at the wrist. Thin individuals have a groove lateral to the flexor tendon of the wrist. Feel the radial pulse with light palpation in the groove (see Figure 31-48, *B*). The ulnar pulse is on the opposite side of the wrist and feels less

prominent (see Figure 31-48, *C*). Palpate the ulnar pulse only when evaluating arterial insufficiency to the hand.

To palpate the brachial pulse, find the groove between the biceps and triceps muscle above the elbow at the antecubital fossa (see Figure 31-48, *D*). The artery runs along the medial side of the extended arm. Palpate it with the fingertips of the first three fingers in the muscle groove.

The femoral artery is the primary artery in the leg, delivering blood to the popliteal, posterior tibial, and dorsalis pedis arteries (Figure 31-49, *A*). An interconnection between the posterior tibial and dorsalis pedis arteries guards against local arterial occlusion.

Find the femoral pulse with the patient lying down with the inguinal area exposed (see Figure 31-49, *B*). The femoral artery runs below the inguinal ligament, midway between the symphysis pubis and the anterosuperior iliac spine. Sometimes deep palpation is necessary to feel the pulse. Bimanual palpation is effective in obese patients. Place the fingertips of both hands on opposite sides of the pulse site. Feel a pulsatile sensation when the arterial pulsation pushes the fingertips apart.

The popliteal pulse runs behind the knee. Have the patient slightly flex the knee with the foot resting on the examination table or assume a prone position with the knee slightly flexed (see Figure 31-49, *C*). Instruct him or her to keep leg muscles relaxed. Palpate with the fingers of both hands deeply into the popliteal fossa, just lateral to the midline. The popliteal pulse is difficult to locate.

With the patient's foot relaxed, locate the dorsalis pedis pulse. The artery runs along the top of the foot in line with the groove between the extensor tendons of the great toe and first toe (see Figure 31-49, *D*). To find the pulse, place the fingertips between the first and second toes and slowly move up the dorsum of the foot. This pulse is sometimes congenitally absent.

Find the posterior tibial pulse on the inner side of each ankle (Figure 31-49, *E*). Place the fingers behind and below the medial malleolus (ankle bone). With the foot relaxed and slightly extended, palpate the artery.

Ultrasound Stethoscopes. If a pulse is difficult to palpate, an ultrasound (Doppler) stethoscope is a useful tool that amplifies the sounds of a pulse wave. Factors that weaken a pulse or make palpation difficult include obesity, reduction in the stroke volume of the heart, diminished blood volume, or arterial obstruction. Apply a thin layer of transmission gel to the patient's skin at the pulse site or directly onto the transducer tip of the probe. Turn on the volume control and place the tip of the transducer at a 45- to 90-degree angle on the skin (Figure 31-50). Move the transducer until you hear a pulsating "whooshing" sound that indicates that arterial blood flow is present.

Tissue Perfusion. The condition of the skin, mucosa, and nail beds offers useful data about the status of circulatory blood flow. Examine the face and upper extremities, looking at the color of the skin, mucosa, and nail beds. The presence of cyanosis requires special attention. Heart disease sometimes causes central cyanosis, which indicates poor arterial oxygenation. Some characteristics of this are a bluish discoloration of the lips, mouth, and conjunctivae. Blue lips, earlobes, and nail beds are signs of peripheral cyanosis, which indicates peripheral vasoconstriction. When cyanosis is present, consult with a health care provider to request laboratory testing of oxygen saturation to determine the severity of the problem. Examination of the nails involves inspection for **clubbing,** a bulging of the tissues at the nail base. Clubbing is caused by insufficient oxygenation at the periphery resulting from conditions such as chronic emphysema and congenital heart disease.

Inspect the lower extremities for changes in color, temperature, and condition of the skin, indicating either arterial or venous

TABLE 31-25 Signs of Venous and Arterial Insufficiency

Assessment Criterion	Venous	Arterial
Color	Normal or cyanotic	Pale; worsened by elevation of extremity; dusky red when extremity is lowered
Temperature	Normal	Cool (blood flow blocked to extremity)
Pulse	Normal	Decreased or absent
Edema	Often marked	Absent or mild
Skin changes	Brown pigmentation around ankles	Thin, shiny skin; decreased hair growth; thickened nails

alterations (Table 31-25). This is a good time to ask the patient about any history of pain in the legs. If an arterial occlusion is present, the patient has signs resulting from an absence of blood flow. Pain is distal to the occlusion. The five *P*s—pain, pallor, pulselessness, paresthesias, and paralysis—characterize an occlusion. Venous congestion causes tissue changes that indicate an inadequate circulatory flow back to the heart.

During examination of the lower extremities, also inspect skin and nail texture; hair distribution on the lower legs, feet, and toes; the venous pattern; and scars, pigmentation, or ulcers. Palpate the legs and feet for color and temperature. Capillary refill, traditionally used to determine adequacy of peripheral blood flow to the digits, has limited value.

The absence of hair growth over the legs indicates circulatory insufficiency. Remember not to confuse absence of hair on the legs with shaved legs. In addition, men who wear tight-fitting dress socks or jeans may have less hair on their calves. Chronic recurring ulcers of the feet or lower legs are a serious sign of circulatory insufficiency and require a health care provider's intervention.

Peripheral Veins. Assess the status of the peripheral veins by asking the patient to assume sitting and standing positions. Assessment includes inspection and palpation for varicosities, peripheral edema, and phlebitis. Varicosities are superficial veins that become dilated, especially when the legs are in a dependent position. They are common in older adults because the veins normally fibrose, dilate, and stretch. They are also common in people who stand for prolonged periods. Varicosities in the anterior or medial part of the thigh and the posterolateral part of the calf are abnormal.

Dependent edema around the area of the feet and ankles is a sign of venous insufficiency or right-sided heart failure. It is common in older adults and people who spend a lot of time standing (e.g., waitresses, security guards, and nurses). To assess for pitting edema, use the index finger to press firmly for several seconds and release over the medial malleolus or the shins. A depression left in the skin indicates edema. Grading 1+ through 4+ characterizes the severity of the edema (see Figure 31-6).

Phlebitis is an inflammation of a vein that occurs commonly after trauma to the vessel wall, infection, immobilization, and prolonged insertion of IV catheters. To assess for phlebitis in the leg, inspect the calves for localized redness, tenderness, and swelling over vein sites. Gentle palpation of calf muscles reveals warmth, tenderness, and firmness of the muscle. Unilateral edema of the affected leg is one of the most reliable findings of phlebitis. Homans' sign is no longer a reliable indicator of phlebitis or deep vein thrombosis (DVT) and is present in other conditions (Ball et al., 2015). The Homans' sign is contraindicated in patients with DVT. If a clot is present in the leg, it may become dislodged from its original site during this test, resulting in a pulmonary embolism.

Lymphatic System

Assess the lymphatic drainage of the lower extremities during examination of the vascular system or during the female or male genital examination. Superficial and deep nodes drain the legs, but only two groups of superficial nodes are palpable. With the patient supine, palpate the area of the superficial inguinal nodes in the groin area (Figure 31-51, *A*). Then move the fingertips toward the inner thigh, feeling for any inferior nodes. Use a firm but gentle pressure when palpating over each lymphatic chain. Multiple nodes normally are not palpable, although a few soft, nontender nodes are not unusual. Enlarged, hardened, tender nodes reveal potential sites of infection or metastatic disease.

In the upper extremities lymph is carried by the collecting ducts from the upper extremities to the subclavian lymphatic trunk. To assess this lymph system, gently palpate the epitrochlear nodes, located on the medial aspect of the arms near the antecubital fossa (see Figure 31-51, *B*). The proximal part of the upper-extremity lymph system is located in the axilla and is usually assessed during examination of the breasts.

BREASTS

It is important to examine the breasts of both female and male patients. Men have a small amount of glandular tissue, a potential site for the growth of cancer cells, in the breast. In contrast, the majority of the female breast is glandular tissue.

Female Breasts

New cases of invasive breast cancer were predicted to affect an estimated 231,840 women in the United States during 2015; about 2,350 new cases were expected in men (ACS, 2015a). The disease is second

to lung cancer as the leading cause of death in women with cancer. Early detection is the key to cure (Box 31-20). A major responsibility for nurses is to teach patients health behaviors such as breast self-examination (BSE) (Box 31-21).

Women need to be taught to know how their breasts usually look and feel and report changes to a health care professional. In addition, they need to know about the benefits and limitations of performing a systematic BSE. Once thought essential for early breast cancer detection, BSEs are now considered optional because there is limited evidence as to the benefits in locating cancerous tumors (ACS, 2015b). If a female patient already performs BSE, assess the method she uses and times she does the examination in relation to her menstrual cycle. The best time for a BSE is the fourth through seventh day of the menstrual cycle or right after the menstrual cycle ends, when the breast is no longer swollen or tender from hormone elevations. If the woman is postmenopausal, advise her to check her breasts on the same day each month. The pregnant woman should also check her breasts on a monthly basis.

Older women require special attention when reviewing the need for regular BSE. Fixed incomes limit many older women; thus they fail to pursue regular clinical breast examination and mammography. Unfortunately many older women ignore changes in their breasts, assuming that they are a part of aging. In addition, physiological factors affect the ease with which older women perform a BSE. Musculoskeletal limitations, diminished peripheral sensation, reduced eyesight, and changes in joint range of motion (ROM) limit palpation

BOX 31-20 EVIDENCE-BASED PRACTICE

Detection of Breast Cancer

PICO Question: Does the use of a targeted intervention compared with standard teaching methods increase the rate of annual mammograms in African-American women?

Evidence Summary

The mortality rate from breast cancer is higher in African-American women than in other racial groups (Conway-Phillips and Janusek, 2014; Northington et al., 2011). This is often because of a low rate of breast cancer screening, leading to the diagnosis of breast cancer when it is in a more advanced stage (Brooks et al., 2013). A number of factors contribute to this low screening rate, including but not limited to lack of health insurance, preconceived beliefs or lack of knowledge about the importance of screening, attitudes toward screening, financial burden, low level of education or income, fear of radiation, and distrust of the health care system (Conway-Phillips and Janusek, 2014; Northington et al., 2011). Specific targeted interventions have been successful in increasing mammograms in this population. Khaliq et al. (2013) found that, in a group of high-risk breast cancer women from lower socioeconomic levels, inpatient hospital stays were an effective time to offer mammogram screening along with screening education. In this group a higher percentage of women agreed to have an inpatient screening mammogram while in the hospital if it was offered (Khaliq et al., 2013). Women who watched a narrative video from an African-American breast cancer survivor reported fewer barriers to mammography and increased confidence that mammograms were effective screening measures (Kreuter et al., 2010). Women with lower educational levels who watched the narrative video had higher mammogram rates than women who watched the standard information video (Kreuter et al., 2010). Research found that targeted postcard reminders were effective if barriers were removed. Likelihood of obtaining a mammogram was related to belief in preventive screening (Feldstein et al., 2011). Conway-Phillips and Janusek (2014) also found that spirituality was a strong predictor of likelihood of an African-American woman to obtain breast cancer screening.

Application to Nursing Practice

• Remember that it is important to identify barriers to breast cancer screening. Removal of the barriers is often necessary to be able to develop effective targeted strategies to increase screening (Conway-Phillips and Janusek, 2014; Northington et al., 2011).
• Discuss with the health care provider the opportunity to offer screening mammograms to hospitalized patients (Khaliq et al., 2013).
• Use inpatient hospitalizations as an opportunity to teach women about the importance of breast cancer screening (Khaliq et al., 2013).
• Collaborate with the faith community nurses in African-American churches to provide breast cancer screening education to church members (Conway-Phillips and Janusek, 2014).
• Develop and use narrative videos of African-American women who are breast cancer survivors as educational tools related to the importance of breast cancer screening (Kreuter et al., 2010).

and inspection abilities. Find resources for older women, including free screening programs. Teach family members to perform the patient's examination.

Table 31-3 outlines the American Cancer Society (ACS, 2015b) guidelines for the early detection of breast cancer in women at average risk. Monthly BSE is no longer recommended by the ACS (2015b) for women at any age, but other health organizations encourage BSE as an important option for women (National Breast Cancer Foundation, 2015). Encourage women to ask their personal physician what he or she recommends in regards to screening.

BOX 31-21   Breast Self-Examination

There is recent controversy over the value of women performing breast self-examinations (BSE) to screen for cancer. In 2015, the American Cancer Society (ACS) reported that research does not show a clear benefit of physical breast exams done by either a health professional or by the individual woman (ACS, 2015b). Due to this lack of evidence, regular clinical breast exams and breast self-exams are not recommended by the ACS. However, many physicians argue that women should be familiar with how their breasts normally look and feel and report any changes to a health care provider right away. Thus many physicians still recommend regular BSE.

When instructing women about BSE, explain the benefits and limitations of breast self-examination (BSE) (National Breast Cancer Foundation, 2015). Emphasize the importance of prompt reporting of any new breast symptoms to a health care professional. Women who choose to do BSE should receive instruction and have their technique reviewed. BSE done once a month helps women become familiar with the usual appearance and feel of their breasts. Familiarity makes it easier to notice any changes in the breast from one month to another. Early discovery of a change from "normal" is the main idea behind BSE.

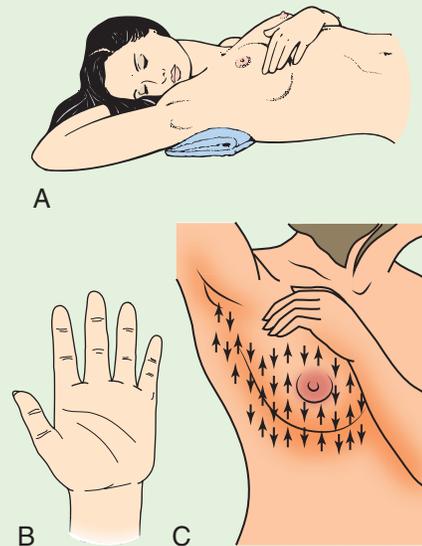
For women who menstruate, the best time to do BSE is the fourth through the seventh day of the menstrual cycle or right after the menstrual cycle ends, when the breasts are least likely to be tender or swollen. Women who no longer menstruate should pick a day such as the first day of the month to remind them to do BSE. Males should also examine their breast, areolas, nipples, and axillae for any swelling, nodules, or ulcerations.

When a woman has breast implants, it might be helpful for the surgeon to identify the edges of the implant. Women who are pregnant or breastfeeding should also do a BSE.

Procedure

1. Examine your right breast. Lie on your back and place your right arm behind your head (see illustration A). The examination is best completed lying down, not standing up, because when you lie down the breast tissue spreads evenly over the chest wall and is as thin as possible, making it much easier to feel all of it.
2. Use finger pads of the three middle fingers on your left hand to feel for lumps in the right breast (see illustration B). Use overlapping dime-size circular motions of the finger pads to feel the breast tissue. Use three different levels of pressure to feel all the breast tissue. Light pressure is needed to feel the tissue closest to the skin; medium pressure to feel a little deeper; and firm pressure to feel the tissue closest to the chest and ribs. It is normal to feel a firm ridge in the lower curve of each breast, but you should tell your health care provider if you feel anything else out of the ordinary. If you're not sure how hard to press, discuss this with your health care provider. Use each pressure level to feel the breast tissue before moving on to the next spot.
3. Move around the breast in an up-and-down pattern starting at an imaginary line drawn straight down your side from the under arm and moving across the breast to the middle of the chest bone (sternum or breastbone). Be sure to check the entire breast area, going down until you feel only ribs and up to the neck or collar bone (clavicle) (see illustration C). Evidence shows that the up-and-down pattern is the most effective pattern for covering the entire breast.
4. Repeat self-examination in the left breast, putting your left arm behind your head and examining the left breast as noted in Steps 1 to 3.
5. While standing in front of a mirror with your hands pressing firmly down on your hips, look at your breasts, observing for any changes in size, shape, contour, dimpling, redness, or scaliness of the nipple or breast tissue. Pressing down on your hips contracts the chest wall muscles and enhances any breast changes.
6. Examine each underarm while sitting or standing and with your arm only slightly raised so you can feel any lumps or changes in this area easily. Raising your arm straight tightens the tissue in this area, making it harder to examine.
7. If implants are present, help the patient determine the edges of each implant and how to evaluate each breast.
8. Instruct patient to call the health care provider if she finds a lump or other abnormality.
9. Use **Teach Back.** State to the patient, "I want to be sure I explained to you how to conduct a breast self-examination. Can you show me how to conduct an examination on both of your breasts?" Document your evaluation of patient learning. Revise your instruction or develop a plan for revised patient teaching to be implemented at an appropriate time if patient is not able to teach back correctly.

A

B   C


The ACS (2015b) recommends that women who are at high risk for breast cancer based on certain factors should get an MRI and a mammogram every year. This includes women who:

- Have a lifetime risk of breast cancer of about 20% to 25% or greater, according to risk assessment tools that are based mainly on family history
- Have a known *BRCA1* or *BRCA2* gene mutation
- Have a first-degree relative (parent, brother, sister, or child) with a *BRCA1* or *BRCA2* gene mutation and have not had genetic testing themselves
- Had radiation therapy to the chest when they were between the 10 and 30 years of age

The patient's history (Table 31-26) reveals normal developmental changes and signs of breast disease. Because of its glandular structure, the breast undergoes changes during a woman's life. Knowing these changes (Box 31-22) allows complete and accurate assessment. Encourage both men and women to observe their breasts for changes.

Inspection. Have the patient remove the top gown or drape to allow simultaneous visualization of both breasts. Have her stand or sit with her arms hanging loosely at her sides. If possible, place a mirror in front of her during inspection so she sees what to look for when performing a BSE. To recognize abnormalities the patient needs to

TABLE 31-26 Nursing History for Breast Assessment

Assessment	Rationale
Determine if woman is over age 40; has a personal or family history of breast cancer, especially with the BRCA1 or BRCA2 inherited gene mutations; early-onset menarche (before age 12) or late-age menopause (after age 55); has never had children or gave birth to first child after age 31; or has recently used oral contraceptives.	These are risk factors for breast cancer (ACS, 2015a).
Ask if patient (both sexes) has noticed lump, thickening, pain, or tenderness of breast; discharge, distortion, retraction, or scaling of the nipple; or change in size of breast.	Potential signs and symptoms of breast cancer allow nurse to focus on specific areas of breast during assessment.
Determine patient's use of medications (oral contraceptives, digitalis, diuretics, steroids, or estrogen). Determine his or her caffeine intake.	Some medications cause nipple discharge. Hormones and caffeine cause fibrocystic changes in breast.
Determine patient's level of activity, alcoholic intake, and weight.	Breast cancer incidence rates correlate with being overweight or obese (postmenopausal), physical inactivity, and consumption of one or more alcoholic beverages per day (ACS, 2015a).
Ask if patient performs monthly breast self-examination (BSE). If so, determine time of month she performs examination in relation to menstrual cycle. Have her describe or demonstrate method used.	Nurse's role is to educate patient about breast cancer and correct techniques for BSE.
If patient reports a breast mass, ask about length of time since she first noticed the lump. Does lump come and go, or is it always present? Have there been changes in the lump (e.g., size, relationship to menses), and are there associated symptoms?	Assessment helps to determine nature of mass (e.g., breast cancer versus fibrocystic disease).

BOX 31-22 Normal Changes in the Breast During a Woman's Life Span

Puberty (8 to 20 Years)
Breasts mature in five stages. One breast may grow more rapidly than the other. The ages at which changes occur and rate of developmental progression vary.

Stage 1 (Preadolescent)
This stage involves elevation of the nipple only.

Stage 2
The breast and nipple elevate as a small mound, and the areolar diameters enlarge.

Stage 3
There is further enlargement and elevation of the breast and areola, with no separation of contour.

Stage 4
The areola and nipple project into the secondary mound above the level of the breast (does not occur in all girls).

Stage 5 (Mature Breast)
Only the nipple projects, and the areola recedes (varies in some women).

Young Adulthood (20 to 31 Years)
Breasts reach full (nonpregnant) size. Shape is generally symmetrical. Breasts are sometimes unequal in size.

Pregnancy
Breast size gradually enlarges to 2 to 3 times the previous size. Nipples enlarge and become erect. Areolas darken, and diameters increase. Superficial veins become prominent. The nipples expel a yellowish fluid (colostrum).

Menopause
Breasts shrink. Tissue becomes softer, sometimes flabby.

Older Adulthood
Breasts become elongated, pendulous, and flaccid as a result of glandular tissue atrophy. The skin of the breasts tends to wrinkle, appearing loose and flabby.
  Nipples become smaller and flatter and lose erectile ability. They sometimes invert because of shrinkage and fibrotic changes.

Data from Touhy TA, Jett KF: *Ebersole and Hess' gerontological nursing & healthy aging*, ed 4, St Louis, 2014, Elsevier; Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children*, ed 10, St Louis, 2015, Mosby; and Ball JW et al: *Seidel's guide to physical examination*, ed 8, St Louis, 2015, Mosby.

be familiar with the normal appearance of her breasts. Describe observations or findings in relation to imaginary lines that divide the breast into four quadrants and a tail. The lines cross at the center of the nipple. Each tail extends outward from the upper outer quadrant (Figure 31-52).

Inspect the breasts for size and symmetry. Normally they extend from the third to the sixth ribs, with the nipple at the level of the fourth intercostal space. It is common for one breast to be smaller. However, inflammation or a mass causes a difference in size. As a woman ages, the ligaments supporting the breast tissue weaken, causing the breasts to sag and the nipples to lower.

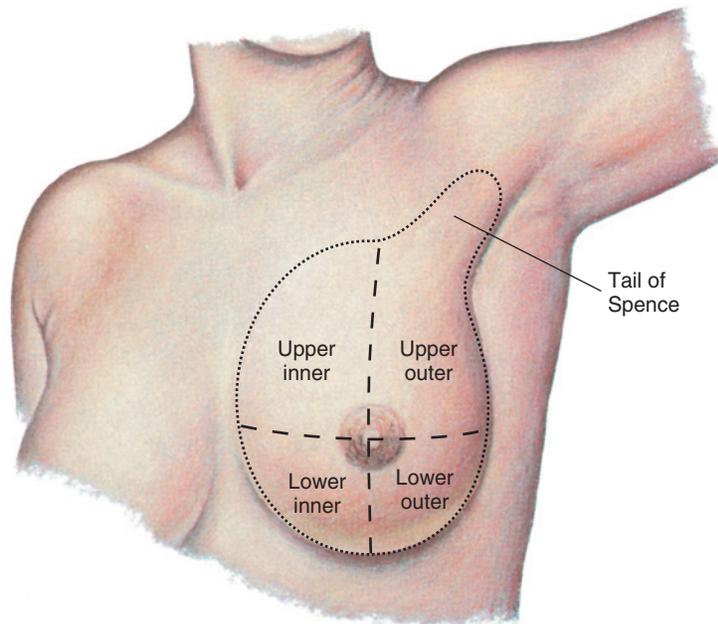
Observe the contour or shape of the breasts and note masses, flattening, retraction, or dimpling. Breasts vary in shape from convex to pendulous or conical. Retraction or dimpling can result from invasion of underlying ligaments by tumors. The ligaments fibrose and pull the overlying skin inward toward the tumor. Edema also changes the contour of the breasts. To bring out retraction or changes in the shape of breasts, ask the patient to assume three positions: raise arms above the head, press hands against the hips, and extend arms straight ahead while sitting and leaning forward. Each maneuver causes a contraction of the pectoral muscles, which accentuates the presence of any retraction.


FIGURE 31-52 Quadrants of left breast and axillary tail of Spence. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

Carefully inspect the skin for color; venous pattern; and the presence of lesions, edema, or inflammation. Lift each breast when necessary to observe lower and lateral aspects for color and texture changes. The breasts are the color of neighboring skin, and venous patterns are the same bilaterally. Venous patterns are easily visible in thin or pregnant women. Women with large breasts often have redness and excoriation of the undersurfaces caused by rubbing of skin surfaces.

Inspect the nipple and areola for size, color, shape, discharge, and the direction in which the nipples point. The normal areolas are round or oval and nearly equal bilaterally. Color ranges from pink to brown. In light-skinned women the areola turns brown during pregnancy and remains dark. In dark-skinned women the areola is brown before pregnancy (Ball et al., 2015). Normally the nipples point in symmetrical directions, are everted, and have no drainage. If the nipples are inverted, ask if this has been a lifetime history. A recent inversion or inward turning of the nipple indicates an underlying growth. Rashes or ulcerations are not normal on the breast or nipples. Note any bleeding or discharge from the nipple. Clear yellow discharge 2 days after childbirth is common. While inspecting the breasts, explain the characteristics you see. Teach patients the significance of abnormal signs or symptoms.

Palpation. Palpation assesses the condition of underlying breast tissue and lymph nodes. Breast tissue consists of glandular tissue, fibrous supportive ligaments, and fat. Glandular tissue is organized into lobes that end in ducts that open onto the surface of the nipple. The largest part of glandular tissue is in the upper outer quadrant and tail of each breast. Suspensory ligaments connect to skin and fascia underlying the breast to support the breast and maintain its upright position. Fatty tissue is located superficially and to the sides of the breast.

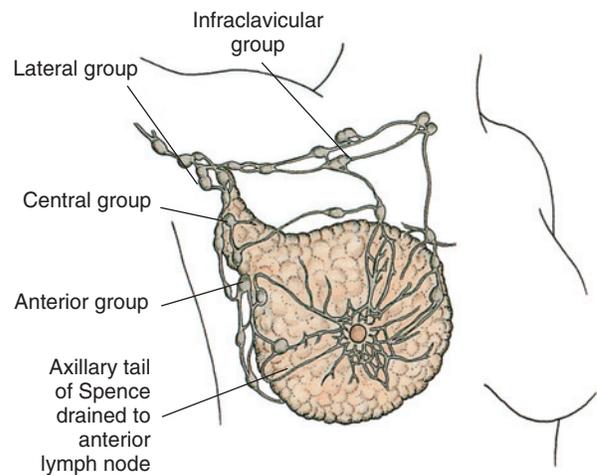
A large part of lymph from the breasts drains into axillary lymph nodes. If cancerous lesions metastasize (spread), the nodes commonly become involved. Study the location of supraclavicular, infraclavicular, and axillary nodes (Figure 31-53). The axillary nodes drain lymph from the chest wall, breasts, arms, and hands. A tumor of one breast sometimes involves nodes on the same and opposite sides.


FIGURE 31-53 Anatomical position of axillary and clavicular lymph nodes.

To palpate the lymph nodes have the patient sit with her arms at her sides and muscles relaxed. While facing the patient and standing on the side you are examining, support her arm in a flexed position and abduct it from the chest wall. Place the free hand against the patient's chest wall and high in the axillary hollow. With the fingertips press gently down over the surface of the ribs and muscles. Palpate the axillary nodes with the fingertips, gently rolling soft tissue (Figure 31-54). Palpate four areas of the axilla: at the edge of the pectoralis major muscle along the anterior axillary line, the chest wall in the midaxillary area, the upper part of the humerus, and the anterior edge of the latissimus dorsi muscle along the posterior axillary line.

Normally lymph nodes are not palpable. Carefully assess each area and note their number, consistency, mobility, and size. One or two small, soft, nontender palpable nodes are normal. An abnormal palpable node feels like a small mass that is hard, tender, and immobile. Continue to palpate along the upper and lower clavicular ridges. Reverse the procedure for the patient's other side.

FIGURE 31-54 Support patient's arm and palpate axillary lymph nodes. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

FIGURE 31-55 **A,** Patient lies flat with arm abducted and hand under head to help flatten breast tissue evenly over chest wall. **B,** Each breast is palpated in a systematic fashion. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

It is sometimes difficult for a patient to learn to palpate for lymph nodes. Lying down with the arm abducted makes the area more accessible. Instruct the patient to use her left hand for the right axillary and clavicular areas. Take the patient's fingertips and move them in the proper fashion. Then have the patient use her right hand to palpate for nodes on the left side.

With the patient lying supine and one arm under the head and neck (alternating with each breast), palpate her breast tissue. The supine position allows the breast tissue to flatten evenly against the chest wall. The position of the arm and hand further stretches and positions breast tissue evenly (Figure 31-55, *A*). Place a small pillow or towel

---

BOX 31-23   **PATIENT TEACHING**

Female Breast Assessment

Objective
- Patient will follow prevention and detection practices to ensure breast health.

Teaching Strategies
- Have patient perform return demonstration of breast self-examination (BSE) and offer the opportunity to ask questions.
- Explain recommended frequency of mammography and assessment by the patient's health care provider.
- Discuss signs and symptoms of breast cancer.
- Discuss signs and symptoms of benign (fibrocystic) breast disease.
- Inform a woman who is obese or has a family history of breast cancer that she is at higher risk for the disease (ACS, 2015a). Encourage dietary changes, including limiting meat consumption to well-trimmed, lean beef, pork, or lamb; removing skin from cooked chicken before eating it; selecting tuna and salmon packed in water and not oil; and using low-fat dairy products.
- Encourage patient to reduce intake of caffeine and theophyllines. Although this approach is controversial, it can reduce symptoms of benign (fibrocystic) breast disease.

Evaluation
- Have patient demonstrate BSE.
- During follow-up visit determine whether patient has had mammography performed.
- Ask patient to explain frequency of mammography for her situation.
- Have patient describe signs and symptoms of breast cancer compared with benign (fibrocystic) breast disease.

---

under the patient's shoulder blade to further position breast tissue. Palpate the tail of Spence (see Figure 31-55, *B*).

The consistency of normal breast tissue varies widely. The breasts of a young patient are firm and elastic. In an older patient the tissue sometimes feels stringy and nodular. A patient's familiarity with the texture of her own breasts is very important. Patients gain familiarity through monthly BSE (Box 31-23).

If the patient complains of a mass, examine the opposite breast to ensure an objective comparison of normal and abnormal tissue. Use the pads of the first three fingers to compress breast tissue gently against the chest wall, noting tissue consistency. Perform palpation systematically in one of three ways: (1) using a vertical technique with the fingers moving up and down each quadrant; (2) clockwise or counterclockwise, forming small concentric circles with the fingers along each quadrant and the tail; or (3) palpating from the center of the breast in a radial fashion, returning to the areola to begin each spoke (Figure 31-56, *A* to *C*). Whichever approach you use, be sure to cover the entire breast and tail, directing attention to any areas of tenderness. Use a bimanual technique when palpating large, pendulous breasts. Support the inferior part of the breast in one hand while using the other hand to palpate breast tissue against the supporting hand.

During palpation note the consistency of breast tissue. It normally feels dense, firm, and elastic. With menopause breast tissue shrinks and becomes softer. The lobular feel of glandular tissue is normal. The lower edge of each breast sometimes feels firm and hard. This is the normal inframammary ridge and not a tumor. It helps to move the patient's hand so she can feel normal tissue variations. Palpate abnormal masses to determine location in relation to quadrants, diameter in centimeters, shape (e.g., round or discoid), consistency (soft,

firm, or hard), tenderness, mobility, and discreteness (clear or unclear boundaries).

Cancerous lesions are hard, fixed, nontender, irregular in shape, and usually unilateral. A common benign condition of the breast is benign (fibrocystic) breast disease. Bilateral lumpy, painful breasts and sometimes nipple discharge characterize this condition. Symptoms are more apparent during the menstrual period. When palpated, the cysts (lumps) are soft, well differentiated, and movable. Deep cysts feel hard.

Give special attention to palpating the nipple and areola. Palpate the entire surface gently. Use the thumb and index finger to compress the nipple and note any discharge. During the examination of the

nipple and areola, the nipple sometimes becomes erect with wrinkling of the areola. These changes are normal. Continue by positioning the patient and examining the other breast.

After completing the examination, have the patient demonstrate self-palpation. Observe the patient's technique and emphasize the importance of a systematic approach. Urge the patient to see her health care provider if she discovers an abnormal mass during BSE. She also needs to know all of the signs and symptoms of breast cancer.

Male Breasts

Examination of the male breast is relatively easy. Inspect the nipple and areola for nodules, edema, and ulceration. An enlarged male breast results from obesity or glandular enlargement. Breast enlargement in young males results from steroid use. Fatty tissue feels soft, whereas glandular tissue is firm. Use the same techniques to palpate for masses used in examination of the female breast. Because breast cancer in men is relatively rare, routine self-examinations are unnecessary. However, men who have a first-degree relative (e.g., mother or sister) with breast cancer are at risk for breast cancer and need to palpate their breasts at regular intervals. Men at high risk may be scheduled by their health care provider for routine mammograms.

ABDOMEN

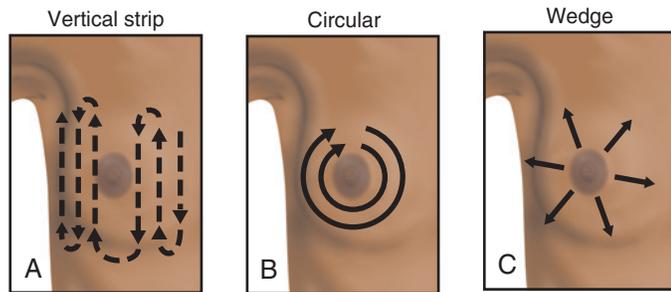
The abdominal examination is complex because of the number of organs located within and near the abdominal cavity. A thorough nursing history (Table 31-27) helps interpret physical signs. The


FIGURE 31-56 Various methods for palpation of breast. **A,** Palpate from top to bottom in vertical strips. **B,** Palpate in concentric circles. **C,** Palpate out from center in wedge sections. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

TABLE 31-27 Nursing History for Abdominal Assessment

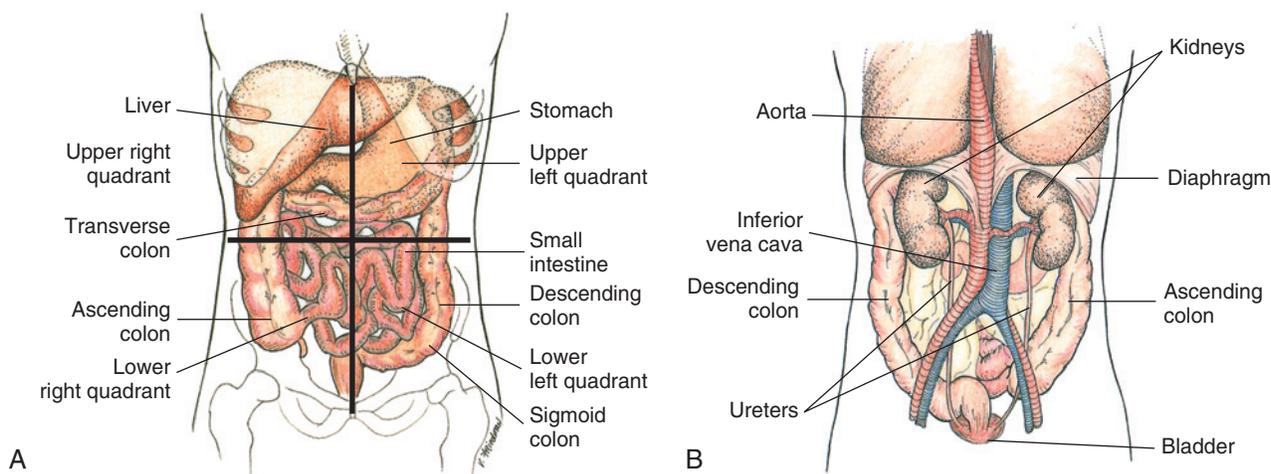
Assessment	Rationale
If patient has abdominal or low back pain, assess character of pain in detail (location, onset, frequency, precipitating factors, aggravating factors, type of pain, severity, course).	Pattern of characteristics of pain helps determine its source.
Carefully observe patient's movement and position, including lying still with knees drawn up, moving restlessly to find comfortable position, and lying on one side or sitting with knees drawn to chest.	Positions assumed by patient reveal nature and source of pain, including peritonitis, renal stone, and pancreatitis.
Assess normal bowel habits and stool character; ask if patient uses laxatives.	Data compared with physical findings help identify cause and nature of elimination problems.
Determine if patient has had abdominal surgery, trauma, or diagnostic tests of gastrointestinal (GI) tract.	Surgical or traumatic alterations of abdominal organs cause changes in expected findings (e.g., position of underlying organs). Diagnostic tests change character of stool.
Assess if patient has had recent weight changes or intolerance to diet (e.g., nausea, vomiting, cramping, especially in last 24 hours).	Data can indicate alterations in upper GI tract (stomach or gallbladder) or lower colon.
Assess for difficulty in swallowing, belching, flatulence (gas), bloody emesis (hematemesis), black or tarry stools (melena), heartburn, diarrhea, or constipation.	These characteristic signs and symptoms indicate GI alterations.
Ask if patient takes antiinflammatory medication (e.g., aspirin, ibuprofen, steroids) or antibiotics.	Pharmacological agents cause GI upset or bleeding.
Ask patient to locate tender areas before examination begins.	Assess painful areas last to minimize discomfort and anxiety.
Inquire about family history of cancer, kidney disease, alcoholism, hypertension, or heart disease.	Data can reveal risk for alterations identifiable during examination.
Determine if female patient is pregnant; note last menstrual period.	Pregnancy causes changes in abdominal shape and contour.
Assess patient's usual intake of alcohol.	Chronic alcohol ingestion causes GI and liver problems, including liver, colon and pancreatic cancer (ACS, 2015a).
Review patient's history for the following: health care occupation, hemodialysis, intravenous drug user, household or sexual contact with hepatitis B virus (HBV) carrier, heterosexual person with more than one sex partner in previous 6 months, sexually active homosexual or bisexual male, international traveler in area of high HBV infection rate.	Risk factors for HBV exposure.


FIGURE 31-57 A, Anterior view of abdomen divided by quadrants. **B,** Posterior view of abdominal section.

examination includes an assessment of structures of the lower gastro-intestinal (GI) tract in addition to the liver, stomach, uterus, ovaries, kidneys, and bladder. Abdominal pain is one of the most common symptoms that patients report when seeking medical care. An accurate assessment requires matching patient history data with a careful assessment of the location of physical symptoms.

Assess the organs anteriorly and posteriorly. A system of landmarks help map out the abdominal region. The xiphoid process (tip of the sternum) is the upper boundary of the anterior abdominal region. The symphysis pubis marks the lower boundary. Divide the abdomen into four imaginary quadrants (Figure 31-57, A); refer to assessment findings and record them in relation to each quadrant. Posteriorly the lower ribs and heavy back muscles protect the kidneys, which are located from the T12 to L3 vertebrae (see Figure 31-57, B). The costovertebral angle formed by the last rib and vertebral column is a landmark used during kidney palpation.

During the abdominal examination the patient needs to relax. A tightening of abdominal muscles hinders palpation. Ask the patient to void before beginning. Be sure that the room is warm and drape upper chest and legs. The patient lies supine or in a dorsal recumbent position with the arms at the sides and knees slightly bent. Place small pillows beneath the knees. If the patient places the arms under the head, the abdominal muscles tighten. Proceed calmly and slowly, being sure that there is adequate lighting. Expose the abdomen from just above the xiphoid process down to the symphysis pubis. Warm hands and stethoscope further promote relaxation. Ask the patient to report pain and point out tender areas. Assess tender areas last.

The order of an abdominal examination differs slightly from previous assessments. Begin with inspection and follow with auscultation. By using auscultation before palpation there is less chance of altering the frequency and character of bowel sounds. Be sure to have a tape measure and marking pen available during the examination.

Inspection

Make it a habit to observe the patient during routine care activities. Note his or her posture and look for evidence of abdominal splinting: lying with the knees drawn up or moving restlessly in bed. A patient free from abdominal pain does not guard or splint the abdomen. To inspect the abdomen for abnormal movement or shadows, stand on the patient's right side and inspect from above the abdomen. After sitting or stooping down to look across the abdomen, assess abdominal contour. Direct the examination light over the abdomen.

Skin. Inspect the skin over the abdomen for color, scars, venous patterns, lesions, and **striae** (stretch marks). The skin is subject to the same color variations as the rest of the body. Venous patterns are normally faint, except in thin patients. Striae result from stretching of tissue by obesity or pregnancy. Artificial openings indicate drainage sites resulting from surgery (see Chapter 50) or an ostomy (see Chapters 46 and 47). Scars reveal evidence of past trauma or surgery that has created permanent changes in underlying organ anatomy. Bruising indicates accidental injury, physical abuse, or a type of bleeding disorder. If needle marks or bruises are present, ask if the patient self-administers injections (e.g., low-molecular-weight heparin or insulin). Unexpected findings include generalized color changes such as jaundice or cyanosis. Shiny abdominal skin with a taut (tight) appearance can indicate ascites.

Umbilicus. Note the position; shape; color; and signs of inflammation, discharge, or protruding masses. A normal umbilicus is flat or concave, with the color the same as that of the surrounding skin. Underlying masses cause displacement of the umbilicus. An everted (pouched-out) umbilicus usually indicates distention. Hernias (protrusion of abdominal organs through the muscle wall) cause upward protrusion of the umbilicus. Normally the umbilical area does not emit discharge.

Contour and Symmetry. Inspect for contour, symmetry, and surface motion of the abdomen, noting any masses, bulging, or distention. A flat abdomen forms a horizontal plane from the xiphoid process to the symphysis pubis. A round abdomen protrudes in a convex sphere from the horizontal plane. A concave abdomen appears to sink into the muscular wall. Each of these findings is normal if the shape of the abdomen is symmetrical. In older adults there is often an overall increased distribution of adipose tissue. The presence of masses on only one side, or asymmetry, can indicate an underlying pathological condition.

Intestinal gas, a tumor, or fluid in the abdominal cavity causes **distention** (swelling). When distention is generalized, the entire abdomen protrudes. The skin often appears taut, as if it were stretched over the abdomen. When gas causes distention, the flanks (side muscles) do not bulge. However, if fluid is the source of the problem, the flanks bulge. Ask the patient to roll onto one side. A protuberance forms on the dependent side if fluid is the cause of the distention. Ask the patient if the abdomen feels unusually tight. Be careful not to

confuse distention with obesity. In obesity the abdomen is large, rolls of adipose tissue are often present along the flanks, and the patient does not complain of tightness in the abdomen. If distention is expected, measure the abdomen by placing a tape measure around it at the level of the umbilicus (this may require the patient to roll side-to-side as you position the tape measure). Consecutive measurements show any increase or decrease in distention. Use a marking pen to indicate the location of the tape measure.

Enlarged Organs or Masses. Observe the contour of the abdomen while asking the patient to take a deep breath and hold it. Normally the contour remains smooth and symmetrical. This maneuver forces the diaphragm downward and reduces the size of the abdominal cavity. Any enlarged organs in the upper abdominal cavity (e.g., liver or spleen) descend below the rib cage to cause a bulge. Perform a closer examination with palpation. To evaluate the abdominal musculature have the patient raise the head. This position causes superficial abdominal wall masses, hernias, and muscle separations to become more apparent.

Movement or Pulsations. Inspect for movement. Normally men breathe abdominally, and women breathe more costally. A patient with severe pain has diminished respiratory movement and tightens the abdominal muscles to guard against the pain. Closely inspect for peristaltic movement and aortic pulsation by looking across the abdomen from the side. These movements are visible in thin patients; otherwise no movement is present.

Auscultation

Auscultate before palpation during the abdominal assessment because manipulation of the abdomen alters the frequency and intensity of bowel sounds. Ask patients not to talk. Patients with GI tubes connected to suction need them temporarily turned off before beginning an examination.

Bowel Motility. Peristalsis, or the movement of contents through the intestines, is a normal function of the small and large intestine. Bowel sounds are the audible passage of air and fluid that peristalsis creates. Place the warmed diaphragm of the stethoscope lightly over each of the four quadrants. Normally air and fluid move through the intestines, creating soft gurgling or clicking sounds that occur irregularly 5 to 35 times per minute (Ball et al., 2015). Sounds usually last $\frac{1}{2}$ second to several seconds. It normally takes 5 to 20 seconds to hear a bowel sound. However, it takes 5 minutes of continuous listening before determining that bowel sounds are absent (Ball et al., 2015). Auscultate all four quadrants to be sure that you do not miss any sounds. The best time to auscultate is between meals. Sounds are generally described as normal, audible, absent, hyperactive, or hypoactive. Absent sounds indicate a lack of peristalsis, possibly the result of late-stage bowel obstruction; paralytic ileus; or peritonitis. Normally absent or hypoactive bowel sounds occur after surgery following general anesthesia. Hyperactive sounds are loud, "growling" sounds called **borborygmi,** which indicate increased GI motility. Inflammation of the bowel, anxiety, diarrhea, bleeding, excessive ingestion of laxatives, and reaction of the intestines to certain foods cause increased motility. Teach patients practices to promote normal elimination patterns (Box 31-24).

Vascular Sounds. Bruits indicate narrowing of the major blood vessels and disruption of blood flow. The presence of bruits in the abdominal area can reveal aneurysms or stenotic vessels. Use the bell of the stethoscope to auscultate in the epigastric region and each of

---

BOX 31-24   PATIENT TEACHING

Abdominal Assessment

Objective
- Patient will maintain normal bowel elimination.

Teaching Strategies
- Explain factors that promote normal bowel elimination such as diet (fruits, vegetables, fiber), regular exercise, limited use of over-the-counter drugs causing constipation, establishment of regular elimination schedule, and a good fluid intake (see Chapter 46). Stress importance for older adults.
- Caution patients about dangers of excessive use of laxatives or enemas.
- Instruct patient to have acute abdominal pain evaluated by a health care provider.

Evaluation
- Reassess patient's bowel elimination pattern and stool character after therapies begin.
- Observe patient using pain-relief measures and reassess character of pain.

---

the four quadrants. Normally there are no vascular sounds over the aorta (midline through the abdomen) or femoral arteries (lower quadrants). You can hear renal artery bruits by placing the stethoscope over each upper quadrant anteriorly or over the costovertebral angle posteriorly. Report a bruit immediately to a health care provider.

Kidney Tenderness. With the patient sitting or standing erect, use direct or indirect percussion to assess for kidney inflammation. You might require an advanced practice nurse to help you with this skill. With the ulnar surface of the partially closed fist, percuss posteriorly the costovertebral angle at the scapular line. If the kidneys are inflamed, the patient feels tenderness during percussion.

Palpation

Palpation primarily detects areas of abdominal tenderness, distention, or masses. As your skill base increases, learn to palpate for specific organs by using light and deep palpation.

Use light palpation over each abdominal quadrant to detect areas of tenderness. Initially avoid areas previously identified as problem spots. Lay the palm of the hand with fingers extended and approximated lightly on the abdomen. Explain the maneuver to the patient and, with the palmar surface of the fingers, depress approximately 1.3 cm ($\frac{1}{2}$ inch) in a gentle dipping motion (Figure 31-58). Avoid quick jabs and use smooth, coordinated movements. If the patient is ticklish, first place his or her hand on the abdomen with your hand on the patient's; continue this until the patient tolerates palpation.

Use a systematic palpation approach for each quadrant and assess for muscular resistance, distention, tenderness, and superficial organs or masses. Observe the patient's face for signs of discomfort. The abdomen is normally smooth with consistent softness and nontender without masses. In contrast to firm muscles found among young adults, an older adult often lacks abdominal tone. Guarding or muscle tenseness sometimes occurs while palpating a sensitive area. If tightening remains after the patient relaxes, peritonitis, acute cholecystitis, or appendicitis is sometimes the cause. It is easy to detect a distended bladder with light palpation. Normally the bladder lies below the umbilicus and above the symphysis pubis. Routinely check for a distended bladder if the patient has been unable to void (e.g., because of anesthesia or sedation or has been incontinent or if an indwelling urinary catheter is not draining well.

FIGURE 31-58 Light palpation of abdomen. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

FIGURE 31-59 Deep palpation of abdomen. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

With practice and experience perform deep palpation to delineate abdominal organs and detect less obvious masses. You need short fingernails. It is important for the patient to be relaxed while the hands depress approximately 2.5 to 7.5 cm (1 to 3 inches) into the abdomen (Figure 31-59). Never use deep palpation over a surgical incision or over extremely tender organs. It is also unwise to use palpation on abnormal masses. Deep pressure causes tenderness in a healthy patient over the cecum, sigmoid colon, aorta, and the midline near the xiphoid process (Ball et al., 2015).

Survey each quadrant systematically. Palpate masses for size, location, shape, consistency, tenderness, pulsation, and mobility. Test for rebound tenderness by pressing a hand slowly and deeply into the involved area and letting go quickly. The test is positive if the patient feels pain with the release of the hand. Rebound tenderness occurs in patients with peritoneal irritation such as occurs in appendicitis; pancreatitis; or any peritoneal injury causing bile, blood, or enzymes to enter the peritoneal cavity.

Aortic Pulsation. Palpate with the thumb and forefinger of one hand deeply into the upper abdomen just left of the midline to assess aortic pulsation. Normally a pulsation is transmitted forward. If the aorta is enlarged because of an aneurysm (localized dilation of a vessel wall), the pulsation expands laterally. Do not palpate a pulsating abdominal mass. When enlargement from an aneurysm is present, palpate this area only lightly, referring the finding to the health care provider. In obese patients it is often necessary to palpate with both hands, one on each side of the aorta.

FEMALE GENITALIA AND REPRODUCTIVE TRACT

Examination of the female genitalia is embarrassing to a patient unless you use a calm, relaxed approach. The gynecological examination is one of the most difficult experiences for adolescents. A person's cultural background further adds to apprehension. For example, female Mexican-Americans have a strong social value that women do not expose their bodies to men or even to other women. Similarly, Chinese Americans believe that the examination of genitalia is offensive. Muslim women value respect for female modesty. Provide a thorough explanation of the reason for the procedures used in an examination. The lithotomy position assumed during the examination is an added source of embarrassment. A patient is more comfortable when you use correct positioning and draping. Be sure to explain each part of the examination in advance so patients anticipate necessary actions. Adolescents sometimes choose to have parents present in the examination room.

Sometimes a patient requires a complete examination of the female reproductive organs, including assessing the external genitalia and performing a vaginal examination. You can examine external genitalia while performing routine hygiene measures or when preparing to insert a urinary catheter. An internal examination is part of each woman's preventive health care because ovarian cancer causes more deaths than any other cancer of the female reproductive system (ACS, 2014b).

Adolescents and young adults are examined because of the growing incidence of sexually transmitted infections (STIs). The average age of menarche among young girls has declined, and the majority of male and female teenagers are sexually active by age 19 (Hockenberry and Wilson, 2015). It is important to assess a patient's level of anxiety when obtaining the nursing history (Table 31-28). Combine rectal and anal assessments with the pelvic examination since the patient is situated in a lithotomy or dorsal recumbent position.

Preparation of the Patient

As a new nurse, you are responsible for assisting a patient's health care provider with a pelvic examination. For a complete examination the following equipment is needed: examination table with stirrups, vaginal speculum of correct size, adjustable light source, sink, clean disposable gloves, sterile cotton swabs, glass slides, plastic or wooden spatula, cervical brush or broom device, cytological fixative, and culture plates or media (Ball et al., 2015).

Make sure that the equipment is ready before the examination begins. Ask the patient to empty her bladder so the uterus and ovaries are readily palpable. Often it is necessary to collect a urine specimen. Help the patient to the lithotomy position in bed or on an examination table for the external genitalia assessment. Assist her into stirrups for a speculum examination. Have a woman stabilize each foot in a stirrup and slide the buttocks down to the edge of the examining table. Place a hand at the edge of the table and instruct the patient to move until touching the hand. The patient's arms should be at her sides or folded across the chest to prevent tightening of abdominal muscles.

Some women suffering from pain or deformity of the joints are unable to assume a lithotomy position. In this situation it is necessary to have the patient abduct only one leg or have another assist in separating the patient's thighs. In addition, use the side-lying position with the patient on the left side with the right thigh and knee drawn up to her chest.

Give the patient a square drape or sheet. She holds one corner over her sternum, the adjacent corners fall over each knee, and the fourth corner covers the perineum. After the examination begins, lift the

TABLE 31-28 Nursing History for Female Genitalia and Reproductive Tract Assessment

Assessment	Rationale
Determine if patient has had previous illness or surgery involving reproductive organs, including STIs.	Illness or surgery influences appearance and position of organs being examined.
Determine if patient has received HPV vaccine.	HPV increases patient's risk for development of cervical cancer.
Review menstrual history, including age at menarche, frequency and duration of menstrual cycle, character of flow (e.g., amount, presence of clots), presence of dysmenorrhea (painful menstruation), pelvic pain, dates of last two menstrual periods, and premenstrual symptoms.	This information helps to reveal level of reproductive health, including normalcy of menstrual cycle.
Ask patient to describe obstetrical history, including each pregnancy and history of abortions or miscarriages.	Observed physical findings vary, depending on woman's history of pregnancy.
Determine whether patient uses safe sex practices; have patient describe current and past contraceptive practices and problems encountered. Discuss risk of STIs and HIV infection.	Use of certain types of contraceptives influences reproductive health (e.g., sensitivity reaction to spermicidal jelly). Sexual history reveals risk for and understanding of STIs.
Assess if patient has signs and symptoms of vaginal discharge, painful or swollen perianal tissues, or genital lesions.	These signs and symptoms may indicate STI or other pathological condition.
Determine if patient has symptoms or history of genitourinary problems, including burning during urination, frequency, urgency, nocturia, hematuria, incontinence, or stress incontinence (see Chapter 46).	Urinary problems are associated with gynecological disorders, including STIs.
Ask if patient has had signs of bleeding outside of normal menstrual period or after menopause or has had unusual vaginal discharge.	These are warning signs for cervical and endometrial cancer or vaginal infection.
Determine if patient has history of HPV (condyloma acuminatum, herpes simplex, or cervical dysplasia), has multiple sex partners, smokes cigarettes, has had multiple pregnancies, or was young at first intercourse.	These are risk factors for cervical cancer (ACS, 2015a).
A strong family history of breast or ovarian cancer, women who have had breast cancer or who have tested positive for inherited mutations in BRCA1 or BRCA2 genes are at increased risk. Other medical conditions associated with increased risk include pelvic inflammatory disease and Lynch syndrome. The use of estrogen alone as menopausal hormone therapy has been shown to increase risk. Tobacco smoking increases the risk of mucinous ovarian cancer. Heavier body weight may be associated with increased risk of ovarian cancer.	These are risk factors for ovarian cancer (ACS, 2015a).
Determine if patient is postmenopausal, is obese, has abdominal fat, or is infertile. Assess if patient received menopausal estrogen therapy, had late menopause, never had children, and had a history of polycystic ovary syndrome. Tamoxifen, a drug used to reduce breast cancer risk, increases the risk slightly because it has estrogen-like effects on the uterus. Medical conditions that increase the risk include Lynch syndrome and diabetes.	These are risk factors for endometrial cancer (ACS, 2015a).

HIV, Human immunodeficiency virus; *HPV,* human papillomavirus (HPV) vaccine; *STI,* sexually transmitted infection.

drape over the perineum. A male examiner always needs to have a female attendant present during the examination, whereas a female examiner may choose to work alone. An additional female should be present if the patient requests it.

External Genitalia

You can perform this examination independently of a health care provider. Make sure that the perineal area is well illuminated. Follow standard precautions and wear clean gloves to prevent contact with infectious organisms. The perineum is sensitive and tender; do not touch the area suddenly without warning a patient. It is best to touch the inner thigh first before touching the perineum.

While sitting at the end of the examination table or bed, inspect the quantity and distribution of hair growth. Preadolescents have no pubic hair. During adolescence hair grows along the labia, becoming darker, coarser, and curlier. In an adult hair grows in a triangle over the female perineum and along the medial surfaces of the thighs. The underlying skin is free of inflammation, irritation, or lesions.

Inspect surface characteristics of the labia majora. The skin of the perineum is smooth, clean, and slightly darker than other skin. The mucous membranes appear dark pink and moist. The labia majora can be gaping or closed, appear dry or moist, and are usually symmetrical. After childbirth the labia majora separate, causing the labia minora to become more prominent. When a woman reaches menopause, the labia majora become thinned; they become atrophied in older age. The labia majora are normally without inflammation, edema, lesions, or lacerations.

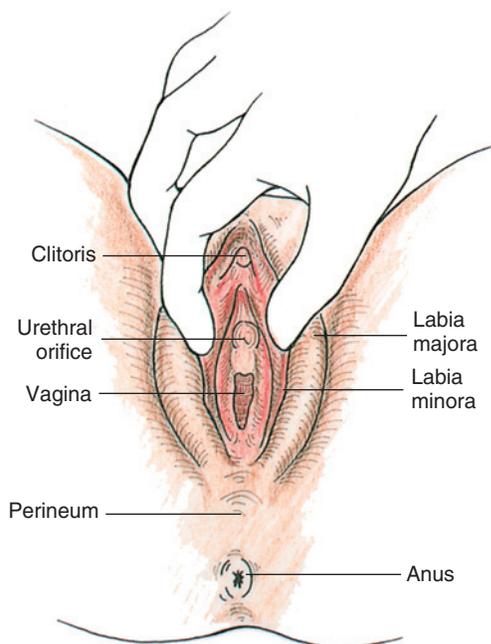
To inspect the remaining external structures, use your nondominant hand and gently place the thumb and index finger inside the labia minora and retract the tissues outwardly (Figure 31-60). Be sure to have a firm hold to avoid repeated retraction against the sensitive tissues. Use the other hand to palpate the labia minora between the thumb and second finger. On inspection the labia minora are normally thinner than the labia majora, and one side is sometimes larger. The tissue feels soft on palpation and without tenderness. The size of the clitoris varies, but it normally does not exceed 2 cm (1 inch) in length and 0.5 cm (¼ inch) in width. Look for atrophy, inflammation, or adhesions. If inflamed, the clitoris is a bright cherry red. In young women it is a common site for syphilitic lesions, or chancres, which appear as small open ulcers that drain serous material.


FIGURE 31-60 Female external genitalia.

Inspect the urethral orifice carefully for color and position. It is normally intact without inflammation. The urethral meatus is anterior to the vaginal orifice and is pink. It appears as a small slit or pinhole opening just above the vaginal canal. Note any discharge, polyps, or fistulas.

Inspect the vaginal orifice for inflammation, edema, discoloration, discharge, and lesions. Normally the opening is a thin, vertical slit; and the tissue is moist. While inspecting the vaginal orifice, note the condition of the hymen, which is just inside the opening. In the virgin female the hymen restricts the opening of the vagina, but the tissue retracts or disappears after sexual intercourse.

Inspect the anus, looking for lesions and hemorrhoids (see rectal examination). After completion of the external examination, dispose of examination gloves and offer the patient soft disposable cloths for perineal hygiene.

Patients who are at risk for contracting an STI need to learn to perform a genital self-examination (Box 31-25). The purpose of the examination is to detect any signs or symptoms of an STI. Many people do not know that they have an STI (e.g., chlamydia), and some STIs (e.g., syphilis) remain undetected for years.

Speculum Examination of Internal Genitalia

An examination of the internal genitalia requires much skill and practice. Advanced nurse practitioners and primary care providers perform this examination. As a nursing student you observe the procedure or assist the examiner by helping the patient with positioning, handing off specimen supplies, and providing emotional support for the patient.

The examination involves use of a plastic or metal speculum consisting of two blades and an adjustment device. The examiner inserts the speculum into the vagina to assess the internal genitalia for cancerous lesions and other abnormalities. During the examination the examiner collects a specimen for a Papanicolaou (Pap) test for cervical and vaginal cancer. The cervix is inspected for color, position, size, surface characteristics, and discharge (Ball et al., 2015).

BOX 31-25 PATIENT TEACHING

Female Genitalia and Reproductive Tract Assessment

Objective
- Patient will use measures to maintain sexual health and prevent acquisition and transmission of sexually transmitted infections (STIs).

Teaching Strategies
- Instruct patient about purpose and recommended frequency of Papanicolaou (Pap) smears and gynecological examinations. Explain that the Pap smear is relatively painless and needed annually with a pelvic examination for women who are sexually active or over the age of 21. Patients are screened more often if certain risk factors exist such as a weak immune system, multiple sex partners, smoking, and a history of infections (e.g., human papillomavirus [HPV]).
- Counsel patient with an STI about the implications of diagnosis and treatment.
- Counsel young males and females and their parents about genital HPV infection and the need to receive the HPV vaccine before becoming sexually active. The vaccine is recommended for preteen boys and girls at age 11 or 12 (CDC, 2015b). Adolescent boys and girls who did not start or finish the HPV vaccine series when they were younger should get it now. Young women can get an HPV vaccine through age 26, and young men can get vaccinated through age 21 (CDC, 2015b).
- Instruct in genital self-examination (GSE). Using a mirror, position self to examine the area covered by the pubic hair. Spread the hair apart, looking for bumps, sores, or blisters. Also look for any warts, which appear as small, bumpy spots and enlarge to fleshy, cauliflower-like lesions. Next spread the outer vaginal lips apart and look at the clitoris for bumps, blisters, sores, or warts. Look at both sides of the inner vaginal lips. Inspect the area around the urinary and vaginal opening for bumps, blisters, sores, or warts.
- Explain warning signs of STIs: pain or burning on urination, pain during sex, pain in pelvic area, bleeding between menstruation, itchy rash around vagina, and abnormal vaginal discharge.
- Teach measures to prevent STIs: male partner's use of condoms, restricting number of sexual partners, avoiding sex with people who have several other partners, and perineal hygiene measures.
- Tell patients with an STI to inform sexual partners of the need for an examination.
- Reinforce the importance of performing perineal hygiene (as appropriate).

Evaluation
- Determine if parents followed through in having their child immunized for HPV.
- Ask patient to explain when she should routinely have a gynecological examination and Pap test.
- Have patient describe ways to prevent transmission of STIs.
- For patient with an STI, determine during follow-up visit if she has followed safe sexual practices (use nonthreatening inquiry).

MALE GENITALIA

An examination of the male genitalia assesses the integrity of the external genitalia (Figure 31-61), inguinal ring, and canal. Because the incidence of STIs in adolescents and young adults is high, an assessment of the genitalia needs to be a routine part of any health maintenance examination for this age-group (Box 31-26). The examination begins by having the patient void. Make sure the examination room is warm. Have the patient lie supine with the chest, abdomen, and lower legs draped or stand during the examination. Apply clean gloves.

Use a calm, gentle approach to lessen the patient's anxiety. The position and exposure of the body during the examination is embarrassing for some men. To minimize his anxiety, it often helps to offer explanation of the steps of examination so he anticipates all actions. Manipulate the genitalia gently to avoid causing erection or discomfort. Obtain a thorough history (Table 31-29) before the examination, ensuring that the assessment is complete.

Sexual Maturity

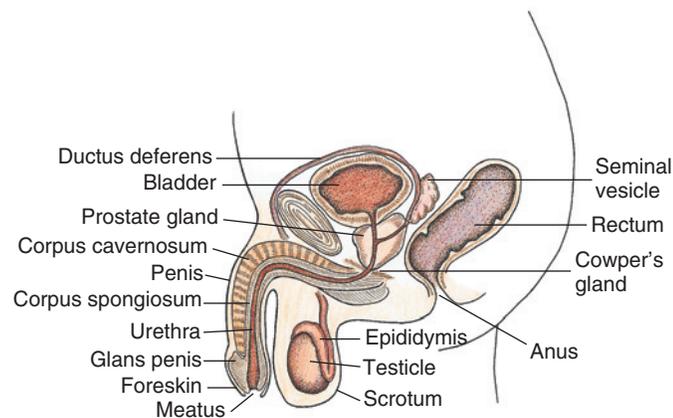
First note the sexual maturity of the patient by observing the size and shape of the penis and testes; the size, color, and texture of the scrotal skin; and the character and distribution of pubic hair. The testes first increase in size in preadolescence. During this time there is no pubic hair. By the end of puberty, the testes and penis enlarge to adult size and shape, and scrotal skin darkens and becomes wrinkled. With puberty hair is coarse and abundant in the pubic area. The penis has no hair, and the scrotum has very little hair (Figure 31-62, *A* and *B*). Also inspect the skin covering the genitalia for lice, rashes, excoriations, or lesions. Normally it is clear, without lesions.


FIGURE 31-61 External and internal male sex organs.

Penis

To inspect penile surfaces, manipulate the genitalia or have the patient assist. Inspect the shaft, corona, prepuce (foreskin), glans, and urethral meatus. The dorsal vein is apparent on inspection. In uncircumcised males retract the foreskin to reveal the glans and urethral meatus. The

---

BOX 31-26 PATIENT TEACHING

Male Genitalia Assessment

Objective
- Patient will use measures to maintain sexual health and prevent acquisition and transmission of sexually transmitted infections (STIs).

Teaching Strategies
- Teach patient how to perform genital self-examination (see Box 31-27).
- Counsel patient who has an STI about diagnosis implications and treatment.
- Explain warning signs of STIs: pain on urination and during sex, abnormal penile discharge (different from usual), swollen lymph nodes, or rash or ulcer on skin or genitalia.
- Teach measures to prevent STIs: HPV immunization, use of condoms, avoiding sex with infected partner, restricting number of sexual partners, avoiding sex with people who have multiple partners, and using regular perineal hygiene.
- Recommend HPV vaccine for preteen boys age 11 or 12; young men can get vaccinated through age 21 (CDC, 2015b).
- Tell patients with an STI to inform their sexual partners of the need to have an examination.
- Instruct patient to seek treatment as soon as possible if partner becomes infected with an STI.

Evaluation
- Ask patient to describe methods for preventing and treating STIs.
- During a follow-up visit determine whether patient with an STI has used safe sex practices.
- Ask parents or patient if HPV vaccination was achieved.

TABLE 31-29 Nursing History for Male Genitalia Assessment

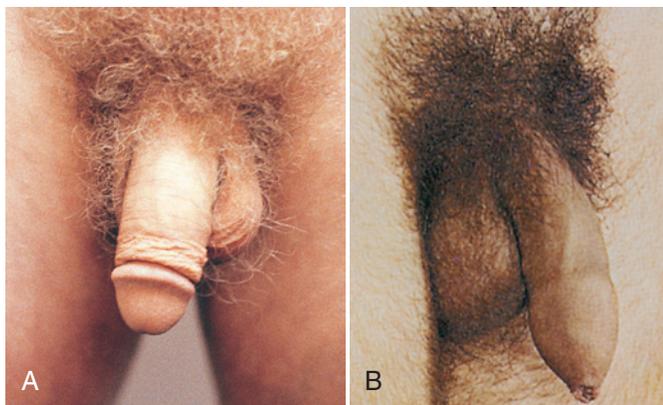
Assessment	Rationale
Review normal urinary elimination pattern, including frequency of voiding; history of nocturia; character and volume of urine; daily fluid intake; symptoms of burning, urgency, and frequency; difficulty starting stream; and hematuria (see Chapter 46).	Urinary problems are directly associated with genitourinary problems because of anatomical structure of men's reproductive and urinary systems.
Assess patient's sexual history and use of safe sex habits (multiple partners, infection in partners, failure to use condom).	Sexual history reveals risk for and understanding of sexually transmitted diseases (STIs) and human immunodeficiency virus (HIV).
Determine if patient has received the human papillomavirus (HPV) vaccine.	HPV is associated with genital warts in males and can lead to cervical cancer in females (CDC, 2014).
Determine if patient has had previous surgery or illness involving urinary or reproductive organs, including STI.	Alterations resulting from disease or surgery are sometimes responsible for symptoms or changes in organ structure or function.
Ask if patient has noted penile pain or swelling, genital lesions, or urethral discharge.	These signs and symptoms may indicate STI.
Determine if patient has noticed heaviness or painless enlargement of testis or irregular lumps.	These signs and symptoms are early warning signs for testicular cancer.
If patient reports an enlargement in inguinal area, assess if it is intermittent or constant, associated with straining or lifting, and painful; and whether pain is affected by coughing, lifting, or straining at stool.	Signs and symptoms reflect potential inguinal hernia.
Ask if patient has difficulty achieving erection or ejaculation; also review whether patient is taking diuretics, sedatives, antihypertensives, or tranquilizers.	These medications influence sexual performance.


FIGURE 31-62 Appearance of male genitalia. **A,** Circumcised. **B,** Uncircumcised. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

foreskin usually retracts easily. A small amount of white, thick smegma sometimes collects under this foreskin. Obtain a culture if abnormal discharge is present. The urethral meatus is slitlike in appearance and positioned on the ventral surface just millimeters from the tip of the glans. In some congenital conditions the meatus is displaced along the penile shaft. The area between the foreskin and glans is a common site for venereal lesions. Gently compress the glans between the thumb and index finger; this opens the urethral meatus for inspection of lesions, edema, and inflammation. Normally the opening is glistening and pink without discharge. Palpate any lesion gently to note tenderness, size, consistency, and shape. When inspection and palpation of the glans is complete, pull the foreskin down to its original position.

Continue by inspecting the entire shaft of the penis, including the undersurface, looking for lesions, scars, or edema. Palpate the shaft between the thumb and first two fingers to detect localized areas of hardness or tenderness. A patient who has lain in bed for a prolonged time sometimes develops dependent edema in the penis shaft.

It is important for any male patient to learn to perform a genital self-examination to detect signs or symptoms of STIs, especially men who have had more than one sexual partner or whose partner has had other partners. Men may have an STI but not be aware of it; self-examination is a routine part of self-care (Box 31-27).

Scrotum

Be particularly cautious while inspecting and palpating the scrotum because the structures lying within the scrotal sac are very sensitive. The scrotum is divided internally into two halves. Each half contains a testicle, epididymis, and the vas deferens, which travels upward into the inguinal ring. Normally the left testicle is lower than the right. Inspect the size, shape, and symmetry of the scrotum while observing for lesions or edema. Gently lift the scrotum to view the posterior surface. The scrotal skin is usually loose, and the surface is coarse. The scrotal skin is more deeply pigmented than body skin. Tightening of the skin or loss of wrinkling reveals edema. The size of the scrotum normally changes with temperature variations because the dartos muscle contracts in cold and relaxes in warm temperatures. Lumps in the scrotal skin are commonly sebaceous cysts.

Testicular cancer is a solid tumor common in young men ages 18 to 34 years. Early detection is critical. Explain testicular self-examination (see Box 31-27) while examining the patient. The testes are normally sensitive but not tender. The underlying testicles are normally ovoid and approximately 2 to 4 cm (1 to $1\frac{1}{2}$ inch) in size. Gently palpate

the testicles and epididymis between the thumb and first two fingers. The testes feel smooth, rubbery, and free of nodules. The epididymis is resilient. Note the size, shape, and consistency of the organs. The most common symptoms of testicular cancer are a painless enlargement of one testis and the appearance of a palpable, small, hard lump, about the size of a pea, on the front or side of the testicle. In the older adult the testicles decrease in size and are less firm during palpation. Continue to palpate the vas deferens separately as it forms the spermatic cord toward the inguinal ring, noting nodules or swelling. It normally feels smooth and discrete.

Inguinal Ring and Canal

The external inguinal ring provides the opening for the spermatic cord to pass into the inguinal canal. The canal forms a passage through the abdominal wall, a potential site for hernia formation. A hernia is a protrusion of a part of intestine through the inguinal wall or canal. Sometimes an intestinal loop enters the scrotum. Have the patient stand during this part of the examination.

During inspection ask the patient to strain or bear down. The maneuver helps to make a hernia more visible. Look for obvious bulging in the inguinal area.

Complete the examination by palpating for inguinal lymph nodes. Normally small, nontender, mobile horizontal nodes are palpable. Any abnormality indicates local or systemic infection or malignant disease.

RECTUM AND ANUS

A good time to perform the rectal examination is after the genital examination. Usually this examination is not performed for young children or adolescents. It detects colorectal cancer in its early stages. The rectal examination also detects prostatic tumors in men. Collect a health history (Table 31-30) to detect the patient's risk for bowel or rectal disease (men and women) or prostate disease (men). Teach the patient about the purpose of the examination (Box 31-28).

The rectal examination is uncomfortable; thus explaining all steps helps a patient relax. Use a calm, slow-paced, gentle approach during the examination. Female patients remain in the dorsal recumbent position following genitalia examination or they assume a side-lying (Sims') position. The best way to examine men is to have the patient stand and bend over forward with hips flexed and upper body resting across an examination table. Examine a nonambulatory patient in the Sims' position. Use nonlatex clean gloves.

Inspection

Using the nondominant hand, gently retract the buttocks to view the perianal and sacrococcygeal areas. Perianal skin is smooth, more pigmented, and coarser than skin over the buttocks. Inspect anal tissue for skin characteristics, lesions, external hemorrhoids (dilated veins that appear as reddened protrusions), ulcers, fissures and fistulas, inflammation, rashes, or excoriation. Anal tissues are moist and hairless, and the voluntary external muscle sphincter holds the anus closed. Next ask a patient to bear down as though having a bowel movement. Any internal hemorrhoids or fissures appear at this time. Use clock reference (e.g., 3 o'clock or 8 o'clock) to describe location of findings. Normally there is no protrusion of tissue.

Digital Palpation

Examine the anal canal and sphincters with digital palpation, and in male patients palpate the prostate gland to rule out enlargement. Usually advanced practitioners perform this part of the examination. This technique is not discussed here.

BOX 31-27 Male Genital Self-Examination

All men 15 years and older need to perform this examination monthly using the following steps.

Genital Examination
- Perform the examination after a warm bath or shower when the scrotal skin is less thick.
- Stand naked in front of a mirror, hold the penis in your hand, and examine the head. Pull back the foreskin if uncircumcised to expose the glans.
- Inspect and palpate the entire head of the penis in a clockwise motion, looking carefully for any bumps, sores, or blisters (bumps and blisters may be light colored or red, resemble pimples).
- Look also for any genital warts (see illustration).
- Look at the opening (urethral meatus) at the end of the penis for discharge.
- Look along the entire shaft of the penis for the same signs.
- Be sure to separate pubic hair at the base of the penis and carefully examine the skin underneath.

Testicular Self-Examination
- Look for swelling or lumps in the skin of the scrotum while looking in the mirror.
- Use both hands, placing the index and middle fingers under the testicles and the thumb on top (see illustration).
- Gently roll the testicle, feeling for lumps, swelling, soreness, or a harder consistency.
- Find the epididymis (a cordlike structure on the top and back of the testicle; it is not a lump).
- Feel for small, pea-size lumps on the front and side of the testicle. Abnormal lumps are usually painless.
- Call your health care provider for abnormal findings.

Illustrations from Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.

TABLE 31-30 Nursing History for Rectal and Anal Assessment

Assessment	Rationale
Determine whether patient has experienced bleeding from rectum, black or tarry stools (melena), rectal pain, or change in bowel habits (constipation or diarrhea).	These are warning signs of colorectal cancer* or other gastrointestinal alterations.
Determine whether patient has personal or strong family history of colorectal cancer, polyps, or chronic inflammatory bowel disease. Ask if patient is over age 40.	These are risk factors for colorectal cancer (ACS, 2014a).*
Assess dietary habits, including high fat intake, diet high in processed or red meats, or deficient fiber content (inadequate fruits and vegetables).	Bowel cancer is often linked to dietary intake of fat or insufficient fiber intake.*
Determine if patient is obese, is physically inactive, smokes, or consumes alcohol.	These are risk factors for colorectal cancer (ACS, 2014a).
Determine whether patient has undergone screening for colorectal cancer (digital examination, fecal occult blood test, flexible sigmoidoscopy, and colonoscopy).	Undergoing this screening reflects understanding and compliance with preventive health care measures.
Assess medication history for use of laxatives or cathartic medications.	Repeated use causes diarrhea and eventual loss of intestinal muscle tone.
Assess for use of codeine or iron preparations.	Codeine causes constipation. Iron turns the color of feces black and tarry.
Ask male patient if he has experienced weak or interrupted urine flow, inability to urinate, difficulty starting or stopping urine flow, polyuria, nocturia, hematuria, or dysuria. Does patient have continuing pain in lower back, pelvis, or upper thighs?	These are warning signs of prostate cancer.* Symptoms also suggest infection or prostate enlargement.

*Data from American Cancer Society: *Cancer facts and figures 2015,* Atlanta, 2015, The Society.

BOX 31-28 PATIENT TEACHING

Rectal and Anal Assessment

Objective
- Patient will be able to identify symptoms of colorectal and prostatic cancer.

Teaching Strategies
- Discuss the guidelines of the American Cancer Society (ACS, 2014a) for early detection of colorectal cancer. **Beginning at age 50,** both men and women of average risk should use one of these screening tests (ACS, 2015a):
  - Fecal occult blood test (FOBT) or fecal immunochemical test (FIT) annually
  - Stool DNA test performed every 3 years
  - Flexible sigmoidoscopy (FSIG): Visual inspection of the rectum and lower colon with a hollow, lighted tube performed by a health care provider every 5 years OR
  - Double-contrast barium enema every 5 years if recommended by health care provider
  - Colonoscopy every 10 years if recommended
  - Computed tomography (CT) colonoscopy every 5 years if recommended
- Individuals at increased risk should discuss options with their health care provider
- Discuss warning signs of colorectal cancer (see Table 31-30)
- Discuss with male patient the ACS guidelines (2015a) for early detection of prostate cancer:
- For men ages 50+, Digital rectal examination (DRE) and prostate-specific antigen test (PSA). The ACS recommends that men who have at least a 10-year life expectancy should have an opportunity to make an informed decision with their health care provider about whether to be screened for prostate cancer after receiving information about the potential benefits, risks, and uncertainties of testing.
- Discuss warning signs of prostate cancer.

Evaluation
- During follow-up visit determine whether patient has had appropriate screening tests performed.
- Have patient explain warning signs of colorectal and prostate cancer.

MUSCULOSKELETAL SYSTEM

The musculoskeletal assessment can be performed as a separate examination or integrated with other parts of the total physical examination. In addition, you can assess the patient's movements while performing other nursing care measures such as bathing or positioning. The assessment of musculoskeletal function focuses on determining range of joint motion, muscle strength and tone, and joint and muscle condition. Assessing musculoskeletal integrity is especially important when a patient reports pain or loss of function in a joint or muscle. Because muscular disorders are often the result of neurological disease, you may choose to perform a simultaneous neurological assessment.

While examining a patient's musculoskeletal function, visualize the anatomy of bone and muscle placement and joint structure (see Chapter 28). Joints vary in degree of mobility, depending on the type of joint.

For a complete examination expose the muscles and joints so they are free to move. Have the patient assume a sitting, supine, prone, or standing position while assessing specific muscle groups. Table 31-31 lists the information gathered in the nursing history.

General Inspection

Observe the patient's gait when he or she enters the examination room. When the patient is unaware of the nature of your observation, gait is more natural. Later a more formal test has the patient walk in a straight line away from and returning to the point of origin. Note how the patient walks, sits, and rises from a sitting position. Normally patients walk with the arms swinging freely at the sides and the head leading the body. Older adults often walk with smaller steps and a wider base of support. Note foot dragging, limping, shuffling, and the position of the trunk in relation to the legs.

Observe the patient from the side and while facing him or her in a standing position. The normal standing posture is upright with parallel alignment of the hips and shoulders (Figure 31-63, A to C). There is an even contour of the shoulders, level scapulae and iliac crests, alignment of the head over the gluteal folds, and symmetry of extremities. While observing from the side of the patient, note the normal cervical, thoracic, and lumbar curves. Holding the head erect is normal. As the patient sits, some degree of rounding of the shoulders is normal. Older adults tend to assume a stooped, forward-bent posture with the hips and knees somewhat flexed and arms bent at the elbows, raising the level of the arms.

Common postural abnormalities include kyphosis, lordosis, and scoliosis (Figure 31-64, A to C). **Kyphosis,** or hunchback, is an exaggeration of the posterior curvature of the thoracic spine. This postural abnormality is common in older adults. **Lordosis,** or swayback, is an increased lumbar curvature. A lateral spinal curvature is called **scoliosis**. Loss of height is frequently the first clinical sign of osteoporosis, in which height loss occurs in the trunk as a result of vertebral fracture and collapse. **Osteoporosis** is a systemic skeletal condition that is noted to have both decreased bone mass and deterioration of bone tissue, making bones fragile and at risk for fracture (Nelson et al., 2010). Osteopenia, characterized by low bone mass of the hip, puts people at risk for osteoporosis, fractures, and potential complications later in life. Approximately 80% of people with osteoporosis are women; approximately 20% of the time the disease affects men. It affects any age-group, including children. Patients should be taught ways to reduce the chance of developing this disease (Box 31-29).

During general inspection look at the extremities for overall size, gross deformity, bony enlargement, alignment, and symmetry. Normally there is bilateral symmetry in length, circumference, alignment, and position and in the number of skinfolds (Ball et al., 2015). A general review pinpoints areas requiring specialized assessment.

Palpation

Apply gentle palpation to all bones, joints, and surrounding muscles during a complete examination. For a focused assessment only examine the involved area. Note any heat, tenderness, edema, or resistance to pressure. The patient should not feel any discomfort when you palpate. Muscles should be firm.

Range of Joint Motion

The examination includes comparison of both active and passive ROM. Ask the patient to put each major joint through active and passive full ROM (see Chapter 28). Learn the correct terminology for the movements that the joints are capable of making (Table 31-32) and teach the patient how to move through each ROM. Demonstrate ROM to the patient when possible. To assess ROM passively, ask the patient to relax and then passively move the extremities through their ROM. Compare the same body parts for equality in movement. Figure 31-65, A to F, shows an example of ROM positions for the hand and wrist. Do not force a joint into a painful position. Know the normal range of each joint and the extent to which you can move the patient's joints.

TABLE 31-31 **Nursing History for Musculoskeletal Assessment**	
Assessment	**Rationale**
Determine if patient is involved in competitive sports (particularly involving collision and contact), fails to warm up adequately, is in poor physical condition, or has had a rapid growth spurt (adolescents).	These are risk factors for sports injury.
Assess for risk factors of osteoporosis. Uncontrollable risk factors: • Over age 50 • Female • Nulliparous • Menopause before age 45 • Family history of osteoporosis • Low body weight/being small and thin/constant dieting • Broken bones or height loss Controllable risk factors: • Not getting enough calcium (less than 500 mg) and vitamin D • Not eating enough fruits and vegetables • Getting too much protein, sodium and caffeine • Having an inactive lifestyle • Smoking • Drinking too much alcohol • Losing weight Long-term use of certain medications: aluminum-containing antacids; antiseizure medicines such as Dilantin or Phenobarbital; aromatase inhibitors such as Arimidex, Aromasin, and Femara; cancer chemotherapeutic drugs, and heparin.	These are risk factors for osteoporosis (Walker, 2010; NOF, n.d.).
Ask patient to describe history of problems in bone, muscle, or joint function (e.g., recent fall, trauma, lifting of heavy objects, history of bone or joint disease with sudden or gradual onset, location of alteration).	History helps to assess nature of musculoskeletal problem.
Assess nature and extent of pain, including location, duration, severity, predisposing and aggravating factors, relieving factors, and type.	Pain frequently accompanies alterations in bone, joints, or muscle. This has implications not only for comfort, but also for ability to perform activities of daily living.
Assess patient's normal activity pattern, including type of exercise routinely performed.	Provides baseline in assessment. Sedentary lifestyle and lack of appropriate exercise increase bone loss and risk of fractures.
Determine how alteration influences ability to perform activities of daily living (e.g., bathing, feeding, dressing, toileting, ambulating) and social functions (e.g., household chores, work, recreation, sexual activities).	The extent to which patient is able to perform self-care determines the level of nursing care. Type and degree of restriction in continuing social activities influence topics for patient education and ability of nurse to identify alternative ways to maintain function.
Assess height loss of woman over age 50 by subtracting current height from recall of maximum adult height. Refer to physician for bone density exam (women 65 years and older).	Measurement is useful screening tool to predict osteoporosis. Bone density recommended by USPSTF (2011).

ROM is equal between contralateral joints. Ideally assess the patient's normal range to determine a baseline for assessing later change.

A **goniometer,** frequently used by physical and occupational therapists, measures the precise degree of motion in a particular joint and is mainly for patients who have a suspected reduction in joint movement. The instrument has two flexible arms with a 180-degree protractor in the center. Position the center of the protractor at the center of the joint you are measuring (Figure 31-66). The arms extend along the body parts on each side of the protractor. Measure the joint angle before moving the joint. After taking the joint through a full ROM, measure the angle again to determine the degree of movement. Compare the reading with the normal degree of joint movement.

Joints are typically free from stiffness, instability, swelling, or inflammation. There should be no discomfort when applying pressure to bones and joints. In older adults joints often become swollen and stiff with reduced ROM resulting from cartilage erosion and fibrosis

of synovial membranes (see Chapter 28). If a joint appears swollen and inflamed, palpate it for warmth.

Muscle Tone and Strength

Assess muscle strength and tone during ROM measurement. Integrate these findings with those from the neurological assessment. Note muscle tone, the slight muscular resistance felt as you move the relaxed extremity passively through its ROM.

Ask the patient to allow an extremity to relax or hang limp. This is often difficult, particularly if the patient feels pain in it. Support the extremity and grasp each limb, moving it through the normal ROM (Figure 31-67). Normal tone causes a mild, even resistance to movement through the entire range.

If a muscle has increased tone, or **hypertonicity,** there is considerable resistance with any sudden passive movement of a joint. Continued movement eventually causes the muscle to relax. A muscle that has

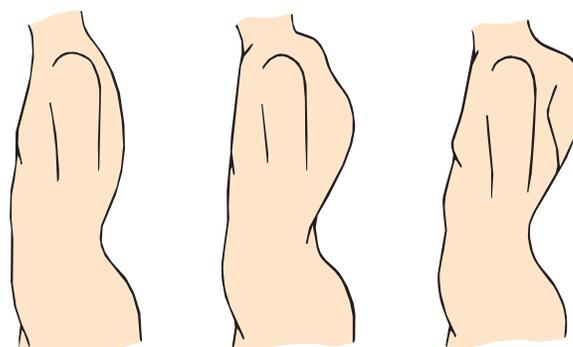

FIGURE 31-64 Common postural abnormalities. **A,** Lordosis. **B,** Kyphosis. **C,** Scoliosis.

BOX 31-29   PATIENT TEACHING

Health Promotion to Prevent Osteoporosis in Women

Objective
- Patient will follow measures to prevent or minimize osteoporosis.

Teaching Strategies
- Recommend women age 65 and older for routine screening for osteoporosis (USPSTF, 2011). Recommend men for screening as well; they are at risk for development of osteoporosis equally as they age.
- To reduce bone demineralization, instruct older adults in a proper exercise program (e.g., weight-bearing, muscle-strengthening, and balance-training exercises) to be followed 3 or more times a week.
- Encourage intake of calcium to meet the recommended daily allowance. Increased vitamin D aids calcium absorption.
- Recommendation for calcium supplements for adults over age 25 is 1000 to 1500 mg/day. Instruct patient to take no more than 500 mg of calcium at one time.

- Instruct older adults and those with osteoporosis in proper body mechanics and range-of-motion and moderate weight-bearing exercises (e.g., swimming and walking) to minimize trauma and subsequent fracture of bones.
- Instruct older patients to pace activities to compensate for loss in muscle strength.

Evaluation
- Observe patient's posture.
- Ask patient to describe therapies for preventing osteoporosis.
- Observe patient perform range-of-motion exercises.
- Have patient keep log of regular weight-training exercises.

TABLE 31-32   Terminology for Normal Range-of-Motion Positions

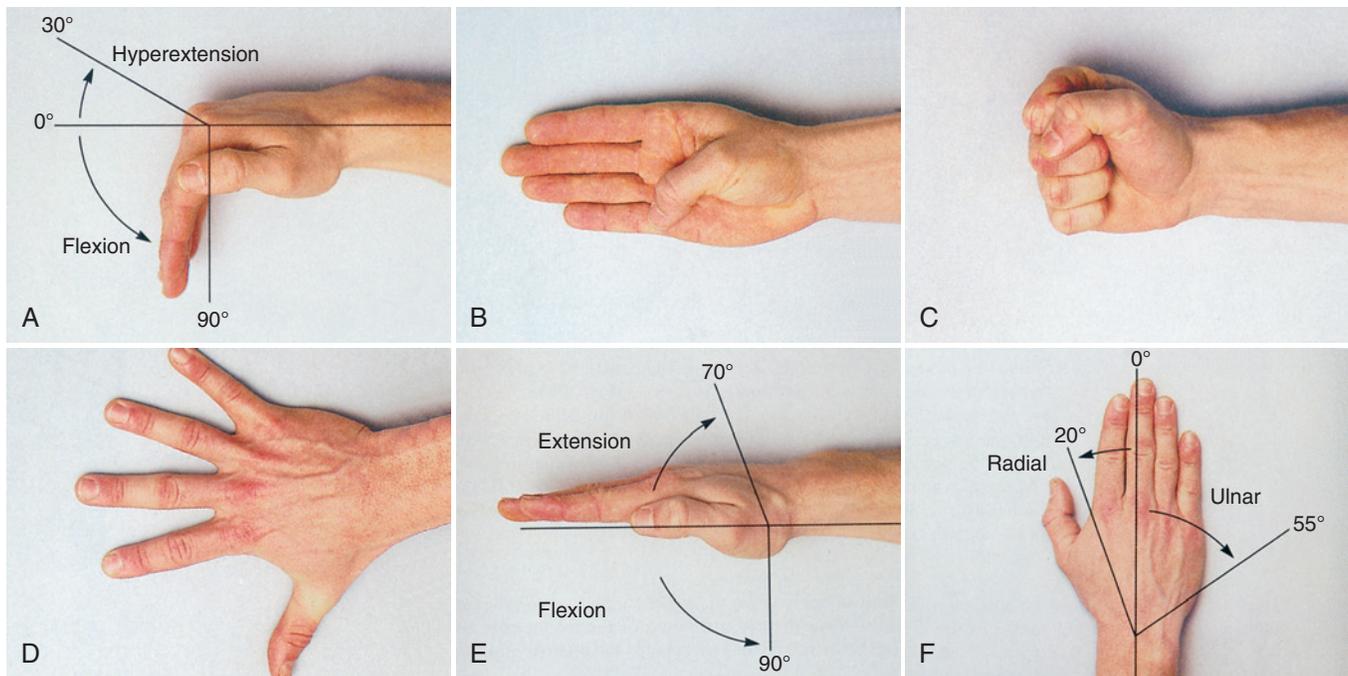
Term	Range of Motion	Examples of Joints
Flexion	Movement decreasing angle between two adjoining bones; bending of limb	Elbow, fingers, knee
Extension	Movement increasing angle between two adjoining bones	Elbow, knee, fingers
Hyperextension	Movement of body part beyond its normal resting extended position	Head
Pronation	Movement of body part so front or ventral surface faces downward	Hand, forearm
Supination	Movement of body part so front or ventral surface faces upward	Hand, forearm
Abduction	Movement of extremity away from midline of body	Leg, arm, fingers
Adduction	Movement of extremity toward midline of body	Leg, arm, fingers
Internal rotation	Rotation of joint inward	Knee, hip
External rotation	Rotation of joint outward	Knee, hip
Eversion	Turning of body part away from midline	Foot
Inversion	Turning of body part toward midline	Foot
Dorsiflexion	Flexion of toes and foot upward	Foot
Plantar flexion	Bending of toes and foot downward	Foot


FIGURE 31-65 Range of motion of hand and wrist. **A,** Metacarpophalangeal flexion and hyperextension. **B,** Finger flexion: thumb to each fingertip and to base of little finger. **C,** Finger flexion, fist formation. **D,** Finger abduction. **E,** Wrist flexion and hyperextension. **F,** Wrist radial and ulnar movement. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)
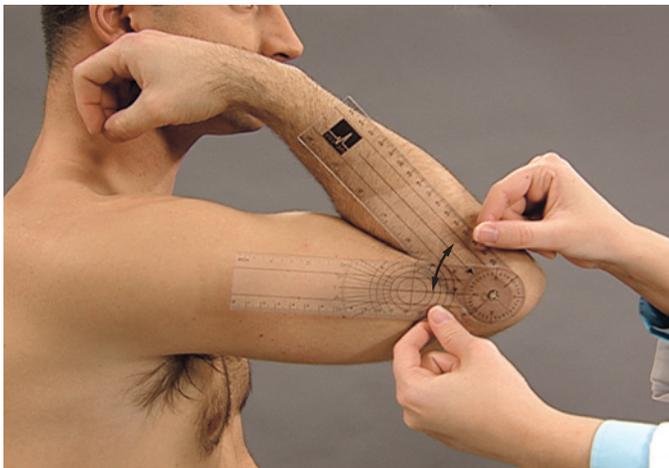

FIGURE 31-66 The patient flexes the arm; the goniometer measures joint range of motion. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

FIGURE 31-67 Assessing muscle tone.

little tone (**hypotonicity**) feels flabby. The involved extremity hangs loosely in a position determined by gravity.

For assessment of muscle strength, have the patient assume a stable position. He or she performs maneuvers demonstrating strength of major muscle groups (Table 31-33). Use a grading scale of "0 to 5" to compare symmetrical muscle pairs for strength (Table 31-34). The arm on the dominant side normally is stronger than the arm on the nondominant side. In older adults a loss of muscle mass causes bilateral weakness, but muscle strength remains greater in the dominant arm or leg.

Examine each muscle group. Ask the patient to first flex the muscle you are examining and then to resist when you apply an opposing force against that flexion. It is important to not allow the patient to move

the joint. Gradually increase pressure to a muscle group (e.g., elbow extension). Have the patient resist the pressure you apply by attempting to move against resistance (e.g., elbow flexion) until instructed to stop. Vary the amount of pressure applied and observe the joint move. If you identify a weakness, compare the size of the muscle with its opposite counterpart by measuring the circumference of the muscle body with a tape measure. A muscle that has **atrophied** (reduced in size) feels soft and boggy when palpated.

NEUROLOGICAL SYSTEM

The neurological system is responsible for many functions, including initiation and coordination of movement, reception and perception of

sensory stimuli, organization of thought processes, control of speech, and storage of memory. A close integration exists between the neurological system and all other body systems. For example, urine production relies in part on the adequacy of blood flow to the kidneys and on neural control, which affects the size of arterioles supplying the kidneys.

A full assessment of neurological function requires much time and attention to detail. For efficiency, integrate neurological measurements with other parts of the physical examination. For example, test cranial nerve function while assessing the head and neck. Observe mental and emotional status during the initial interview.

Consider many variables when deciding the extent of the neurological examination. A patient's level of consciousness influences his or her ability to follow directions. General physical status influences tolerance to assessment. A patient's chief complaint also helps determine the need for a thorough neurological assessment. If a patient complains of headache or a recent loss of function in an extremity, he or she needs a complete neurological review. Table 31-35 lists the data

TABLE 31-33 Maneuvers to Assess Muscle Strength

Muscle Group	Maneuver
Neck (sternocleidomastoid)	Place hand firmly against patient's upper jaw. Ask patient to turn head laterally against resistance.
Shoulder (trapezius)	Place hand over midline of patient's shoulder, exerting firm pressure. Have patient raise shoulders against resistance.
Elbow	
Biceps	Pull down on forearm as patient attempts to flex arm.
Triceps	As you flex patient's arm, apply pressure against forearm. Ask patient to straighten arm.
Hip	
Quadriceps	When patient is sitting, apply downward pressure to thigh. Ask patient to raise leg up from table.
Gastrocnemius	Patient sits while examiner holds shin of flexed leg. Ask patient to straighten leg against resistance.

TABLE 31-34 Muscle Strength

Muscle Function Level	SCALES		
	Grade	% Normal	Lovett Scale
No evidence of contractility	0	0	0 (zero)
Slight contractility, no movement	1	10	T (trace)
Full range of motion, gravity eliminated*	2	25	P (poor)
Full range of motion with gravity	3	50	F (fair)
Full range of motion against gravity, some resistance	4	75	G (good)
Full range of motion against gravity, full resistance	5	100	N (normal)

Modified from Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby; and Walker J: The role of the nurse in the management of osteoporosis, *Br J Nurs* 19(19):1243, 2010.
*Passive movement.

TABLE 31-35 Nursing History for Neurological Assessment

Assessment	Rationale
Determine if patient uses analgesics, alcohol, sedatives, hypnotics, antipsychotics, antidepressants, nervous system stimulants, or recreational drugs.	These medications alter level of consciousness or cause behavioral changes. Abuse sometimes causes tremors, ataxia, and changes in peripheral nerve function.
Determine if patient has recent history of seizures/convulsions: clarify sequence of events (aura, fall to ground, motor activity, loss of consciousness); character of any symptoms; and relationship of seizure to time of day, fatigue, or emotional stress.	Seizure activity often originates from central nervous system alteration. Characteristics of seizure help determine its origin.
Screen patient for symptoms of headache, tremors, dizziness, vertigo, numbness or tingling of body part, visual changes, weakness, pain, or changes in speech. Presence of any symptom requires more detailed review (onset, severity, precipitating factors or sequence of events).	These symptoms frequently originate from alterations in central or peripheral nervous system function. Identification of specific patterns aids in diagnosis of pathological condition.
Discuss with patient's family any recent changes in patient's behavior (e.g., increased irritability, mood swings, memory loss, change in energy level).	Behavioral changes sometimes result from intracranial pathological states.
Assess patient for history of change in vision, hearing, smell, taste, or touch.	Major sensory nerves originate from brainstem. These symptoms help to localize nature of problem.
If an older patient displays sudden acute confusion (delirium), review history for drug toxicity (anticholinergics, diuretics, digoxin, cimetidine, sedatives, antihypertensives, antiarrhythmics), serious infections, metabolic disturbances, heart failure, and severe anemia.	Delirium is one of the most common mental disorders in older people. Condition is always potentially reversible (see Box 31-31).
Review past history for head or spinal cord injury, meningitis, congenital anomalies, neurological disease, or psychiatric counseling.	Factors cause neurological symptoms or behavioral changes to develop, focusing assessment on possible cause.

collected in the nursing history. You will need the following items for a complete examination:

- Reading material
- Vials containing aromatic substances (e.g., vanilla extract and coffee)
- Opposite tip of cotton swab or tongue blade broken in half
- Snellen eye chart
- Penlight
- Vials containing sugar, salt, lemon with applicators
- Tongue blade
- Two test tubes, one filled with hot water and the other with cold water
- Cotton balls or cotton-tipped applicators
- Tuning fork
- Reflex hammer

Mental and Emotional Status

You learn a great deal about mental capacities and emotional state simply by interacting with a patient. Ask questions during an examination to gather data and observe the appropriateness of emotions and thoughts. Special assessment tools are designed to assess a patient's mental status. The Mini-Mental State Examination (MMSE) is an instrument developed by Folstein et al. (1975) that measures orientation and cognitive function. The questions in Box 31-30 offer examples of questions found on the MMSE. The maximum score on the MMSE is 31. Patients with scores of 21 or less generally reveal cognitive impairment requiring further evaluation.

To ensure an objective assessment, consider a patient's cultural and educational background, values, beliefs, and previous experiences. Such factors influence response to questions. An alteration in mental or emotional status reflects a disturbance in cerebral functioning. The cerebral cortex controls and integrates intellectual and emotional functioning. Primary brain disorders, medication, and metabolic changes are examples of factors that change cerebral function.

Delirium is an acute mental disorder that occurs among hospitalized patients. Obtain a thorough history of a patient's behavior before delirium develops to recognize the condition early. Family members are usually a good resource. Among older adults delirium most often presents within the first 48 to 72 hours of hospital admission (Rigney, 2010). It is an acute mental disorder characterized by confusion, disorientation, and restlessness. It is often a sign of an impending or underlying physical illness in older adults. The acute condition differs from dementia, a more progressive, organic mental disorder such as Alzheimer's disease. You need to recognize the difference so you can try to learn the underlying cause of delirium. Fortunately the condition often reverses when it is correctly assessed and the underlying cause is treated (i.e., central nervous system [CNS], metabolic, and cardiopulmonary disorders; systemic illnesses; and sensory deprivation or overload). To avoid misdiagnosis you need to adequately assess mental status. Frequently patients who develop delirium are labeled with "sundown syndrome" because the delirium frequently worsens at night. Many practitioners mistake this as being common with old age. Be aware that children are vulnerable to delirium from causes such as infection, drugs, serious trauma, autoimmune disorders, and general anesthesia and after transplant (Hatherill and Fisher, 2010). Box 31-31 summarizes clinical criteria for delirium.

Level of Consciousness. A person's level of consciousness exists along a continuum from full awakening, alertness, and cooperation to unresponsiveness to any form of external stimuli. Talk with the patient, asking questions about events involving his or her concerns about any health problems. A fully conscious patient responds to questions quickly and expresses ideas logically. With a lowering of a patient's consciousness, use the Glasgow Coma Scale (GCS) for an objective measurement of consciousness on a numerical scale (Table 31-36). The patient needs to be as alert as possible before testing. Take care when using the scale if the patient has sensory losses (e.g., vision or hearing). The GCS allows evaluation of a patient's neurological status over time.

BOX 31-30 Mini-Mental State Examination Sample Questions

- Orientation to time
  "What is the date?"
- Registration
  "Listen carefully. I am going to say three words. Say them back after I stop. Ready? Here they are . . .
  HOUSE (pause), CAR (pause), LAKE (pause). Now repeat these words back to me."
  (Repeat up to 5 times but score only the first trial.)
- Naming
  "What is this?" (Point to a pencil or pen.)
- Reading
  "Please read this and do what it says." (Show examinee the words on the stimulus form.)
  CLOSE YOUR EYES

BOX 31-31 Clinical Criteria for Delirium

Definition: An acute disturbance of consciousness that is accompanied by a change in cognition. It is not caused by a preexisting or evolving dementia. Delirium develops over a short period of time, usually hours to days, and tends to fluctuate during the course of the day. It is usually a direct physiological consequence of a general medical condition. It is most common in older adults but occasionally occurs in younger patients.

- There is reduced clarity of awareness of the environment.
- Ability to focus, sustain, or shift attention is impaired (questions must be repeated).
- Irrelevant stimuli easily distract the person.
- There is an accompanying change in cognition (memory impairment, disorientation, or language disturbance).
- Recent memory commonly is affected.
- Disorientation usually occurs, with patient disoriented to time, place, or person.
- Language disturbance involves impaired ability to name objects or ability to write; speech is sometimes rambling.
- Perceptual disturbances include misinterpretations, delusions, or visual and auditory hallucinations. Neurological signs include tremor, unsteady gait, asterixis, or myoclonus.

TABLE 31-36 Glasgow Coma Scale

(The total score is the sum of the scores in the three categories.)

Action	Response	Score
Eyes open	Spontaneously	4
	To speech	3
	To pain	2
	None	1
Best verbal response	Oriented	5
	Confused	4
	Inappropriate words	3
	Incomprehensible sounds	2
	None	1
Best motor response	Obeys commands	6
	Localized pain	5
	Flexion withdrawal	4
	Abnormal flexion	3
	Abnormal extension	2
	Flaccid	1
	TOTAL SCORE	**3 to 15**

The higher the score, the better the patient's neurological function. Ask short, simple questions such as "What is your name?" "Where are you?" and "What day is this?" Also ask the patient to follow simple commands such as "Move your toes."

If the patient is not conscious enough to follow commands, try to elicit the pain response. Apply firm pressure with the thumb over the root of the patient's fingernail. The normal response to the painful stimuli is withdrawal of the body part from the stimulus. A patient with serious neurological impairment exhibits abnormal posturing in response to pain. A flaccid response indicates the absence of muscle tone in the extremities and severe injury to brain tissue.

Behavior and Appearance. Behavior, moods, hygiene, grooming, and choice of dress reveal pertinent information about mental status. Remain perceptive of a patient's mannerisms and actions during the entire physical assessment. Note nonverbal and verbal behaviors. Does the patient respond appropriately to directions? Does his or her mood vary with no apparent cause? Does he or she show concern about appearance? Is his or her hair clean and neatly groomed, and are the nails trim and clean? The patient should behave in a manner expressing concern and interest in the examination. He or she should make eye contact with you and express appropriate feelings that correspond to the situation. Normally the patient shows some degree of personal hygiene.

Choice and fit of clothing reflect socioeconomic background or personal taste rather than deficiency in self-concept or self-care. Avoid being judgmental and focus assessment on the appropriateness of clothing for the weather. Older adults sometimes neglect their appearance because of a lack of energy, finances, or reduced vision.

Language. Normal cerebral function allows a person to understand spoken or written words and express the self through written words or gestures. Assess the patient's voice inflection, tone, and manner of speech. Normally a patient's voice has inflections, is clear and strong, and increases in volume appropriately. Speech is fluent. When communication is clearly ineffective (e.g., omission or addition of letters and words, misuse of words, or hesitations), assess for aphasia. Injury to the cerebral cortex results in aphasia.

The two types of aphasia are sensory (or receptive) and motor (or expressive). With receptive aphasia a person cannot understand written or verbal speech. With expressive aphasia a person understands written and verbal speech but cannot write or speak appropriately when attempting to communicate. A patient sometimes suffers a combination of receptive and expressive aphasia. Assess language capabilities when it is clear that a patient is communicating ineffectively. Some simple assessment techniques include the following:

- Point to a familiar object and ask the patient to name it.
- Ask the patient to respond to simple verbal and written commands such as "Stand up" or "Sit down."
- Ask the patient to read simple sentences out loud.

Normally a patient names objects correctly, follows commands, and reads sentences correctly.

Intellectual Function

Intellectual function includes memory (recent, immediate, and past), knowledge, abstract thinking, association, and judgment. Testing each aspect of function involves a specific technique. However, because cultural and educational background influences the ability to respond to test questions, do not ask questions related to concepts or ideas with which a patient is unfamiliar.

Memory. Assess immediate recall and recent and remote memory. Patients demonstrate immediate recall by repeating a series of numbers (e.g., 7, 4, 1) in the order they are presented or in reverse order. Patients normally recall a series of five-to-eight digits forward and four-to-six digits backward.

First ask to test the patient's memory. Then state clearly and slowly the name of three unrelated objects. After mentioning all three, ask the patient to repeat each. Continue until he or she is successful. Later in the assessment ask the patient to repeat the three words again. He or she should be able to identify them. Another test for recent memory involves asking the patient to recall events occurring during the same day (e.g., what was eaten for breakfast). Validate information with a family member.

To assess past memory, ask the patient to recall his or her mother's maiden name, a birthday, or a special date in history. It is best to ask open-ended rather than simple yes-or-no questions. A patient usually has immediate recall of such information. With older adults do not interpret hearing loss as confusion. Good communication techniques are essential throughout the examination to ensure that a patient clearly understands all directions and testing.

Knowledge. Assess knowledge by asking how much the patient knows about his or her illness or the reason for seeking health care. A knowledge assessment allows you to determine a patient's ability to learn or understand. If there is an opportunity to teach, test a patient's mental status by asking for feedback during a follow-up visit.

Abstract Thinking. Interpreting abstract ideas or concepts reflects the capacity for abstract thinking. For an individual to explain common phrases such as "A stitch in time saves nine" or "Don't count your chickens before they're hatched" requires a higher level of intellectual function. Note whether a patient's explanations are relevant and concrete. A patient with altered mental status probably interprets the phrase literally or merely rephrases the words.

Association. Another higher level of intellectual functioning involves finding similarities or associations between concepts: a dog is to a beagle as a cat is to a Siamese. Name related concepts and ask the

TABLE 31-37 Cranial Nerve Function and Assessment

Number	Name	Type	Function	Method
I	Olfactory	Sensory	Sense of smell	Ask patient to identify different nonirritating aromas such as coffee and vanilla.
II	Optic	Sensory	Visual acuity	Use Snellen chart or ask patient to read printed material while wearing glasses.
III	Oculomotor	Motor	Extraocular eye movements: inward, up and inward, up and outward, down and outward	Assess six directions of gaze.
			Pupil constriction and dilation	Measure pupillary reaction to light reflex and accommodation.
			Opening the eye	
IV	Trochlear	Motor	Downward, inward eye movements	Assess six directions of gaze.
V	Trigeminal	Sensory and motor	Sensory nerve to skin of face	Lightly touch cornea with wisp of cotton. Assess corneal reflex. Measure sensation of light pain and touch across skin of face.
			Motor nerve to muscles of jaw	Palpate temples as patient clenches teeth.
VI	Abducens	Motor	Lateral movement of eyeballs	Assess six directions of gaze.
VII	Facial	Sensory and motor	Facial expression	As patient smiles, frowns, puffs out cheeks, and raises and lowers eyebrows, look for asymmetry.
			Taste	Have patient identify salty or sweet taste on front of tongue.
VIII	Auditory	Sensory	Hearing	Assess ability to hear spoken word.
IX	Glossopharyngeal	Sensory and motor	Taste	Ask patient to identify sour or sweet taste on back of tongue.
			Ability to swallow	Use tongue blade to elicit gag reflex.
X	Vagus	Sensory and motor	Sensation of pharynx	Ask patient to say "ah." Observe movement of palate and pharynx.
			Movement of vocal cords	Assess speech for hoarseness.
			Parasympathetic innervation to glands of mucous membranes of the pharynx, larynx, organs in the neck, thorax (heart and lungs), and abdomen	Assess heart rate, presence of peristalsis.
XI	Spinal accessory	Motor	Movement of head and shoulders	Ask patient to shrug shoulders and turn head against passive resistance.
XII	Hypoglossal	Motor	Position of tongue	Ask patient to stick out tongue to midline and move it from side to side.

patient to identify their associations. Ask questions that are appropriate to the patient's level of intelligence, using simple concepts.

Judgment. Judgment requires a comparison and evaluation of facts and ideas to understand their relationships and form appropriate conclusions. Attempt to measure the patient's ability to make logical decisions with questions such as "Why did you seek health care?" or "What would you do if you became ill at home?" Normally a patient makes logical decisions.

Cranial Nerve Function

To assess cranial nerve function, you may test all 12 cranial nerves, a single nerve, or a related group of nerves. A dysfunction in one nerve reflects an alteration at some point along the distribution of the cranial nerve. Measurements used to assess the integrity of organs within the head and neck also assess cranial nerve function. A complete assessment involves testing the 12 cranial nerves in their numerical order. To remember the order of the nerves, use this simple phrase, "On old Olympus' towering tops, a Finn and German viewed some hops." The first letter of each word in the phrase is the same as the first letter of the names of the cranial nerves listed in order (Table 31-37).

Sensory Function

The sensory pathways of the CNS conduct sensations of pain, temperature, position, vibration, and crude and finely localized touch. Different nerve pathways relay the sensations. Most patients require only a quick screening of sensory function unless there are symptoms of reduced sensation, motor impairment, or paralysis. The risk of skin breakdown is greater in a patient with impaired sensation. When assessing decreased sensation, complete a skin assessment of the area affected by the sensory loss. In addition, teach the patient to avoid pressure, thermal, and/or chemical trauma to the area.

Normally a patient has sensory responses to all stimuli that are tested. He or she feels sensations equally on both sides of the body in all areas. Assess the major sensory nerves by knowing the sensory dermatome zones (Figure 31-68, *A* and *B*). Some areas of the skin are innervated by specific dorsal root cutaneous nerves. For example, if assessment reveals reduced sensation when checking for light touch along an area of the skin (e.g., the lower neck), this determines in general where a neurological lesion exists (e.g., fourth cervical spinal cord segment).

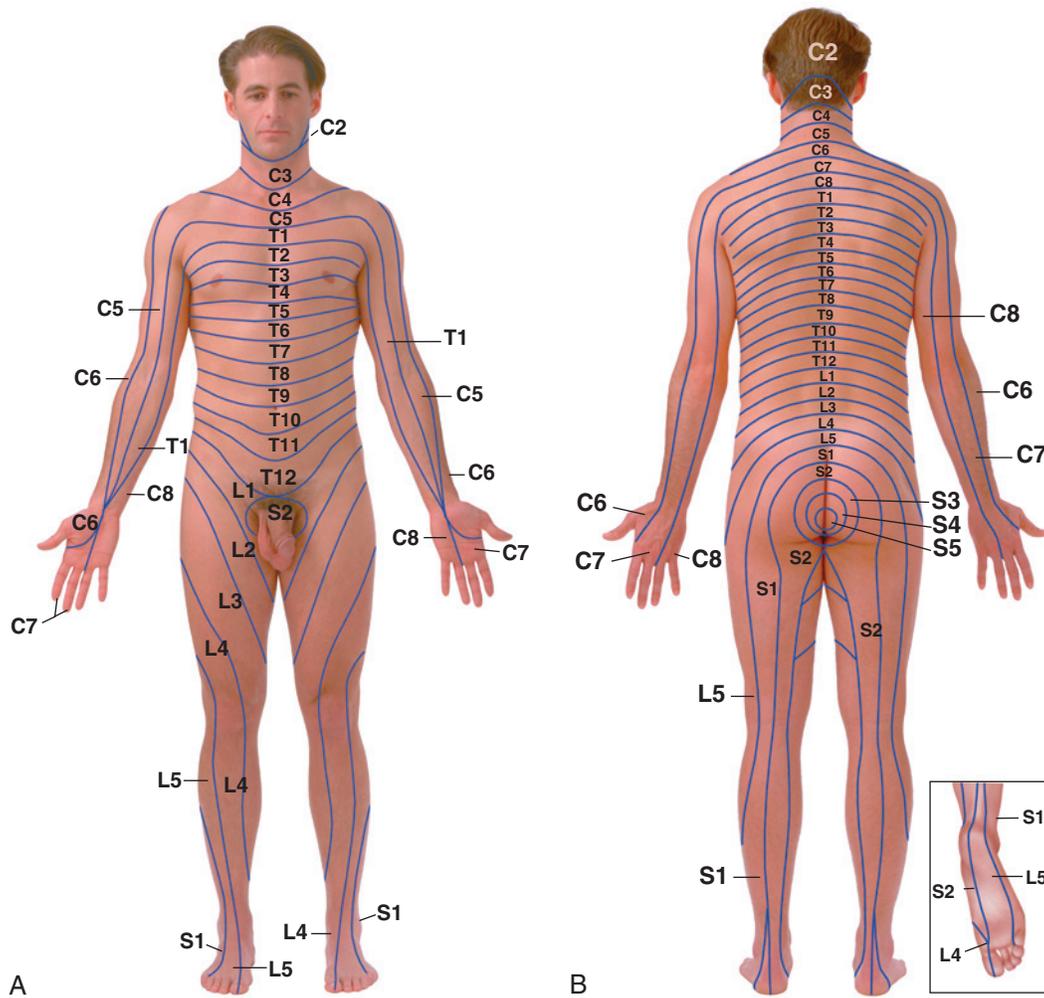
Perform all sensory testing with the patient's eyes closed so he or she is unable to see when or where a stimulus touches the skin


FIGURE 31-68 Dermatomes of body (body surface areas innervated by particular spinal nerves); C1 usually has no cutaneous distribution. **A,** Anterior view. **B,** Posterior view. It appears that there is a distinct separation of surface area controlled by each dermatome, but there is almost always overlap between spinal nerves. (From Ball JW et al: *Seidel's guide to physical examination,* ed 8, St Louis, 2015, Mosby.)

(Table 31-38). Then touch the patient's skin in a random, unpredictable order to maintain his or her attention and prevent detection of a predictable pattern. Ask the patient to describe when, what, and where he or she feels each stimulus. Compare symmetrical areas of the body while applying stimuli to the patient's arms, trunk, and legs.

Motor Function

An examination of motor function includes assessments made during the musculoskeletal examination. In addition, you assess the patient's cerebellar function. The cerebellum coordinates muscular activity, maintains balance and equilibrium, and controls posture.

Coordination. To avoid confusion, demonstrate each maneuver and have the patient repeat it, observing for smoothness and balance in his or her movements (Box 31-32). In older adults normally slow reaction time causes movements to be less rhythmical.

To assess fine-motor function, have the patient extend the arms out to the sides and touch each forefinger alternately to the nose (first with eyes open, then with eyes closed). Normally a patient alternately touches the nose smoothly. Performing rapid, rhythmical, alternating movements demonstrates coordination in the upper extremities. While sitting, the patient begins by patting the knees with both hands. Then

he or she alternately turns up the palm and back of the hands while continuously patting the knees. Normally patients perform the maneuver smoothly and regularly with increasing speed.

An additional maneuver for upper-extremity coordination involves touching each finger with the thumb of the same hand in rapid sequence. A patient moves from the index finger to the little finger and back, with one hand tested at a time. The dominant hand is slightly less awkward when performing this movement. Movement is smooth and in succession.

Test lower-extremity coordination with the patient lying supine, legs extended. Place a hand at the ball of the patient's foot. The patient taps the hand with the foot as quickly as possible. Test each foot for speed and smoothness. The feet do not move as rapidly or evenly as the hands.

Balance. Use one or two of the following tests to assess balance and gross-motor function. When examining the older adult for balance and equilibrium, be aware of the risk for falls. Some older adults need help with this part of the examination.

Have the patient perform a Romberg's test by standing with feet together, arms at the sides, both with eyes open and eyes closed. Protect the patient's safety by standing at the side, observe for swaying. Expect

TABLE 31-38 Assessment of Sensory Nerve Function

Function	Equipment	Method	Precautions
Pain	End of paper clip or wooden end of cotton applicator	Ask patients to voice when they feel dull or sharp sensation. Alternately apply sharp and blunt ends of the paper clip or broken cotton applicator to surface of skin. Note areas of numbness or increased sensitivity.	Remember that areas where skin is thick such as heel or sole of foot are less sensitive to pain.
Temperature	Two test tubes, one filled with hot water and another with cold	Touch skin with tube. Ask patient to identify hot or cold sensation.	Omit test if pain sensation is normal.
Light touch	Cotton ball or cotton-tip applicator	Apply light wisp of cotton to different points along surface of skin. Ask patients to voice when they feel a sensation.	Apply at areas where skin is thin or more sensitive (e.g., face, neck, inner aspect of arms, top of feet and hands).
Vibration	Tuning fork	Apply stem of vibrating fork to distal interphalangeal joint of fingers and interphalangeal joint of great toe, elbow, and wrist. Have patients voice when and where they feel vibration.	Be sure that patient feels vibration and not merely pressure.
Position		Grasp finger or toe, holding it by its sides with thumb and index finger. Alternate moving finger or toe up and down. Ask patient to state when finger is up or down. Repeat with toes.	Avoid rubbing adjacent appendages as you move finger or toe. Do not move joint laterally; return to neutral position before moving again.
Two-point discrimination	Two ends of paper clips	Lightly apply one or both ends of paper clips simultaneously to the surface of the skin. Ask patients whether they feel one or two pricks. Find the distance at which patient can no longer distinguish two points.	Apply blade tips to same anatomical site (e.g., fingertips, palm of hand, or upper arms). Minimum distance at which patient discriminates two points varies (2 to 8 mm on fingertips).

BOX 31-32 PATIENT TEACHING

Neurological Assessment

Objective
- Patient and family or significant others will understand relationship of patient's behavioral and mental changes to physical status.

Teaching Strategies
- Explain to family caregiver the implications of any behavioral or mental impairment shown by patient.
- If patient has sensory or motor impairments, explain measures to ensure safety (e.g., wearing glasses or hearing aids, use of ambulation aids or safety bars in bathrooms or stairways) (see Chapter 49).
- Teach older adult to plan enough time to complete tasks because reaction time is slow.
- Teach older adult to observe skin surfaces for areas of trauma since pain perception is reduced.

Evaluation
- Ask family member to discuss patient behaviors that result from neurological impairments.
- Have patient explain safety measures used to avoid injury from sensory and motor limitations.
- Have older patient explain reason for inspecting skin surface routinely.

---

slight swaying of the body in the Romberg's test. A loss of balance (positive Romberg) causes a patient to fall to the side. Normally he or she does not break the stance.

Have the patient close the eyes, with arms held straight at the sides, and stand on one foot and then the other. Normally patients are able to maintain balance for 5 seconds with slight swaying. Another test

involves asking the patient to walk a straight line by placing the heel of one foot directly in front of the toes of the other foot.

Reflexes

Eliciting reflex reactions provides data about the integrity of sensory and motor pathways of the reflex arc and specific spinal cord segments. Assessment of reflexes does not determine higher neural center functioning but helps to assess peripheral-spinal nerve function. Figure 31-69 traces the pathway of the reflex arc. Each muscle contains a small sensory unit called a *muscle spindle,* which controls muscle tone and detects changes in the length of muscle fibers. Tapping a tendon with a reflex hammer stretches the muscle and tendon, lengthening the spindle. The spindle sends nerve impulses along afferent nerve pathways to the dorsal horn of the spinal cord segment. Within milliseconds the impulses reach the spinal cord and synapse to travel to the efferent motor neuron in the spinal cord. A motor nerve sends the impulses back to the muscle, causing the reflex response.

The two categories of normal reflexes are deep tendon reflexes, elicited by mildly stretching a muscle and tapping a tendon, and cutaneous reflexes, elicited by stimulating the skin superficially. Grade reflexes as follows (Ball et al., 2015):

0: No response
1+: Sluggish or diminished
2+: Active or expected response
3+: More brisk than expected, slightly hyperactive
4+: Brisk and hyperactive with intermittent or transient clonus

When assessing reflexes, have the patient relax as much as possible to avoid voluntary movement or tensing of muscles. Position the limbs to slightly stretch the muscle being tested. Hold the reflex hammer loosely between the thumb and fingers so it is able to swing freely and tap the tendon briskly (Figure 31-70). Compare the responses on corresponding sides. Normally the older adult presents with diminished reflexes. Reflexes are hyperactive in patients with alcohol, cocaine, or

TABLE 31-39 Assessment of Common Reflexes

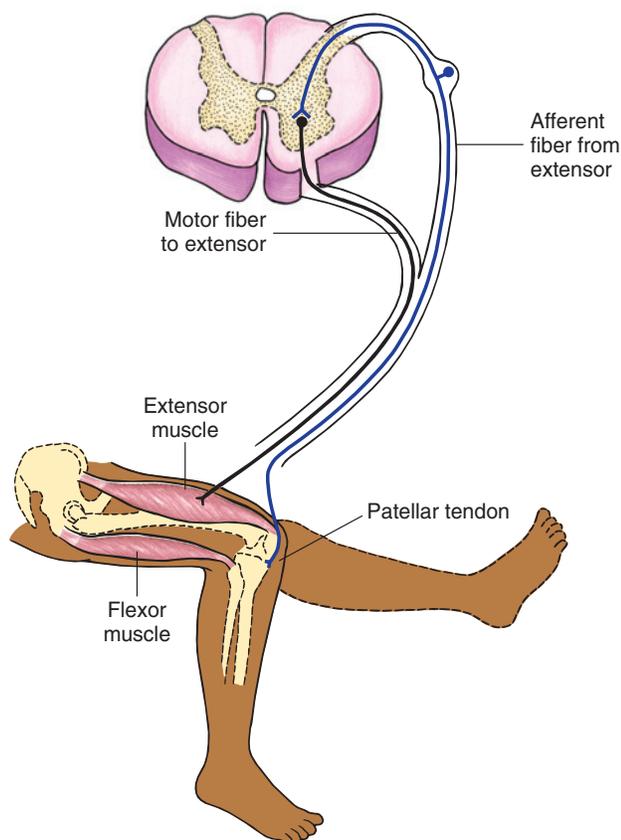
Type	Procedure	Normal Reflex
Deep Tendon Reflexes		
Biceps	Flex patient's arm up to 45 degrees at elbow with palms down. Place your thumb in antecubital fossa at base of biceps tendon and your fingers over biceps muscle. Strike biceps tendon with reflex hammer.	Flexion of arm at elbow
Triceps	Flex patient's arm at elbow, holding arm across chest, or hold upper arm horizontally and allow lower arm to go limp. Strike triceps tendon just above elbow.	Extension at elbow
Patellar	Have patient sit with legs hanging freely over side of table or chair or have him or her lie supine and support knee in a flexed 90-degree position. Briskly tap patellar tendon just below patella.	Extension of lower leg
Achilles	Have patient assume same position as for patellar reflex. Slightly dorsiflex patient's ankle by grasping toes in palm of your hand. Strike Achilles tendon just above heel at ankle malleolus.	Plantar flexion of foot
Cutaneous Reflexes		
Plantar	Have patient lie supine with legs straight and feet relaxed. Take handle end of reflex hammer and stroke lateral aspect of sole from heel to ball of foot, curving across ball of foot toward big toe.	Plantar flexion of all toes
Abdominal	Have patient stand or lie supine. Stroke abdominal skin with base of cotton applicator over lateral borders of rectus abdominis muscle toward midline. Repeat test in each abdominal quadrant.	Contraction of rectus abdominis muscle with pulling of umbilicus toward stimulated side


FIGURE 31-69 Pathway of reflex arc.

FIGURE 31-70 Position for eliciting patellar tendon reflex. Lower leg normally extends.

opioid intoxication. Table 31-39 summarizes common deep tendon and cutaneous reflexes.

AFTER THE EXAMINATION

Record findings from the physical assessment either during the examination or when it is completed. Special forms are available to record data both electronically and on printed forms. Review all findings before helping patients dress in case it is necessary to recheck any information or gather additional data. Integrate physical assessment findings into the plan of care.

After completing an assessment, give the patient time to dress. The hospitalized patient sometimes needs help with hygiene and returning

to bed. When the patient is comfortable, it helps to share a summary of the assessment findings. If the findings have revealed serious abnormalities such as a mass or highly irregular heart rate, consult the patient's health care provider before revealing them. It is the health care provider's responsibility to make definitive medical diagnoses. Explain the type of abnormality found and the need for the health care provider to conduct an additional examination.

Delegate cleaning the examination area to support staff if needed. Use infection control practice to remove materials or instruments soiled with potentially infectious wastes. If the patient's bedside was the examination site, clear away soiled items from the bedside table and make sure that the bed linen is dry and clean. A patient appreciates a clean gown and the opportunity to wash the face and hands. Afterward be sure to perform hand hygiene.

Be sure to record a complete assessment. If you delayed entering any items into the assessment form, record them at this time to avoid forgetting any important information. If you made entries periodically during the examination, review them for accuracy and thoroughness. Communicate significant findings to appropriate medical and nursing personnel, either verbally or in the patient's written care plan.

QSEN **QSEN: BUILDING COMPETENCY IN SAFETY** You are preparing to examine a 75-year-old female who arrives at the clinic in a wheelchair. She explains, "I can't walk very well because my legs just won't carry me far anymore! I use this wheelchair so I don't wear out or lose my breath. I refuse to let these problems get in the way of doing what I want—getting out of the house and going places. I'm just not as spry as I was when I was young girl." You immediately observe that she has kyphosis. To climb onto the examination table, a patient needs to climb on a 6-inch step; turn around; and sit on an elevated, padded table surface. Which component findings from the general survey guide your decision about how and where to continue with the physical examination?

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

KEY POINTS

- Baseline assessment findings reflect a patient's functional abilities and serve as the basis for comparison with subsequent assessment findings.
- Physical assessment of a child or infant requires the application of the principles of growth and development.
- Recognize that the normal process of aging affects physical findings collected from an older adult.
- Integrate patient teaching throughout an examination to help patients learn about health promotion, disease prevention, and skills to help with any current health issues.
- Inspection requires a careful, systematic approach that compares a body part with its counterpart on the opposite side of the body.
- Use auscultation to assess the character of sounds created in various body organs.
- Perform a physical examination only after proper preparation of the environment and equipment and after preparing a patient physically and psychologically.
- Throughout an examination keep the patient warm, comfortable, and informed of each step of the process.
- A competent examiner is systematic while combining assessment of different body systems simultaneously.
- Information from the history helps to focus on body systems likely to be affected.
- When assessing a seriously ill patient, first concentrate on the body systems most affected.

- Creating a mental image of internal organs in relation to external anatomical landmarks enhances accuracy in assessing the thorax, heart, and abdomen.
- When assessing heart sounds, imagine events occurring during the cardiac cycle.
- Never palpate both of the carotid arteries simultaneously.
- When examining a woman's breasts, explain the techniques for BSE.
- The order of the abdominal assessment is inspection, auscultation, percussion (if used), and palpation.
- During assessment of the genitalia explain the technique for genital self-examination.
- Conduct an assessment of musculoskeletal function when observing a patient ambulate or participate in other active movements.
- Assess mental and emotional status by interacting with a patient throughout the examination.
- At the end of the examination provide for the patient's comfort and then document a detailed summary of physical assessment findings.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You receive morning report for Mrs. Malone, age 71, admitted to the hospital yesterday with fatigue, a cough, and dyspnea; she is diagnosed with chronic heart failure. She states that she had increasing difficulty with shortness of breath and swelling in her legs. Pedal pulses are +1 bilaterally. On auscultation you hear bilateral crackles in the lung bases and an S_3 gallop when auscultating the heart. Respiratory rate is 18; heart rate is 84 and regular. The patient has an occasional nonproductive cough. She is receiving 2 L of oxygen by nasal cannula.

1. Mrs. Malone tells you that the health care provider told her that she has an S_3 gallop. She asks you what this means. Provide an explanation for Mrs. Malone.
2. During an examination of Mrs. Malone, what additional assessment would be appropriate involving the peripheral arteries and veins? Explain.
3. During the assessment of the patient's heart, what position should Mrs. Malone assume, and what might you expect as you locate the PMI?

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

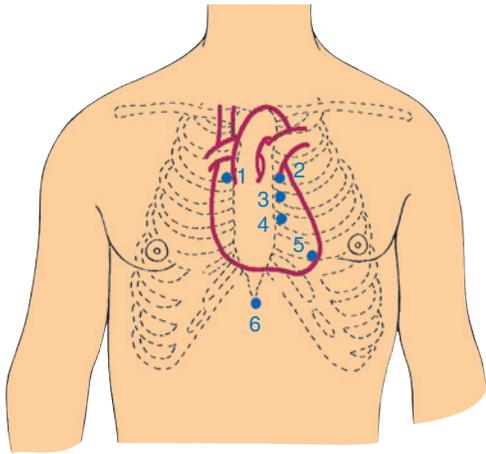
REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse prepares to conduct a general survey on an adult patient. Which assessment is performed first while the nurse initiates the nurse-patient relationship?
   1. Appearance and behavior
   2. Measurement of vital signs
   3. Observing specific body systems
   4. Conducting a detailed health history
2. The nurse is performing an abdominal assessment on a patient. In what order does the nurse perform the steps?
   1. Percussion
   2. Inspection
   3. Auscultation
   4. Palpation
3. While auscultating the adult patient's lungs, the nurse hears loud, bubbly sounds during inspiration that did not disappear after the

patient coughed. Which finding should the nurse document from the lung assessment?
1. Rhonchi
2. Coarse crackles
3. Sibilant wheeze
4. Pleural friction rub

4. During assessment of the skin, the nurse assesses a lesion on the arm of the patient. The lesion is irregularly shaped, elevated with edema, and about 3 cm. What type of lesion does the patient have?
1. Nodule
2. Macule
3. Wheal
4. Pustule

5. Which number corresponds to the area of the chest where you would auscultate for the tricuspid valve?
1. 1
2. 2
3. 3
4. 4
5. 5
6. 6


6. The nurse is assessing a patient who returned 1 hour ago from surgery for an abdominal hysterectomy. Which assessment finding would require immediate follow-up?
1. Auscultation of an apical heart rate of 76
2. Absence of bowel sounds on abdominal assessment
3. Respiratory rate of 8 breaths/min
4. Palpation of dorsalis pedis pulses with strength of +2

7. Which statement made by the patient indicates an understanding about teaching related to early detection of colorectal cancer?
1. "I'll make sure to schedule my colonoscopy annually after the age of 60."
2. "I'll make sure to have a computed tomography (CT) colonoscopy every 5 years."
3. "I'll make sure to have a flexible sigmoidoscopy every year once I turn 55."
4. "I'll make sure to have a fecal occult blood test annually once I turn 50."

8. The nurse is teaching a patient to prevent heart disease. Which information should the nurse include? (Select all that apply.)
1. Limit intake of cholesterol to less than 400 mg/day.
2. Talk with your health care provider about taking a daily low dose of aspirin.
3. Work with your health care provider to develop a regular exercise program.
4. Limit daily intake of fats to less than 25% to 35% of total calories.
5. Review strategies to encourage the patient to quit smoking.

9. How should the patient be positioned to best palpate for lumps or tumors during an examination of the right breast?
1. Supine with both arms overhead with palms upward
2. Sitting with hands clasped just above the umbilicus

3. Supine with the right arm abducted and hand under the head and neck
4. Lying on the right side, adducting the right arm on the side of the body

10. The nurse is assessing the cranial nerves. Match the cranial nerve with its related function.

Cranial Nerves	Cranial Nerve Function
1. XII Hypoglossal	a. Motor innervation to the muscles of the jaw
2. V Trigeminal	b. Lateral movement of the eyeballs
3. VI Adducens	c. Sensation of the pharynx
4. IV Trochlear	d. Downward, inward eye movements
5. X Vagus	e. Position of the tongue

11. The nurse is teaching a patient how to perform a testicular self-examination. Which statement made by the patient indicates a need for further teaching?
1. "I'll recognize abnormal lumps because they are very painful."
2. "I'll start performing testicular self-examination monthly after I turn 15."
3. "I'll perform the self-examination in front of a mirror."
4. "I'll gently roll the testicle between my fingers."

12. The nurse is observing the student nurse perform a respiratory assessment on a patient. Which action by the student nurse requires the nurse to intervene?
1. The student stands at a midline position behind the patient observing for position of the spine and scapula.
2. The student palpates the thoracic muscles for masses, pulsations, or abnormal movements.
3. The student places the bell of the stethoscope on the anterior chest wall to auscultate breath sounds.
4. The student places the palm of the hand over the intercostal spaces and asks the patient to say "ninety-nine."

13. The nurse plans to assess the patient's memory. Which task should the nurse ask the patient to perform?
1. "Tell me where you are."
2. "What can you tell me about your illness?"
3. "Repeat these numbers back to me: 7…5…8."
4. "What does this mean: 'A stitch in time saves nine?'"

14. A patient has undergone surgery for a femoral artery bypass. The surgeon's orders include assessment of dorsalis pedis pulses. The nurse will use which of the following techniques to assess the pulses? (Select all that apply.)
1. Place the fingers behind and below the medial malleolus.
2. Have the patient slightly flex the knee with the foot resting on the bed.
3. Have the patient relax the foot while lying supine.
4. Palpate the groove lateral to the flexor tendon of the wrist.
5. Palpate along the top of the foot in a line with the groove between extensor tendons of great and first toes.

15. The faith community nurse is teaching the community center women's group about breast cancer risk factors. Which factors does the nurse include? (Select all that apply.)
1. First child at the age of 26 years
2. Menopause onset at the age of 49 years
3. Family history with BRCA1 inherited gene mutation
4. Age over 40 years
5. Onset of menses before the age of 12
6. Recent use of oral contraceptives

Medication Administration

OBJECTIVES

- Discuss nursing roles and responsibilities in medication administration.
- Describe the physiological mechanisms of medication action.
- Differentiate among different types of medication actions.
- Discuss developmental factors that influence pharmacokinetics.
- Discuss factors that influence medication actions.
- Discuss methods used to educate patients about prescribed medications.
- Compare and contrast the roles of the health care provider, pharmacist, and nurse in medication administration.
- Implement nursing actions to prevent medication errors.
- Describe factors to consider when choosing routes of medication administration.
- Calculate prescribed medication doses correctly.
- Discuss factors to include in assessing a patient's needs for and response to medication therapy.
- Identify the six rights of medication administration and apply them in clinical settings.
- Correctly and safely prepare and administer medications.

Patients with health problems use a variety of strategies to restore or maintain their health. One strategy they often use is medication, a substance used in the diagnosis, treatment, cure, relief, or prevention of health problems. No matter where patients receive health care (i.e., hospitals, clinics, or home), nurses play an essential role in preparing, administering, and evaluating the effects of medications. Family members, friends, or home care personnel often administer medications when patients cannot administer them themselves at home. In all settings nurses are responsible for evaluating the effects of medications on the patient's ongoing health status, teaching him or her about

medications and side effects, encouraging adherence to the medication regimen, and evaluating the patient's and family caregiver's ability to administer medications.

SCIENTIFIC KNOWLEDGE BASE

Because medication administration and evaluation are a critical part of nursing practice, nurses need to understand the actions and effects of all medications taken by their patients. Administering medications safely requires an understanding of legal aspects of health care,

pharmacology, pharmacokinetics, the life sciences, pathophysiology, human anatomy, and mathematics.

Medication Legislation and Standards

Federal Regulations. The U.S. government protects the health of the people by ensuring that medications are safe and effective. The first American law to regulate medications was the Pure Food and Drug Act. This law simply requires all medications to be free of impure products. Subsequent legislation created standards related to safety, potency, and efficacy. Currently the Food and Drug Administration (FDA) enforces medication laws that ensure that all medications on the market undergo vigorous testing before they are sold to the public. Federal medication laws also control medication sales and distribution; testing, naming, and labeling; and the use of controlled substances. Official publications such as the *United States Pharmacopeia* (USP) and the *National Formulary* set standards for medication strength, quality, purity, packaging, safety, labeling, and dose form. In 1993 the FDA instituted the MedWatch program. This voluntary program encourages nurses and other health care professionals to report when a medication, product, or medical event causes serious harm to a patient by completing the MedWatch form. The form is available on the MedWatch website (USFDA, 2015).

State and Local Regulation of Medication. State and local medication laws must conform to federal legislation. States often have additional controls, including control of substances not regulated by the federal government. Local governmental bodies regulate the use of alcohol and tobacco.

Health Care Institutions and Medication Laws. Health care agencies establish individual policies to meet federal, state, and local regulations. The size of the agency, the services it provides, and the professional personnel it employs influence these policies. Agency policies are often more restrictive than governmental controls. For example, a common agency policy is the automatic discontinuation of narcotics after a set number of days. Although a health care provider can reorder the narcotic, this policy helps to control unnecessarily prolonged medication therapy because it requires the health care provider to regularly review the need for the medication.

Medication Regulations and Nursing Practice. State **Nurse Practice Acts (NPAs)** define the scope of nurses' professional functions and responsibilities. Most NPAs are purposefully broad so nurses' professional responsibilities are not limited. Health care agencies can interpret specific actions allowed under NPAs; but they cannot modify, expand, or restrict the intent of the act. The primary intent of NPAs is to protect the public from unskilled, undereducated, and unlicensed personnel.

A nurse is responsible for following legal provisions when administering controlled substances such as opioids, which are carefully controlled through federal and state guidelines. Violations of the Controlled Substances Act are punishable by fines, imprisonment, and loss of nurse licensure. Hospitals and other health care agencies have policies for the proper storage and distribution of narcotics (Box 32-1).

Pharmacological Concepts

Medication Names. Some medications have as many as three different names. The chemical name of a medication provides an exact description of its composition and molecular structure. Nurses rarely use chemical names in clinical practice. An example of a chemical name is *N*-acetyl-para-aminophenol, which is commonly known as Tylenol. The manufacturer who first develops the medication gives the

---

BOX 32-1   Guidelines for Safe Narcotic Administration and Control

- Store all narcotics in a locked, secure cabinet or container (e.g., computerized, locked cabinets are preferred).
- Maintain a running count of narcotics by counting them whenever dispensing them. If you find a discrepancy, correct and report it immediately.
- Use a special inventory record each time a narcotic is dispensed. Records are often kept electronically and provide an accurate ongoing count of narcotics used, wasted, and remaining.
- Use the record to document the patient's name, date, time of medication administration, name of medication, and dosage. If the agency keeps a paper record, the nurse dispensing the medication signs the record. If the agency uses a computerized system, the computer records the nurse's name.
- A second nurse witnesses disposal of the unused part if a nurse gives only part of a dose of a controlled substance. Computerized systems record the nurses' names electronically. If paper records are kept, both nurses sign their names on the form. Follow agency policy for appropriate waste of narcotics. Do not place wasted parts of medications in sharps containers.

---

generic or nonproprietary name, with United States Adopted Names (USAN) Council approval (AMA, 2015). Acetaminophen is an example of the generic name for Tylenol. The generic name becomes the official name listed in official publications such as the United States Pharmacopeia (USP). The trade name, brand name, or proprietary name is the name under which a manufacturer markets a medication. The trade name has the symbol (™) at the upper right of the name, indicating that the manufacturer has trademarked the name of the medication (e.g., Panadol™, and Tempra™).

Manufacturers choose trade names that are easy to pronounce, spell, and remember. Many companies produce the same medication, and similarities in trade names are often confusing. Therefore be careful to obtain the exact name and spelling for each medication you administer to your patients. Because similarities in drug names are a common cause of medical errors, the Institute for Safe Medication Practices (ISMP) (2015a) (http://www.ismp.org/Tools/confuseddrugnames.pdf) publishes a list of medications that are frequently confused with one another. The ISMP recommends the use of Food and Drug Administration (FDA)-approved tall-man or mixed-case letters when possible (e.g., aMILoride versus amLODIPine) to help health care providers easily recognize the difference between these commonly confused medications.

Classification. Medication classification indicates the effect of a medication on a body system, the symptoms a medication relieves, or its desired effect. Usually each class contains more than one medication that is used for the same type of health problem. For example, patients who have asthma often take a variety of medications to control their illness such as beta$_2$-adrenergic agonists. The *beta$_2$-adrenergic* classification contains more than 15 different medications (Lehne, 2013). Some medications are in more than one class. For example, aspirin is an analgesic, an antipyretic, and an antiinflammatory medication.

Medication Forms. Medications are available in a variety of forms, or preparations. The form of the medication determines its route of administration. The composition of a medication enhances its absorption and metabolism. Many medications come in several forms such as tablets, capsules, elixirs, and suppositories. When

TABLE 32-1 Forms of Medication

Form	Description
Medication Forms Commonly Prepared for Administration by Oral Route	
Solid Forms	
Caplet	Solid dosage form for oral use; shaped like capsule and coated for ease of swallowing
Capsule	Medication encased in gelatin shell
Tablet	Powdered medication compressed into hard disk or cylinder; in addition to primary medication, contains binders (adhesive to allow powder to stick together), disintegrators (to promote tablet dissolution), lubricants (for ease of manufacturing), and fillers (for convenient tablet size)
Enteric-coated tablet	Coated tablet that does not dissolve in stomach; coatings dissolve in intestine, where medication is absorbed
Liquid Forms	
Elixir	Clear fluid containing water and/or alcohol; often sweetened
Extract	Concentrated medication form made by removing the active part of medication from its other components
Aqueous solution	Substance dissolved in water and syrups
Aqueous suspension	Finely dissolved drug particles dispersed in liquid medium; when suspension is left standing, particles settle to bottom of container
Syrup	Medication dissolved in a concentrated sugar solution
Other Oral Forms and Terms Associated with Oral Preparations	
Troche (lozenge)	Flat, round tablets that dissolve in mouth to release medication; not meant for ingestion
Aerosol	Aqueous medication sprayed and absorbed in mouth and upper airway; not meant for ingestion
Sustained release	Tablet or capsule that contains small particles of a medication coated with material that requires a varying amount of time to dissolve
Medication Forms Commonly Prepared for Administration by Topical Route	
Ointment (salve or cream)	Semisolid, externally applied preparation, usually containing one or more medications
Liniment	Usually contains alcohol, oil, or soapy emollient applied to skin
Lotion	Semiliquid suspension that usually protects, cools, or cleanses skin
Paste	Thick ointment; absorbed through skin more slowly than ointment; often used for skin protection
Transdermal disk or patch	Medicated disk or patch absorbed through skin slowly over long period of time (e.g., 24 hours)
Medication Forms Commonly Prepared for Administration by Parenteral Route	
Solution	Sterile preparation that contains water with one or more dissolved compounds
Powder	Sterile particles of medication that are dissolved in a sterile liquid (e.g., water, normal saline) before administration
Medication Forms Commonly Prepared for Instillation Into Body Cavities	
Intraocular disk	Small, flexible oval (similar to contact lens) consisting of two soft, outer layers and a middle layer containing medication; slowly releases medication when moistened by ocular fluid
Suppository	Solid dosage form mixed with gelatin and shaped in form of pellet for insertion into body cavity (rectum or vagina); melts when it reaches body temperature, releasing medication for absorption

administering a medication, be certain to use the proper form (Table 32-1).

Pharmacokinetics As the Basis of Medication Actions

For a medication to be useful therapeutically, it must be taken into a patient's body; be absorbed and distributed to cells, tissues, or a specific organ; and alter physiological functions. **Pharmacokinetics** is the study of how medications enter the body, reach their site of action, metabolize, and exit the body. You use knowledge of pharmacokinetics when timing medication administration, selecting the route of administration, and evaluating a patient's response.

Absorption. **Absorption** occurs when medication molecules pass into the blood from the site of medication administration. Factors that influence absorption are the route of administration, ability of the medication to dissolve, blood flow to the site of administration, body surface area (BSA), and lipid solubility of medication.

Route of Administration. Each route of medication administration has a different rate of absorption. When applying medications on the skin, absorption is slow because of the physical makeup of the skin. Because orally administered medications pass through the gastrointestinal (GI) tract, the overall rate of absorption is usually slow. Medications placed on the mucous membranes and respiratory airways are absorbed quickly because these tissues contain many blood vessels. Intravenous (IV) **injection** produces the most rapid absorption because medications are available immediately when they enter the systemic circulation.

Ability of a Medication to Dissolve. The ability of an oral medication to dissolve depends largely on its form or preparation. The body absorbs solutions and suspensions already in a liquid state more readily

than tablets or capsules. Acidic medications pass through the gastric mucosa rapidly. Medications that are basic are not absorbed before reaching the small intestine.

Blood Flow to the Site of Administration. The blood supply to the site of administration will determine how quickly the body can absorb a drug. Medications are absorbed as blood comes in contact with the site of administration. The richer the blood supply to the site of administration, the faster a medication is absorbed.

Body Surface Area. When a medication comes in contact with a large surface area, it is absorbed at a faster rate. This helps explain why the majority of medications are absorbed in the small intestine rather than the stomach (Lehne, 2013).

Lipid Solubility. Because the cell membrane has a lipid layer, highly lipid-soluble medications cross cell membranes easily and are absorbed quickly. Another factor that often affects medication absorption is whether or not food is in the stomach. Some oral medications are absorbed more easily when administered between meals because food changes the structure of a medication and sometimes impairs its absorption. When some medications are administered together, they interfere with one another, impairing the absorption of both medications.

Safe medication administration requires knowledge of factors that alter or impair absorption of prescribed medications. You need to understand medication pharmacokinetics, a patient's health history, physical examination data, and knowledge gained through daily patient interactions. Use your knowledge to plan medication administration times that will promote optimal absorption. For example, plan medication administration times around meals (e.g., before or after meals) when medications interact with food. When they interact with one another, make sure that you do not give them at the same time. Consult and collaborate with your patient's health care provider or a pharmacist when setting medication times to ensure that the patient achieves the therapeutic effect of all medications. Before administering any medication, check pharmacology books, drug references, or package inserts or consult with pharmacists to identify medication-medication or medication-food interactions.

Distribution. After a medication is absorbed, it is distributed within the body to tissues and organs and ultimately to its specific site of action. The rate and extent of distribution depend on the physical and chemical properties of the medication and the physiology of the person taking it.

Circulation. Once a medication enters the bloodstream, it is carried throughout the tissues and organs. How fast it reaches a site depends on the vascularity of the various tissues and organs. Conditions that limit blood flow or blood perfusion inhibit the distribution of a medication. For example, patients with heart failure have impaired circulation, which slows medication delivery to the intended site of action. Therefore the effectiveness of medications in these patients is often delayed or altered.

Membrane Permeability. Membrane permeability refers to the ability of a medication to pass through tissues and membranes to enter target cells. To be distributed to an organ, a medication has to pass through all of the tissues and biological membranes of the organ. Some membranes serve as barriers to the passage of medications. For example, the blood-brain barrier allows only fat-soluble medications to pass into the brain and cerebral spinal fluid. Therefore central nervous system infections often require treatment with antibiotics injected directly into the subarachnoid space in the spinal cord. Some older adults experience adverse effects (e.g., confusion) as a result of the change in the permeability of the blood-brain barrier, with easier passage of fat-soluble medications.

Protein Binding. The degree to which medications bind to serum proteins such as albumin affects their distribution. Most medications partially bind to albumin, reducing the ability of a drug to exert pharmacological activity. The unbound or "free" medication is its active form. Older adults and patients with liver disease or malnutrition have decreased albumin in the bloodstream. Because more medication is unbound in these patients, they are at risk for an increase in medication activity, toxicity, or both.

Metabolism. After a medication reaches its site of action, it becomes metabolized into a less active or an inactive form that is easier to excrete. **Biotransformation** occurs under the influence of enzymes that **detoxify**, break down, and remove biologically active chemicals. Most biotransformation occurs within the liver, although the lungs, kidneys, blood, and intestines also metabolize medications. The liver is especially important because its specialized structure oxidizes and transforms many toxic substances. The liver degrades many harmful chemicals before they become distributed to the tissues. If a decrease in liver function occurs such as with aging or liver disease, a medication is usually eliminated more slowly, resulting in its accumulation. Patients are at risk for medication toxicity if organs that metabolize medications are not functioning correctly. For example, a small sedative dose of a barbiturate sometimes causes a patient with liver disease to lapse into a coma.

Excretion. After medications are metabolized, they exit the body through the kidneys, liver, bowel, lungs, and exocrine glands. The chemical makeup of a medication determines the organ of excretion. Gaseous and volatile compounds such as nitrous oxide and alcohol exit through the lungs. Deep breathing and coughing (see Chapter 41) help patients eliminate anesthetic gases more rapidly after surgery. The exocrine glands excrete lipid-soluble medications. When medications exit through sweat glands, the skin often becomes irritated, requiring you to teach patients good hygiene practices (see Chapter 40). If a medication is excreted through the mammary glands, there is a risk that a nursing infant will ingest the chemicals. Check the safety of any medication used in breastfeeding women.

The GI tract is another route for medication excretion. Medications that enter the hepatic circulation are broken down by the liver and excreted into the bile. After chemicals enter the intestines through the biliary tract, the intestines resorb them. Factors that increase peristalsis (e.g., laxatives and enemas) accelerate medication excretion through the feces, whereas factors that slow peristalsis (e.g., inactivity and improper diet) often prolong the effects of a medication.

The kidneys are the main organs for medication excretion. Some medications escape extensive metabolism and exit unchanged in the urine. Others undergo biotransformation in the liver before the kidneys excrete them. Maintenance of an adequate fluid intake (50 mL/kg/hr) promotes proper elimination of medications for the average adult. If a patient's renal function declines, the kidneys cannot excrete medications adequately. Thus the risk for medication toxicity increases. Health care providers usually reduce medication doses when this happens.

Types of Medication Action

Medications vary considerably in the way they act and their types of action. Patients do not always respond in the same way to each successive dose of a medication. Sometimes the same medication causes very different responses in different patients. Therefore you need to understand all the effects that medications you administer have on patients.

Therapeutic Effects. The **therapeutic effect** is the expected or predicted physiological response caused by a medication. For example, nitroglycerin reduces cardiac workload and increases myocardial oxygen supply. Some medications have more than one therapeutic effect. For example, prednisone, a steroid, decreases swelling, inhibits inflammation, reduces allergic responses, and prevents rejection of transplanted organs. Knowing the desired therapeutic effect for each medication allows you to provide patient education and accurately evaluate the desired effect of a medication.

Adverse Effects. Every medication has the ability to harm a patient. Undesired, unintended, and often unpredictable responses to medication are referred to as **adverse effects**. Adverse drug effects range from mild to severe. Some happen immediately, whereas others develop over time. Be alert and assess for unusual individual responses to drugs, especially with newly prescribed medications. Patients most at risk for adverse medication reactions include the very young and older adults, women, patients taking multiple medications, patients extremely underweight or overweight, and patients with renal or liver disease. If adverse effects are mild and tolerable, patients often remain on the medications. However, if they are not tolerated and are potentially harmful, stop giving the medication immediately. When adverse responses to medications occur, the health care provider discontinues the medication immediately. Health care providers report adverse effects to the FDA using the MedWatch program (USFDA, 2015).

Side Effects. A **side effect** is a predictable and often unavoidable adverse effect produced at a usual therapeutic dose. For example, some antihypertensive medications cause impotence in men. Side effects range from being harmless to causing serious symptoms or injury. If the side effects are serious enough to negate the beneficial effects of the therapeutic action of the medication, the health care provider discontinues the medication. Patients often stop taking medications because of side effects, the most common of which are anorexia, nausea, vomiting, constipation, drowsiness, and diarrhea.

Toxic Effects. **Toxic effects** often develop after prolonged intake of a medication or when a medication accumulates in the blood because of impaired metabolism or excretion. Excess amounts of a medication within the body sometimes have lethal effects, depending on its action. For example, toxic levels of morphine, an opioid, cause severe respiratory depression and death. Antidotes are available to treat specific types of medication toxicity. For example, naloxone (Narcan), an opioid antagonist, reverses the effects of opioid toxicity.

Idiosyncratic Reactions. Medications sometimes cause unpredictable effects such as an **idiosyncratic reaction,** in which a patient overreacts or underreacts to a medication or has a reaction different from normal. For example, a child who receives diphenhydramine (Benadryl), an antihistamine, becomes extremely agitated or excited instead of drowsy. It is not always possible to predict if a patient will have an idiosyncratic response to a medication.

Allergic Reactions. Allergic reactions also are unpredictable responses to a medication. Some patients become immunologically sensitized to the initial dose of a medication. With repeated administration the patient develops an allergic response to it, its chemical preservatives, or a metabolite. The medication or chemical acts as an antigen, triggering the release of the antibodies in the body. A patient's **medication allergy** symptoms vary, depending on the individual and the medication (Table 32-2). Among the different classes of medications, antibiotics cause a high incidence of allergic reactions. Severe or **anaphylactic reactions,** which are life threatening, are characterized by sudden constriction of bronchiolar muscles, edema of the pharynx and larynx, and severe wheezing and shortness of breath. Immediate medical attention is required to treat anaphylactic reactions. A patient

TABLE 32-2	Mild Allergic Reactions
Symptom	**Description**
Urticaria (hives)	Raised, irregularly shaped skin eruptions with varying sizes and shapes; eruptions have reddened margins and pale centers
Rash	Small, raised vesicles that are usually reddened; often distributed over entire body
Pruritus	Itching of skin; accompanies most rashes
Rhinitis	Inflammation of mucous membranes lining nose; causes swelling and clear, watery discharge

FIGURE 32-1 Allergy identification bracelet and medal.

with a known history of an allergy to a medication needs to avoid taking that medication in the future and wear an identification bracelet or medal (Figure 32-1), which alerts nurses and other health care providers to the allergy if a patient is unable to communicate when receiving medical care.

Medication Interactions. When one medication modifies the action of another, a **medication interaction** occurs. Medication interactions are common when individuals take several medications. Some medications increase or diminish the action of others or alter the way another medication is absorbed, metabolized, or eliminated from the body. When two medications have a **synergistic effect,** their combined effect is greater than the effect of the medications when given separately. For example, alcohol is a central nervous system depressant that has a synergistic effect on antihistamines, antidepressants, barbiturates, and narcotic analgesics. Sometimes a medication interaction is desired. Health care providers often combine medications to create an interaction that has a beneficial effect. For example, a patient with high blood pressure takes several medications such as diuretics and vasodilators that act together to control blood pressure when one medication is not effective on its own.

Timing of Medication Dose Responses

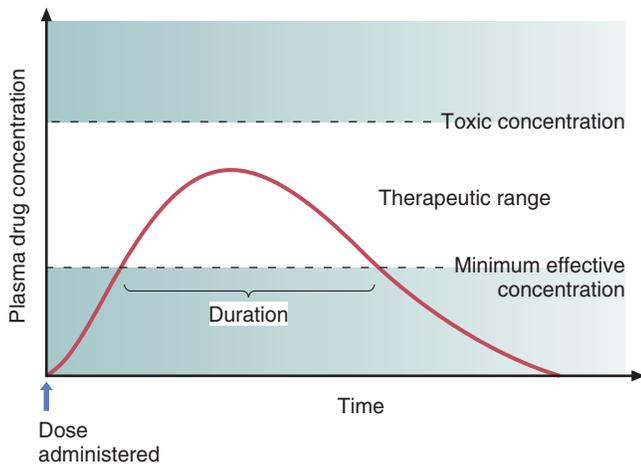
Medications administered intravenously enter the bloodstream and act immediately, whereas those given in other routes take time to enter the bloodstream and have an effect. The quantity and distribution of a medication in different body compartments change constantly.


FIGURE 32-2 The therapeutic range of a medication occurs between the minimum effective concentration and the toxic concentration. (From Lehne RA: *Pharmacology for nursing care*, ed 8, St Louis, 2013, Saunders.)

TABLE 32-3 Common Dosage Administration Schedules

Dosage Schedule (Meaning)	Abbreviation
Before meals	AC, ac
As desired	ad lib
Twice each day	BID, bid
After meals	PC, pc
Whenever there is a need	prn
Every morning, every AM	qam
Every hour	qh
Every day	Daily
Every 4 hours	Q4h
4 times per day	QID, qid
Give immediately	STAT, stat
3 times per day	TID, tid

Medications are ordered at various times, depending on when their response begins, becomes most intense, and ceases.

The minimum effective concentration (MEC) is the plasma level of a medication below which the effect of the medication does not occur. The toxic concentration is the level at which toxic effects occur. When a medication is prescribed, the goal is to achieve a constant blood level within a safe therapeutic range, which falls between the MEC and the toxic concentration (Figure 32-2). When a medication is administered repeatedly, its serum level fluctuates between doses. The highest level is called the **peak** concentration, and the lowest level is called the **trough** concentration. After reaching its peak, the serum concentration of the medication falls progressively. With IV **infusions** the peak concentration occurs quickly, but the serum level also begins to fall immediately. Some medication doses (e.g., vancomycin) are based on peak and trough serum levels. The trough level is generally drawn 30 minutes before administering the drug, and the peak level is drawn whenever the drug is expected to reach its peak concentration. The time it takes for a drug to reach its peak concentration varies, depending on the pharmacokinetics of the medication.

All medications have a **biological half-life,** which is the time it takes for excretion processes to lower the amount of unchanged medication by half. A medication with a short half-life needs to be given more frequently than a medication with a longer half-life. The half-life does not change, no matter how much medication is given. For example, if the nurse gives 1 g of a medication that has a half-life of 8 hours, the patient excretes 500 mg of the medication in 8 hours. In the next 8 hours the patient excretes 250 mg. This process continues until the medication is totally eliminated from the body.

To maintain a therapeutic plateau the patient must receive regular fixed doses. For example, pain medications for certain cancer patients are most effective when they are given around the clock (ATC) rather than when the patient intermittently complains of pain because ATC allows the body to maintain an almost constant level of pain medication. After an initial medication dose, a patient receives each successive dose when the previous dose reaches its half-life (Burchum and Rosenthal, 2016).

Safe drug administration involves adherence to prescribed doses and dosage schedules (Table 32-3). Some agencies set schedules for medication administration. However, nurses are able to alter this schedule on the basis of knowledge about a medication. For example, at some agencies medications that are to be taken once a day are given

at 9:00 AM. However, if a medication works best when given before bedtime, the nurse administers it before the patient goes to sleep. In addition, acute care agencies use guidelines from the ISMP (CMS, 2011; ISMP, 2011) to determine safe, effective, and timely administration of scheduled medications. According to ISMP guidelines, hospitals need to determine which medications are time critical and which are non–time critical. Time-critical medications are medications in which early or delayed administration of maintenance doses (more than 30 minutes before or after the scheduled dose) will most likely result in harm or subtherapeutic responses in a patient. Non–time-critical medications include medications in which the timing of administration will most likely not affect the desired effect of the medication if given 1 to 2 hours before or after its scheduled time. You need to administer time-critical medications at a precise time or within 30 minutes before or after the scheduled time. You administer non–time-critical medications within 1 to 2 hours of their scheduled time. Follow the medication administration policies of your agency about the timing of medications to ensure that you administer medications at the right time (CMS, 2011; ISMP, 2011).

When you teach patients about medication schedules, use familiar language. For example, instruct a patient who needs to take a medication twice a day to take it in the morning and again in the evening. Use knowledge about time intervals and terms used to describe medication actions to anticipate the effect of a medication and educate the patient about when to expect a response (Table 32-4).

QSEN **QSEN: BUILDING COMPETENCY IN EVIDENCE-BASED PRACTICE.** You are a member of the shared governance practice council in your hospital. The practice council is investigating evidence-based practices to reduce medication errors. The chairperson explains to the committee that evidence-based practice changes are based on the current best evidence, resources, nursing expertise, and patient preferences. One of the nurses asks, "How can we ensure that patient preferences are respected when we are administering medications?" How would you respond?

Answers to QSEN Activities can be found on the Evolve website.

TABLE 32-4 Terms Associated with Medication Actions

Term	Meaning
Onset	Time it takes after a medication is administered for it to produce a response
Peak	Time it takes for a medication to reach its highest effective concentration
Trough	Minimum blood serum concentration of medication reached just before the next scheduled dose
Duration	Time during which medication is present in concentration great enough to produce a response
Plateau	Blood serum concentration of medication reached and maintained after repeated fixed doses

FIGURE 32-3 Sublingual administration of a tablet.

FIGURE 32-4 Buccal administration of a tablet.

Routes of Administration

The route prescribed for administering a medication depends on the properties and desired effect of the medication and the patient's physical and mental condition (Table 32-5). Work with the health care provider to determine the best route for a patient's medication.

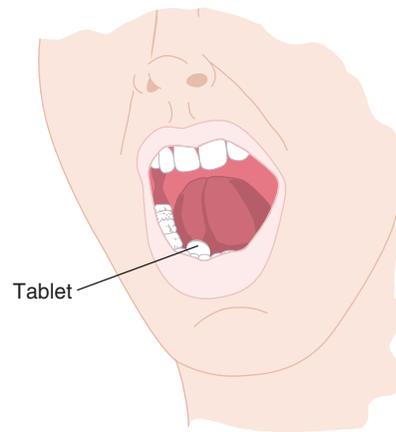
Oral Routes. The oral route is the easiest and the most commonly used route of medication administration. Medications are given by mouth and swallowed with fluid. Oral medications have a slower onset of action and a more prolonged effect than parenteral medications. Patients generally prefer the oral route.

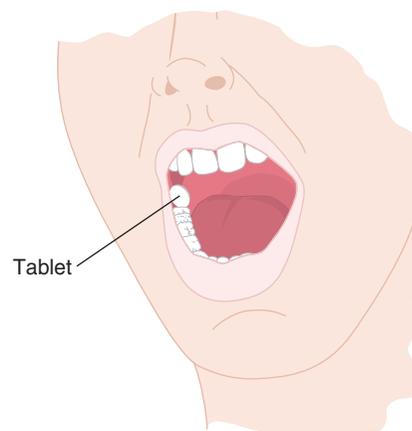
Sublingual Administration. Some medications (e.g., nitroglycerin) are readily absorbed after being placed under the tongue to dissolve (Figure 32-3). Instruct patients not to swallow a medication given by the **sublingual** route or drink anything until the medication is completely dissolved to ensure that the medication will have the desired effect.

Buccal Administration. Administration of a medication by the **buccal** route involves placing the solid medication in the mouth against the mucous membranes of the cheek until it dissolves (Figure 32-4). Teach patients to alternate cheeks with each subsequent dose to avoid mucosal irritation. Warn patients not to chew or swallow the medication or to take any liquids with it. A buccal medication acts locally on the mucosa or systemically as it is swallowed in a person's saliva.

Parenteral Routes. **Parenteral administration** involves injecting a medication into body tissues. The following are the four major sites of injection:

1. **Intradermal (ID):** Injection into the dermis just under the epidermis
2. **Subcutaneous:** Injection into tissues just below the dermis of the skin
3. **Intramuscular (IM):** Injection into a muscle
4. **Intravenous (IV):** Injection into a vein

Some medications are administered into body cavities through other routes, including epidural, intrathecal, intraosseous, intraperitoneal, intrapleural, and intraarterial. Nurses usually are not responsible for the administration of medications through these advanced techniques. Whether or not you actually administer a medication, you remain responsible for monitoring the integrity of the medication delivery system, understanding the therapeutic value of the medication, and evaluating a patient's response to the therapy.




Epidural. Epidural medications are administered in the epidural space via a catheter, which is placed by a nurse anesthetist or an anesthesiologist. This route is used for the administration of regional analgesia for surgical procedures (see Chapters 44 and 50). Nurses who have advanced education in the epidural route can administer medications by continuous infusion or a bolus dose.

Intrathecal. Physicians and specially educated nurses administer intrathecal medications through a catheter surgically placed in the subarachnoid space or one of the ventricles of the brain. Intrathecal medication administration often is a long-term treatment.

Intraosseous. This method of medication administration involves the infusion of medication directly into the bone marrow. It is used most commonly in infants and toddlers who have poor access to their intravascular space or when an emergency arises and IV access is impossible.

Intraperitoneal. Medications administered into the peritoneal cavity are absorbed into the circulation. Chemotherapeutic agents, insulin, and antibiotics are administered in this fashion.

Intrapleural. A syringe and needle or a chest tube is used to administer intrapleural medications directly into the pleural space. Chemotherapeutic agents are the most common medications administered via this method. Physicians also instill medications that help resolve persistent pleural effusion to promote adhesion between the visceral and parietal pleura. This is called *pleurodesis*.

Intraarterial. Intraarterial medications are administered directly into the arteries. Intraarterial infusions are common in patients who have arterial clots and receive clot-dissolving agents. A nurse manages

TABLE 32-5 Factors Influencing Choice of Administration Routes	
Advantages by Route	**Disadvantages/Contraindications**
Oral, Buccal, Sublingual Routes	
Convenient and comfortable	Oral route is avoided when patient has alterations in gastrointestinal (GI) function (e.g.,
Economical	nausea, vomiting), reduced GI motility (after general anesthesia or bowel inflammation),
Easy to administer	and surgical resection of the GI tract.
Often produce local or systemic effects	Oral administration is contraindicated in patients unable to swallow (e.g., patients with
Rarely cause anxiety for patient	neuromuscular disorders, esophageal strictures, mouth lesions).
	Oral administration is contraindicated in patients who are unconscious, confused, or
	unable or unwilling to swallow or hold medication under tongue.
	Oral medications cannot be administered when patients have gastric suction; are
	contraindicated before some tests or surgery.
	Oral medications sometimes irritate lining of GI tract, discolor teeth, or have unpleasant
	taste.
	Gastric secretions destroy some medications.
Parenteral Routes (Subcutaneous, Intramuscular, Intravenous, Intradermal)	
Can be used when oral medications are contraindicated	There is risk of introducing infection.
More rapid absorption than with topical or oral routes	Some medications are expensive.
Intravenous (IV) infusion provides medication delivery when patient is	Some patients experience pain from repeated needlesticks.
critically ill or long-term therapy is necessary; if peripheral	Subcutaneous, intramuscular (IM), and intradermal (ID) routes are avoided in patients with
perfusion is poor, IV route preferred over injections	bleeding tendencies.
	There is risk of tissue damage.
	IM and IV routes have higher absorption rates, thus placing patient at higher risk for
	reactions.
	They often cause considerable anxiety in many patients, especially children.
Topical Routes	
Skin	
Primarily provides local effect	Patients with skin abrasions are at risk for rapid medication absorption and systemic
Painless	effects.
Limited side effects	Medications are absorbed through skin slowly.
Transdermal	
Prolonged systemic effects with limited side effects	Medication leaves oily or pasty substance on skin and sometimes soils clothing.
*Mucous Membranes**	
Therapeutic effects provided by local application to involved sites	Mucous membranes are highly sensitive to some medication concentrations.
Aqueous solutions readily absorbed and capable of causing systemic	Patients with ruptured eardrum cannot receive ear irrigations.
effects	Insertion of rectal and vaginal medication often causes embarrassment.
Potential route of administration when oral medications are	Rectal suppositories contraindicated if patient has had rectal surgery or if active rectal
contraindicated	bleeding is present.
Other Routes	
Inhalation	
Provides rapid relief for local respiratory problems	Some local agents cause serious systemic effects.
Used for introduction of general anesthetic gases	
Intraocular Disk	
Route advantageous because it does not require frequent	Local reactions possible; expensive
administration as eyedrops do	Patients must be taught to insert and remove disk
	Contraindicated in eye infections

*Includes eyes, ears, nose, vagina, rectum, and ostomy.

a continuous infusion of the clot-dissolving agent and carefully monitors the integrity of the infusion to prevent inadvertent disconnection of the system and subsequent bleeding.

Other methods of medication administration that are usually limited to physician administration are **intracardiac,** an injection of a medication directly into cardiac tissue, and **intraarticular,** an injection of a medication into a joint.

Topical Administration. Medications applied to the skin and mucous membranes generally have local effects. You apply topical medications to the skin by painting or spreading the medication over an area, applying moist dressings, soaking body parts in a solution, or giving medicated baths. Systemic effects often occur if a patient's skin is thin or broken down, the medication concentration is high, or contact with the skin is prolonged. A **transdermal disk** or patch

(e.g., nitroglycerin, scopolamine, and estrogens) has systemic effects. The disk secures the medicated ointment to the skin. These topical applications are left in place for as little as 12 hours or as long as 7 days.

You apply topical medications to mucous membranes in the following ways:

1. Direct application of a liquid or ointment (e.g., eyedrops, gargling, or swabbing the throat)
2. Insertion of a medication into a body cavity (e.g., placing a suppository in rectum or vagina or inserting medicated packing into vagina)
3. Instillation of fluid into a body cavity (e.g., eardrops, nose drops, or bladder and rectal **instillation** [fluid is retained])
4. Irrigation of a body cavity (e.g., flushing eye, ear, vagina, bladder, or rectum with medicated fluid [fluid is not retained])
5. Spraying a medication into a body cavity (e.g., instillation into nose and throat)

Inhalation Route. The deeper passages of the respiratory tract provide a large surface area for medication absorption. Nurses administer inhaled medications through the nasal and oral passages or endotracheal or tracheostomy tubes. Endotracheal tubes enter the patient's mouth and end in the trachea, whereas tracheostomy tubes enter the trachea directly through an incision made in the neck. Inhaled medications are readily absorbed and work rapidly because of the rich vascular alveolar capillary network present in the pulmonary tissue. Many inhaled medications have local or systemic effects.

Intraocular Route. **Intraocular** medication delivery involves inserting a medication similar to a contact lens into a patient's eye. The eye medication disk has two soft outer layers that have medication enclosed in them. The nurse inserts the disk into the patient's eye, much like a contact lens. The medication remains in the eye for up to 1 week.

Systems of Medication Measurement

The proper administration of a medication depends on your ability to compute medication doses accurately and measure medications correctly. Fatal errors often occur when nurses make mistakes in calculating or measuring medications. As a nurse you are responsible for checking calculations carefully before giving a medication. Many agencies have policies related to the administration of high-risk medications (e.g., heparin and insulin) that may need a second nurse check before administration.

Medication therapy uses the metric, apothecary, and household systems of measurement. The apothecary system is used infrequently today. Although the U.S. Congress has not officially adopted the metric system, most health professionals in the United States use it.

Metric System. As a decimal system, the **metric system** is the most logically organized. You convert and compute metric units using simple multiplication and division. Each basic unit of measurement is organized into units of 10. Multiplying or dividing by 10 forms secondary units. In multiplication the decimal point moves to the right; in division the decimal moves to the left. For example:

$$10 \text{ mg} \times 10 = 100 \text{ mg}$$
$$10 \text{ mg} \div 10 = 1 \text{ mg}$$

The basic units of measurement in the metric system are the meter (length), the liter (volume), and the gram (weight). For medication calculations only use the volume and weight units. The metric system

uses lowercase or capital letters or a combination of lowercase and capital letters to designate basic units:

$$\text{Gram} = \text{g or Gm}$$
$$\text{Liter} = \text{l or L}$$
$$\text{Milligram} = \text{mg}$$
$$\text{Milliliter} = \text{mL}$$

A system of Latin prefixes designates subdivision of the basic units: *deci-* (1/10 or 0.1), *centi-* (1/100 or 0.01), and *milli-* (1/1000 or 0.001). Greek prefixes designate multiples of the basic units: *deka-* (10), *hecto-* (100), and *kilo-* (1000). When writing medication doses in metric units, health care providers and nurses use fractions or multiples of a unit. Convert fractions to decimals.

$$500 \text{ mg or } 0.5 \text{ g, } \textit{not } \tfrac{1}{2} \text{ g}$$
$$10 \text{ mL or } 0.01 \text{ L, } \textit{not } \tfrac{1}{100} \text{ L}$$

Many actual and potential medication errors happen with the use of fractions and decimal points. Follow practice standards when medications are ordered in fractions to prevent these errors. For example, to make the decimal point more visible, a leading zero is *always* placed in front of a decimal (e.g., use 0.25 *not* .25). *Never* use a trailing zero (i.e., a zero after a decimal point) because, if a health care worker does not see the decimal point, the patient may receive 10 times more medication than that prescribed (e.g., use 5 *not* 5.0) (ISMP, 2013a).

Household Measurements. Household units of measure are familiar to most people. Household measures include drops, teaspoons, tablespoons, and cups for volume and pints and quarts for weight. The advantage of household measurements is their convenience and familiarity. Their disadvantage is their inaccuracy if a patient uses household utensils such as teaspoons and cups. Encourage patients to never use household measuring devices to give liquid medicines. The devices are inaccurate and may deliver more or less than prescribed (Consumer Med Safety, 2015). Today's over-the-counter (OTC) liquid medicines almost always have their own measuring devices (Consumer Med Safety, 2015). Scales to measure pints or quarts are not well calibrated. To calculate medications accurately, you need to know common equivalents of metric and household units (Table 32-6).

TABLE 32-6	Equivalents of Measurement	
Metric	**Apothecary**	**Household**
1 mL	15-16 minims*	15 drops (gtt)
5 mL	1 dram*	1 teaspoon (tsp)
15 mL	4 drams*	1 tablespoon (tbsp)
30 mL	1 fluid ounce	2 tablespoons (tbsp)
240 mL	8 fluid ounces	1 cup (c)
480 mL (approximately 500 mL)	1 pint (pt)	1 pint (pt)
960 mL (approximately 1 L)	1 quart (qt)	1 quart (qt)
3840 mL (approximately 4 L)	1 gallon (gal)	1 gallon (gal)

*Minims and drams are no longer acceptable units of measure for medication administration, although some medication cups and syringes still have them listed. Use mL for safe medication preparation (Morris, 2014).

Solutions. Nurses use solutions of various concentrations for injections, **irrigations,** and infusions. A **solution** is a given mass of solid substance dissolved in a known volume of fluid or a given volume of liquid dissolved in a known volume of another fluid. When a solid is dissolved in a fluid, the concentration is in units of mass per units of volume (e.g., g/L, mg/mL). You can also express a concentration of a solution as a percentage. For example, a 10% solution is 10 g of solid dissolved in 100 mL of solution. A proportion also expresses concentrations. A $\frac{1}{1000}$ solution represents a solution containing 1 g of solid in 1000 mL of liquid or 1 mL of liquid mixed with 1000 mL of another liquid.

NURSING KNOWLEDGE BASE

The Institute of Medicine (IOM) published the book *To Err Is Human: Building a Safer Health System* (IOM, 1999). This book created a new national awareness of problems within the health care system. It estimated that up to 98,000 people die in any given year from medical errors that occur in hospitals. This means that more people die from medical errors than from motor vehicle accidents, breast cancer, acquired immunodeficiency syndrome (AIDS), and workplace injuries. Health care experts estimate that medication-related errors for hospitalized patients cost more than $3.5 billion annually (CDC, 2012).

Nurses play an important role in patient safety, especially in the area of medication administration. The safe administration of medications is also an important topic for current nursing researchers (Box 32-2). As a nurse you need to know how to calculate medication doses accurately and understand the different roles that members of the health care team play in prescribing and administering medications. Apply your knowledge and think critically to ensure safe medication administration.

Clinical Calculations

To administer medications safely, you need to have an understanding of basic mathematics skills to calculate medication doses, mix solutions, and perform a variety of other activities. This is important because medications are not always dispensed in the unit of measure in which they are ordered. Medication companies package and bottle medications in standard dosages. For example, a patient's health care provider orders 20 mg of a medication that is available only in 40-mg vials. Nurses frequently convert available units of volume and weight to desired doses. Therefore it is important to be aware of equivalents in all major measurement systems. You use equivalents when performing other nursing actions such as when calculating patients' intake and output and IV flow rates.

Conversions Within One System. Converting measurements within one system is relatively easy; simply divide or multiply in the metric system. To change milligrams to grams, divide by 1000, moving the decimal 3 points to the left.

$$1000 \text{ mg} = 1 \text{ g}$$
$$350 \text{ mg} = 0.35 \text{ g}$$

To convert liters to milliliters, multiply by 1000 or move the decimal 3 points to the right.

$$1 \text{ L} = 1000 \text{ mL}$$
$$0.25 \text{ L} = 250 \text{ mL}$$

To convert units of measurement within the household system, consult an equivalent table. For example, when converting fluid ounces to

---

BOX 32-2   EVIDENCE-BASED PRACTICE

Reducing Errors During Medication Administration

PICO Question: In hospitals does the use of computerized prescription order entry (CPOE), automated medication dispensers (AMDs), and bar-code medication administration (BCMA) during medication administration decrease the incidence of medication errors made by nurses when compared with nurses who do not use these health technologies?

Evidence Summary

Medication administration is a highly complex process. Errors often result from problems within one or more parts of the process. Many errors occur either when a medication is ordered or when it is administered (Grou Volpe et al., 2014). Research shows that the implementation of medication administration technologies such as CPOE, AMD, and BCMA helps to decrease medication errors in various patient care settings (Ching et al., 2013; Cochran and Haynatzki, 2013; Cousein et al., 2014). However, health care agencies cannot rely on technology alone. Considering human factors such as staffing levels of nurses and pharmacists (Cochran and Haynatzki, 2013) and integrating technology into nursing work flow (Ching et al., 2013) are also essential in promoting medication safety.

Application to Nursing Practice

- The process of implementing medication administration technology is complex and needs to be well planned and involve health care staff, including nurses, to ensure successful implementation (Ching et al., 2013).
- Even though using CPOE, AMD, and BCMA reduces many medication errors, it does not eliminate all of them (Ching et al., 2013; Cousein et al., 2014). Therefore nurses need to remain vigilant and consistently follow medication administration policies and protocols to ensure safe medication administration.
- Because medication errors are often associated with high nursing workloads, increased complexity and acuity of patient care, and reduced pharmacy support, health care administrators, including nurse leaders, need to ensure appropriate nurse and pharmacist staffing levels that are based on patient acuity and workload (Cochran and Haynatzki, 2013; Grou Volpe et al., 2014).

---

quarts, you first need to know that 32 ounces is the equivalent of 1 quart. To convert 8 ounces to a quart measurement, divide 8 by 32 to get the equivalent, $\frac{1}{4}$ or 0.25 quart.

Conversion Between Systems. Nurses frequently determine the proper dose of a medication by converting weights or volumes from one system of measurement to another. Thus sometimes you convert metric units to equivalent household measures for use at home. To calculate medications it is necessary to work with units in the same measurement system. Tables of equivalent measurements are available in all health care agencies. A pharmacist is also a good resource.

Before converting, compare the measurement system available with the system used when the medication was ordered. For example, a patient is ordered guaifenesin (Robitussin) 30 mL, but the patient only has tablespoons at home. To properly instruct him or her on how to prepare the dose, you convert mL to tablespoons, which requires you to know the equivalent or refer to a table such as Table 32-6.

Dose Calculations. Methods used to calculate medication doses include the ratio and proportion method, the formula method,

and dimensional analysis. Before completing any calculation, make a mental estimate of the approximate and reasonable dosage. If the estimate does not match the calculated solution, recheck the calculation before preparing and administering the medication. Many nursing students are anxious when calculating medication doses. To enhance accuracy and reduce anxiety, think critically about the processes used during the calculation and practice doing calculations until you feel confident about your mathematics skills (Hunter Revell and McCurry, 2013). In addition, choose the method of calculation with which you are most comfortable and use it consistently (Morris, 2014). Most health care agencies require a nurse to double-check calculations with another nurse before giving medications, especially when the risk for giving the wrong medication is high (e.g., heparin, insulin). *Always* have another nurse double-check your work if you are unsure about the answer or if the answer to a medication calculation seems unreasonable or inappropriate.

The Ratio and Proportion Method. A ratio indicates the relationship between two numbers separated by a colon (:). The colon in the ratio indicates the need to use division. Think of a ratio as a fraction; the number to the left is the numerator, and the number to the right is the denominator. For example, the ratio 1:2 is the same as $\frac{1}{2}$. A proportion is an equation that has two ratios of equal value. Write a proportion in one of three ways:

Example 1: 1:2 = 4:8
Example 2: 1:2 :: 4:8
Example 3: 1/2 = 4/8

In a proportion the first and last numbers are called the *extremes,* and the second and third numbers are called the *means.* When multiplying the extremes, the answer is the same when multiplying the means. For example, in the previous proportions, multiplying the extremes ($1 \times 8 = 8$) is the same result as multiplying the means ($2 \times 4 = 8$). Because of this relationship, if you know three of the numbers in the proportion, calculating the unknown fourth number is easy. The numbers need to all be in the same unit and system of measurement. To solve a calculation using the ratio and proportion method, first estimate the answer in your mind. Then set up the proportion, labeling all the terms. Put the terms of the ratio in the same sequence (e.g., mg : mL = mg : mL). Cross-multiply the means and the extremes and divide both sides by the number before the x to obtain the dosage. *Always* label the answer; if the answer is not close to the estimate, recheck the calculation.

Example: The health care provider orders 500 mg of amoxicillin to be administered in a gastric tube every 8 hours. The bottle of amoxicillin is labeled 400 mg/5 mL. Use the following steps to calculate how much amoxicillin to give:
1. **Estimate the answer:** The amount to be given is a little more than the labeled dose per 5 mL (unit dose) that is provided in the solution; therefore the answer is a little more than 5 mL.
2. **Set up the proportion:**

$$\frac{400 \text{ mg}}{5 \text{ mL}} = \frac{500 \text{ mg}}{x \text{ mL}}$$

3. **Cross-multiply the means and the extremes:**

$$400x = 500 \times 5$$
$$400x = 2500$$

4. **Divide both sides by the number before x:**

$$\frac{400x}{400} = \frac{2500}{400}$$
$$x = \frac{2500}{400}$$
$$x = 6.25 \text{ mL}$$

5. **Compare the estimate in Step 1 with the answer in Step 4:** The answer (6.25 mL) is close to the estimated amount (a little more than 5 mL). Therefore the answer is correct; prepare and administer 6.25 mL in the patient's gastric tube.

The Formula Method. Using this method requires you to first memorize the formula. Estimate the answer and then place all the information from the medication order into the formula. Label all the parts of the formula and ensure that all measures in the formula are in the same units and system of measurement before calculating the dosage. If the measures are not in the same measurement system, convert the numbers to the same system before calculating the dose. Calculate and label the answer and compare the answer with the estimated answer. If the estimate is not similar to the answer, recheck the calculation. Use the following basic formula when using the formula method:

$$\frac{\text{Dose ordered}}{\text{Dose on hand}} \times \text{Amount on hand} = \text{Amount to administer}$$

The dose ordered is the amount of medication prescribed. The dose on hand is the dose (e.g., mg, units) of medication supplied by the pharmacy. The amount on hand is the basic unit or quantity of the medication that contains the dose on hand. For solid medications the amount on hand is often one capsule; the amount of liquid on hand is sometimes 1 mL or 1 L, depending on the container. For example, a liquid medication comes in the strength of 125 mg per 5 mL. In this case 125 mg is the dose on hand, and 5 mL is the amount on hand. The amount to administer is the actual amount of medication the nurse administers. Always express the amount to administer in the same unit as the amount on hand.

Example: The health care provider orders morphine sulfate 2 mg IV. The medication is available in a vial containing 10 mg/mL. The formula is applied as follows:
1. **Estimate the answer:** The medication is a liquid; thus the answer will be in milliliters (mL). The amount to be given is less than $\frac{1}{2}$ of the dose; thus the answer will be less than $\frac{1}{2}$ mL.
2. **Set up the formula:**

$$\frac{\text{Dose ordered}}{\text{Dose on hand}} \times \text{Amount on hand} = \text{Amount to administer}$$
$$\frac{2 \text{ mg}}{10 \text{ mg}} \times 1 \text{ mL} = \text{Amount to administer}$$

3. **Calculate the answer:**

$$\frac{2 \text{ mg}}{10 \text{ mg}} \times 1 \text{ mL} = 0.2 \text{ mL}$$

4. **Compare the estimate in Step 1 with the answer in Step 3:** The answer is less than $\frac{1}{2}$ mL; thus it is close to the estimated answer. Prepare 0.2 mL of the medication in a syringe and administer it to the patient.

Dimensional Analysis. Dimensional analysis is the factor-label or the unit-factor method. There is no need to memorize a formula since only one equation is needed and the same steps are used in solving every medication calculation. Nursing students who use dimensional analysis to calculate medication dosages often find it easier to calculate medications than when they use the formula method (Cookson, 2013). Use the following steps to calculate medication doses by dimensional analysis:

1. Identify the unit of measure that you need to administer. For example, if you are giving a pill, you usually give a tablet or a capsule; for parenteral or liquid oral medications, the unit is milliliters.
2. Estimate the answer.
3. Place the name or appropriate abbreviation for x on the left side of the equation (e.g., x tab, x mL).
4. Place available information from the problem in a fraction format on the right side of the equation. Place the abbreviation or unit that matches what you are going to administer (determined in Step 1) in the numerator.
5. Look at the medication order and add other factors into the problem. Set up the numerator so it matches the unit in the previous denominator.
6. Cancel out like units of measurement on the right side of the equation. You should end up with only one unit left in the equation, and it should match the unit on the left side of the equation.
7. Reduce to the lowest terms if possible and solve the problem or solve for x. Label your answer.
8. Compare your estimate from Step 1 with your answer in Step 2.

Example: The health care provider orders 0.45 g penicillin V potassium through a gastric tube. The vial label reads: penicillin V potassium 125 mg/5 mL.

1. **Identify the unit of measure that you need to administer.** This medication is given in a gastric tube, which is a liquid medication; therefore the answer will be in milliliters (mL).
2. **Estimate the answer.** The medication order is more than 3 times but less than 4 times the unit dose in the vial; thus the answer is more than 15 mL but less than 20 mL.
3. **Place the name or appropriate abbreviation for x on the left side of the equation.**

$$x \text{ mL} =$$

4. **Place available information from the problem in a fraction format on the right side of the equation**. Since the medication will be administered in milliliters, place mL in the numerator.

$$x \text{ mL} = \frac{5 \text{ mL}}{125 \text{ mg}}$$

5. **Look at the medication order and add other factors into the problem.** Set up the numerator so it matches the unit in the previous denominator. The order is for 0.45 g, and the medication is available in 125-mg bottles. Knowing that 1 g = 1000 mg, add this conversion to the calculation.

$$x \text{ mL} = \frac{5 \text{ mL}}{125 \text{ mg}} \times \frac{1000 \text{ mg}}{1 \text{ g}} \times \frac{0.45 \text{ g}}{1}$$

6. **Cancel out like units of measurement on the right side of the equation.**

$$x \text{ mL} = \frac{5 \text{ mL}}{125 \text{ \sout{mg}}} \times \frac{1000 \text{ \sout{mg}}}{1 \text{ \sout{g}}} \times \frac{0.45 \text{ \sout{g}}}{1}$$

7. **Reduce to the lowest terms if possible and solve the problem or solve for x.** Label your answer.

$$x \text{ mL} = \frac{5 \times 1000 \times 0.45}{125}$$
$$x = \frac{2250}{125}$$
$$x = 18 \text{ mL}$$

8. **Compare the estimate from Step 2 with the answer in Step 7.** The calculated answer is 18 mL, which is between 15 mL and 20 mL. This matches the estimate made in Step 2. Prepare and administer 18 mL of medication as ordered.

Pediatric Doses. Current evidence shows that children are at a much higher risk for experiencing a medication error than adults, and medication errors in children have a much greater chance of causing serious and even fatal consequences (Kaufmann et al., 2012; Rinke et al., 2014). Medication errors involving children frequently happen for the following reasons (Morris, 2014):

- Confusion between formulations for adults and children
- Availability of multiple pediatric concentrations of oral liquid medications
- Inaccurate preparation of medications that need to be diluted
- Similar packaging of medications and names of medications that look alike and sound alike
- Parents who do not understand how to prepare and administer medications correctly
- Errors in calculation and use of inaccurate measuring devices (e.g., household teaspoons and tablespoons) as opposed to devices made to measure small-volume doses

Calculating children's medication doses requires caution (Hockenberry and Wilson, 2015). Even small errors or discrepancies in medication amounts can affect a child's health negatively (Morris, 2014). A child's age, weight, and maturity of body systems affect the ability to metabolize and excrete medications. Nurses sometimes have difficulty evaluating a child's response to a medication, especially when he or she cannot communicate verbally. For example, a side effect of vancomycin is ototoxicity. If a child cannot talk yet, it is challenging to assess for ototoxicity. Use the following guidelines when calculating pediatric doses:

1. Most pediatric medications are ordered in milligrams per kilogram (mg/kg). Therefore weigh the patient in kilograms before administering medications. Avoid converting the patient's weight from pound to kilograms to prevent errors.
2. Pediatric doses are usually a lot smaller than adult doses for the same medication. You frequently use micrograms and small syringes (e.g., tuberculin or 1 mL).
3. IM doses are very small and usually do not exceed 1 mL in small children or 0.5 mL in infants.
4. Subcutaneous dosages are also very small and do not usually exceed 0.5 mL.
5. Most medications are not rounded off to the nearest tenth. Instead they are rounded to the nearest thousandth.
6. Measure dosages that are less than 1 mL in syringes that are marked in tenths of a milliliter if the dosage calculation comes out even and does not need to be rounded. Use a tuberculin syringe for medication preparation when the medication needs to be rounded to the nearest thousandth.
7. Estimate the patient's dose before beginning the calculation; label and compare the answer with the estimate before preparing the medication.
8. To determine if a dose is safe before giving the medication, compare and evaluate the amount of medication ordered over 24 hours with the recommended dosage.

Different formulas and methods are used to calculate drug dosages in children. The two most common methods of calculating pediatric dosages are based on a child's weight or BSA. BSA is used in rare situations (e.g., determining chemotherapy doses). Refer to a pediatric or pharmacology resource and consult with the patient's health care provider or the pharmacist if you have to calculate a medication based on BSA.

Most of the time you calculate medications based on a child's weight. You can use the ratio and proportion method, the formula method, or dimensional analysis to calculate a pediatric dose using body weight. Refer to the previous sections on ratio and proportion, formula method, and dimensional analysis to select a method easier for you to use.

Health Care Provider's Role

A physician, nurse practitioner, or physician's assistant prescribes medications by writing an order on a form in a patient's medical record, in an order book, or on a legal prescription pad. Some health care providers use a desktop, laptop, or handheld electronic device to enter medication orders. Many hospitals implement computerized physician order entry (CPOE) to handle medication orders to decrease medication errors (Ghaemmaghami, 2014). In these systems the health care provider completes all computerized fields before the order for the medication is filled, thus avoiding incomplete or illegible orders.

Sometimes a health care provider orders a medication by telephone or talking to a nurse in person. An order for a medication or medical treatment made over the telephone is called a *telephone order*. If the order is given verbally to the nurse, it is called a **verbal order**. When a verbal or telephone order is received, the nurse who took the order writes the complete order or enters it into a computer, reads it back, and receives confirmation from the health care provider to confirm accuracy. The nurse indicates the time and name of the health care provider who gave the order, signs it, and follows agency policy to indicate that it was read back. The health care provider countersigns the order at a later time, usually within 24 hours after giving it. Follow guidelines for taking telephone or verbal orders for medications safely (Box 32-3). Agency policies vary regarding personnel who can take telephone or verbal orders. Nursing students cannot take medication orders of any kind. They only give newly ordered medications after a registered nurse has written and verified the order.

Common abbreviations are often used when writing orders. Abbreviations indicate dosage frequencies or times, routes of administration, and special information for giving the medication (see Table 32-3). Medication errors frequently involve the use of abbreviations. Table 32-7 lists abbreviations that are associated with a high incidence of medication errors. Do *not* use these abbreviations when

---

BOX 32-3 Guidelines for Telephone and Verbal Orders

- Only authorized staff receive and record telephone or verbal orders. Agency identifies in writing the staff who are authorized.
- Clearly identify patient's name, room number, and diagnosis.
- Read back all orders to health care provider (TJC, 2016).
- Use clarification questions to avoid misunderstandings.
- Write "TO" (telephone order) or "VO" (verbal order), including date and time, name of patient, and complete order; sign the name of the health care provider and nurse.
- Follow agency policies; some agencies require documentation of the "read-back" or require two nurses to review and sign telephone or verbal orders.
- Health care provider co-signs the order within the time frame required by the agency (usually 24 hours; verify agency policy).

---

documenting medication orders or other information about medications (ISMP, 2013a; TJC, 2014a). Sometimes abbreviations used in different agencies vary. Check agency policy to determine which abbreviations are acceptable to use and their meaning.

QSEN **QSEN: BUILDING COMPETENCY IN SAFETY.** Your patient's health care provider has written the following orders. Which orders do you need to clarify before administering the medication? Provide rationale for your answers and rewrite the order so it follows the ISMP current medication order safety guidelines.

Timolol .5% solution 1 drop OD BID
Losartan 12.50 mg QD
Insulin Lispro 6 u SC twice a day
Captopril 25 mg. PO three times a day, hold for systolic blood pressure <100

e *Answers to QSEN Activities can be found on the Evolve website.*

Types of Orders in Acute Care Agencies

A medication cannot be given to a patient without a health care provider order. The frequency and urgency of medication administration forms the basis for medication orders. Some conditions change the status of a patient's medication orders. For example, in some agencies a patient's preoperative medications are discontinued automatically, and the health care provider writes new medication orders after surgery (see Chapter 50). Agency policies that surround medication orders vary. Nurses need to be aware of and follow these policies.

Standing Orders or Routine Medication Orders. A standing order is carried out until the health care provider cancels it by another order or a prescribed number of days elapse. Some standing orders indicate a final date or number of treatments or doses. Know your agency policies surrounding the discontinuation of standing orders. The following are examples of standing orders:

Tetracycline 500 mg PO q6h
Decadron 10 mg daily × 5 days

prn Orders. Sometimes the health care provider orders a medication to be given only when a patient requires it. This is a prn order. Use objective and subjective assessment (e.g., severity of pain, body temperature) and discretion in determining whether or not the patient needs the medication. An example of a prn order is:

Morphine sulfate 2 mg IV q2h prn for incisional pain

This order indicates that the patient needs to wait at least 2 hours between doses and can take the medication if experiencing pain at the incision. When administering prn medications, document assessment findings to show why the patient needs the medication and the time of administration. Frequently evaluate the effectiveness of the medication and record evaluation data appropriately. Unclear orders for prn medications that include a range (e.g., morphine sulfate IM 5-10 mg every 4-6 hours) are a source of medication errors. If a range order is written, ensure that the order follows agency policy for these types of orders. An example of a safer range order is to increase morphine dosage 50% to 100% if pain is moderate to severe based on use of the agency pain scale.

When multiple prn medications with the same action are ordered, the orders need to identify when to use each medication and how to use the medications in relationship to each other. The order below provides an example of a safe prn order for two medications used for treatment of constipation:

Docusate 100 mg PO TID prn constipation. Bisacodyl 10 mg suppository rectally daily prn constipation in addition to docusate if no bowel movement every 2 days

TABLE 32-7 Prohibited and Error-Prone Abbreviations*

The abbreviations, symbols, and dose designations found in this table have been reported to ISMP through the USP-ISMP Medication Error Reporting Program as being frequently misinterpreted and involved in harmful medication errors. They should NEVER be used when communicating medical information. This includes internal communications, telephone/verbal prescriptions, computer-generated labels, labels for drug storage bins, medication administration records, and pharmacy and prescriber computer order entry screens. The Joint Commission (TJC) has established a National Patient Safety Goal that specifies that certain abbreviations must appear on the do-not-use list of the accredited organization; they are highlighted with a double asterisk (**). However, we hope that you will consider others beyond the minimum TJC requirements. By using and promoting safe practices and educating one another about hazards, we can better protect our patients.

Abbreviations	Intended Meaning	Misinterpretation	Correction
µg	Microgram	Mistaken as "mg"	Use "mcg"
AD, AS, AU	Right ear, left ear, each ear	Mistaken as OD, OS, OU (right eye, left eye, each eye)	Use "right ear," "left ear," or "each ear"
OD, OS, OU	Right eye, left eye, each eye	Mistaken as AD, AS, AU (right ear, left ear, each ear)	Use "right eye," "left eye," or "each eye"
BT	Bedtime	Mistaken as "BID" (twice daily)	Use "bedtime"
HS	Half-strength	Mistaken as bedtime	Use "half-strength" or "bedtime"
hs	At bedtime, hours of sleep	Mistaken as half-strength	Use "bedtime" or "half-strength"
IU**	International unit	Mistaken as IV (intravenous) or 10 (ten)	Use "units"
o.d. or OD	Once daily	Mistaken as "right eye" (OD—oculus dexter), leading to oral liquid medications administered in the eye	Use "daily"
Per os	By mouth, orally	The "os" can be mistaken as "left eye" (OS—oculus sinister)	Use "PO," "by mouth," or "orally"
q.d. or QD**	Every day	Mistaken as q.i.d., especially if the period after the "q" or the tail of the "q" is misunderstood as an "I"	Use "daily"
qhs	Nightly at bedtime	Mistaken as "qhr" or every hour	Use "nightly"
SC, SQ, sub q	Subcutaneous	SC mistaken as SL (sublingual); SQ mistaken as "5 every"; the "q" in "sub q" has been mistaken as "every" (e.g., a heparin dose ordered "sub q 2 hours before surgery" misunderstood as every 2 hours before surgery)	Use "subcut" or "subcutaneously"
TIW or tiw	3 times a week	Mistaken as "3 times a day" or "twice in a week"	Use "3 times weekly"
U or u**	Unit	Mistaken as the number 0 or 4, causing a 10-fold overdose or greater (e.g., 4 U seen as "40" or 4 u seen as "44"); mistaken as "cc" so dose given in volume instead of units (e.g., 4 u seen as 4 cc)	Use "unit"

Dose Designations and Other Information	Intended Meaning	Misinterpretation	Correction
Trailing zero after decimal point (e.g., 1.0 mg)†	1 mg	Mistaken as 10 mg if the decimal point is not seen	Do not use trailing zeros for doses expressed in whole numbers
"Naked" decimal point (e.g., .5 mg)**	0.5 mg	Mistaken as 5 mg if the decimal point is not seen	Use zero before a decimal point when the dose is less than a whole unit
Abbreviations such as mg. or mL. with a period following the abbreviation	mg mL	The period is unnecessary and could be mistaken as the number 1 if written poorly	Use mg, mL, etc. without a terminal period

Drug Name Abbreviations	Intended Meaning	Misinterpretation	Correction
HCl	hydrochloric acid or hydrochloride	Mistaken as potassium chloride (The "H" is misinterpreted as "K")	Use complete drug name unless expressed as a salt of a drug
HCT	hydrocortisone	Mistaken as hydrochlorothiazide	Use complete drug name
HCTZ	hydrochlorothiazide	Mistaken as hydrocortisone (seen as HCT250 mg)	Use complete drug name

*Applies to all orders and medication-related documentation that is handwritten (including free-text computer entry or on preprinted forms).
**These abbreviations are included on The Joint Commission "minimum list" of dangerous abbreviations, acronyms, and symbols that must be included on the "Do Not Use" list of an organization, effective January 1, 2004.
†Exception: A "trailing zero" may be used only where required to show precision of a reported value (e.g., laboratory test results), in studies that report the size of lesions, or for catheter and tube sizes. A "trailing zero" cannot be used in medication orders or medication-related documentation (ISMP, 2013a).

TABLE 32-7 Prohibited and Error-Prone Abbreviations—cont'd

MgSO4**	magnesium sulfate	Mistaken as morphine sulphate	Use complete drug name
MS, MSO4**	morphine sulfate	Mistaken as magnesium sulphate	Use complete drug name
PCA	procainamide	Mistaken as patient-controlled analgesia	Use complete drug name
Stemmed Drug Names	**Intended Meaning**	**Misinterpretation**	**Correction**
"Nitro" drip	nitroglycerin infusion	Mistaken as sodium nitroprusside infusion	Use complete drug name
Symbols	**Intended Meaning**	**Misinterpretation**	**Correction**
ℨ	Dram	Symbol for dram mistaken as "3"	Use metric system
×3d	For three days	Mistaken as "3 doses"	Use "for three days"
> and <	Greater than and less than	Mistaken as opposite of intended; mistakenly use incorrect symbol; "<10" mistaken as "40"	Use "greater than" or "less than"
@	At	Mistaken as "2"	Use "at"
&	And	Mistaken as "2"	Use "and"
+	Plus or and	Mistaken as "4"	Use "and"
°	Hour	Mistaken as a zero (e.g., q2° seen as q20)	Use "hr," "h," or "hour"

From The Joint Commission (TJC): *Facts about the Official "Do Not Use" List of Abbreviations,* 2014, http://www.jointcommission.org/assets/1/18/Do_Not_Use_List.pdf. Accessed June 6, 2015. Reprinted with permission.

FIGURE 32-5 Example of a medication prescription. (Courtesy Saint Louis University Medical Center, St Louis, MO.)

Single (One-Time) Orders. Sometimes a health care provider orders a medication to be given once at a specified time. This is common for preoperative medications or medications given before diagnostic examinations. The following is an example of a single order:

Ativan 1 mg IV on call to MRI

STAT Orders. A STAT order signifies that a single dose of a medication is to be given immediately and only once. STAT orders are often written for emergencies when a patient's condition changes suddenly. For example:

Apresoline 10 mg IV STAT

Now Orders. A now order is more specific than a 1-time order and is used when a patient needs a medication quickly but not right away, as in a STAT order. When receiving a now order, the nurse has up to 90 minutes to administer the medication. Only administer now medications 1 time. For example:

Vancomycin 1 g IV piggyback now

Prescriptions. The health care provider writes **prescriptions** for patients who are to take medications outside of the hospital. The prescription includes more detailed information than a medication order because the patient needs to understand how to take the medication and when to refill the prescription if necessary. Some agencies require health care providers to write prescriptions for controlled substances on a special prescription pad that is different (e.g., a different color) than the prescription pad used for other medications. Figure 32-5 illustrates the parts of a prescription.

Pharmacist's Role

The pharmacist prepares and distributes prescribed medications. Pharmacists work with nurses, physicians, and other health care providers to evaluate the effectiveness of patients' medications. They are responsible for filling prescriptions accurately and being sure that prescriptions are valid. Pharmacists in health care agencies rarely mix compounds or solutions, except in the case of IV solutions. Most medication companies deliver medications in a form ready for use. Dispensing the correct medication, in the proper dosage and amount, with an accurate label is the pharmacist's main task. Pharmacists also provide information about medication side effects, toxicity, interactions, and incompatibilities.

Distribution Systems

Systems for storing and distributing medications vary. Health care agencies have a special area for stocking and dispensing medications. Examples of storage areas include special medication rooms, portable locked carts, computerized medication cabinets, and individual storage units next to patients' rooms. Medication storage areas need to be locked when unattended.

Unit Dose. A unit-dose system is a storage system that varies by health care agency. Pharmacists provide the medications in single-unit packages that contain the ordered dose of medication that a patient receives at one time. Nurses distribute the medications to patients. Each tablet or capsule is wrapped separately. Usually no more than a 24-hour supply of medication is available at any given time. Some unit-dose systems use carts containing a drawer with a 24-hour supply of medications for each patient. Each drawer is labeled with the name of the patient in his or her designated room. At a designated time each day the pharmacist or a pharmacy technician refills the drawers in the cart with a fresh medication supply. The cart also contains limited amounts of prn and stock medications for special situations. Controlled substances are not kept in an individual patient drawer. Instead they are kept in a larger locked drawer to keep them secure. The unit-dose system reduces medication errors, decreases the amount of medication that is stocked in patient care areas, and saves time for nurses and pharmacists.

Automated Medication Dispensing Systems. Automated medication dispensing systems (AMDSs) are used throughout the country (Figure 32-6). The systems within an agency are networked

FIGURE 32-6 Automated medication dispensing system.

with one another and with other agency computer systems (e.g., computerized medical record). AMDSs control the dispensing of all medications, including narcotics. Each nurse accesses the system by entering a security code. Some systems require bio-identification as well. In these systems you place your finger on a screen to access the computer. You select the patient's name and his or her drug profile before the AMDS dispenses a medication. In these systems you are allowed to select the desired medication, dosage, and route from a list displayed on the computer screen. The system causes the drawer containing medication to open, records it, and charges it to the patient. Systems that are connected to the patient's computerized medical record then record information about the medication (e.g., medication name, dose, time) and the nurse's name in the patient's medical record. The bar-code medication administration (BCMA) system is often used with AMDSs. BCMA requires nurses to scan bar codes to identify the patient, the medication, and an identification tag of the nurse administering the medication before recording this information in the patient's computerized medical record. Agencies that implement AMDS with BCMA often reduce the incidence of medication errors (see Box 32-2).

Nurse's Role

Administering medications requires unique nursing knowledge and skills. You first determine that the medication ordered is the correct medication. As a nurse you need to assess the patient's ability to self-administer medications, determine whether a patient should receive a medication at a given time, administer medications correctly, and then closely monitor their effects. Do not delegate any part of the medication administration process to nursing assistive personnel (NAP) and use the nursing process to integrate medication therapy into care.

Patient and family education about proper medication administration and monitoring is an integral part of your role. Begin instruction about medications that the patient will be taking home as soon as possible. This often does not occur until the day of discharge; but, if you can obtain this information sooner, the patient will benefit.

Medication Errors

A **medication error** can cause or lead to inappropriate medication use or patient harm. Medication errors include inaccurate prescribing, administering the wrong medication, giving the medication using the wrong route or time interval, administering extra doses, and/or failing to administer a medication. Preventing medication errors is essential. The process of administering medications has many steps and involves many members of the health care team. Because nurses play an essential role in preparing and administering medications, they need to be vigilant in preventing errors (Box 32-4). Advances in health care informatics have helped to decrease the occurrence of medication errors (Box 32-5).

Medication errors can be caused by many factors such as technology workarounds, the design of medication labels, and medication distribution systems. When an error occurs, the patient's safety and well-being are the top priorities. You first assess and examine the patient's condition and notify the health care provider of the incident as soon as possible. Once the patient is stable, report the incident to the appropriate person in the agency (e.g., manager or supervisor). You are responsible for preparing and filing an occurrence or incident report as soon as possible after the error occurs. The report includes patient identification information; the location and time of the incident; an accurate, factual description of what occurred and actions taken; and your signature. The occurrence report is not a permanent part of the medical record and is not referred to anywhere in a patient's medical record to legally protect the nurse and health care agency (see

BOX 32-4 Steps to Take to Prevent Medication Errors

- Prepare medications for only one patient at a time.
- Follow the six rights of medication administration.
- Be sure to read labels at least 3 times (comparing medication administration record [MAR] with label) before administering the medication.
- Use at least two patient identifiers and review the patient's allergies whenever administering a medication.
- Do not allow any other activity to interrupt administration of medication to a patient (e.g., phone call, pager, discussion with other staff) (Hopkinson and Jennings, 2013).
- Double-check all calculations and other high-risk medication administration processes (e.g., patient-controlled analgesia) and verify with another nurse.
- Do not interpret illegible handwriting; clarify with health care provider.
- Question unusually large or small doses.
- Document all medications as soon as they are given.
- When you have made an error, reflect on what went wrong and ask how you could have prevented the error. Complete an occurrence report per agency policy.
- Evaluate the context or situation in which a medication error occurred. This helps to determine if nurses have the necessary resources for safe medication administration.
- Attend in-service programs that focus on the medications commonly administered.
- Ensure that you are well rested when caring for patients. Nurses make more errors when they are tired (Murphy and While, 2012).
- Involve and educate patients when administering medications. Address patients' concerns about medications before administering them (e.g., concerns about their appearance or side effects).
- Follow established agency policies and procedures when using technology to administer medications (e.g., automated medication dispensers [AMDs] and bar-code scanning). Medication errors occur when nurses "work around" the technology (e.g., override alerts without thinking about them) (Voshall et al., 2013).

BOX 32-5 Informatics and Medication Safety

Many medication errors occur when a nurse incorrectly administers medications at the patient's bedside. The following innovations and advances in technology have helped reduce the number of medication errors in nursing practice.

- Networked computers allow all the patient's health care providers to see a current list of ordered and discontinued medications.
- Internet and intranet access allows nurses and other health care providers to access current information about medications (e.g., indications, desired effects, adverse effects) and specific agency policies that address medication administration (e.g., how fast to administer an intravenous [IV] push medication, how to administer medications through a nasogastric tube).
- In some agencies health care providers use computerized prescription order entry [CPOE], allowing them to enter medication orders directly into a networked computer system or a personal handheld computer.
- Automated medication dispensers [AMDs] and electronic medication administration records (eMARs) help with medication reconciliation, administration, and documentation.
- Bar-coding technology requires nurses to scan the medication, the patient's identification bracelet, and the nurse's identification badge before administering the medication, which helps ensure the six rights of medication administration.

Application to Nursing Practice
- Actively participate in selecting and evaluating advanced technologies and creating nursing policies and protocols used for medication administration.
- Always follow agency policies when administering medications.
- Implement agency policies when the technology cannot be used (e.g., during down time or power outages).
- Follow manufacturer guidelines for care of electronic equipment and report problems with technology immediately.

Chapters 23 and 26). Occurrence reports track incident patterns and indicate the need to implement quality improvement actions.

Report all medication errors that reach the patient, including those that do not cause harm. You also need to report near misses. For example, you are caring for a patient who has a urinary tract infection and is allergic to sulfa drugs. The patient's health care provider orders trimethoprim/sulfamethoxazole (TMP/SMZ). You know TMP/SMZ contains sulfa. You contact the health care provider before you administer the medication to obtain an order for a different medication. This type of medication error is a near miss because it did not actually reach the patient. All health care workers, including nurses, need to feel comfortable in reporting an error and not fear repercussions from managers or administrators. Even when a patient suffers no harm from a medication error, the agency can still learn why the mistake occurred and what can be done to avoid similar errors in the future.

Some medication errors happen when patients experience a transition in care such as when a patient is admitted or discharged from a hospital, is transferred from an intensive care unit to a general patient care unit, or sees a new health care provider. During these times the risk of unintended changes in medication orders increases. Thus reconciling medication information is a key Hospital National Patient Safety Goal (TJC, 2016). During **medication reconciliation** nurses, pharmacists, and other health care providers compare the medication that a patient is taking currently with what the patient should be taking and any newly ordered medications (Box 32-6). Throughout this

BOX 32-6 Process for Medication Reconciliation

1. **Obtain, Verify, Document:** Obtain a comprehensive and current list of a patient's medications whenever he or she experiences a change in health care setting (e.g., during admission, transfer, discharge). Include all current prescriptions and over-the-counter (OTC) medications.
2. **Consider and Compare:** Review what the patient was taking at home or preadmission and make sure that the list of medications, dosages, and frequencies is accurate. Compare this list to the current ordered medications and treatment plan to ensure accuracy. Include family caregiver in this discussion when appropriate.
3. **Reconcile:** Compare new medication orders with the current list; investigate any discrepancies with the patient's health care provider and document changes.
4. **Communicate:** Ensure that all the patient's health care providers have the most updated list of medications. Communicate and verify changes in medications as with the patient.

Data from Gleason KM et al; Agency for Healthcare Research and Quality: *Medications at transitions and clinical handoffs (MATCH) toolkit for medication reconciliation,* http://www.ahrq.gov/professionals/quality-patient-safety/patient-safety-resources/resources/match/match.pdf. Accessed June 6, 2015.

process you identify and resolve orders that are duplicated and omitted. You also evaluate the risk for unintended medication interactions. Creating and maintaining an accurate list of all patient medications helps to ensure safe and effective patient care (Gleason et al., 2012). For example, when you admit a patient who is having a hip replacement to an orthopedic unit, you compare the medications that the patient took at home with those ordered in the hospital. When the patient is discharged to a rehabilitation unit, you communicate the patient's current medications with the nurse who is accepting the patient. The nurse on the rehabilitation unit reconciles the patient's medications when the patient is discharged with the home health nurse. Many agencies have computerized or written forms to facilitate the process of medication reconciliation. The process is challenging and takes a lot of time and concentration. Eliminate distractions and go slowly when reconciling patients' medications. Always clarify information when needed and question for accuracy. Accurate medication reconciliation requires consulting with the patient, family caregivers, other clinicians, pharmacists, and other members of the health care team.

CRITICAL THINKING

Knowledge

You use knowledge from many disciplines when administering medications. Your knowledge helps you understand why a medication is prescribed for a patient and how it will alter the patient's physiology to have a therapeutic effect. For example, in physiology you learn that potassium is a major intracellular ion. When patients do not have enough potassium in their body (hypokalemia), they experience signs and symptoms such as muscle fatigue or weakness. In some cases severe hypokalemia is fatal as a result of associated cardiac dysrhythmias. Prescribed medications help to restore the patient's potassium level to normal, which relieves the signs and symptoms of hypokalemia. In another example knowledge about child development indicates that children often associate medication administration with a negative experience. Use principles from child development to ensure that the child cooperates with the medication experience.

Patients take a variety of medications, and new medications are constantly approved. As a result you will not always understand all the medications ordered for a patient. Critical thinkers admit what they do not know and acquire the knowledge needed to safely administer unfamiliar medications. This means that, when you do not know all the medications you need to administer, you will consult a reliable source (e.g., a more expert nurse, pharmacist, the health care provider, or a reference book) *before* administering the medication.

Experience

Nursing students have limited experience with medication administration as it applies to professional practice. Clinical experiences give you opportunities to use the nursing process as it applies to medication administration. As you gain experience, your psychomotor skills ("the how-to") become more refined. However, psychomotor skills represent a small part of medication administration. Patient attitudes, knowledge, physical and mental status, and responses make medication administration a complex responsibility.

Attitudes

Use your critical thinking skills to administer medications safely. Be disciplined and take adequate time to prepare and administer medications. Take the time to read your patient's medical record before administering medications and carefully review the patient's history,

physical examination, and orders. Look up medications that you do not know in a medication reference and determine why each patient is taking each of the prescribed medications. Every step of safe medication administration requires a disciplined attitude and a comprehensive, systematic approach. Following the same procedure each time medications are administered ensures safe administration.

Responsibility and accountability are other critical thinking attitudes essential to safe medication administration. Accept full accountability and responsibility for all actions surrounding the administration of medications. Do not assume that a medication that is ordered for a patient is the correct medication or the correct dose. Be responsible for knowing that the medications and doses ordered are correct and appropriate. You are accountable if you give an ordered medication that is not appropriate for a patient. Therefore be familiar with each medication, including its therapeutic effect, usual dosage, anticipated changes in laboratory data, and side effects. You are also responsible for ensuring that patients or caregivers who administer medications have been properly informed about all aspects of self-administration (TJC, 2016). If you determine that a patient cannot self-administer medications safely, design interventions such as involving family caregivers to ensure safe administration.

Standards

Standards are actions that ensure safe nursing practice. Standards for medication administration are set by health care agencies and the nursing profession. Agency policy sets limits on a nurse's ability to administer medications in certain units of the acute care setting. Sometimes nurses are limited by certain medication routes or dosages. Most agencies have nursing procedure manuals that contain policies that define the types of medications nurses can and cannot administer. The types and dosages of some medications that nurses deliver vary from unit to unit within the same agency. For example, phenytoin (Dilantin), a medication for treating seizures, may be administered by mouth or IV push. In large dosages phenytoin affects heart rhythm. Therefore some agencies place limits on how much nurses can administer to a patient on a nursing unit that does not have the ability to monitor a patient's heart rate and rhythm. Not all health care providers are aware of the limitations and sometimes prescribe medications that nurses cannot give in a particular health care setting. Recognize these limitations and inform the health care provider accordingly. Take appropriate actions to ensure that patients receive medications as prescribed and within the time prescribed in the appropriate environment.

Professional standards such as *Nursing: Scope and Standards of Practice* (ANA, 2010) (see Chapters 1 and 23) apply to the activity of medication administration. To prevent medication errors, follow the six rights of medication administration consistently every time you administer medications. Many medication errors can be linked in some way to an inconsistency in adhering to these six rights:

1. The right medication
2. The right dose
3. The right patient
4. The right route
5. The right time
6. The right documentation

Right Medication. A medication order is required for every medication that you administer to a patient. Sometimes health care providers write orders by hand in the patient's medical record. Alternatively some agencies use CPOE. CPOE allows a health care provider to order medications electronically, eliminating the need for written orders and enhancing medication safety (Radley et al., 2013).

Regardless of how a nurse receives a medication order, he or she compares the health care provider's written orders with the medication administration record (MAR) or electronic MAR (eMAR) when it is ordered initially. Nurses verify medication information whenever new MARs are created or distributed or when patients transfer from one nursing unit or health care setting to another.

Once you determine that information on a patient's MAR is accurate, use it to prepare and administer medications. When preparing medications from bottles or containers, compare the label of the medication container with the MAR 3 times: (1) before removing the container from the drawer or shelf; (2) as the amount of medication ordered is removed from the container; and (3) at the patient's bedside before administering the medication to the patient. Never prepare medications from unmarked containers or containers with illegible labels (TJC, 2016). With unit-dose prepackaged medications, check the label with the MAR when taking medications out of the medication dispensing system. Finally verify all medications at the patient's bedside with the patient's MAR and use at least two identifiers before giving the patient any medications (TJC, 2016).

Patients who self-administer medications need to keep them in their original labeled containers, separate from other medications, to avoid confusion. Many hospitals require that nurses administer all medications rather than letting patients self-administer to enhance accuracy and patient safety. Because the nurse who administers the medication is responsible for any errors related to it, nurses administer only the medications they prepare. You cannot delegate preparation of medication to another person and then administer the medication to the patient. If a patient questions the medication, do not ignore these concerns. A patient or a family caregiver familiar with a patient's medications often knows whether a medication is different from those received before. In most cases a patient's medication order has changed; however, sometimes patient questions reveal an error. When this occurs, withhold the medication and recheck it against the health care provider's orders. If a patient refuses a medication, discard it rather than returning it to the original container. Unit-dose medications can be saved if they are not opened. If a patient refuses narcotics, follow proper agency procedure by having someone else witness the "wasted" medication.

Right Dose. The unit-dose system is designed to minimize errors. When preparing a medication from a larger volume or strength than needed or when the health care provider orders a system of measurement different from that which the pharmacy supplies, the chance of error increases. You need to have another qualified nurse check the calculated doses when performing medication calculations or conversions. Prepare medications using standard measurement devices such as graduated cups, syringes, and scaled droppers to measure medications accurately. At home educate patients to use similar measurement devices such as measuring spoons rather than household teaspoons and tablespoons, which are inaccurate.

Medication errors often occur when pills need to be split. To promote patient safety in inpatient settings, pharmacists split the medications, label and package them, and then send them to the nurse for administration. Because pill splitting is particularly problematic in the home care setting, the U.S. FDA (USFDA) (2013) developed suggestions to help with this process. They include ensuring that the tablet is designed to be split, using a tablet splitter and not splitting the entire prescription at one time, and determining if the patient has the motor dexterity or visual acuity to split tablets. If at all possible, health care providers need to avoid ordering medications that require splitting.

Tablets are sometimes crushed and mixed with food. Be sure to completely clean a crushing device before crushing the tablet. Remnants of previously crushed medications increase the concentration of a medication or result in the patient receiving part of a medication that was not prescribed. Mix crushed medications with very small amounts of food or liquid (e.g., a single tablespoon). Do not use a patient's favorite foods or liquids because medications alter their taste and decrease the patient's desire for them. This is especially a concern for pediatric patients.

Not all medications are suitable for crushing. Some medications (e.g., extended-release capsules) have special coatings to prevent them from being absorbed too quickly. These medications should not be crushed. Refer to the "Do Not Crush List" (ISMP, 2014a), http://www.ismp.org/tools/donotcrush.pdf) to ensure that a medication is safe to crush.

Right Patient. Medication errors often occur because a patient gets a drug intended for another patient. Therefore an important step in safe medication administration is being sure that you give the right medication to the right patient. It is difficult to remember every patient's name and face. Before administering a medication, use at least two patient identifiers (TJC, 2016). Acceptable patient identifiers include the patient's name, his or her medical record number assigned by a health care agency, or a telephone number. Do not use the patient's room number as an identifier. To identify a patient correctly, you usually compare the patient identifiers on the MAR with the patient's identification bracelet while at the patient's bedside. If an identification bracelet becomes smudged or illegible or is missing, obtain a new one. All agencies in all health care settings need to use a system that verifies the patient's identification with at least two identifiers before administering medications and other treatments.

Patients do not need to state their names and other identifiers when you administer medications. Collect patient identifiers reliably when he or she is admitted to a health care setting. Once the identifiers are assigned to the patient (e.g., putting identifiers on an armband and placing the armband on the patient), you use the identifiers to match the patient with the MAR, which lists the correct medications. Asking patients to state their full names and identification information provides a third way to verify that the nurse is giving medications to the right patient.

In addition to using two identifiers, some agencies use BCMA to help identify the right patient (Figure 32-7). This system requires

FIGURE 32-7 Nurse using bar-code scanner to identify patient during medication administration.

nurses to scan a personal bar code that is commonly placed on their name tag first. Then the nurse scans a bar code on the single-dose medication package. Finally the nurse scans the patient's armband. All this information is then stored in a computer for documentation purposes. This system helps eliminate medication errors because it provides another step to ensure that the right patient receives the right medication (Ching et al., 2013).

Right Route. Always consult the health care provider if an order does not include a route of administration. Likewise alert the health care provider immediately if the specified route is not the recommended route. Recent evidence shows that medication errors involving the wrong route are common. For example, when nurses need to prepare an oral medication in a syringe, the risk to administer the medication via the wrong route (e.g., intravenously) is very high and often results in fatal consequences. Thus the ISMP (2015b) recommends that pharmacists, *not nurses,* prepare all oral medications that are not prepared commercially as a unit product to enhance patient safety. The IV injection of a liquid designed for oral use produces local complications such as sterile abscess or fatal systemic effects. If you are in a setting that requires you to prepare oral medications, only use enteral syringes when preparing the medication. The enteral syringes are often a different color than the parenteral syringes and are clearly labeled for oral or enteral use. The syringe tips of enteral syringes will not connect with parenteral medication administration systems. Needles do not attach to the syringes, and the syringes cannot be inserted into any type of IV line. Label the syringe after preparing the medication and be sure to remove any caps from the tip of an oral syringe before administering the medication. Failure to remove the cap can result in the patient aspirating it, thus blocking the trachea.

Right Time. To administer medications safely, you need to know why a medication is ordered for certain times of the day and whether you are able to alter the time schedule. For example, two medications are ordered, one q8h (every 8 hours) and the other 3 times a day. Both medications are scheduled for 3 times within a 24-hour period. You need to give the q8h medication every 8 hours ATC to maintain therapeutic blood levels of the medication. In contrast, you need to give the 3-times-a-day medication at 3 different times while the patient is awake. Each agency has a recommended time schedule for medications ordered at frequent intervals. You can alter these recommended times if necessary or appropriate.

The health care provider often gives specific instructions about when to administer a medication. A preoperative medication to be given "on call" means that you give the medication when the operating room staff members notify you that they are coming to get a patient for surgery. Give a medication ordered PC (after meals) within half an hour after a meal, when a patient has a full stomach. Give a STAT medication immediately.

Give priority to time-critical medications that must act and therefore be given at certain times. Hospitals designate which medications are time critical and which are non–time critical (CMS, 2011; ISMP, 2011). You administer time-critical medications within 30 minutes before or after their scheduled time. For example, give insulin (a time-critical medication) at a precise interval before a meal. Give antibiotics 30 minutes before or after they are scheduled ATC to maintain therapeutic blood levels. Give all routinely ordered non–time-critical medications within 1 to 2 hours before or after the scheduled time or per agency policy (CMS, 2011; ISMP, 2011).

Some medications require a nurse's clinical judgment in deciding the proper time for administration. Administer a prn sleeping medication when a patient is prepared for bed. In addition, use judgment when administering prn analgesics. For example, you may need to obtain a STAT order from the health care provider if a patient requires a medication before the prn interval has elapsed. Always document when you call a patient's health care provider to obtain a change in a medication order.

Before discharge from the hospital setting, evaluate a patient's need for home care, especially if he or she was admitted to the hospital because of a problem with medication self-administration. Patients often leave the hospital with a basic knowledge of their medications but are unable to remember or implement this knowledge once back home. Before patients are discharged from the hospital, evaluate whether the medications are adequate or prescribed at therapeutic levels for them.

At home some patients take several medications throughout the day. Help to plan schedules on the basis of preferred medication intervals, the pharmacokinetics of the medications, and the patient's daily schedule. For patients who have difficulty remembering when to take medications, make a chart that lists the times to take each one or prepare a special container to hold each timed dose.

Right Documentation. Nurses and other health care providers use accurate documentation to communicate with one another. Many medication errors result from inaccurate documentation. Therefore always document medications accurately at the time of administration and verify any inaccurate documentation before giving medications.

Before administering a medication, ensure that the MAR clearly reflects a patient's full name; the full name of the ordered medication (no medication name abbreviations); the time the medication is to be administered; and the dosage, route, and frequency. Common problems with medication orders include incomplete information; inaccurate dosage form or strength; illegible order or signature; incorrect placement of decimals, leading to the wrong dosage; and nonstandard terminology. If there is any question about a medication order because it is incomplete, illegible, vague, or not understood, contact the health care provider before administering the medication. The health care provider is responsible to provide accurate, complete, and understandable medication orders. If he or she is unable to do this, nurses implement agency policy (usually a "chain of command" policy) to determine who to contact until they resolve issues related to patients' medications. You are responsible to begin this chain of command to ensure that patients receive the correct medication for documenting any preassessment data required of certain medications such as a blood pressure measurement for antihypertensive medications or laboratory values, as in the case of warfarin, before giving the drug.

After administering a medication, immediately document which medication was given on a patient's MAR per agency policy to verify that it was given as ordered. Inaccurate documentation such as failing to document giving a medication or documenting an incorrect dose leads to errors in subsequent decisions about patient care. For example, errors in documentation about insulin often result in negative patient outcomes. Consider the following situation: a patient receives insulin before breakfast, but the nurse who gave the insulin forgot to document it. The nurse caring for the patient goes home, and you are the patient's new nurse for the day. You notice that the insulin is not documented, you assume that the previous nurse did not give the insulin, and you give the patient another dose of insulin. Approximately 2 hours later, the patient experiences a low blood glucose level, which results in seizure activity. Accurate documentation and following up with the nurse from the previous shift to verify that the insulin was given as ordered would have prevented this situation from happening.

Never document that you have given a medication until you have actually given it. Document the name of the medication, the dose, the time of administration, and the route on the MAR. Also document the site of any injections and the patient's responses to medications, either positive or negative. Notify a patient's health care provider of any negative responses to medications and document the time, date, and name of the health care provider who was notified in the patient's medical record. The efforts you make to ensure proper documentation help provide safe care.

Maintaining Patients' Rights. In accordance with *The Patient Care Partnership* (American Hospital Association, 2003) and because of the potential risks related to medication administration, a patient has the following rights:

- To be informed of the name, purpose, action, and potential undesired effects of a medication
- To refuse a medication regardless of the consequences
- To have qualified nurses or physicians assess a medication history, including allergies and use of herbals
- To be properly advised of the experimental nature of medication therapy and give written consent for its use
- To receive labeled medications safely without discomfort in accordance with the six rights of medication administration
- To receive appropriate supportive therapy in relation to medication therapy
- To not receive unnecessary medications
- To be informed if medications are a part of a research study

Know these rights and handle all patient and family questions courteously and professionally. Do not become defensive if a patient refuses medication therapy, recognizing that every person of consenting age has a right to refusal.

❖ NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

◆ Assessment

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. Use professional knowledge, skills, and attitudes to provide compassionate and coordinated care. Consider patients' preferences, values, and needs while determining their need for and possible responses to medication therapy. Assess their experiences and encourage them to express their beliefs, feelings, and concerns about their medications. For example, ask them how their religious or family backgrounds influence their beliefs about taking medications. Putting patients in the center of their care helps you to see the situation through their eyes and contributes to safe medication administration. Begin your assessment by asking a variety of questions to help you better understand your patients' current medication management routine, their ability to afford medications, and their beliefs and expectations about medications.

History. Before you administer medications, review a patient's medical history to help you understand the indications or contraindications for medication therapy. Some illnesses place patients at risk for adverse medication effects. For example, if a patient has a gastric ulcer,

medications containing aspirin increase the likelihood of bleeding. Long-term health problems (e.g., diabetes or arthritis) require specific medications. This knowledge helps you anticipate the type of medications that a patient requires. A patient's surgical history also sometimes indicates the need for medications. For example, after a thyroidectomy a patient requires thyroid hormone replacement.

Allergies. Inform the other members of the health care team if a patient has a history of allergies to medications and foods. Many medications have ingredients also found in food sources. For example, propofol (Diprivan), which is used for anesthesia and sedation, includes egg lecithin and soybean oil as inactive ingredients. Therefore patients who have an egg or soy allergy should not receive propofol (Skidmore-Roth, 2015). In most health care settings patients wear identification bands listing medication and food allergies. Ensure that all your patient's allergies and their allergic reactions are documented appropriately in the patient's medical record (e.g., history and physical, MAR) to facilitate communication of this essential information to members of the health care team.

Medications. Ask your patients questions to find out about each medication they take (Box 32-7). Possible questions include: How long have you been taking these medications? What is the current dosage of each medication? Do you experience side effects or adverse effects from your medications? In addition, review the action, purpose, normal dosage, routes, side effects, and nursing implications for administering and monitoring each medication. You often need to consult several resources such as pharmacology textbooks; medication manuals available on a computer, electronic tablet, or AMDS; nursing journals; the *Physician's Desk Reference* (PDR); medication package inserts; and pharmacists to gather necessary information. As a nurse you are responsible for knowing as much as possible about each medication your patients take.

Diet History. A diet history reveals a patient's normal eating patterns and food preferences. Use your patient's diet history to plan an effective and individualized medication dosage schedule. Teach your patient to avoid foods that interact with medications. In addition, provide education when your patients take medications that need to be taken before, with, or after meals.

Patient's Perceptual or Coordination Problems. Patients with perceptual, fine-motor, or coordination limitations often have difficulty self-administering medications. For example, a patient who takes insulin to manage blood glucose and has arthritis has difficulty

manipulating a syringe. Assess the patient's ability to prepare doses and take medications correctly. If a patient is unable to self-administer medications, assess if family or friends are available to help or make a home care referral.

Patient's Current Condition. The ongoing physical or mental status of a patient affects whether a medication is given and how it is administered. *Assess a patient carefully before giving any medication.* For example, check a patient's blood pressure before giving an antihypertensive. A patient who is vomiting is unable to take medications by mouth. Notify the patient's health care provider when this happens. Assessment findings serve as a baseline in evaluating the effects of medication therapy.

Patient's Attitude About Medication Use. A patient's attitudes about medications (e.g., benefit, risk, likelihood to cure) sometimes reveals a level of medication dependence or drug avoidance. Some patients do not express their feelings about taking a particular medication, particularly if dependence is a problem. Listen carefully when a patient describes how he or she uses medications to identify evidence of dependence or avoidance. Also be aware that cultural beliefs about Western medicine sometimes interfere with medication adherence (Box 32-8; see Chapter 9).

Factors Affecting Adherence to Medication Therapy. Many complex factors affect a patient's ability to adhere to prescribed medication therapy. For example, a patient's knowledge and understanding of medication therapy influence the willingness or ability to follow a medication regimen. If a patient has a history of poor adherence (e.g., frequently missed doses or failure to fill prescriptions), investigate if he or she can afford prescribed medications and review resources available for purchase of medications if indicated. Also determine if the patient understands the purpose of the medication, the importance of regular dosage schedules, proper administration methods, and the possible side effects. Without adequate funding, knowledge, and motivation, adherence to medication schedules is unlikely (Viswanathan et al., 2012).

Patient's Learning Needs. Health-related information is difficult to understand because of the use of technical terminology. Serious errors can occur when patients do not understand information about their medications. Assess patients' health literacy regarding medication administration to determine their need for instruction (Weekes, 2012; Zullig et al., 2014) (see Chapter 25). Have the patient explain the medication schedule of a typical day. Have him or her read a medication label and explain what it includes. Health literacy also includes numeracy. Have a patient show how to give a medication dose if it is necessary to split a pill or give more than one in a container. Consider patient responses to your medication assessment questions such as those listed in Box 32-7. When a patient is unable to answer questions about medications appropriately, assess his or her health literacy.

◆ Nursing Diagnosis

Assessment provides data about the patient's condition, ability to self-administer medications, and medication adherence. Use these data to determine a patient's actual or potential problems with medication therapy. Certain data are defining characteristics that, when clustered together, reveal actual nursing diagnoses. For example, *Ineffective Health Management related to complexity of treatment regimen* is indicated when patients have a complex medication schedule and admit to having difficulty integrating their medications into their daily routine.

⊕ BOX 32-8 CULTURAL ASPECTS OF CARE
Influences in Medication Administration

Health beliefs vary by culture and often influence how patients manage and respond to drug therapy. Significant differences in values, beliefs, and attitudes affect a patient's adherence to drug therapy (Alhalaiqa et al., 2013). Some cultures attach different symbolic meanings to medications and drug therapy. Herbal remedies and alternative therapies are common in various cultures and ethnic groups and sometimes interfere with prescribed medications (Li et al., 2012). Some people stop taking medications when their symptoms are resolved, even if the medications are still needed for management of a chronic illness. In addition, health beliefs often differ markedly between health providers and patients, further affecting a patient's adherence to medical therapy (Polinski et al., 2014). In addition to the psychosocial aspect of medication therapy, pharmacological research has shown that differences in drug response, metabolism, and side effects may be affected by patients' ethnicity, genetics, gender, and age (Blazquez et al., 2012).

Implications for Patient-Centered Care
- Assess cultural beliefs, attitudes, and values when administering medications and teaching patients about self-administration.
- Establish trust with patients and resolve conflicts between medications and cultural beliefs to achieve optimal patient outcomes (Polinski et al., 2014).
- Investigate if the patient practices any alternative therapies or is taking any herbal preparations (Li et al., 2012).
- Consider cultural influences on drug response, metabolism, and side effects if a patient is not responding to drug therapy as expected. Confer with health care provider because a change in the patient's medication is sometimes necessary.
- Assess food preferences that may interfere with patients' medication therapy (Giger, 2013).

This list of nursing diagnoses may apply during medication administration in a variety of settings:
- *Anxiety*
- *Ineffective Health Maintenance*
- *Deficient Knowledge (Medication Self-Administration)*
- *Noncompliance (Medications)*
- *Impaired Swallowing*
- *Impaired Memory*
- *Caregiver Role Strain (Caregiving Activities)*

After selecting the diagnosis, identify the related factor (if applicable) that drives the selection of nursing interventions. In the example of *Noncompliance*, the related factors of *financial barriers* versus *insufficient knowledge about the regimen* require different interventions. If a patient's nursing diagnosis is related to inadequate finances, you collaborate with family members, social workers, case managers, or community agencies to connect the patient with necessary financial resources and develop a medication regimen the patient can afford. If the related factor is *insufficient knowledge,* you implement a teaching plan with appropriate follow-up.

◆ Planning

Always organize your care activities to ensure the safe administration of medications. Rushing to give patients medications leads to errors. It is important to minimize distractions or interruptions when preparing and administering medications (Ching et al., 2013; Donaldson et al., 2014). No-interruption zones (NIZs) have been recommended to reduce distractions and interruptions during medication administration (Yoder et al., 2015). NIZs are created by placing signs, red tape,

or some type of borders on the floor around medication carts or areas. Nurses standing in these areas are not to be interrupted.

Goals and Outcomes. Setting goals and related outcomes contributes to patient safety and allows for effective use of time during medication administration. For example, a nurse establishes the following goal and related outcomes for a patient with newly diagnosed type 2 diabetes who has the diagnosis of *Deficient Knowledge related to insufficient information*:

Goal: The patient will safely self-administer all ordered medications before discharge.

Outcomes:

- The patient verbalizes understanding of desired and adverse effects of medications.
- The patient states signs, symptoms, and treatment of hypoglycemia.
- The patient is able to monitor blood glucose levels to determine if it is safe to take medication or if an alteration in dose is needed.
- The patient prepares a dose of ordered medication.
- The patient describes a daily routine that will integrate timing of medication with daily activities.

Setting Priorities. Prioritize care when administering medications. Use patient assessment data to determine which medications to give first, whether it is time to evaluate a patient's response to a medication, or if it is appropriate to administer prn medications. For example, if a patient is in pain, it is important to provide pain medication as soon as possible. If the patient's blood pressure is elevated, administer the blood pressure medication before other medications. Nurses also prioritize when providing patient education about medications. Provide the most important information about the medications first. For example, hypoglycemia is a serious side effect of insulin. A patient taking insulin needs to be able to identify and treat hypoglycemia immediately; thus first teach how to recognize and treat hypoglycemia before teaching about how to administer an injection.

Teamwork and Collaboration. Collaboration during medication administration is essential. You need to collaborate with a patient's family caregivers whenever possible. Family caregivers and significant others often reinforce the importance of medication schedules when a patient is at home. Nurses often collaborate with patients' health care providers, pharmacists, and case managers to ensure that patients are able to afford their medications. On discharge ensure that patients know where and how to obtain medications. Be sure that patients are able to read medication labels and medication teaching information. Some patients also need to understand how to calculate dosages and prepare complex medication regimens. Collaborate with community resources (e.g., agency on aging, public health department, medical interpreters) when patients have significant literacy issues or difficulty understanding medication instructions (see Chapter 25).

◆ **Implementation**

Health Promotion. In promoting or maintaining a patient's health, nurses identify factors that improve or diminish well-being. Health beliefs, personal motivation, socioeconomic factors, and habits influence a patient's adherence with medications. Several nursing interventions promote adherence to the medication regimen and foster independence. Teach a patient and family about the benefit of a medication and the knowledge needed to take it correctly. Integrate a patient's health beliefs and cultural practices into the treatment plan. Help a patient and family establish a medication routine that fits into the patient's normal schedule. Make referrals to community resources if a patient is unable to afford or cannot arrange transportation to obtain necessary medications.

Patient and Family Teaching. Some patients take medications incorrectly or not at all because they do not understand their medications. When this happens, you need to provide patient education using language your patient understands (see Chapter 25). Include information about the purpose, actions, timing, dosages, and side effects of medications. Many health care agencies offer easy-to-read teaching sheets written at the sixth grade level about specific types of medications. Patients need to know how to take medications properly and the risks associated when they fail to do so. For example, after receiving a prescription for an antibiotic, a patient needs to understand the importance of taking the full prescription. Failure to do this can lead to a worsening of the condition and the development of bacteria resistant to the medication. Current recommendations suggest the use of Teach Back as a method to confirm patient learning and improve health care provider education (Nouri and Rudd, 2015). Have the patient explain for you the topic about which you instructed him or her so you can confirm understanding.

Nurses teach patients how to administer their medications correctly. For example, teach a patient how to measure a liquid medication accurately. Provide special education to patients who depend on daily injections (Box 32-9). The patient learns to prepare and administer an injection correctly using aseptic technique. Teach family caregivers how to give injections in case the patient becomes ill or physically unable to handle a syringe. Provide specially designed equipment such as syringes with enlarged calibrated scales or medications with labels in braille when patients have visual alterations.

BOX 32-9 PATIENT TEACHING

Safe Insulin Administration

Objective
- Patient will correctly self-administer subcutaneous insulin.

Teaching Strategies
- Teach patient how to determine if insulin is expired.
- Instruct patient to keep medication in its original labeled container and refrigerated if needed.
- Demonstrate how to prepare insulin in a syringe, assessing visual acuity to ensure that patient is able to draw up the correct amount of insulin.
- Coach patient through the steps of administering subcutaneous insulin injection.
- Demonstrate how to rotate insulin injection sites.
- Help patient determine the amount of insulin required on the basis of the results of home capillary glucose monitoring as ordered by the health care provider.
- Show patient how to keep a daily log for insulin injections, including results of home capillary glucose monitoring, type and amount of insulin given, expiration date on insulin vial, time of insulin injection, and injection site used.

Evaluation
- Use Teach Back and ask patient to describe procedure used at home for determining the correct dose of insulin needed and injection site.
- Watch patient prepare insulin dose on the basis of results of capillary glucose monitoring, select injection site, and self-administer injection.
- Review information recorded in patient log for completeness.
- If patient is unable to prepare the correct amount of insulin or self-administer safely, instruct a family caregiver and notify the health care provider.

Patients need to know the symptoms of medication side effects or toxicity. For example, patients taking anticoagulants learn to notify their health care providers immediately when signs of bleeding or bruising develop. Inform family members or friends of medication side effects such as changes in behavior because they are often the first to recognize these effects. Patients cope better with problems caused by medications if they understand how and when to act. All patients need to learn the basic guidelines for medication safety, which ensure the proper use and storage of medications in the home.

Acute Care. Patients are often hospitalized to receive expert nursing observation and documentation of responses to medications. When a nurse receives a medication order, several nursing interventions are essential for safe and effective medication administration.

Receiving, Transcribing, and Communicating Medication Orders. An order is required to administer any medication. In the absence of CPOE, health care providers hand write orders onto order sheets in a patient's chart. If orders are handwritten, be sure that medication names, dosages, and symbols are legible. Clarify and then rewrite any unclear or illegible transcribed orders.

The process of verifying medical orders varies among health care agencies. Nurses follow agency policy and current national patient safety standards when receiving, transcribing, and communicating medication orders. *Nursing students are prohibited from transcribing or receiving verbal and telephone orders.*

Medication orders need to contain all of the elements in Box 32-10. If a medication order is incomplete, inform the health care provider and ensure completeness before carrying it out. Nurses read back verbal or telephone orders to health care providers to ensure that the correct order is obtained. The registered nurse follows agency policy regarding receiving, recording, and transcribing verbal and telephone orders. Generally the health care provider must sign them within 24 hours.

Nurses and pharmacists check all medication orders for accuracy and thoroughness several times during the transcription process. They also take patients' current problems, treatments, laboratory values, and other prescribed medications into consideration. Once the nurse and pharmacist determine that a medication order is safe and appropriate, it is placed on the appropriate medication form, usually called the *MAR*. The MAR is either printed on paper or available electronically. An electronic version of the MAR is called an *eMAR*. Whether it is handwritten, printed from a computer, or in an electronic version, it includes the patient's name, room, and bed number; medical record number; medical and food allergies; other patient identifiers (e.g., birthday); and medication name, dose, frequency, and route and time of administration. Each time a medication dose is prepared, the nurse refers to the MAR.

It is essential to verify the accuracy of every medication you give to your patients with the patients' orders. If the medication order is incomplete, incorrect, or inappropriate or if there is a discrepancy between the original order and the information on the MAR, consult with the health care provider. Do not give a medication until you are certain that you can follow the six rights of medication administration. When you give the wrong medication or an incorrect dose, *you* are legally responsible for the error.

Accurate Dose Calculation and Measurement. When measuring liquid medications, use standard measuring containers. Use a systematic procedure for medication measurement to lessen the chance of error. Calculate each dose when preparing a medication, pay close attention to the process of calculation, and avoid interruptions from other people or nursing activities. Ask another nurse to double-check your calculations against the original medication order if you are *ever* in doubt about the accuracy of your calculation or if you are calculating a dose for the first time or for a high-risk medication.

Correct Administration. For safe administration follow the six rights of medication administration. Verify the patient's identity by using at least two patient identifiers (TJC, 2016). In the acute care setting identifiers are usually on a patient's armband. Carefully compare patient identifiers with the MAR to ensure that you are giving the medication to the right patient. Use aseptic technique and proper procedures when handling and giving medications and perform necessary assessments (e.g., heart rate for antidysrhythmic medications) before administering a medication to a patient. Carefully monitor a patient's response to a medication, especially when the first dose of a new medication is administered.

Recording Medication Administration. Follow all agency policies when documenting medication administration. After administering a medication, appropriately document the name of the medication, dose, route, and exact time of administration immediately. Include the site of any injections per agency policy.

If a patient refuses a medication or is undergoing tests or procedures that result in a missed dose, explain the reason that a medication was not given in the nurses' notes. Some agencies require the nurse to circle the prescribed administration time on the medication record or to notify the health care provider when a patient misses a dose. Be aware of the effects that missing doses have on a patient (e.g., with hypertension or diabetes). Coordinating care with health care providers and other services when testing or diagnostic procedures are being completed helps ensure patient safety and therapeutic control of the disease.

Restorative Care. Because of the numerous types of restorative care settings, medication administration activities vary. Patients with functional limitations often require a nurse to fully administer all medications. In the home care setting patients usually administer their own medications or receive assistance from family caregivers. Regardless of the type of medication activity, the nurse is responsible

---

BOX 32-10 Components of Medication Orders

A medication order needs to have all of the following parts:

Patient's full name: A patient's full name distinguishes the patient from other people with the same last name. In the acute care setting patients are sometimes assigned special identification numbers (e.g., medical record number) to help distinguish patients with the same names. This number is often included on the order form.

Date and time that the order is written: The day, month, year, and time need to be included. Designating the time that an order is written clarifies when certain orders are to start and stop. If an incident occurs involving a medication error, it is easier to document what happened when this information is available.

Medication name: A health care provider orders a medication by its generic or trade name. Correct spelling is essential to prevent confusion with medications with similar spelling.

Dosage: The amount or strength of the medication is included.

Route of administration: A health care provider only uses accepted abbreviations for medication routes. Accuracy is important to ensure that patients receive medications by the intended route.

Time and frequency of administration: A nurse needs to know what time and how frequently to administer medications. Orders for multiple doses establish a routine schedule for medication administration.

Signature of health care provider: The signature makes an order a legal request.

for instructing patients and families in medication action, administration, and side effects. He or she is also responsible for monitoring adherence with medication and determining the effectiveness of medications that have been prescribed.

Special Considerations for Administering Medications to Specific Age-Groups. A patient's developmental level is a factor to consider when administering medications. Knowledge of developmental needs helps you anticipate responses to medication therapy.

Infants and Children. In many pediatric settings the standard of practice is to have another nurse verify all pediatric dose calculations before administration. All children require special psychological preparation before receiving medications. A child's parents are often valuable resources for determining the best way to give a child medication. Sometimes it is less traumatic for a child if a parent gives the medication and the nurse supervises. Supportive care is necessary if a child is expected to cooperate. Explain the procedure to a child, using words appropriate to his or her level of comprehension. Long explanations increase a child's anxiety, especially for painful procedures such as an injection. Providing a child with choices when possible can result in greater success. For example, saying, "It's time to take your pill now. Do you want it with water or juice?" allows a child to make a choice. Do not give the child the option of not taking a medication. After taking a medication, praise the child and offer a simple reward such as a star or token. Tips for administering medication to children are in Box 32-11.

Older Adults. Older adults also require special considerations during medication administration (Box 32-12). In addition to physiological changes of aging (Figure 32-8), behavioral and economic factors influence an older person's use of medications.

Polypharmacy. **Polypharmacy** happens when a patient takes multiple medications or potentially inappropriate or unnecessary medications or when a medication does not match a diagnosis (Touhy and Jett, 2014). For example, polypharmacy exists when a patient takes two medications from the same chemical class to treat the same illness. Suspect polypharmacy if your patient uses two or more medications with the same or similar actions to treat several illnesses simultaneously and mixes nutritional supplements or herbal products with medications. Older adults also often experience polypharmacy when they seek relief from a variety of symptoms (e.g., pain, constipation, insomnia, and indigestion) by using OTC preparations. Sometimes polypharmacy is unavoidable. For example, some patients need to take more than one medication to control their high blood pressure. When a patient experiences polypharmacy, the risk of adverse reactions and medication interactions with other medications and food is increased.

Because many older adults suffer chronic health problems, polypharmacy is common. However, it is also becoming more common in children and patients with mental illnesses. Taking OTC medications frequently, lack of knowledge about medications, incorrect beliefs about medications, and visiting several health care providers to treat different illnesses increase the risk for polypharmacy. To minimize risks associated with polypharmacy, frequent communication among health care providers is essential to make sure that the patients' medication regimen is as simple as possible (Pasina et al, 2014).

◆ Evaluation

Evaluation of medication administration is an essential role of professional nursing that requires assessment skills; critical thinking; analysis; and knowledge of medications, physiology, and pathophysiology. You need to thoroughly and accurately gather data to complete a holistic evaluation. The goal of safe and effective medication administration is met when a patient responds appropriately to medication therapy and assumes responsibility for self-care. When patients do not experience expected outcomes of medication therapy, investigate possible reasons and determine appropriate revisions to the plan of care.

BOX 32-11 Tips for Administering Medications to Children

Oral Medications
- Liquids are safer to swallow than pills to avoid aspiration.
- Use droppers for administering liquids to infants; straws often help older children swallow pills.
- Offer juice, a soft drink, or frozen juice bar, if allowed, after the child swallows a drug.
- When mixing medications in other foods or liquids, use only a small amount. The child may refuse to take all of a larger mixture.
- Avoid mixing a medication in a child's favorite foods or liquids because the child may later refuse them.
- A plastic, disposable oral syringe is the most accurate device for preparing liquid doses, especially those less than 10 mL (cups, teaspoons, and droppers are inaccurate).

Injections
- Use caution when selecting intramuscular (IM) injection sites. Infants and small children have underdeveloped muscles. Follow agency policy.
- Children are sometimes unpredictable and uncooperative. Make sure that someone (preferably another nurse) is available to restrain a child if needed. Have the parent act as a comforter, not restrainer, if restraint is necessary.
- Always awaken a sleeping child before giving an injection.
- Distracting a child with conversation, bubbles, or a toy reduces pain perception.
- If time allows, apply a lidocaine ointment to an injection site before the injection to reduce pain perception during the injection.

BOX 32-12 FOCUS ON OLDER ADULTS

Safety in Medication Administration

- Frequently review a patient's medication history, including use of over-the-counter medications, and consult with health care provider to simplify the drug therapy plan whenever possible (Pasina et al., 2014).
- Keep instructions clear and simple, provide memory aids (e.g., calendar, medication schedule), and ensure that written information about medications is in print large enough for a patient to see (Touhy and Jett, 2014).
- Assess functional status to determine if patient will require assistance in taking medications (Touhy and Jett, 2014).
- Some older adults have a greater sensitivity to drugs, especially those that act on the central nervous system. Therefore carefully monitor patients' responses to medications and anticipate dosage adjustments as needed (Touhy and Jett, 2014).
- If patient has difficulty swallowing a capsule or tablet, ask the health care provider to substitute a liquid medication or instruct patient to place medication on the front of the tongue and then swallow fluid to help wash it to the back of the throat. If the patient continues to have problems, have him or her try taking medication with a very small amount of semisolid food (e.g., applesauce) (Touhy and Jett, 2014).
- Teach alternatives to medications such as proper diet instead of vitamins and exercise instead of laxatives (Touhy and Jett, 2014).

Drug-receptor interaction
Brain receptors become more sensitive, making psychoactive drugs very potent.

Circulation
Vascular nerve control is less stable. Antihypertensives, for example, may overshoot, dropping blood pressure too low. Digoxin, for example, may slow the heart rate too much.

Metabolism
Liver mass shrinks. Hepatic blood flow and enzyme activity decline. Metabolism drops to one half to two thirds the rate of young adults. Enzymes lose ability to process some drugs, thus prolonging drug half-life.

Excretion
In kidneys, renal blood flow, glomerular filtration rate, renal tubular secretion and reabsorption, and number of functional nephrons decline. Blood flow and waste removal slow. Age-related changes lengthen half-life for renally excreted drugs. Antidiabetic drugs, among others, stay in the body longer.

Absorption
Gastric emptying rate and gastrointestinal motility slow. Absorption capacity of cells and active transport mechanism decline.

Distribution
Lean body mass falls. Adipose stores increase. Total body water declines, raising the concentration of water-soluble drugs, such as digoxin, which can cause heart dysfunction. Plasma protein diminishes, reducing sites available for protein-bound drugs and raising blood levels of free drug.

FIGURE 32-8 Effects of aging on medication metabolism. (From Lewis SM et al: *Medical-surgical nursing,* ed 9, St Louis, 2014, Mosby.)

Through the Patient's Eyes. Evaluation is more effective when you value your patients' participation. Therefore partner with your patients and include them in the evaluation process. Ensure that they understand and are able to safely administer their medications. For example, if you are caring for a child who needs an inhaler, be sure to watch the patient use the inhaler. To determine if patients understand their medication schedules, ask them to explain when they take their medications and if they are able to take them as prescribed. When patients struggle with their medication schedule, determine barriers to medication adherence (e.g., cost, lack of knowledge) and remove these barriers if possible. Also remember that patients have different values and define health differently. These values and beliefs influence their perception of the effectiveness of their medications. Therefore ask patients to describe this effectiveness. Ask if they are satisfied with their medications and how they make them feel. Use patients' statements and responses to questions (e.g., "I feel less anxious now") when determining the effectiveness of medications. Including patients in the evaluation process empowers them and helps them become more actively involved in their care.

Patient Outcomes. A patient's clinical condition can change minute by minute. Use knowledge of the desired effect and common side effects of each medication to compare expected outcomes with actual findings. A change in a patient's condition is often physiologically related to changes in health status or results from medications or both. Be alert for reactions in a patient taking several medications. Nurses use a variety of measures to evaluate patient responses to medications such as direct observation of physiological measures (e.g., blood pressure or laboratory values), behavioral responses (e.g., agitation), and rating scales (e.g., rating on a pain or nausea scale). The type of measurement used varies with the medication action being evaluated, the reading skill and knowledge level of the patient, and the patient's cognitive and psychomotor ability. The most common type of measurement is a physiological measure. Examples of physiological measures are blood pressure, heart rate, and visual acuity. Nurses also use patient statements as evaluative measures. Table 32-8 contains examples of goals, expected outcomes, and corresponding evaluative measures.

MEDICATION ADMINISTRATION

A sound knowledge base is required for medications to be administered safely. Nurses need to be prepared to administer medications using a variety of routes.

Oral Administration

The easiest and most desirable route for administering medications is by mouth (see Skill 32-1 on pp. 655-659). Patients usually are able to self-administer oral medications. Food sometimes affects their absorption so give them on an empty stomach if absorption is

TABLE 32-8 Example Evaluation for Patient Goals

Goal	Expected Outcomes	Evaluative Measure with Example
Patient and family will understand medication therapy.	Patient and family describe information about medication, dosage, schedule, purpose, and adverse effects. Patient and family identify situations that require medical intervention. Patient and family demonstrate appropriate administration technique.	Written measurement: Have patient write out medication schedule for a 24-hour period. Oral questioning: Use Teach Back and ask patient to describe purpose, dosage, and adverse effects of each prescribed medication. Oral questioning: Use Teach Back and have family describe what to do when a patient has adverse effects from a medication. Direct observation: Have patient complete return demonstration by filling insulin syringe and administering injection.
Patient will safely self-administer medications.	Patient follows prescribed treatment regimen. Patient performs administration techniques correctly. Patient identifies available resources for obtaining necessary medication.	Anecdotal notes: Have family keep log of patient's adherence to therapy for 1 week. Direct observation: Observe patient instill eyedrops. Oral questioning: Use Teach Back and ask family to identify how to contact local pharmacy or community clinic for necessary medications.

BOX 32-13 Protecting a Patient from Aspiration

- Allow patients to self-administer medications if possible.
- Know signs of dysphagia (difficulty swallowing): cough, change in voice tone or quality after swallowing, delayed swallowing, incomplete oral clearance or pocketing of food, regurgitation.
- Assess patient's ability to swallow and cough by checking for presence of gag reflex and then offering 50 mL of water in 5-mL allotments. Stop if patient begins to cough.
- Prepare oral medications in the form that is easiest to swallow.
- Position patient in an upright, seated position with feet on the floor, hips and knees at 90 degrees, head midline, and back erect if possible.
- If patient has unilateral weakness, place the medication in the stronger side of the mouth. Turning the head toward the weaker side helps the medication move down the stronger side of the esophagus.
- Administer pills one at a time, ensuring that each medication is swallowed properly before the next one is introduced.
- Thicken regular liquids or offer fruit nectars if patient cannot tolerate thin liquids.
- Some medications can be crushed and mixed with pureed foods if necessary. Refer to a medication reference to verify which medications are safe to crush.
- Avoid straws because they decrease the control patient has over volume intake, which increases the risk of aspiration.
- Have patient hold and drink from a cup if possible.
- Time medications to coincide with mealtimes or when patient is well rested and awake if possible.
- Administer medications using another route if risk of aspiration is severe.

decreased. Likewise give medications with meals if absorption is enhanced by food (Burchum and Rosenthal, 2016). Most tablets and capsules need to be swallowed and administered with approximately 60 to 240 mL of fluid (as allowed).

Oral medication administration is contraindicated in some situations (see Table 32-5). Many medications interact with nutritional and herbal supplements. You need to be knowledgeable about these interactions to determine the best time to give oral medications.

An important precaution to take when administering any oral preparation is to protect patients from aspiration. Aspiration occurs when food, fluid, or medication intended for GI administration inadvertently enters the respiratory tract. Protect a patient from aspiration by assessing his or her ability to swallow. Box 32-13 provides techniques that protect patients from aspiration. Proper positioning is

essential. Position a patient in a seated position at a 90-degree angle when administering oral medications if not contraindicated by his or her condition. Usually having the patient slightly flex the head in a chin-down position reduces aspiration. Use a multidisciplinary approach (e.g., speech therapist, dietitian, and occupational therapist) to determine the best techniques for patients who have difficulty swallowing.

Special consideration is needed when administering medications to patients with enteral or small-bore feeding tubes (Box 32-14). Failing to follow current evidence-based recommendations from the American Society for Parenteral and Enteral Nutrition (ASPEN) can result in tube obstruction, reduced medication effectiveness, and increased risk of medication toxicity (Malone, 2014; Phillips and Endacott, 2011). Tubing misconnections continue to cause patient injury because tubes with different functions can be connected with Luer connectors (TJC, 2014b). In response to this issue the International Organization for Standardization (ISO) (ISMP, 2014b) has developed tubing connector standards in which the enteral connector will no longer be Luer compatible. A new enteral-only connector (ENFit) is available, and health care facilities have changed enteral nutrition practices, policies, procedures, and processes per the new guidelines (TJC, 2014b) (Box 32-15). Before giving a medication by this route, verify that the location of the tube (e.g., stomach or jejunum) is compatible with medication absorption. For example, iron dissolves in the stomach and is mostly absorbed in the duodenum. If it is administered through a jejunal tube, it has poor bioavailability.

Use liquid medications when possible. When liquid medications are not available, crush simple tablets or open capsules and dilute them in water. Pierce a gel cap with a sterile needle and empty contents into 30 mL of warm water or other solution as designated by the manufacturer of the medication. You can dissolve gel caps in warm water, but this often takes 15 to 20 minutes. Only use oral syringes when preparing medications for this route to prevent accidental parenteral administration. Flush tubes with at least 30 mL of water before and after giving medications. When administering more than one medication at a time, give each separately and flush between medications with 15 to 30 mL of water. Determine if medications need to be given on an empty stomach or if they are compatible with the patient's enteral feeding. If a medication needs to be given on an empty stomach or is not compatible with the feeding (e.g., phenytoin, carbamazepine [Tegretol], warfarin [Coumadin], fluoroquinolones, proton pump inhibitors), hold the feeding for at least 30 minutes before or 30 minutes after medication administration. Some of these medications may need up to 120 minutes to absorb (Guenter and Boullata, 2013). Verify the time with a drug reference or consult with a pharmacist.

BOX 32-14 **PROCEDURAL GUIDELINES**

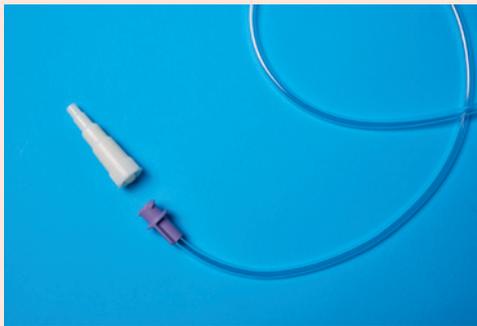
Administering Medications Through an Enteral Tube (Nasogastric Tube, G-Tube, J-Tube, or Small-Bore Feeding Tube)

Delegation Considerations

The skill of giving medications through an enteral tube cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP to:

- Keep the head of the bed elevated for a minimum of 30 degrees (preferably 45 degrees) for 1 hour after medication administration; follow agency policy.
- Immediately report coughing, choking, gagging, or drooling of liquid to the nurse.
- Report occurrence of side effects of medications to the nurse.

Equipment

60-mL oral syringe with appropriate tip (catheter tip for large-bore tube, Luer-Lok tip for small-bore tube) or enteral-only connector (ENFit) (see illustration), if available; gastric pH test strip (scale of 1.0 to 11.0); graduated container; medication to be administered; pill crusher if medication in tablet form; water or sterile water for immunocompromised patient; tongue blade or straw to stir dissolved medication; medication administration record (MAR) (electronic or printed); clean gloves; stethoscope (for evaluation)


Steps

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name and medication name, dosage, and route and time of administration. Recopy or reprint any part of printed MAR that is difficult to read.
2. Assess patient's knowledge about medication. Also assess medical history and for history or allergies to medications and foods. Make sure that patient's food and drug allergies are listed on the MAR and are prominently displayed on the patient's medical record per agency policy.
3. Avoid complicated medication schedules that frequently interrupt enteral feedings. Investigate options with health care provider and use alternative routes of medication administration if possible (e.g., intravenous [IV], transdermal, rectal).
   a. Evaluate where medication is absorbed and ensure that point of absorption is not bypassed by feeding tube. For example, some medications (e.g., antacids) are absorbed in the stomach. If the patient's tube is placed in the intestines, these medications are not absorbed because the tube bypasses the stomach (McIntyre and Monk, 2014; Prohaska and King, 2012).
   b. Determine if medication interacts with enteral feeding. If there is a risk for an interaction, stop the feeding for at least 30 minutes before giving the medication (see agency policy or consult with pharmacist or drug reference) (Phillips and Endacott, 2011).
4. Perform hand hygiene and prepare medication (see Skill 32-1, Steps 1a-g, 1l). Prepare medications in a liquid form when possible to prevent tube obstruction (Bankhead et al., 2009; Lohmann et al., 2015). Check label of medication with MAR 2 times for accuracy. *This is the first and second accuracy check.*

5. *Never* add medications directly to a container or bag of tube feeding (Bankhead et al., 2009). Sometimes the tube feeding needs to be held. Verify this and the amount of time that you hold a feeding with agency policy, a pharmacist, or a medication reference before administering the medication to maximize the therapeutic effect of the medication (Bankhead et al., 2009; Guenter and Boullata, 2013).
6. Take medications to patient at correct time (see agency policy). Give STAT, first-time or loading, and 1-time doses at the time ordered. Give time-critical scheduled medications no later than 30 minutes before or after scheduled dose. Give non–time-critical scheduled medications within 1-2 hours of scheduled dose (ISMP, 2011). Perform hand hygiene.
7. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.
8. Compare label of medications against MAR one more time at patient's bedside. *This is the third accuracy check.*
9. Explain procedure and medications to patient.
10. Remember: Do not give whole or undissolved medications through the feeding tube.
11. Elevate head of bed to a minimum of 30 degrees (preferably 45 degrees) (unless contraindicated) or sit patient up in a chair (Bankhead et al., 2009).
12. Apply clean gloves. NOTE: If patient has a latex allergy, use latex-free gloves.
13. If an enteral tube feeding is infusing, adjust infusion pump to hold tube feeding. Verify placement of any feeding tube that enters the mouth or nose by observing gastric contents and checking pH of aspirated contents. A properly obtained pH value of less than 5.0 is a good indication of gastric placement (Clifford et al., 2015) (see Chapter 45).
14. Assess gastric residual volume (GRV). Draw up 30 mL air into 60-mL syringe, connect to feeding tube, and flush tube with air. Then pull back slowly to aspirate gastric contents (see Chapter 45). Determine GRV using either the scale on the syringe or graduated container. If GRV is 250 mL or less, return aspirated contents to stomach (see agency policy). If GRV is greater than 250 mL, hold medication and aspirated fluid and contact health care provider for orders (see agency policy) (Malone, 2014; Metheny et al., 2010).
15. Pinch or clamp enteral tube and remove syringe used to obtain GRV. Draw up 30 mL of water into syringe. Reinsert syringe tip into tube, release clamp, and flush tubing. Clamp tube again and remove syringe.
16. Administer medication
    a. **Syringe method:** Draw up liquid medication into syringe (do not mix medications); connect tip of syringe to end of enteral tubing. Push medication through tube. If resistance is felt when pushing medication through tube, stop administration and contact patient's health care provider.
    b. **Gravity method:** Remove bulb or plunger from syringe and reinsert syringe into tip of feeding tube. Do not insert into pigtail vent on nasogastric tube. Pour liquid medication or dissolved mixture of crushed medicine into feeding tube and allow it to flow into stomach or intestine freely using gravity. *Do not* mix medications together; administer each separately (Bankhead et al., 2009; Zhu and Zhou, 2013). If medication does not flow freely, raise the height of the syringe or have patient change position slightly. If medication still does not flow, attach bulb or plunger to syringe and follow Step 16a.
17. Flush tube with 15-30 mL of water between each medication (Klang et al., 2013).
18. After giving all the medications, flush tube again with 30-60 mL of water (Klang et al., 2013).

BOX 32-14   PROCEDURAL GUIDELINES

Administering Medications Through an Enteral Tube (Nasogastric Tube, G-Tube, J-Tube, or Small-Bore Feeding Tube)—cont'd

19. Restart tube feeding if appropriate. Clamp proximal end of tube if feeding is not being administered or needs to be held for 30 minutes or longer to avoid alterations in medication bioavailability (Bankhead et al., 2009).
20. Help patient to comfortable position and keep head of bed elevated for at least 1 hour (per agency policy). Clean area and put supplies away. Remove gloves and perform hand hygiene.
21. Document administration of medications, dose, route, and time on MAR.
22. Monitor patient for signs of aspiration such as choking, gurgling speech, or congested breath sounds during and after medication administration.
23. Evaluate patient's response to medication at times that correspond with onset, peak, and duration of medication. If desired effect is not achieved, a different medication or route of administration is probably indicated because of problems with drug bioavailability when given the enteral route.
24. Use ***Teach Back*** to determine patient's and family's understanding about enteral medications. State to patient, "I want to be sure I explained the medicines we're giving you through the feeding tube. Can you tell me why you're taking these medicines and what side effects you may develop?" If patient self-administers medications, state, "Show me how you're going to take these medications at home." Revise your instruction now or develop plan for revised teaching if patient or family is not able to teach back correctly.

BOX 32-15   The Joint Commission (TJC) Recommendations for New Enteral Tube Connectors

- Trace tubing or catheter from the patient to the point of origin:
  - Before connecting or reconnecting any device or infusion.
  - At any transition such as to a new setting or service.
  - As part of the hand-off process.
- Route tubes and catheters with different purposes in standard directions (e.g., toward the head, toward the feet) and label the tubes at both the proximal and distal ends.
- Use tubing and related equipment only for their intended use.
  - Never use standard Luer syringes for oral medications or enteral feedings.
  - Do not use intravenous (IV) tubing or IV pumps for enteral feedings.
  - Use distinctly different pumps for IV applications.
  - Eliminate the use of temporary adapters as soon as possible.
  - Do not force connections and avoid workarounds.
- Use safe practices for high-alert medications.
  - Label the tubing or catheter.
  - Do not use tubing or catheter with injection ports.
  - Use an independent double-check procedure.
- Educate staff.
  - Provide adequate staff education for anyone using this new equipment.
  - Provide a reference manual.
- Create a culture of safety and reporting of adverse events.

Adapted from The Joint Commission (TJC): *Sentinel alert event: managing risk during transition to new ISO connector standards,* 2014b, http://www.jointcommission.org/assets/1/6/SEA_53_Connectors_8_19_14_final.pdf. Accessed June 8, 2015.

Monitor the patient closely for adverse reactions. The risk for drug-drug interactions is high when two or more medications are given in this route because they can interact together as soon as they are administered.

Topical Medication Applications

Topical medications are medications that are applied locally, most often to intact skin. They come in many forms (see Table 32-1). They are also applied to mucous membranes.

Skin Applications. Because many locally applied medications such as lotions, pastes, and ointments create systemic and local effects, apply these medications with gloves and applicators. Use sterile technique if a patient has an open wound. Skin encrustation and dead tissues harbor microorganisms and block contact of medications with the tissues to be treated. Before applying medications, clean the skin thoroughly by washing the area gently with soap and water, soaking an involved site, or locally debriding tissue.

Apply each type of medication according to directions to ensure proper penetration and absorption. When applying ointments or pastes, spread the medication evenly over the involved surface and cover the area well without applying an overly thick layer. Health care providers sometimes order a gauze dressing to be applied over the medication to prevent soiling clothes and wiping away the medication. Lightly spread lotions and creams onto the surface of the skin; rubbing often causes irritation. Apply a liniment by rubbing it gently but firmly into the skin. Dust a powder lightly to cover the affected area with a thin layer.

Some topical medications are applied in the form of a transdermal patch that remains in place for an extended amount of time (e.g., 12 hours or 7 days). Before applying a new patch, don disposable gloves and remove the old one. Medication remains on the patch even after its recommended duration of use. Nurses and patients have inadvertently left old transdermal patches in place, resulting in the patient receiving an overdose of the medication. For example, patients who use fentanyl transdermal patches for pain management can experience respiratory depression, coma, and death when the patches are not removed. In addition, some people, especially children, have experienced life-threatening harm from accidental exposure to fentanyl patches that were not disposed of properly (USFDA, 2012). Many patches are clear, which makes them difficult to see. Therefore carefully assess the patient's skin and be sure to remove the existing patch before applying a new one. Follow these guidelines to ensure safe administration of transdermal or topical medications:

- When taking a medication history or reconciling medications, specifically ask patients if they take any medications in the forms of patches, topical creams, or any route other than the oral route.
- When applying a transdermal patch, ask the patient if he or she has an existing patch.
- Wear disposable gloves when removing and applying transdermal patches.
- If the dressing or patch is difficult to see (e.g., clear), apply a noticeable label to the patch.
- Document the location on the patient's body where the medication was placed on the MAR.
- Document removal of the patch or medication on the MAR. Fold sticky sides of the patch together and dispose of the patch in a child-proof container.

Nasal Instillation. Patients with nasal sinus alterations sometimes receive medications by spray, drops, or tampons (Box 32-16). The most commonly administered form of nasal instillation is decongestant spray or drops, used to relieve symptoms of sinus congestion and colds. Caution patients to avoid abuse of medications because overuse leads to a rebound effect in which the nasal congestion worsens. When excess decongestant solution is swallowed, serious systemic effects also develop, especially in children. Saline drops are safer than nasal preparations that contain sympathomimetics (e.g., Afrin or Neo-Synephrine) as a decongestant for children.

It is easier to have patients self-administer sprays because they are able to control the spray and inhale as the medication enters the nasal passages. For patients who use nasal sprays repeatedly, check the nares for irritation. When used to treat a sinus infection, position patients to permit the nasal medication to reach the affected sinus. Severe nosebleeds are usually treated with packing or nasal tampons, which are treated with epinephrine, to reduce blood flow. Usually a physician or advanced practice clinician places nasal tampons.

Eye Instillation. Some patients use OTC eyedrops and ointments such as artificial tears and vasoconstrictors (e.g., Visine and Murine). Other patients, especially older adults, receive prescribed **ophthalmic** medications for eye conditions such as glaucoma or after cataract extraction. Age-related problems, including poor vision, hand tremors, and difficulty grasping or manipulating containers, affect an older adult's ability to self-administer eye medications. Instruct patients and family members about the proper techniques for administering them (see Skill 32-2 on pp. 660-663). Determine a patient's and family caregiver's ability to self-administer through a return demonstration of the procedure. Show patients each step for instilling eyedrops to help them understand the procedure. Follow these principles when administering eye medications:

- Avoid instilling any form of eye medications directly onto the cornea. The cornea of the eye has many pain fibers and thus is very sensitive to anything applied to it.
- Avoid touching the eyelids or other eye structures with eyedroppers or ointment tubes. The risk of transmitting infection from one eye to the other is high.
- Use eye medication only for the patient's affected eye.
- Never allow a patient to use another patient's eye medications.

Intraocular Administration. One less common way to administer eye medications is by the intraocular route (see Skill 32-2). These medications resemble a contact lens. You place the medication into the conjunctival sac where it remains for up to 1 week. You need to teach patients how to insert and remove the disk and to monitor for adverse medication reactions.

Ear Instillation. Because internal ear structures are very sensitive to temperature extremes, you need to instill eardrops at room temperature to prevent vertigo, dizziness, or nausea. Although the structures of the outer ear are not sterile, sterile solutions are used in case the eardrum is ruptured. The entrance of nonsterile solutions into middle ear structures often results in infection. If a patient has ear drainage, be sure that the eardrum has not ruptured. Never occlude or block the ear canal with the dropper or irrigating syringe. Forcing medication into an occluded ear canal creates pressure that injures the eardrum. Box 32-17 provides guidelines for administering eardrops.

Vaginal Instillation. Vaginal medications are available as suppositories, foam, jellies, or creams. Solid, oval-shaped suppositories are packaged individually in foil wrappers and are sometimes stored in the refrigerator to prevent them from melting. After a suppository is inserted into the vaginal cavity, body temperature causes it to melt and be distributed and absorbed. Foam, jellies, and creams are administered with an applicator inserter (Box 32-18). Give a suppository with a gloved hand in accordance with standard precautions (see Chapter 29). Patients often prefer administering their own vaginal medications and need privacy. Because vaginal medications are often given to treat infection, discharge is usually foul smelling. Follow aseptic technique and offer the patient frequent opportunities to maintain perineal hygiene (see Chapter 40).

Rectal Instillation. Rectal suppositories are thinner and more bullet shaped than vaginal suppositories. The rounded end prevents anal trauma during insertion. Rectal suppositories contain medications that exert local effects such as promoting defecation or systemic effects such as reducing nausea. They are stored in a refrigerator until administered. Sometimes it is necessary to clear the rectum with a small cleansing enema before inserting a suppository (Box 32-19).

Administering Medications by Inhalation

Medications administered with handheld inhalers are dispersed through an aerosol spray, mist, or powder that penetrates lung airways. The alveolar-capillary network absorbs medications rapidly.

Pressurized metered-dose inhalers (pMDIs), breath-actuated metered-dose inhalers (BAIs), and dry powder inhalers (DPIs) deliver medications that produce local effects such as bronchodilation. Some medications create serious systemic side effects. pMDIs use a chemical propellant to push the medication out of the inhaler and require the patient to apply approximately 5 to 10 lbs of pressure to the top of the canister to administer the medication. Children or older adults with chronic respiratory diseases often use pMDIs. These two populations have diminished hand strength; therefore it is essential to assess if they

---

BOX 32-16 PROCEDURAL GUIDELINES

Administering Nasal Medications

Delegation Considerations

The skill of administering nasal medications cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP to:

- Watch for potential side effects of medications and report their occurrence.

Equipment

Prepared medication with clean dropper or spray container, facial tissue, small pillow (optional), washcloth (optional), clean gloves (if patient has extensive nasal drainage), medication administration record (MAR) (electronic or printed), penlight

Steps

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name and medication name, dosage, and route and time of administration. Recopy or reprint any part of printed MAR that is difficult to read.
2. Refer to the medical record to determine which sinus is affected if giving nasal drops.
3. Assess patient's medical history (e.g., history of hypertension, heart disease, diabetes mellitus, hyperthyroidism) and for history or allergies to medications and foods. Make sure that patient's food and drug allergies

BOX 32-16 PROCEDURAL GUIDELINES

Administering Nasal Medications—cont'd

are listed on the MAR and prominently displayed on his or her medical record per agency policy.

4. Perform hand hygiene. Using a penlight, inspect condition of nose and sinuses. Palpate sinuses for tenderness (see Chapter 31).

5. Assess patient's knowledge regarding use of and technique for nasal instillation and willingness to learn self-administration.

6. Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.

7. Perform hand hygiene and prepare medication (see Skill 32-1, Steps 1a-g, 1l). Compare medication label against MAR at least 2 times while preparing medication. *This is the first and second accuracy check.*

8. Take medication to patient at correct time (see agency policy). Give STAT, first-time or loading, and 1-time doses at the time ordered. Give time-critical scheduled medications no later than 30 minutes before or after scheduled dose. Give non–time-critical scheduled medications within 1-2 hours of scheduled dose (ISMP, 2011). Perform hand hygiene.

9. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.

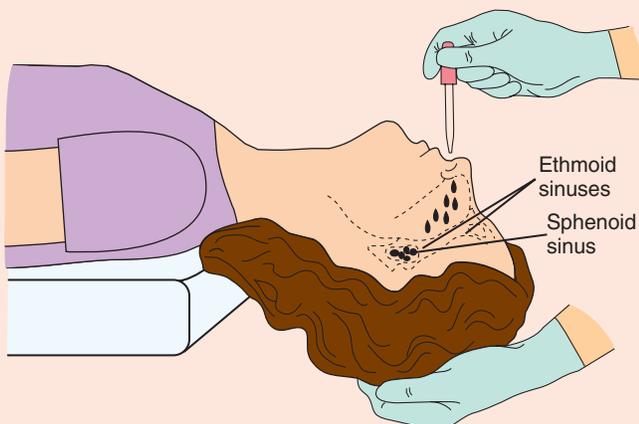
10. Compare names of medication on label with MAR one more time at patient's bedside. *This is the third accuracy check.*

11. Explain procedure to patient regarding positioning and sensations to expect such as burning or stinging of mucosa or choking sensation as medication trickles into throat.

12. Arrange supplies and medications at bedside. Apply clean gloves if patient has nasal drainage. NOTE: If patient has a latex allergy, use latex-free gloves.

13. Gently roll or shake container.

14. Instruct patient to clear or blow nose gently unless contraindicated (e.g., risk of increased intracranial pressure or nosebleeds). Teach patient about medication purpose, dose, time to instill, and possible side effects.

15. *Administer nasal drops:*
    a. Help patient to supine position and position head properly.
       (1) For access to posterior pharynx, tilt patient's head backward.
       (2) For access to ethmoid or sphenoid sinus, tilt head back over edge of bed or place small pillow under patient's shoulder and tilt head back (see illustration).


STEP 15a(2) Position for instilling nose drops into ethmoid or sphenoid sinus.

       (3) For access to frontal and maxillary sinus, tilt head back over edge of bed or pillow with head turned toward side to be treated (see illustration).

STEP 15a(3) Position for instilling nose drops into frontal and maxillary sinus.

    b. Support patient's head with nondominant hand.
    c. Instruct patient to breathe through mouth.
    d. Hold dropper 1 cm ($\frac{1}{2}$ inch) above nares and instill prescribed number of drops toward midline of ethmoid bone.
    e. Have patient remain in supine position 5 minutes.
    f. Offer facial tissue to blot runny nose but caution patient against blowing nose for several minutes.

16. *Administer nasal spray:*
    a. Prime nasal spray if indicated by manufacturer. Help patient to supine position and position head slightly tilted forward.
    b. Help patient place spray nozzle into appropriate nares, pointing nozzle to side and away from center of nose. Gently close opposite nostril with a finger.
    c. Have patient spray medication into nose while inhaling.
    d. Help patient take nozzle out of nose and instruct him or her to hold breath for a few seconds and then breathe out through the mouth.
    e. Offer facial tissue but caution patient against blowing nose for several minutes.

17. Help patient to a comfortable position after medication is absorbed.

18. Wipe tip of bottle with clean, dry tissue and replace the cap; dispose of soiled supplies in proper container; remove and dispose of gloves and perform hand hygiene.

19. Document name of medication, dose, route, and time of administration on MAR.

20. Observe patient for onset of side effects 15 to 30 minutes after administration. Ask if he or she is able to breathe through nose after decongestant administration. It may be necessary to have patient occlude one nostril at a time and breathe deeply.

21. Evaluate patient's response to medications at times that correlate with the onset, peak, and duration of the medication. Evaluate patient for both desired effect and adverse effects. Reinspect condition of nasal passages between instillations.

22. Use ***Teach Back*** to determine patient's and family's understanding about nasal medications. State to patient, "I want to be sure I explained your nasal spray correctly. Can you tell me the best time for you to use this spray? What side effects may you get from using the spray?" If patient self-administers medications at home, state, "Show me how you're going to take this medication at home." Revise your instruction now or develop plan for revised teaching if patient or family is not able to teach back correctly.

BOX 32-17   PROCEDURAL GUIDELINES

Administering Ear Medications

Delegation Considerations

The skill of administering ear medications cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP to:

- Watch for potential medication side effects and report their occurrence.

Equipment

Drops: Medication bottle with dropper, cotton-tipped applicator, cotton ball (optional), clean gloves if patient has drainage from ear; *Irrigation:* irrigating solution and syringe, kidney-shaped basin, towel; medication administration record (MAR) (electronic or printed)

Steps

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name and medication name, dosage, and route and time of administration. Recopy or reprint any part of printed MAR that is difficult to read.
2. Assess patient's medical history (e.g., history of dizziness, hearing loss); medication history; and history of allergies to medications, food, and latex.
3. Review pertinent information related to medication: action, purpose, normal dose and route (correct ear), side effects, time of onset and peak action, and nursing implications.
4. Assess patient's knowledge of medication.
5. Perform hand hygiene. Prepare medication (see Skill 32-1, Steps 1a-g, 1l). Check label of medication with MAR 2 times for accuracy. *This is the first and second accuracy check.*
6. Take medication to patient at correct time (see agency policy). Give STAT, first-time or loading, and 1-time doses at the time ordered. Give time-critical scheduled medications no later than 30 minutes before or after scheduled dose. Give non–time-critical scheduled medications within 1-2 hours of scheduled dose (ISMP, 2011). Perform hand hygiene.
7. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on the patient's MAR or medical record.
8. Compare names of medications on label with the MAR one more time at the patient's bedside. *This is the third accuracy check.* Hold medication container in hands for a few minutes to bring medication to body temperature.
9. Explain procedure to patient regarding positioning and sensations to expect such as hearing bubbling or feeling water in ear as medication trickles into ear.
10. Teach patient about action of medication, dose, time of instillation, and possible side effects.
11. Administer eardrops:

a. Apply clean gloves and gently clean outer ear with washcloth if drainage is present. NOTE: If patient has a latex allergy, use latex-free gloves.
b. Place patient in side-lying position (if not contraindicated by his or her condition) with ear to be treated facing up or have him or her sit in chair or at the bedside. If eardrops are a cloudy suspension, shake them for about 10 seconds.
c. Straighten ear canal by pulling auricle down and back (children younger than 3 years) or upward and outward (children 3 years of age and older and adults).
d. Instill prescribed drops holding dropper 1 cm ($\frac{1}{2}$ inch) above ear canal (see illustration).

STEP 11d Instill prescribed drops above ear canal.

e. Ask patient to remain in side-lying position 2 to 3 minutes. Apply gentle massage or pressure to tragus of ear with finger unless contraindicated because of pain.
f. If cotton ball is needed, place it into outermost part of canal. Do not press cotton deep into canal. Remove it after 15 minutes.
12. Clean the area and put supplies away.
13. Remove gloves and perform hand hygiene.
14. Document medication administration on MAR.
15. Use **Teach Back** to determine patient's and family's understanding about ear medications. State to patient, "I want to be sure I explained your eardrops correctly. Can you tell me why you are taking these and what side effects might develop?" If patient self-administers medications, state, "Show me how you're going to take these eardrops at home." Revise your instruction now or develop plan for revised teaching if patient or family is not able to teach back correctly.

BOX 32-18   PROCEDURAL GUIDELINES

Administering Vaginal Medications

Delegation Considerations

The skill of administering vaginal medications cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP to:

- Report new or increased vaginal discharge or bleeding and occurrence of side effects of medications.
- Offer to provide perineal care following medication administration.

Equipment

Vaginal cream, foam, jelly, or suppository with applicator (if required); clean gloves; towels and/or washcloth; perineal pad; drape or sheet; water-soluble lubricating jelly; medication administration record (MAR) (electronic or printed)

Steps

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name and medication name, form (cream or suppository), dosage, and route and time of administration. Recopy or reprint any part of printed MAR that is difficult to read.
2. Assess patient's medical history (e.g., history of vaginal drainage); medication history; and history of allergies to medications, food, and latex.

BOX 32-18 PROCEDURAL GUIDELINES

Administering Vaginal Medications—cont'd

3. Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.

4. Assess patient's knowledge of medication.

5. Perform hand hygiene. Prepare medication (see Skill 32-1, Steps 1a-g, 1l). Check name of medication on label with MAR 2 times for accuracy. *This is the first and second accuracy check.*

6. Take medication to patient at the correct time (see agency policy). Give STAT, first-time or loading, and 1-time doses at the time ordered. Give time-critical scheduled medications no later than 30 minutes before or after scheduled dose. Give non–time-critical scheduled medications within 1-2 hours of scheduled dose (ISMP, 2011). Perform hand hygiene.

7. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.

8. Compare names of medication on label with the MAR one more time at patient's bedside. *This is the third accuracy check.*

9. Teach patient about the action of medication, dose, time for instillation, and possible side effects. Explain procedure regarding positioning and sensations to expect such as feelings of moisture or wetness in the vaginal area. Be sure that patient understands the procedure if she plans to self-administer the medication.

10. Close room door or pull curtain to provide privacy. Determine patient's ability to manipulate applicator or suppository and ability to position self to insert medication.

11. Apply clean gloves. NOTE: If patient has a latex allergy, use latex-free gloves.

12. Help patient into dorsal recumbent position and keep abdomen and lower extremities draped.

13. Be sure that lighting is adequate to visualize vaginal opening. Inspect condition of external genitalia and vaginal canal (see Chapter 31), noting appearance of any discharge. Clean area with washcloth or towel if necessary (see Chapter 40).

14. Administer vaginal suppository:
    a. Remove suppository from foil wrapper and apply liberal amount of sterile, water-based lubricating jelly to smooth or rounded end. Lubricate gloved index finger of dominant hand.
    b. With nondominant gloved hand expose vaginal orifice by gently retracting labial folds.
    c. With dominant gloved hand gently insert rounded end of suppository along posterior wall of vaginal canal entire length of finger (7.5 to 10 cm [3 to 4 inches]) to ensure equal distribution of medication along walls of vaginal cavity (see illustration).

STEP 14c Insertion of suppository into vaginal canal.

d. Withdraw finger and wipe away remaining lubricant from around orifice and labia.

15. Administer cream or foam:
    a. Fill cream or foam applicator following package directions.
    b. With nondominant gloved hand, expose vaginal orifice by gently retracting labial folds.
    c. With dominant gloved hand, insert applicator approximately 5 to 7.5 cm (2 to 3 inches). Push applicator plunger to deposit medication into vagina to allow equal distribution of medication (see illustration).

STEP 15c Instillation of medication in vaginal canal.

d. Withdraw applicator and place on paper towel. Wipe off residual cream from labia or vaginal orifice.

16. Dispose of supplies, remove and dispose of gloves, and perform hand hygiene.

17. Instruct patient to remain on back for at least 10 minutes to allow medication to be distributed and absorbed evenly throughout vaginal cavity and not lost through orifice.

18. Document medication administration on MAR.

19. If using an applicator, wear gloves while washing with soap and warm water, rinse, and store for future use.

20. Offer patient perineal pad when she resumes ambulation.

21. Use ***Teach Back*** to determine patient and family's understanding about vaginal medications. State to patient, "I want to be sure I explained your vaginal medication correctly. Can you tell me why you're taking these suppositories and what type of side effects may develop?" If patient self-administers medications, state, "Show me how you're going to take your vaginal medications at home." Revise your instruction now or develop plan for revised teaching if patient or family is not able to teach back correctly.

BOX 32-19   PROCEDURAL GUIDELINES

Administering Rectal Suppositories

Delegation Considerations

The skill of administering rectal suppositories cannot be delegated to nursing assistive personnel (NAP). Instruct NAP to:

- Watch for and report fecal discharge or bowel movement.
- Report occurrence of medication side effects.
- Offer to provide perineal care following medication administration.

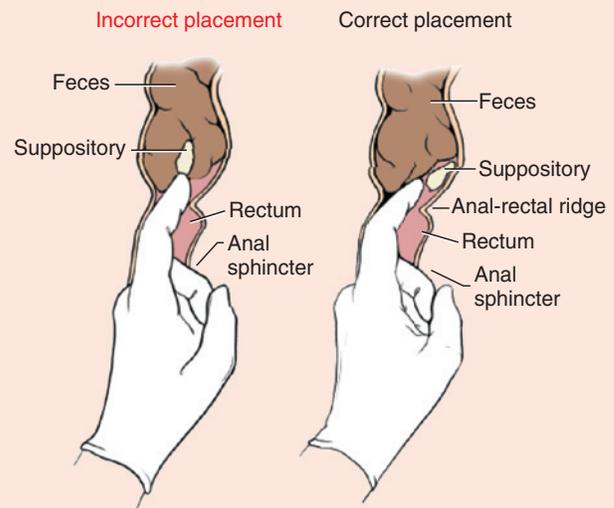
Equipment

Rectal suppository, water-soluble lubricating jelly, clean gloves, drape or sheet, tissue, medication administration record (MAR) (electronic or printed)

Steps

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name and medication name, dosage, and route and time of administration. Recopy or reprint any part of printed MAR that is difficult to read.
2. Review medical history (e.g., hemorrhoids, anal fissures, rectal surgery, or bleeding); medication history; and history of allergies to medications, food, and latex.
3. Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.
4. Assess patient's understanding of medication and experience with self-administration.
5. Perform hand hygiene and prepare medication (see Skill 32-1, Steps 1a-g, 1l). Compare names of medication on label with the MAR 2 times for accuracy. *This is the first and second accuracy check.*
6. Take medication to patient at the correct time. Give STAT, first-time or loading, and 1-time doses at the time ordered. Give time-critical scheduled medications no later than 30 minutes before or after scheduled dose. Give non–time-critical scheduled medications within 1-2 hours of scheduled dose (ISMP, 2011). Perform hand hygiene.
7. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.
8. Compare names of medication on label with the MAR one more time at patient's bedside. *This is the third accuracy check.*
9. Teach patient about the medication. Explain procedure regarding positioning and sensations to expect such as feelings of needing to defecate. Be sure that patient understands the procedure if he or she is going to self-administer the medication.
10. Close room door or pull curtain to ensure privacy.
11. Apply clean gloves. NOTE: If patient has a latex allergy, use latex-free gloves.
12. Help patient to Sims' position. Keep him or her draped with only anal area exposed.
13. Be sure that lighting is adequate to visualize anus. Examine condition of anus externally and palpate rectal walls as needed (see Chapter 31). Dispose of gloves in proper receptacle if soiled.
14. Apply new pair of clean gloves (if previous gloves were soiled). NOTE: If patient has a latex allergy, use latex-free gloves.
15. Remove suppository from wrapper and lubricate rounded end (see illustration) with sterile water-soluble lubricating jelly. Lubricate index finger of dominant hand with water-soluble lubricant.

STEP 15 Remove suppository from wrapper.

16. Ask patient to take slow, deep breaths through mouth and relax anal sphincter.
17. Retract buttocks with nondominant hand. Insert suppository gently through anus, past internal sphincter and against rectal wall, 10 cm (4 inches) in adults, 5 cm (2 inches) in children and infants (see illustration). Apply gentle pressure to hold buttocks together momentarily if needed to keep medication in place.


STEP 17 Inserting rectal suppository. (From deWit S: *Fundamental concepts and skills for nursing,* ed 4, Philadelphia, 2014, Saunders.)

18. Withdraw finger and wipe anal area with tissue.
19. Dispose of supplies, remove gloves, and perform hand hygiene.
20. Ask patient to remain flat or on side for at least 5 minutes to prevent expulsion of suppository.
21. Place call light within patient's reach.
22. Document medication administration on MAR.
23. Observe for effects of suppository (e.g., bowel movement, relief of nausea, temperature reduction) at times that correlate with the onset, peak, and duration of the medication.
24. Use **Teach Back** to determine patient's and family's understanding about rectal medications. State to patient, "I want to be sure I explained your rectal suppository correctly. Can you tell me why you're taking these suppositories and what side effects may develop?" If patient self-administers medications, state, "Show me how you're going to take these rectal medications at home." Revise your instruction now or develop plan for revised teaching if patient or family is not able to teach back correctly.

have enough strength to use the pMDI. BAIs release medication when a patient raises a lever and inhales. Release of the medication depends on the strength of the patient's breath on inspiration, and a BAI is a good choice for patients who have difficulty using pMDIs because it eliminates the need for hand-breath coordination (Ari and Restrepo, 2012).

DPIs hold dry powder medication and create an aerosol when the patient inhales through a reservoir that contains a dose of the medication. Some DPIs are unit dosed. These inhalers require patients to load a single dose of medication into the inhaler with each use. Other DPIs hold enough medication for 1 month. DPIs require less manual dexterity. Because the device is activated with the patient's breath, there is no need to coordinate puffs with inhalation. However, the medication inside the DPI can clump if the patient is in a humid climate, and some patients cannot inspire fast enough to administer the entire dose of the medication.

Patients who receive medications by inhalation frequently suffer chronic respiratory disease such as chronic asthma, emphysema, or bronchitis. Different respiratory problems require different inhaled medication. For example, patients with asthma usually receive antiinflammatory medications because asthma is primarily an inflammatory disease, whereas patients with chronic obstructive pulmonary disease (COPD) receive bronchodilators because they usually have problems with bronchoconstriction. Inhaled medications are also often described as "rescue" or "maintenance" medications. Rescue medications are short acting and taken for immediate relief of acute respiratory distress. Maintenance medications are used on a daily schedule to prevent acute respiratory distress. The effects of maintenance medications start within hours of administration and last for a longer period of time than rescue medications. Some inhalers contain combinations of rescue and maintenance medications. Because patients depend on inhaled medications for disease control and current evidence shows that many patients do not use their inhalers correctly, nurses need to teach and reteach their patients about their safe and effective use (Ari and Restrepo, 2012) (see Skill 32-3 on pp. 663-666).

Some patients use a spacer with the pMDI. The spacer is a 10- to 20-cm (4- to 8-inch) long tube that attaches to the pMDI and allows the particles of medication to slow down and break into smaller pieces, which improves drug absorption in a patient's airway. Spacers have a face mask for infants and children less than 4 years of age. They are especially helpful when a patient has difficulty coordinating the steps involved in self-administering inhaled medications. When patients do not use their inhalers and spacers correctly, they do not receive the full effect of the medication. Therefore patient education is essential. BAIs and DPIs do not require the use of spacers.

One important aspect of patient teaching is to help the patient determine when the MDI, BAI, or DPI is empty and needs to be replaced. Floating an MDI in water to determine how much medication is left is not recommended because extra propellant causes the container to float even if no medication remains in the inhaler. Devices that count down the number of remaining doses are available for MDIs. Some DPIs have mechanisms that indicate how many doses are left. However, these mechanisms are not always accurate. Therefore, to calculate how long medication in an inhaler will last, divide the number of doses in the container by the number of doses the patient takes per day. For example, a patient is to take albuterol 2 puffs 4 times a day. The canister has a total of 200 puffs. Complete the following calculation to determine how long the MDI will last:

$$2 \text{ puffs} \times 4 \text{ times a day} = 8 \text{ puffs per day}$$
$$200 \text{ puffs} \div 8 \text{ puffs per day} = 25 \text{ days}$$

The canister in this example will last 25 days. To ensure that the patient does not run out of medication, teach him or her to refill it at least 7 to 10 days before it runs out.

Administering Medications by Irrigations

Some medications irrigate or wash out a body cavity and are delivered through a stream of solution. Irrigations most commonly use sterile water, saline, or antiseptic solutions on the eye, ear, throat, vagina, and urinary tract. Use aseptic technique if there is a break in the skin or mucosa. Use clean technique when the cavity to be irrigated is not sterile, as in the case of the ear canal or vagina. Irrigations cleanse an area, instill a medication, or apply hot or cold to injured tissue (see Chapter 48).

Parenteral Administration of Medications

Parenteral administration of medications is the administration of medications by injection into body tissues. This is an invasive procedure that is performed using aseptic techniques (Box 32-20). A risk of infection occurs after a needle pierces the skin. Each type of injection requires certain skills to ensure that the medication reaches the proper location. The effects of a parenteral medication develop rapidly, depending on the rate of medication absorption. You must closely observe a patient's response to parental medications.

Equipment. A variety of syringes and needles are available, each designed to deliver a certain volume of a medication to a specific type of tissue. Use nursing judgment when determining the syringe size or needle length and gauge that will be most effective.

Syringes. Syringes consist of a cylindrical barrel with a tip designed to fit the hub of a hypodermic needle and a close-fitting plunger. In general syringes are classified as being Luer-Lok or non–Luer-Lok. This terminology is based on the design of the tip of the syringe. Luer-Lok syringes have needles that are twisted onto the tip and lock themselves in place (Figure 32-9, *A* and *B*). This design prevents the inadvertent removal of the needle. Non–Luer-Lok syringes (Figure 32-9, *C* and *D*) have needles that slip onto the tip. Syringes have safety devices to prevent needlestick injury.

Syringes come in a number of sizes, from 0.5 to 60 mL. It is unusual to use a syringe larger than 5 mL for an injection. A 1- to 3-mL syringe is usually adequate for a subcutaneous or IM injection. A larger volume creates discomfort. Use larger syringes to administer certain IV medications and irrigate wounds or drainage tubes. Syringes often come prepackaged with a needle attached. However, you sometimes change a needle on the basis of the route of administration and size of a patient.

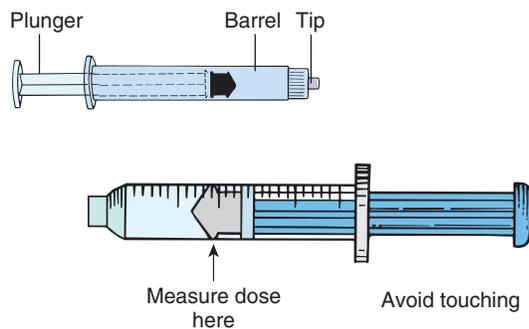
FIGURE 32-9 Types of syringes. **A,** 5-mL syringe. **B,** 3-mL syringe. **C,** Tuberculin syringe marked in 0.01 (hundredths) for doses less than 1 mL. **D,** Insulin syringe marked in units (50).


FIGURE 32-10 Parts of a syringe.

FIGURE 32-11 Parts of the needle.

FIGURE 32-12 Hypodermic needles *(top to bottom)*: 18 gauge, 1½-inch length; 21 gauge, 1½-inch length; 22 gauge, 1½-inch length; 23 gauge, 1-inch length; and 25 gauge, ⅝ -inch length.

The tuberculin syringe (see Figure 32-9, *C*) is calibrated in six-teenths of a minim and hundredths of a milliliter and has a capacity of 1 mL. Use a tuberculin syringe to prepare small amounts of medications (e.g., ID or subcutaneous injections). A tuberculin syringe is also useful when preparing small, precise doses for infants or young children.

Insulin syringes (see Figure 32-9, *D*) are available in sizes that hold 0.3 to 1 mL and are calibrated in units. Most insulin syringes are U-100s, designed to be used with U-100 strength insulin. Each milliliter of U-100 insulin contains 100 units of insulin.

Fill a syringe by pulling the plunger outward while the needle tip remains immersed in the prepared solution. Only touch the outside of the syringe barrel and the handle of the plunger to maintain sterility. Avoid letting any unsterile object touch the tip or inside of the barrel, the hub, the shaft of the plunger, or the needle (Figure 32-10).

Needles. Some needles come packaged in individual sheaths to allow flexibility in choosing the right needle for a patient, whereas others are preattached to standard-size syringes. Most needles are made of stainless steel, and all are disposable. A needle has three parts: the hub, which fits onto the tip of a syringe; the shaft, which connects to the hub; and the bevel, or slanted tip (Figure 32-11). The tip of a needle, or the bevel, is always slanted. The bevel creates a narrow slit when injected into tissue that quickly closes when the needle is removed to prevent leakage of medication, blood, or serum. Long, beveled tips are sharper and narrower, minimizing discomfort when entering tissue used for subcutaneous or IM injections.

Most needles vary in length from ¼ to 3 inches (Figure 32-12). Choose the needle length according to a patient's size and weight and the type of tissue into which the medication is to be injected. Current evidence suggests that needle length should be based on the patient's weight (Davidson and Rourke, 2013). There should be a 5-mm depth of muscle penetration to achieve an IM injection (Hibbard et al., 2015). A child or slender adult generally requires a shorter needle. Use longer needles (1 to 1½ inches) for IM injections and a shorter needle (⅜ to ⅝ inch) for subcutaneous injections. As the needle gauge becomes smaller, the diameter becomes larger. The selection of a gauge depends on the viscosity of fluid to be injected or infused.

Disposable Injection Units. Disposable, single-dose, prefilled syringes are available for some medications. Be careful to check the medication and concentration because prefilled syringes appear very similar. With these syringes you do not have to prepare medication doses, except perhaps to expel parts of unneeded medications.

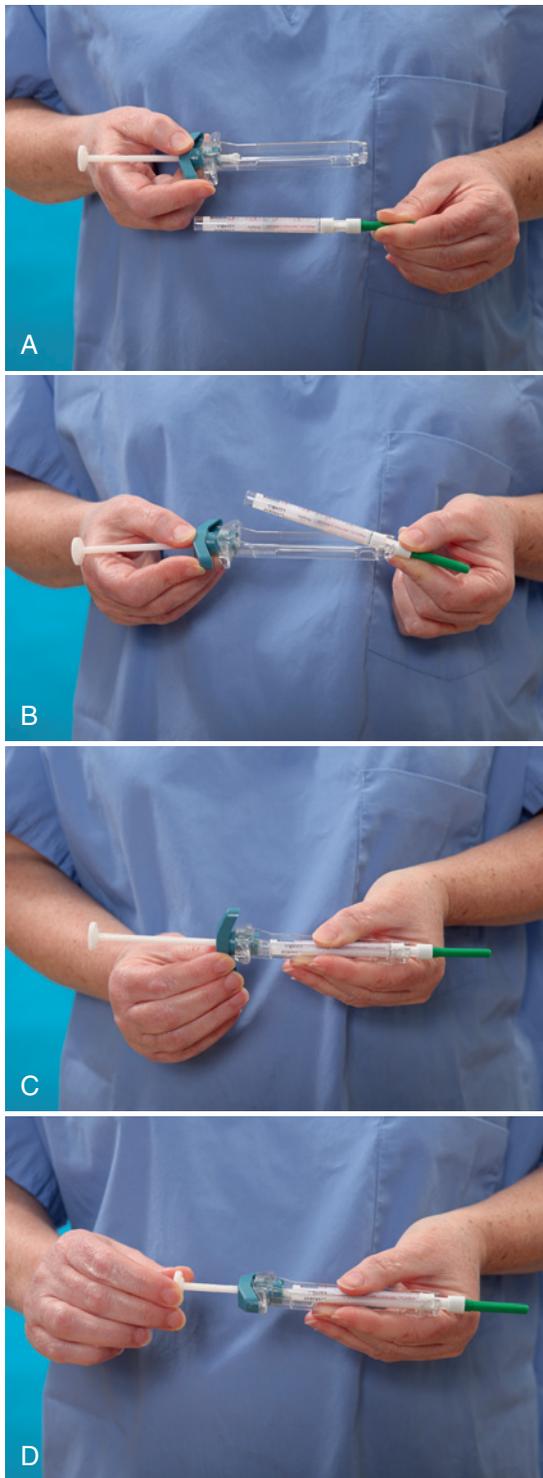
The Tubex and Carpuject injection systems include reusable plastic mechanisms that hold prefilled, disposable, sterile cartridge-needle units (Figure 32-13). To assemble a prefilled system, place the cartridge barrel first into the plastic syringe holder. Following manufacturer directions, turn the plunger rod to the left (counterclockwise) and the lock to the right (clockwise) until it "clicks." Finally remove the needle guard and advance the plunger to expel air and excess medication as in a regular syringe. The glass cartridge can be used with needleless systems or safety needles. After giving the medication, safely dispose of the glass cartridge in a puncture-proof, leak-proof receptacle.


FIGURE 32-13 A, Carpuject syringe and prefilled sterile cartridge with needle. **B,** Assembling the Carpuject. **C,** Cartridge slides into syringe barrel. Turn and lock syringe into cartridge. **D,** Screw plunger into end of cartridge. Expel excess medication to obtain accurate dose *(not pictured).*

Preparing an Injection from an Ampule. Ampules contain single doses of medication in a liquid. They are available in several sizes, from 1 mL to 10 mL or more (Figure 32-14, *A*). An ampule is made of glass with a constricted neck that must be snapped off to allow access to the medication. A colored ring around the neck indicates

FIGURE 32-14 A, Medication in ampules. **B,** Medication in vials.

where the ampule is prescored so you can break it easily. Carefully aspirate the medication into a syringe (see Skill 32-4 on pp. 666-670) with a filter needle. The use of a filter needle prevents particulate matter such as small glass fragments from entering the syringe (Alexander et al., 2014). Replace the filter needle with an appropriate-size needle or a needleless access device before administering the injection.

Preparing an Injection from a Vial. A vial is a single-dose or multidose container with a rubber seal at the top (see Figure 32-14, *B*). A metal cap protects the seal until it is ready for use. Vials contain liquid or dry forms of medications. Medications that are unstable in solution are packaged dry. The vial label specifies the solvent or diluent used to dissolve the medication and the amount of diluent needed to prepare a desired medication concentration. Normal saline and sterile distilled water are commonly used to dissolve medications.

Unlike the ampule, the vial is a closed system, and air needs to be injected into it to permit easy withdrawal of the solution. Failure to inject air when withdrawing creates a vacuum within the vial that makes withdrawal difficult. If concerned about drawing up parts of the rubber stopper or other particles into the syringe, use a filter needle when preparing medications from vials (Alexander et al., 2014). Some vials contain powder, which is mixed with a diluent during preparation and before injection (see Skill 32-4). After mixing multidose vials, make a label that includes the date and time of mixing and the concentration of medication per milliliter. Some multidose vials require refrigeration after the contents are reconstituted.

Mixing Medications. If two medications are compatible, it is possible to mix them in one injection if the total dose is within accepted limits. This prevents a patient from having to receive more than one injection at a time. Most nursing units have charts that list common compatible medications. If there is any uncertainty about medication compatibilities, consult a pharmacist or a medication reference.

Mixing Medications from a Vial and an Ampule. When mixing medication from both a vial and ampule, prepare medication from the vial first. Using the same syringe and filter needle, next withdraw medication from the ampule. Nurses prepare the combination in this order because it is not necessary to add air to withdraw medication from an ampule.

Mixing Medications from Two Vials. Apply these principles when mixing medications from two vials:

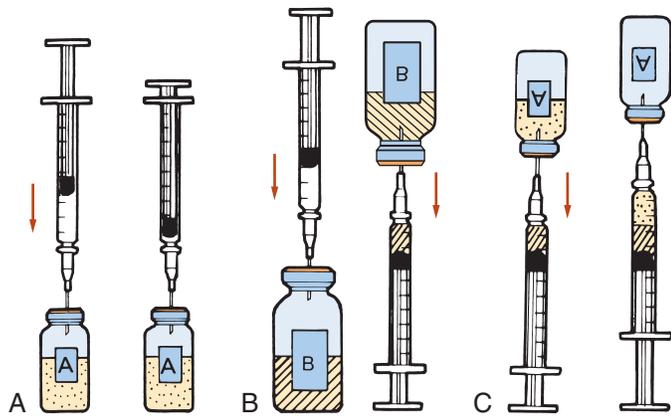
1. Do not contaminate one medication with another.
2. Ensure that the final dose is accurate.
3. Maintain aseptic technique.


FIGURE 32-15 A, Injecting air into vial A. **B,** Injecting air into vial B and withdrawing dose. **C,** Withdrawing medication from vial A; medications are now mixed.

Use only one syringe with a needle or needleless access device attached to mix medications from two vials (Figure 32-15). Aspirate the volume of air equivalent to the dose of the first medication (vial A) (see Figure 32-15, A). Inject the air into vial A, making sure that the needle does not touch the solution. Withdraw the needle and aspirate air equivalent to the dose of the second medication (vial B). Inject the volume of air into vial B (see Figure 32-15, B). Immediately withdraw the medication from vial B into the syringe and insert the needle back into vial A, being careful not to push the plunger and expel the medication within the syringe into the vial. Withdraw the desired amount of medication from vial A into the syringe (see Figure 32-15, C). After withdrawing the necessary amount, withdraw the needle and apply a new safety needle or needleless access device suitable for injection.

Insulin Preparation. Insulin is the hormone used to treat diabetes mellitus. It is administered by injection because the GI tract breaks down and destroys an oral form of insulin. Most patients with diabetes mellitus who take insulin injections learn to administer their own injections. In the United States and Canada, health care providers usually prescribe insulin in concentrations of 100 units per milliliter of solution. This is called *U-100 insulin.* Insulin is also commercially available in concentrations of 500 units per milliliter of solution; it is called *U-500 insulin.* U-500 insulin is 5 times as strong as U-100 insulin and is used only in rare cases when patients are very resistant to insulin.

Use the correct syringe when preparing insulin. Use a 100-unit insulin syringe or an insulin pen to prepare U-100 insulin. Because there is no syringe currently designed to prepare U-500 insulin, many medication errors result with this kind of insulin. To prevent errors, ensure that the order for U-500 specifies units and volume (e.g., 150 units, 0.3 mL of U-500 insulin) and use tuberculin syringes to draw up the doses (ISMP, 2013b). Verify every injection you prepare with another nurse before administering it. Additional safety measures common with U-500 insulin include listing the insulin as being concentrated in computerized medication dispensing systems, making health care providers and pharmacists verify that a patient is to receive U-500 insulin when it is ordered, and only stocking U-500 insulin on patient care units when it is ordered for a specific patient (ISMP, 2013b).

Insulin is classified by rate of action, including rapid-acting, short-acting, intermediate-acting, and long-acting. To provide safe and effective care, you need to know the onset, peak, and duration for each of your patients' ordered insulin doses. Refer to a medication reference or consult with a pharmacist if you are unsure of this information.

BOX 32-21   Example of Correction Insulin Order

Give regular U-100 insulin subcutaneously:
  2 units for glucose 150 to 200 mg/dL
  4 units for glucose 201 to 275 mg/dL
  Call for glucose greater than 275 mg/dL
Clinical scenario: Before lunch patient's blood glucose level is 201. After referring to patient's correction insulin order, the nurse administers 4 units of insulin to patient.

Regular insulin is the only type of insulin that can be given intravenously.

A patient with diabetes mellitus sometimes requires more than one type of insulin. For example, by receiving a short-acting (regular) and intermediate-acting (NPH) insulin, a patient receives more sustained control of blood glucose levels over 24 hours. The timing of insulin injections attempts to imitate the normal pattern of insulin release from the pancreas. Some insulins come in a stable premixed solution (e.g., 70/30 insulin is 70% NPH [intermediate] and 30% regular), eliminating the need to mix the insulins in a syringe. Other patients use an insulin pen. The insulin pen provides multiple doses and allows a patient to dial in the dose, avoiding the need to use a syringe for insulin preparation. Research shows that different types of a patient's blood cells can enter into the insulin pen after an injection. Several U.S. health care organizations recently reported that the same insulin pen was inadvertently used on multiple patients, exposing the patients to bloodborne illnesses (e.g., human immunodeficiency virus [HIV], hepatitis B, and hepatitis C). Thus the ISMP recommends that insulin pens only be used at home and that inpatient settings such as hospitals stop using them whenever possible (ISMP, 2013c).

Insulin is ordered by a specific dose at select times. Correction insulin, also known as sliding-scale insulin, provides a dose of insulin based on the patient's blood glucose level (Box 32-21). The term *correction insulin* is preferred because it indicates that small doses of rapid- or short-acting insulin are needed to correct a patient's elevated blood sugar. Reliance on correction insulin is unlikely to achieve long-term glucose control; therefore it should only be ordered on a temporary basis (ADA, 2015).

Before drawing up insulin doses, gently roll all cloudy insulin preparations between the palms of the hands to resuspend the insulin (Diggle, 2014). Do not shake insulin vials; shaking causes bubbles to form. Bubbles take up space in the syringe and alter the dose.

If more than one type of insulin is required to manage the patient's diabetes, you mix two different types of insulin into one syringe *if* they are compatible (Box 32-22). If regular and intermediate-acting insulins are ordered, prepare the regular insulin first to prevent it from becoming contaminated with the intermediate-acting insulin (Diggle, 2014). Use the following principles when mixing insulins (Diggle, 2014; McCulloch, 2015; Novo Nordisk, 2014):

- Patients whose blood glucose levels are well controlled on a mixed-insulin dose need to maintain their individual routine when preparing and administering their insulin.
- Do not mix insulin with any other medications or diluents unless approved by the health care provider.
- Never mix insulin glargine (Lantus) or insulin detemir (Levemir) with other types of insulin.
- Inject rapid-acting insulins mixed with NPH insulin within 15 minutes before a meal.
- Verify insulin doses with another nurse while you are preparing the injection.

BOX 32-22 PROCEDURAL GUIDELINES

Mixing Two Types of Insulin in One Syringe

Delegation Considerations
The skill of mixing two types of insulin in one syringe cannot be delegated to nursing assistive personnel (NAP).

Equipment
Insulin vials, insulin syringe, alcohol swabs, medication administration (MAR) (electronic or printed)

Steps

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name and medication name, dosage, and route and time of administration. Recopy or reprint any part of printed MAR that is difficult to read.
2. Review medical history (e.g., type of diabetes, reason for elevated blood sugars) and allergies to medications, food, and latex.
3. Carefully verify insulin labels; compare labels against the MAR before preparing the dose to ensure that the correct type of insulin is prepared. *This is the first accuracy check.*
4. Perform hand hygiene.
5. If patient takes insulin that is cloudy, roll the bottle of insulin between the hands to resuspend the preparation.
6. Wipe off tops of both insulin vials with alcohol swabs.
7. Verify insulin dosages against MAR a second time. *This is the second accuracy check.*
8. If mixing rapid- or short-acting insulin with intermediate-acting insulin, take insulin syringe and aspirate volume of air equivalent to the dose of insulin to be withdrawn from intermediate-acting insulin first. If two intermediate-acting insulins are mixed, it makes no difference which vial you prepare first.
9. Insert needle and inject air into vial of intermediate-acting insulin. Do not let the tip of the needle touch the insulin.
10. Remove the syringe from the vial of intermediate-acting insulin without aspirating the insulin.
11. With the same syringe, inject air equal to the dose of insulin to be withdrawn into the vial of rapid- or short-acting insulin. Then withdraw the correct dose into the syringe.
12. Remove the syringe from the rapid- or short-acting insulin vial after carefully removing air bubbles in the syringe to ensure correct dose.
13. After verifying insulin dosages with MAR a third time, show insulin prepared in syringe to another nurse to verify that correct dosage was prepared. *This is the third accuracy check.* Determine which point on the syringe scale combined the units of insulin measured by adding the number of units of both insulins together (e.g., 3 units regular + 10 units NPH = 13 units total).
14. Place the needle of the syringe back into the vial of intermediate-acting insulin. Be careful not to push the plunger and inject insulin in syringe into the vial.
15. Invert vial and carefully withdraw the desired amount of insulin into the syringe.
16. Withdraw needle and check the fluid level in syringe. Keep needle of prepared syringe sheathed or capped until ready to administer medication. Show another nurse the syringe to verify that the correct dose was prepared.
17. Dispose of soiled supplies in proper receptacle. Place used vials in puncture-proof, leak-proof container and perform hand hygiene.
18. Because rapid- or short-acting insulin binds with intermediate-acting insulin, which reduces the action of the faster-acting insulin, administer mixture within 5 minutes of preparing it.

Modified from American Diabetes Association (ADA): *Insulin & other injectables*, 2013, http://www.diabetes.org/living-with-diabetes/treatment-and-care/medication/insulin. Administering Injections

Each injection route differs based on the type of tissues the medication enters. The characteristics of the tissues influence the rate of medication absorption, affecting the onset of medication action. Before injecting a medication, know the volume of the medication to administer, the characteristics and viscosity of the medication, and the location of anatomical structures underlying injection sites (see Skill 32-5 on pp. 670-675).

If you do not administer injections correctly, negative patient outcomes result. Failure to select an injection site in relation to anatomical landmarks results in nerve or bone damage during needle insertion. Inability to maintain stability of the needle and syringe unit can result in pain and tissue damage. If you fail to aspirate the syringe before injecting an IM medication, the medication may be injected accidentally directly into an artery or vein. Injecting too large a volume of medication for the site selected causes extreme pain and results in local tissue damage.

Many patients, particularly children, fear injections. Patients with serious or chronic illness often are given several injections daily. Minimize discomfort in the following ways:

- Use a sharp-beveled needle in the smallest suitable length and gauge.
- Position a patient as comfortably as possible to reduce muscular tension.
- Select the proper injection site, using anatomical landmarks.
- Apply a vapocoolant spray (e.g., Fluori-Methane spray or ethyl chloride) or topical anesthetic (e.g., EMLA cream) to the injection site before giving the medication when possible.
- Divert the patient's attention from the injection through conversation using open-ended questioning.
- Insert the needle quickly and smoothly to minimize tissue pulling.
- Hold the syringe steady while the needle remains in tissues.
- Inject the medication slowly and steadily.

Subcutaneous Injections. Subcutaneous injections involve placing medications into the loose connective tissue under the dermis (see Skill 32-5). Because subcutaneous tissue is not as richly supplied with blood as the muscles, medication absorption is somewhat slower than with IM injections. However, medications are absorbed completely if the patient's circulatory status is normal. Because subcutaneous tissue contains pain receptors, a patient often experiences slight discomfort.

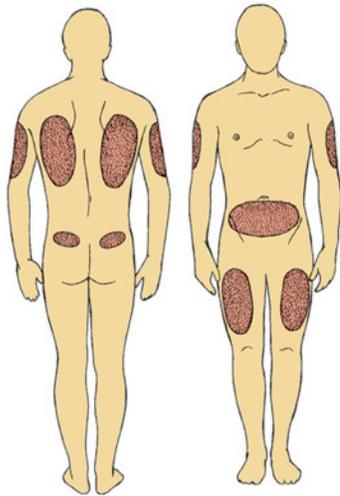
The best subcutaneous injection sites include the outer posterior aspect of the upper arms, the abdomen from below the costal margins to the iliac crests, and the anterior aspects of the thighs (Figure 32-16). The site most frequently recommended for heparin injections is the abdomen (Figure 32-17). Alternative subcutaneous sites for other medications include the scapular areas of the upper back and the upper ventral or dorsal gluteal areas. The injection site you choose needs to


FIGURE 32-16 Sites recommended for subcutaneous injections.

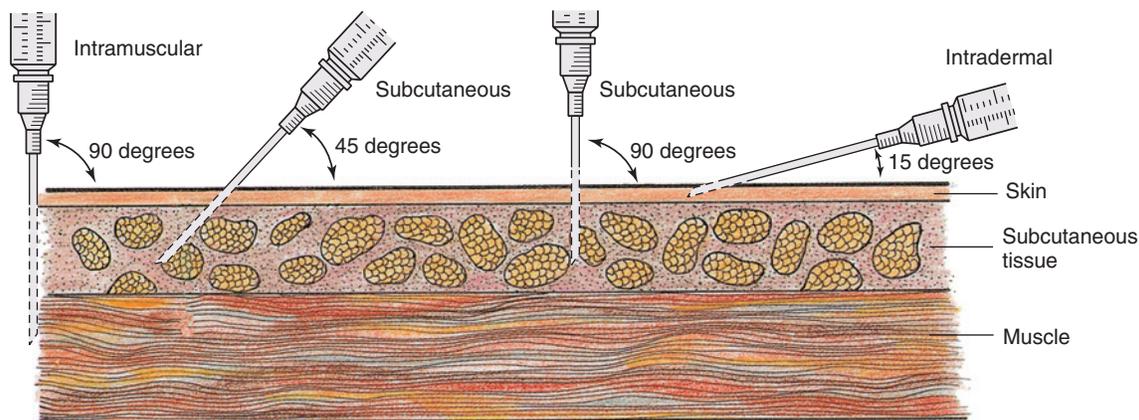
FIGURE 32-17 Giving subcutaneous heparin in abdomen.


FIGURE 32-18 Comparison of angles of insertion for intramuscular (90 degrees), subcutaneous (45 to 90 degrees), and intradermal (15 degrees) injections.

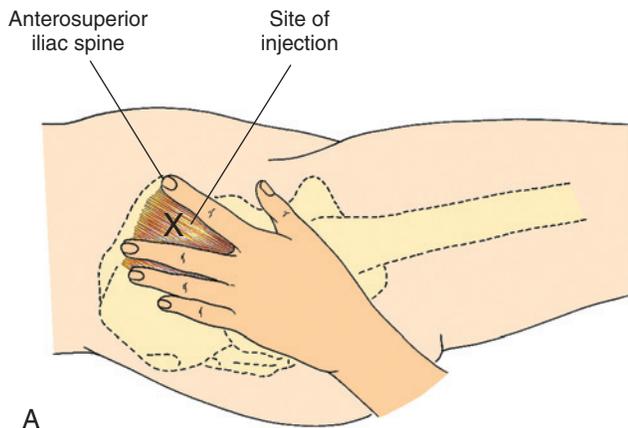
be free of skin lesions, bony prominences, and large underlying muscles or nerves.

The administration of low-molecular-weight heparin (LMWH) (e.g., enoxaparin) requires special considerations. When injecting the medication, use the right or left side of the abdomen at least 2 inches from the umbilicus (the patient's "love handles") and pinch the injection site as you insert the needle. Administer LMWH in its prefilled syringe with the attached needle and do not expel the air bubble in the syringe before giving the medication. There is some new evidence to support a slower injection rate of 30 seconds to reduce bruising and pain (Akbari Sari et al, 2014; Sanofi-Aventis, 2014).

Use U-100 insulin syringes with preattached 32- to 25-gauge needles when giving U-100 insulin and 1-mL tuberculin syringes when giving U-500 insulin (ISMP, 2013b). Recommended sites for insulin injections include the upper arm and the anterior and lateral parts of the thigh, buttocks, and abdomen. Rotating injections within the same body part (intrasite rotation) provides more consistency in the absorption of the insulin. For example, if a patient receives morning insulin in the right arm, give the next injection in a different place in the same arm. The injections are to be given at least 2.5 cm (1 inch) away from the previous site. Injection sites should not be used again for at least 1 month. The rate of insulin absorption varies based on the site; the abdomen has the quickest absorption, followed by the arms, thighs, and buttocks (McCulloch, 2015).

Subcutaneous tissue is sensitive to irritating solutions and large volumes of medications. Thus you only administer small volumes (0.5 to 1.5 mL) of water-soluble medications subcutaneously to adults. You give smaller volumes up to 0.5 mL to children (Hockenberry and Wilson, 2015). Hardened, painful lumps called *sterile abscesses* occur under the skin if medication collects within the tissues.

A patient's body weight indicates the depth of the subcutaneous layer. Therefore choose the needle length and angle of insertion on the basis of a patient's weight and an estimation of the amount of subcutaneous tissue (Juip and Fitzner, 2012). Nurses typically use a 25-gauge, ⅝-inch (16-mm) needle inserted at a 45-degree angle (Figure 32-18) or a ½-inch (12-mm) needle inserted at a 90-degree angle to administer subcutaneous medications to a normal-size adult patient. Some children require only a ½-inch needle. If the patient is obese, pinch the tissue and use a needle long enough to insert through fatty tissue at the base of the skinfold. Thin patients often do not have sufficient tissue for subcutaneous injections; the upper abdomen is usually the best site in this case. To ensure that a subcutaneous medication reaches the subcutaneous tissue, follow this rule: If you can grasp 2 inches (5 cm) of tissue, insert the needle at a 90-degree angle; if you can grasp 2.5 cm (1 inch) of tissue, insert the needle at a 45-degree angle.

Newer research in insulin administration shows that insulin needles that are ⁵⁄₁₆ (8 mm) or longer often enter the muscles of men and people with a body mass index (BMI) of 25 or less. Shorter (³⁄₁₆-inch


A

B

C

FIGURE 32-19 A, Landmarks for ventrogluteal site. **B,** Locating ventrogluteal site in patient. **C,** Giving intramuscular injection in ventrogluteal muscle using Z-track method.

or 4- to 5-mm) needles were associated with less pain, adequate control of blood sugars, and minimal leakage of medication (Diggle, 2014; Gibney et al., 2010; Hirsch et al., 2012; Hoffman et al., 2010). Thus, when administering insulin, needles of $\frac{3}{16}$ inch (4 to 5 mm) administered at a 90-degree angle should be used to reduce pain and achieve adequate control of blood sugars with minimal adverse effects for people of all BMIs, including children (AADE, 2013).

Intramuscular Injections. The IM route provides faster medication absorption than the subcutaneous route because of the greater vascularity of muscles. However, IM injections are associated with many risks. Therefore, whenever administering a medication by the IM route, first verify that the injection is justified (Nicoll and Hesby, 2002; WHO, 2015). Some medications such as hepatitis B and tetanus, diphtheria, and pertussis (Tdap) immunizations are only given intramuscularly.

Use a longer and heavier-gauge needle to pass through subcutaneous tissue and penetrate deep muscle tissue (see Skill 32-5). A patient's BMI and the amount of adipose tissue influence needle size selection. Many needles available in health care settings are not long enough to reach the muscle, especially in patients who are obese and females (Bhalla et al., 2013; Dayananda et al., 2014; Palma and Strohfus, 2013). Because most agencies have needles that range in length from only $\frac{3}{8}$ to $1\frac{1}{2}$ inches, investigate different medication routes, especially when IM injections are ordered for obese female patients.

The angle of insertion for an IM injection is 90 degrees (see Figure 32-18). Muscle is less sensitive to irritating and viscous medications. A normal, well-developed adult patient tolerates 2 to 5 mL of medication into a larger muscle without severe muscle discomfort (Hopkins and Arias, 2013; Nicoll and Hesby, 2002). However, larger volumes of medication (4 to 5 mL) are unlikely to be absorbed properly. Children, older adults, and thin patients tolerate only 2 mL of an IM injection. Do not give more than 1 mL to small children and older infants, and do not give more than 0.5 mL to smaller infants (Hockenberry and Wilson, 2015).

Assess a muscle before giving an injection. Properly identify the site for the IM injection by palpating bony landmarks and be aware of the potential complications associated with each site. The site needs to be free of tenderness because repeated injections in the same muscle cause severe discomfort. With the patient relaxed, palpate the muscle to rule out any hardened lesions. Minimize discomfort during an injection by helping a patient assume a position that helps to reduce muscle strain. Other interventions such as distraction and applying pressure to an IM site decrease pain during an injection.

Sites. When selecting an IM site, consider the following: Is the area free of infection or necrosis? Are there local areas of bruising or abrasions? What is the location of underlying bones, nerves, and major blood vessels? What volume of medication is to be administered? Each site has different advantages and disadvantages.

Ventrogluteal. The ventrogluteal muscle involves the gluteus medius; it is situated deep and away from major nerves and blood vessels. This site is the preferred and safest site for all adults, children, and infants, especially for medications that have larger volumes and are more viscous and irritating (Hockenberry and Wilson, 2015; Hopkins and Arias, 2013; Nicoll and Hesby, 2002). The ventrogluteal site is recommended for volumes greater than 2 mL (Hopkins and Arias, 2013; Nicoll and Hesby, 2002). Research shows that injuries such as fibrosis, nerve damage, abscess, tissue necrosis, muscle contraction, gangrene, and pain are associated with all the common IM sites *except* the ventrogluteal site (Hopkins and Arias, 2013).

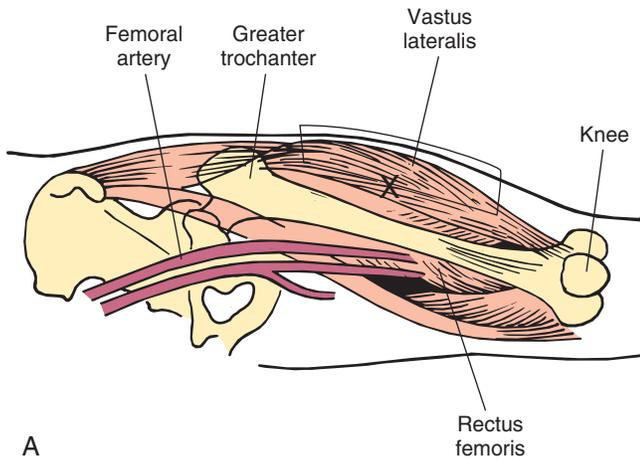
Locate the ventrogluteal muscle by positioning the patient in a supine or lateral position. Flexing the knee and hip helps to relax this muscle. Place the palm of your hand over the greater trochanter of the patient's hip with the wrist perpendicular to the femur. Use the right hand for the left hip and the left hand for the right hip. Point the thumb toward the patient's groin and the index finger toward the anterior superior iliac spine; extend the middle finger back along the iliac crest toward the buttock. The index finger, the middle finger, and the iliac crest form a V-shaped triangle; the injection site is the center of the triangle (Figure 32-19, *A* to *C*).


FIGURE 32-20 A, Landmarks for vastus lateralis site. **B,** Giving intramuscular injection in vastus lateralis muscle.

Vastus Lateralis. The vastus lateralis muscle is another injection site for adults and children. The muscle is thick and well developed, is located on the anterior lateral aspect of the thigh, and extends in an adult from a hand breadth above the knee to a hand breadth below the greater trochanter of the femur (Figure 32-20, *A* and *B*). Use the middle third of the muscle for injection. The width of the muscle usually extends from the midline of the thigh to the midline of the outer side of the thigh. With young children or cachectic patients, it helps to grasp the body of the muscle during injection to be sure that the medication is deposited in muscle tissue. To help relax the muscle, ask a patient to lie flat with the knee slightly flexed or in a sitting position. The vastus lateralis site is often used for infants, toddlers, and children receiving biologicals (e.g., immunoglobulins, vaccines, or toxoids) (Nicoll and Hesby, 2002).

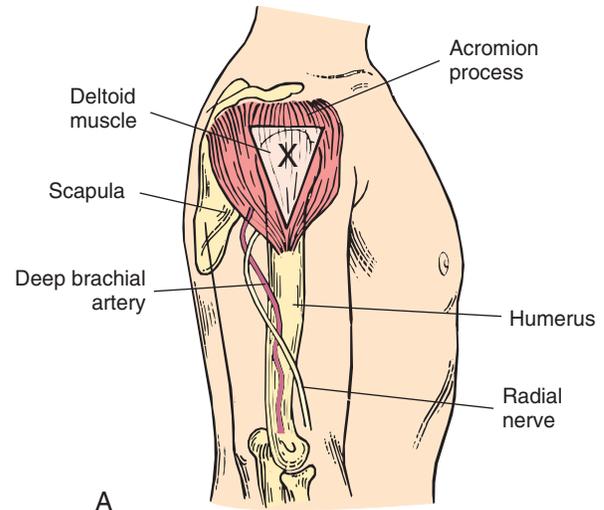
Deltoid. Although the deltoid site is easily accessible, this muscle is not well developed in many adults. There is a potential for injury because the axillary, radial, brachial, and ulnar nerves and the brachial artery lie within the upper arm under the triceps and along the humerus. Use this site for small medication volumes (2 mL or less) (Hopkins and Arias, 2013; Nicoll and Hesby, 2002). Carefully assess the condition of the deltoid muscle, consult medication references for suitability of the medication, and carefully locate the injection site using anatomical landmarks (Figure 32-21, *A*). Use this site only for small medication volumes, when giving immunizations (e.g., hepatitis B, flu shots), or when other sites are inaccessible because of dressings


FIGURE 32-21 A, Landmarks for deltoid site. **B,** Giving intramuscular injection in deltoid muscle.

or casts (Davidson and Rourke, 2013; Nicoll and Hesby, 2002). To locate the muscle, fully expose the patient's upper arm and shoulder. Do not roll up a tight-fitting sleeve. Have the patient relax the arm at the side and flex the elbow. The patient may sit, stand, or lie down (see Figure 32-21, *B*). Palpate the lower edge of the acromion process, which forms the base of a triangle in line with the midpoint of the lateral aspect of the upper arm. The injection site is in the center of the triangle, about 3 to 5 cm (1 to 2 inches) below the acromion process. You can also locate the site by placing four fingers across the deltoid muscle, with the top finger along the acromion process. The injection site is then three finger widths below the acromion process.

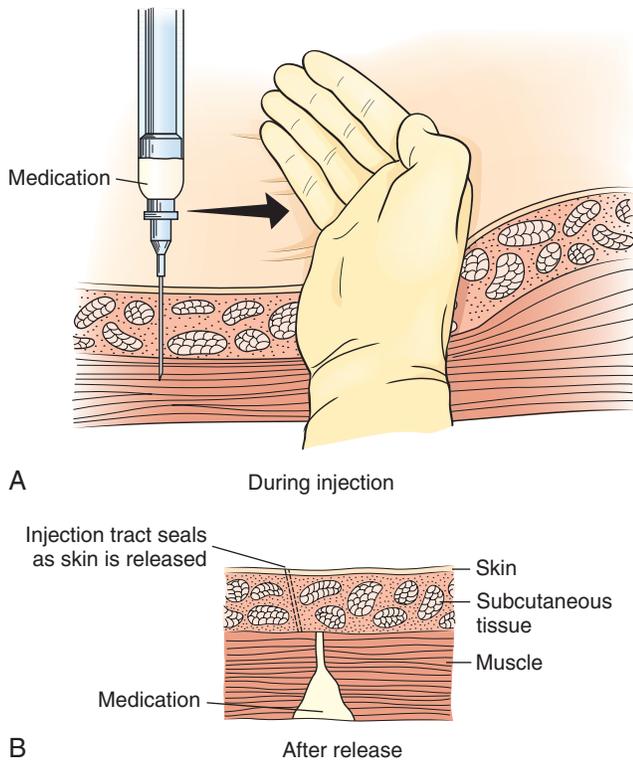
Use of the Z-Track Method in Intramuscular Injections. It is recommended that, when administering IM injections, the **Z-track method** be used to minimize local skin irritation by sealing the medication in muscle tissue (Hopkins and Arias, 2013; Nicoll and Hesby, 2002). To use the Z-track method, put a new needle on the syringe after preparing the medication so no solution remains on the outside needle shaft. Then select an IM site, preferably in a large, deep


FIGURE 32-22 A, Pulling on overlying skin during intramuscular injection moves tissue to prevent later tracking. **B,** Z-track method of injection prevents deposit of medication into sensitive tissue.

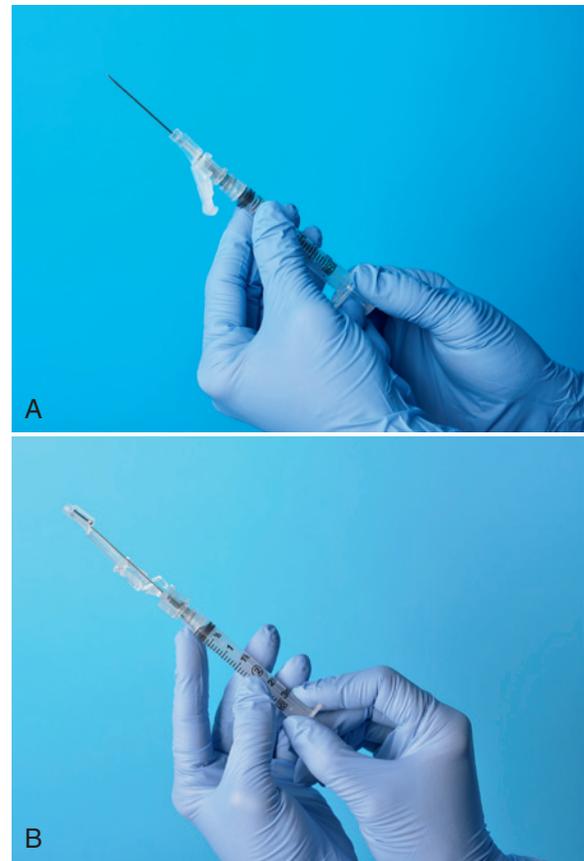
FIGURE 32-23 Needle with plastic guard to prevent needlesticks. **A,** Position of guard before injection. **B,** After injection guard locks in place, covering needle.

muscle such as the ventrogluteal muscle. Place the ulnar side of the nondominant hand just below the site and pull the overlying skin and subcutaneous tissues approximately 2 to 3 cm (1 to 1.2 inches) laterally or downward (Hopkins and Arias, 2013; Nicoll and Hesby, 2002). Hold the skin in this position until you administer the injection. After preparing the site with an antiseptic swab, inject the needle deep into the muscle. Grasp the barrel of the syringe with the thumb and index finger of the nondominant hand and slowly inject the medication if there is no blood return on aspiration. The Centers for Disease Control and Prevention (CDC) no longer recommends aspiration when administering immunizations to reduce discomfort (CDC, 2015; Hopkins and Arias, 2013). The needle remains inserted for 10 seconds to allow the medication to disperse evenly rather than channeling back up the track of the needle. Release the skin after withdrawing the needle. This leaves a zigzag path that seals the needle track where tissue planes slide across one another (Figure 32-22, *A* and *B*). The medication cannot escape from the muscle tissue.

Intradermal Injections. ID injections typically are used for skin testing (e.g., tuberculin screening and allergy tests). Because these medications are potent, they are injected into the dermis, where blood supply is reduced and medication absorption occurs slowly. Some patients have a severe anaphylactic reaction if medications enter the circulation too rapidly. You need to choose skin-testing sites that allow you to easily assess for changes in color and tissue integrity. Thus ID sites need to be lightly pigmented, free of lesions, and relatively hairless. The inner forearm and upper back are ideal locations.

Use a tuberculin or small hypodermic syringe for skin testing. The angle of insertion for an ID injection is 5 to 15 degrees (see Figure


32-18), and the bevel of the needle is pointed up. As you inject the medication, a small bleb resembling a mosquito bite appears on the surface of the skin. If a bleb does not appear or if the site bleeds after needle withdrawal, there is a good chance that the medication entered subcutaneous tissues. In this case test results will not be valid.

Safety in Administering Medications by Injection

Needleless Devices. Approximately 5.6 million health care workers in the United States are at risk of occupational exposure to bloodborne pathogens such as HIV and the hepatitis B virus (OSHA, n.d.). Occupational exposure often occurs through accidental needlesticks and sharps injuries. Needlestick injuries commonly occur when health care workers recap needles, mishandle IV lines and needles, or leave needles at a patient's bedside. Exposure to bloodborne pathogens is one of the deadliest hazards to which nurses are exposed on a daily basis. Most needlestick injuries are preventable with the implementation of safe needle devices. The Needlestick Safety and Prevention Act mandates the use of special needle safety devices to reduce the frequency of needlestick injuries.

Safety syringes have a sheath or guard that covers a needle immediately after it is withdrawn from the skin (Figure 32-23, *A* and *B*). This eliminates the chance for a needlestick injury. The syringe and sheath are disposed of together in a receptacle. Use needleless devices whenever possible to reduce the risk of needlestick and sharps injuries (OSHA, n.d.). Always dispose of needles and other instruments considered sharps into clearly marked, appropriate containers

FIGURE 32-24 Sharps disposal using only one hand.

BOX 32-23 Recommendations for Prevention of Needlestick Injuries

- Avoid using needles when effective needleless systems or sharps with engineered sharps injury protection (SESIP) safety devices are available.
- Do not recap any needle after medication administration.
- Plan safe handling and disposal of needles before beginning a procedure.
- Immediately dispose of needles, needleless systems, and SESIP into puncture-proof, leak-proof sharps disposal containers.
- Maintain a sharps injury log that includes the following: type and brand of device involved in the incident, location of the incident (e.g., department or work area), description of the incident, and privacy of the employees who have had sharps injuries.
- Attend education offerings on bloodborne pathogens and follow recommendations for infection prevention, including receiving the hepatitis B vaccine.
- Participate in the selection and evaluation of SESIP devices with safety features within your agency whenever possible.

Data from Occupational Safety and Health Administration (OSHA): *Bloodborne pathogens and needlestick injuries, 77 FR 19934,* 2012, https://www.osha.gov/FedReg_osha_pdf/FED20120403.pdf. Accessed on January 15, 2015.

(Figure 32-24). Containers need to be puncture proof and leak proof. Never force a needle into a full needle disposal receptacle. Never place used needles and syringes in a wastebasket, in your pocket, on a patient's meal tray, or at the patient's bedside. Box 32-23 summarizes the recommendations for the prevention of needlestick injuries.

Intravenous Administration. Nurses administer medications intravenously by the following methods:
1. As mixtures within large volumes of IV fluids
2. By injection of a bolus or small volume of medication through an existing IV infusion line or intermittent venous access (heparin or saline lock)
3. By "piggyback" infusion of a solution containing the prescribed medication and a small volume of IV fluid through an existing IV line

In all three methods a patient has either an existing IV infusion running continuously or an IV access site for intermittent infusions. Most policies and procedures list who is able to give IV medications and in which patient care units they can be given. These policies are made on the basis of the medication, capability, and availability of staff and the type of monitoring equipment available.

Chapter 42 describes the technique for performing venipuncture and establishing continuous IV fluid infusions. Medication administration is only one reason for supplying IV fluids. IV fluid therapy is used primarily for fluid replacement in patients unable to take oral fluids and as a means of supplying electrolytes and nutrients.

When using any method of IV medication administration, observe patients closely for symptoms of adverse reactions. After a medication enters the bloodstream, it begins to act immediately, and there is no way to stop its action. Thus take special care to avoid errors in dose calculation and preparation. Carefully follow the six rights of safe medication administration, double-check medication calculations with another nurse, and know the desired action and side effects of every medication you give. If the medication has an antidote, make sure that it is available during administration. When administering potent medications, assess vital signs before, during, and after infusion.

Administering medications by the IV route has advantages. Nurses often use this route in emergencies when a fast-acting medication needs to be delivered quickly. The IV route is also best when it is necessary to give medications to establish constant therapeutic blood levels. Some medications are highly alkaline and irritating to muscle and subcutaneous tissue. These medications cause less discomfort when given intravenously. Because IV medications are immediately available to the bloodstream once they are administered, verify the rate of administration with a medication reference or a pharmacist before giving them to ensure that you give them safely over the appropriate amount of time. Patients experience severe adverse reactions if IV medications are administered too quickly.

Large-Volume Infusions. Of the three methods of administering IV medications, mixing them in large volumes of fluids is the safest and easiest. Because the medication is not in a concentrated form, the risk of side effects or fatal reactions is minimal when infused over the prescribed time frame. Medications are diluted in large volumes (500 or 1000 mL) of compatible IV fluids such as normal saline or lactated Ringer's solution. Vitamins and potassium chloride are two types of medications commonly added to IV fluids. There is a danger with continuous infusion: if the IV fluid is infused too rapidly, the patient is at risk for medication overdose and circulatory fluid overload.

In the past nurses mixed medications into IV fluids. However, current safety standards and evidence-based practice no longer support this practice on a routine basis (Alexander et al., 2014; ASHP, 2014; INS, 2011; TJC 2016). Many patient safety risks such as incorrect calculation, nonaseptic preparation, and incorrect labeling occur when nurses have to prepare medications in IV containers on patient care units. Current best practices include use of IV medications that come in standardized concentrations and dosages; standardized procedures for ordering, preparing, and administering IV medications; and ready-to-administer doses when possible (ASHP, 2014).

Nurses only mix medications into IV fluids in emergency situations. The nurse *never* prepares high-alert medications (e.g., heparin, dopamine, dobutamine, nitroglycerin, potassium, antibiotics, or magnesium) on a patient care unit. Check with a pharmacist before mixing a medication in an IV container. If a pharmacist confirms that you need to prepare the medication, ask another nurse to verify your medication calculations and have that nurse watch you during the entire procedure to ensure that you prepare the medication safely. First ensure that the IV fluid and medication are compatible. Then prepare the medication in a syringe (see Skill 32-4) using strict aseptic

technique. Clean the injection port of the IV bag with an alcohol swab, remove the cap from the needle, and insert the needle through the IV port. Push the syringe plunger to instill medication into the IV fluid and mix the solution by turning the IV bag gently end to end. Finally attach a medication label following ISMP (2015b) safe-label guidelines. Administer the medication to the patient at the prescribed rate (see Chapter 42). *Do not* add medications to IV bags that are already hanging because there is no way to tell the exact concentration of the medication. Add medications *only* to new IV bags.

When administering medications in large IV infusions, regulate the IV rate according to the health care provider's order. Monitor patients closely for adverse reactions to the medication and fluid volume overload. Also check the site frequently for infiltration and phlebitis (see Chapter 42).

Intravenous Bolus. An IV bolus involves introducing a concentrated dose of a medication directly into the systemic circulation (see Skill 32-6 on pp. 675-679). Because a bolus requires only a small amount of fluid to deliver the medication, it is an advantage when the amount of fluid that the patient can take is restricted. The IV bolus, or "push," is the most dangerous method for administering medications because there is no time to correct errors. In addition, a bolus may cause direct irritation to the lining of blood vessels. Before administering a bolus confirm placement of the IV line. Never give a medication intravenously if the insertion site appears swollen or edematous or the IV fluid cannot flow at the proper rate. Accidental injection of a medication into the tissues around a vein causes pain, sloughing of tissues, and abscesses, depending on the composition of the medication. Medications that carry a risk of adverse effects if administered too quickly should be diluted and administered as a piggyback or via an infusion pump.

Determine the rate of administration of an IV bolus medication by the amount of medication that can be given each minute. For example, if a patient is to receive 4 mL of a medication over 2 minutes, give 2 mL of the IV bolus medication every minute. Look up each medication to determine the recommended concentration and rate of administration. The ISMP (2003) has recommended avoiding using terms such as "IV push," "IVP," or "bolus" in orders with drugs that require administration over 1 minute or longer. Use more descriptive terms such as "IV over 5 minutes." Remember, consider the purpose for which an IV medication is prescribed and any potential adverse effects related to the rate or route of administration.

Volume-Controlled Infusions. Another way of administering IV medications is through small amounts (50 to 100 mL) of compatible IV fluids. The fluid is within a secondary fluid container separate from the primary fluid bag. The container connects directly to the primary IV line or to separate tubing that inserts into the primary line (see Skill 32-7 on pp. 679-683). Three types of containers are volume-control administration sets (e.g., Volutrol or Pediatrol), piggyback sets, and syringe pumps. Using volume-controlled infusions has several advantages:

- It reduces risk of rapid-dose infusion by IV push. Medications are diluted and infused over longer time intervals (e.g., 30 to 60 minutes).
- It allows for administration of medications (e.g., antibiotics) that are stable for a limited time in solution.
- It allows for control of IV fluid intake.

Piggyback. A piggyback is a small (25 to 250 mL) IV bag or bottle connected to a short tubing line that connects to the *upper* Y-port of a primary infusion line or to an intermittent venous access (Figure 32-25). The label on the medication follows the ISMP IV piggyback medication label format (ISMP, 2015b) (Figure 32-26). The piggyback

FIGURE 32-25 Piggyback setup.

tubing is a microdrip or macrodrip system (see Chapter 42). The set is called a *piggyback* because the small bag or bottle is higher than the primary infusion bag or bottle. In the piggyback setup the main line does not infuse when the piggybacked medication is infusing. The port of the primary IV line contains a back-check valve that automatically stops flow of the primary infusion once the piggyback infusion flows. After the piggyback solution infuses and the solution within the tubing falls below the level of the primary infusion drip chamber, the back-check valve opens, and the primary infusion again flows.

Volume-Control Administration. Volume-control administration (e.g., Buretrol) sets are small (150-mL) containers that attach just below the primary infusion bag or bottle. The set is attached and filled in a manner similar to that used with a regular IV infusion. Follow package directions for priming sets (see Chapter 42).

Syringe Pump. The syringe pump is battery operated and allows medications to be given in very small amounts of fluid (5 to 60 mL) within controlled infusion times using standard syringes.

Intermittent Venous Access. An intermittent venous access (commonly called a *saline lock*) is an IV catheter capped off on the end with a small chamber covered by a rubber diaphragm or a specially designed cap. Special rubber-seal injection caps usually accept needle safety devices (see Chapter 42). Advantages to intermittent venous access include the following:

- Cost savings resulting from the omission of continuous IV therapy
- Effectiveness of nurse's time enhanced by eliminating constant monitoring of flow rates
- Increased mobility, safety, and comfort for the patient

Before administering an IV bolus or piggyback medication, assess the patency and placement of the IV site. After the medication has been administered through an intermittent venous access, the access must

FIGURE 32-26 IV piggyback medication with label following ISMP safe-labeling guidelines.

be flushed with a solution to keep it patent. Generally normal saline is an effective flush solution for peripheral catheters. Some agencies require the use of heparin. Nurses need to verify and follow agency policies regarding the care and maintenance of the IV site.

Administration of Intravenous Therapy in the Home. Sometimes patients need IV therapy at home. Common infusions that patients receive include antibiotics, chemotherapy, total parenteral nutrition, analgesics, and blood transfusions. Most patients typically receive their home IV therapy through a long-term central venous catheter (CVC) (see Chapter 42). Home health nurses assess patients' responses to the medication, monitor the CVC site, and teach patients

and their family caregivers how to administer infusions and maintain the CVC.

Carefully assess patients and their families to determine their ability to manage IV therapy at home. Begin instruction on IV care management as soon as you know that a patient will have IV therapy at home. Your instruction often begins while a patient is hospitalized. Patients and families need to learn how to recognize problems such as signs of infections and other complications related to IV therapy and what to do when these problems occur. Patients also need to know when to notify the home care nurse or health care provider. Plan to teach patients and their families how to maintain IV administration equipment, including the infusion pump.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of a professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

- Be vigilant during the entire process of medication administration. Ensure that your patients receive the appropriate medications. Know why every medication is ordered for your patient, even if you are not administering the medication. Understand what you need to do before, during, and after medication administration. Evaluate the effectiveness and assess for adverse effects after your patients take their medications.
- Take care of yourself. You think as clearly and critically as possible when you are healthy. Healthy behaviors such as getting adequate sleep, making healthy food choices, and getting regular exercise or activity are positive ways to help you better process information and make safe decisions during medication administration.
- Set up and prepare medications in distraction-free, no-interruption zone (NIZ) areas.
- Verify expiration date of every medication during preparation. Do not administer expired medications. Return expired medication to pharmacy.

- Identify each patient using at least two identifiers before administering medications and check against the medication administration record (MAR).
- Clarify all unclear orders and ask for help whenever you are uncertain about a medication order or calculation. Consult with your peers, pharmacists, and other health care providers. Resolve all your concerns related to medication administration before preparing and giving medications.
- Use technology (e.g., bar-code scanning, electronic MARs) that is available to you when preparing and administering medications. Follow all policies related to the safe use of technology and do not use "work-arounds." Nurses who use "work-arounds" fail to follow agency protocols, policies, or procedures during medication administration in an attempt to administer medications to patients in a timelier manner. Failure to follow the standard of care greatly increases the risk for making a medication error, impairs patient safety, and places you at risk for malpractice and disciplinary action (see Chapter 23).
- Educate patients about their medications during medication administration. Patients are often able to identify inappropriate medications. Answer all patient questions and resolve their concerns before giving medications. Include family caregivers in medication education when appropriate.
- In most circumstances you cannot delegate medication administration. Ensure that you follow standards set by your state Nurse Practice Act and guidelines established by the health care agency. Nursing instructors or registered nurses

need to verify all medications and closely supervise nursing students throughout the entire medication preparation and administration process. Licensed practical nurses (LPNs) or licensed vocational nurses (LVNs) can usually administer medications given PO, subcutaneously, intramuscularly, and intradermally. In some cases they can give medications intravenously if they have had special training and if the medications are not high alert. Some states also allow certified medical assistants (CMAs) to administer some types of medications (e.g.,

PO medications) in some health care settings (e.g., long-term care facilities). The skills in this chapter assume that you are not in a setting where you can delegate medication administration to nursing assistive personnel (NAP). If you are practicing in a state and a health care setting that allow you to delegate medication administration, follow the guidelines for safe delegation (see Chapter 21), agency policies, and the standards outlined in the Nurse Practice Act in your state.

SKILL 32-1	ADMINISTERING ORAL MEDICATIONS

DELEGATION CONSIDERATIONS

The skill of administering oral medications cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP about:
- Potential side effects of medications and the need to report their occurrence.
- Informing nurse if patient condition worsens (e.g., increased pain, change in behavior).

EQUIPMENT
- Automated, computer-controlled drug-dispensing system or medication cart
- Disposable medication cups
- Glass of water, juice, or preferred liquid and drinking straw
- Device for crushing or splitting tablets (optional)
- Clean gloves (if handling a medication)
- Medication administration record (MAR) (electronic or printed)
- Paper towels

STEP	RATIONALE

ASSESSMENT

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name, medication name and dosage, and route and time of administration. Recopy or reprint any part of printed MAR that is difficult to read.

The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives correct medications (Mandrack et al., 2012; Sulosaari et al., 2011). Illegible MARs are a source of medication errors (Alassaad et al., 2013).

2. Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.

Allows you to anticipate effects of drug and observe patient's response.

3. Assess for any contraindications to patient receiving oral medication, including being NPO (nothing by mouth), inability to swallow, nausea or vomiting, bowel inflammation or reduced peristalsis, recent gastrointestinal (GI) surgery, gastric suction, and decreased level of consciousness. Check patient's swallow, cough, and gag reflexes.

Alterations in GI function interfere with medication distribution, absorption, and excretion. Patients with GI suction do not receive benefit from oral medications because they are suctioned from the GI tract before they can be absorbed. Risk factors for aspiration include impaired swallowing, decreased level of consciousness (LOC), immobility, and poor functional status (Park et al., 2013).

CLINICAL DECISION: *If there are any contraindications to the patient receiving oral medications or if in doubt about the patient's ability to swallow oral medications, temporarily withhold medication and inform health care provider.*

4. Assess patient's medical, medication, and diet history and history of allergies. List patient's food and drug allergies on each page of the MAR and prominently display it on the patient's medical record per agency policy. When patient has allergy, provide allergy bracelet.

Information reflects patient's need for and potential responses to medications. Information also indicates potential food and drug interactions. Communication of allergies is essential for safe, effective care.

5. Assess risk for aspiration using a dysphagia screening tool if available (see Skill 45-1).

Patients with dysphagia are at risk for aspirating oral medications. Early detection of dysphagia can improve patient outcomes (Speyer, 2013).

6. Gather physical examination and laboratory data that influence medication administration (e.g., vital signs, renal and liver function, laboratory values).

Data sometimes reveal need to hold medication or that medication is contraindicated. Poor liver and kidney function affects metabolism and excretion of medications (Burchum and Rosenthal, 2016).

7. Assess patient's knowledge regarding health and medication use.

Determines patient's need for medication education and guidance needed to achieve drug adherence. Assessment often reveals problems such as medication tolerance, nonadherence, abuse, addiction, or dependence.

8. Assess patient's preferences for fluids. Maintain fluid restrictions when applicable. Determine if medication can be given with preferred fluid.

Fluids ease swallowing and facilitate absorption from the GI tract. Some fluids interfere with absorption of medications.

PLANNING

1. Collect appropriate equipment and MAR.

Enhances time management and efficiency.

2. Plan preparation to avoid interruptions. Do not take phone calls or talk with others. Follow agency policy.

Interruption contributes to medication errors. Use no-interruption zone (NIZ) when possible (Prakash et al., 2014; Yoder et al., 2015).

SKILL 32-1	ADMINISTERING ORAL MEDICATIONS—cont'd

STEP	RATIONALE

IMPLEMENTATION

1. Prepare medications:

   a. Perform hand hygiene. — Reduces transfer of microorganisms.

   b. If using a medication cart, move it outside patient's room. Option: Arrange medication cups in medication preparation area. — Organization of equipment saves time and reduces error.

   c. Log into automated dispensing system (ADS) or unit-dose cart or unlock medicine drawer or cart. — Medications are safeguarded when locked in cabinet, cart, or computerized medication dispensing system.

   d. Prepare medication for one patient at a time. Follow the six rights of medication administration. Keep all pages of MARs for one patient together or look at only one patient's medication administration computer screen at a time. — Preventing distractions limits preparation errors (Kim and Bates, 2013).

   e. Select correct medication from stock supply, unit-dose drawer, or ADS. Compare name of medication on label with MAR (see illustration). Exit ADS after removing drug(s). — Reading labels and comparing them with transcribed order reduces error. *This is the first accuracy check.* Logging out of ADS ensures that no one else can use your identity to remove medications.

   f. Check expiration date on each medication, one at a time. Return outdated drug to pharmacy. — Medications used past their expiration date may lose strength, be inactive, or harm patient.

   g. Check or calculate medication dose as necessary. Double-check calculation. If needed, have another nurse verify calculations. — Double-checking reduces risk of error. Some agencies require nurses to double-check calculations of certain medications (e.g., insulin, heparin) with another nurse (Kim and Bates, 2013).

   h. If preparing a controlled substance, check record for previous medication count and compare current count with supply available. — Controlled substance laws require nurses to carefully monitor and count dispensed narcotics.

   i. Prepare solid forms of oral medications:

     (1) To prepare tablets or capsules from a floor stock bottle, pour required number into bottle cap and transfer medication to medication cup. Do not touch medication with fingers. Return extra tablets or capsules to bottle. — Avoids contamination and waste of medications.

     (2) To prepare unit-dose tablets or capsules, place packaged tablet or capsule directly into medicine cup. Do not remove wrapper (see illustration). — Wrapper maintains cleanliness of medications and allows you to identify medication name and dose at patient's bedside.

     (3) When using a blister pack, "pop" medications through foil or paper backing into a medication cup. — Packs provide 1-month supply, with each "blister" usually containing a single dose.

     (4) If it is necessary to give half a tablet or pill, pharmacy should split, label package, and send medication to unit. — The ISMP (2006) recommends for inpatient settings that, if a pill must be split, a pharmacist splits the pill, repackages and labels it, and sends to nurse for administration. Nurses should not split pills.

CLINICAL DECISION: *Splitting tablets in half, even if they are prescored with a line down the middle, leads to medication errors (Niemann et al., 2015). Medications need to be provided in the correct dose whenever possible. If a pill must be split within inpatient settings, the pharmacist splits the pill with a splitting device, repackages and labels it, and sends it to the nurse for administration. Nurses should not split pills (USFDA, 2013).*

---

     (5) Place all tablets or capsules for patient in one medicine cup, except for those requiring preadministration assessments (e.g., pulse rate or blood pressure); keep medications in their wrappers. — Keeping medications that require preadministration assessments separate from others makes it easier to withhold medications as necessary.

STEP 1e The nurse verifies each medication with medication administration record.

STEP 1i(2) Place tablet into medicine cup without removing wrapper.

STEP	RATIONALE
(6) If patient has difficulty swallowing and liquid medications are not an option, use pill-crushing device (see illustration). Clean crushing device before using it. If a pill-crushing device is not available, place tablet between two medication cups and grind with blunt instrument. Mix ground tablet in small amount (e.g., teaspoon) of soft food (custard or applesauce).	Large tablets are often difficult to swallow. Ground tablet mixed with palatable soft food is usually easier to swallow. Cleaning pill-crushing device ensures that contamination of medications does not occur.

CLINICAL DECISION: *Not all medications can be crushed (e.g., capsules, enteric-coated drugs). Consult with pharmacist and/or the "Do Not Crush List" when in doubt (ISMP, 2014a).*

j. Prepare liquids: **(1)** Unit-dose container with correct amount of medication: Gently shake container. Administer liquid medication packaged in single-dose cup directly from the single-dose cup. Do not pour into medicine cup.	Using unit-dose container with correct dose of medication provides most accurate dose (ISMP, 2015c). Shaking container ensures that medication is mixed before administration.

CLINICAL DECISION: *On the basis of current best practice (ISMP, 2015c), liquid medications that are not available or are not in correct dose in a unit-dose container should be dispensed by the pharmacy in special oral syringes marked "Oral Use Only." These syringes do not connect to any type of parenteral (e.g., intravenous) tubing. In addition, current evidence shows that liquid measuring devices on patient care units result in inaccurate dosing. Having oral medications prepared in the pharmacy ensures that you give the most accurate dose of a medication possible and prevents parenteral administration of oral medications. Steps (2)-(4) that follow are included ONLY if you need to prepare your own liquid medications.*

(2) Liquid medication in bottle or unit-dose container not available in dose ordered: If medication is in multidose bottle, remove bottle cap from container and place cap upside down. Hold multidose bottle with label against palm of hand while pouring.	Verify with pharmacy that you need to prepare your own dose before proceeding (ISMP, 2015c). Keeping cap upside down maintains cleanliness of cap. Spilled liquid does not soil or fade label.
(3) Place medication cup at eye level on hard surface (e.g., countertop). Fill to desired level on scale (see illustration A). Make sure that scale is even with fluid level at its surface or base of meniscus, not edges. Draw up volumes of less than 10 mL in syringe designed for oral medication use without needle (see illustration B). Do not use parenteral syringe to draw up oral medications. Place label on the medication.	Ensures accuracy of measurement. Use of special oral syringe for oral medications prevents accidental parenteral administration of oral medication and is more accurate for small doses of medication (ISMP, 2015c). Labeling ensures that you remember which medication is in the medicine cup or oral medication syringe.
(4) Discard any excess liquid into sink or place specially designated for wasting of medications. Wipe lip and neck of bottle with paper towel.	Prevents contamination of contents of bottle and prevents bottle cap from sticking.
k. Return stock containers or unused unit-dose medications to shelf or ADS drawer and read label again.	Reading label of medications in multiple-dose containers reduces administration errors.
l. Do not leave medications unattended.	Nurse is responsible for safekeeping of drugs.
m. Before going to patient's room, compare patient's name and name of medication on label of prepared drugs with MAR.	Reading labels second time reduces error. *This is the second accuracy check.*
2. Administer medications:	

STEP 1i(6) Pill-crushing device used to crush pills when necessary.

SKILL 32-1   ADMINISTERING ORAL MEDICATIONS—cont'd

STEP	RATIONALE
a. Take medications to patient at correct time (see agency policy). Medications that require exact timing include STAT, first-time or loading, and 1-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (within 30 minutes before or after scheduled dose). Give non–time critical scheduled medications within a range of either 1 or 2 hours of scheduled does (ISMP, 2011). Apply the six rights of medication administration throughout medication administration. Perform hand hygiene.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for timing of medication administration that considers patient needs, prescribed medication, and specific clinical indications (CMS, 2011; ISMP, 2011). Time-critical scheduled medications are medications in which early or delayed administration of maintenance doses of more than 30 minutes before or after the scheduled dose may cause harm or result in suboptimal therapy or pharmacological effect. Non–time-critical medications are medications in which early or delayed administration of 1-2 hours should not cause harm or result in suboptimal therapy or pharmacological effects (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.
b. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).

CLINICAL DECISION: *Replace patient identification bracelets that are missing, illegible, or faded.*

c. Compare names of medications on labels with MAR at patient's bedside.	Final check of medication labels against MAR at patient's bedside reduces medication administration errors. *This is the third check for accuracy.*
d. Explain purpose of each medication, its action, and possible adverse effects to patient. Explore concerns expressed by patient and verify orders if concerns about accuracy of medication orders arise.	Patient has right to be informed; questions often indicate need for teaching or possible nonadherence to therapy. Allows patient to express concerns regarding medications and possibly identifies potential errors in medication orders.
e. Perform necessary preadministration assessments (e.g., blood pressure, pulse). Verify allergies with patient.	Determines whether specific medications should be withheld at that time.
f. Help patient to sitting or Fowler's position. Use side-lying position if sitting is contraindicated. Have patient stay in this position for 30 minutes after administration.	Sitting position prevents aspiration during swallowing (Echevarria and Schwoebel, 2012).
g. Administer medications	
(1) For tablets: Some patients want to hold solid medications in hand or cup before placing in mouth. Offer water or juice to help patient swallow and give full glass if not contraindicated.	Patient becomes familiar with medications by seeing each drug. Choice of fluid can improve fluid intake.
(2) For orally disintegrating formulations (tablets or strips): Remove medication from blister packet just before use. Do not push the tablet through the foil. Place medication on top of patient's tongue and caution against chewing the medication.	These medications begin to dissolve when placed on the tongue. Water is not needed. Because they are thin and fragile, remove them carefully from packaging.
(3) For sublingual medications: Have patient place medication under tongue and allow it to dissolve completely (see Figure 32-3). Caution patient against swallowing tablet.	Medication is absorbed through blood vessels of undersurface of tongue. If swallowed, gastric juices destroy medication, or liver detoxifies it so rapidly that therapeutic blood levels are not attained.
(4) For buccal medications: Have patient place medication in mouth against mucous membranes of cheek until it dissolves (see Figure 32-4). Avoid administering liquids until buccal medication has dissolved.	Buccal medications act locally on mucosa or systemically as they are swallowed in saliva.

STEP 1j(3) A, Pour desired volume of liquid so base of meniscus is level with line on scale. **B,** Use special oral medication syringes to prepare small amounts of liquid medications.

STEP	RATIONALE
(5) **For powdered medications:** Mix with liquids at bedside and give to patient to drink.	When prepared in advance, powdered medications often thicken and even harden, making swallowing difficult.
(6) **For crushed medications mixed in food:** Give each medication separately in teaspoon of food.	Ensures that patient swallows all of medicine.
(7) **For lozenges:** Caution patient against chewing or swallowing lozenges.	Medication acts through slow absorption through oral mucosa, not gastric mucosa.
(8) **For effervescent medication:** Add tablet or powder to glass of liquid. Give immediately after dissolving.	Effervescence improves unpleasant taste and often relieves GI problems.
h. If patient is unable to hold medications, place medication cup to lips and gently introduce each drug into mouth, one at a time. Consider using spoon to place pills in mouth. Do not rush or force medications.	Administering single tablet or capsule eases swallowing and decreases risk of aspiration.

CLINICAL DECISION: *If tablet or capsule falls to the floor, discard it and repeat preparation. Medication is contaminated.*

i. Stay until patient completely takes all medications by their prescribed route. Ask patient to open mouth if uncertain whether medication was swallowed.	You are responsible for ensuring that patient receives ordered dosage. If left unattended, some patients do not take dose or save medications, causing risk to health.
j. For highly acidic medications (e.g., aspirin), offer patient nonfat snack (e.g., crackers) if not contraindicated by his or her condition.	Reduces gastric irritation. The fat content of foods can delay medication absorption.
k. Help patient return to comfortable position.	Maintains patient's comfort.
l. Dispose of soiled supplies and perform hand hygiene.	Hand hygiene reduces transmission of microorganisms.
m. Replenish stock such as cups and straws, return cart to medication room if used, and clean work area.	Maintaining clean and organized workspace enhances efficiency of all staff.

EVALUATION

1. Evaluate patient's response to medications at times that correlate with onset, peak, and duration of the medication.	Evaluates therapeutic benefit of medication and detects onset of side effects or allergic reactions.
2. Ask patient or family member to identify medication name and explain purpose, action, dosage schedule, and potential side effects of drug.	Determines level of knowledge gained by patient and family.
3. Use **Teach Back** to determine patient's and family's understanding about oral medications. State, "I want to be sure I explained how to take your (e.g., sublingual, tablet) medicines. Can you explain how to take these medicines?" Revise your instruction now or develop plan for revised teaching if patient or family is not able to teach back correctly.	Evaluates what the patient and family are able to explain or demonstrate.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Patient exhibits adverse effects (side effect, toxic effect, allergic reaction) such as urticaria, rash, wheezing.
   - *Always* notify health care provider and pharmacy when patient exhibits adverse effects.
   - Withhold further doses and add allergy information to patient's medical record.
2. Patient refuses medication.
   - Explore reasons why patient does not want medication.
   - Educate if misunderstandings of medication therapy are apparent.
   - Do not force patient to take medication; patients have the right to refuse treatment. If patient continues to refuse medication despite educational attempts, record why the drug was withheld on his or her chart and notify health care provider.

RECORDING AND REPORTING

- Chart medication dose, route, and time and date given on MAR immediately after administering.
- Record the reason that any drug is withheld and follow agency policy for proper recording.
- Record and report evaluation of medication effect to health care provider if required (e.g., report urine output following administration of diuretic if ordered by health care provider).
- Document your evaluation of patient and family learning.

HOME CARE CONSIDERATIONS

- Instruct patients and family caregivers about all aspects of medication administration, including dosage, desired effect, when to take medications, proper storage of medications, anticipated side effects, and whether to take medication with or without food, to ensure safe medication administration at home.
- Evaluate patient's ability to safely self-administer medications. If unable to safely self-administer, attempt nursing interventions such as a chart or pillbox to assist in self-administration. If interventions fail and patient still is unable to administer medications safely, notify the health care provider.

SKILL 32-2	ADMINISTERING OPHTHALMIC MEDICATIONS

DELEGATION CONSIDERATIONS

The skill of administering ophthalmic medications cannot be delegated to nursing assistive personnel (NAP). Instruct NAP about:

- Potential side effects of medications and to report their occurrence, including the potential for visual changes.

EQUIPMENT

- Medication bottle with sterile eyedropper, ointment tube, or medicated intra-ocular disk
- Cotton ball or tissue
- Wash basin filled with warm water and washcloth (if eyes have crust or drainage)
- Eye patch and tape (optional)
- Clean gloves
- Medication administration record (MAR) (electronic or printed)

STEP	RATIONALE

ASSESSMENT

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name, medication name and dosage (e.g., number of drops [if a liquid] and eye [right, left, or both eyes]), and route and time of administration. Recopy or reprint any part of MAR that is difficult to read.

The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives correct medications (Mandrack et al., 2012; Sulosaari et al., 2011). Illegible MARs are a source of medication errors (Alassaad et al, 2013).

2. Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.

Allows you to anticipate effects of drug and observe patient's response.

3. Assess condition of external eye structures (see Chapter 31). (You may also do this just before medication administration.)

Provides baseline to later determine if local response to medication occurs. Also indicates need to clean eye before medication application.

4. Assess patient's medical history, history of allergies (including latex), and medication history. If patient has latex allergy, use nonlatex gloves.

Factors in history influence how certain drugs act. Protects patient from risk of allergic medication response.

5. Determine whether patient has any symptoms of visual alterations.

Certain eye medications act to either lessen or increase these symptoms. Provides baseline assessment for recognizing change in patient's condition.

6. Assess patient's level of consciousness and ability to follow directions.

If patient becomes restless or combative during procedure, a greater risk of accidental eye injury exists.

7. Assess patient's knowledge regarding medication therapy and desire to self-administer medication.

Patient's level of understanding determines need for health teaching. Motivation influences teaching approach.

8. Assess patient's ability to manipulate and hold equipment necessary for eye medication (e.g., dropper, ointment tube).

Reflects patient's ability to learn to self-administer medication.

PLANNING

1. Collect appropriate equipment and MAR.

Enhances time management and efficiency.

2. Plan preparation to avoid interruptions. Do not take phone calls. Follow agency policy.

Interruption contributes to medication errors. Use no-interruption zone (NIZ) when possible (Prakash et al., 2014; Yoder et al., 2015).

IMPLEMENTATION

1. Perform hand hygiene and prepare medication (see Skill 32-1, Steps 1a-g). Preparation usually involves taking eyedrops out of refrigerator and rewarming to room temperature before administering to patient. Check expiration date on container. Be sure to check the label 2 times while preparing medication.

Hand hygiene reduces transmission of microorganisms. Warming eyedrops reduces eye irritation. Ensures that patient receives correct medication. Following medication policies and preparing medications in the same way every time helps to prevent medication errors (Murphy and While, 2012). *This is the first and second accuracy check.*

2. Take medications to patient at correct time (see agency policy). Medications that require exact timing include STAT, first-time, loading, and 1-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (within 30 minutes before or after scheduled dose). Give non–time-critical scheduled medications within a range of either 1 or 2 hours of scheduled does (ISMP, 2011). Apply the six rights of medication administration throughout medication administration. Perform hand hygiene.

Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for timing of medication administration that considers patient needs, prescribed medication, and specific clinical indications (CMS, 2011; ISMP, 2011). Time-critical scheduled medications are medications in which early or delayed administration of maintenance doses of more than 30 minutes before or after the scheduled dose may cause harm or result in suboptimal therapy or pharmacological effect. Non–time-critical medications are medications in which early or delayed administration of 1-2 hours should not cause harm or result in suboptimal therapy or pharmacological effects (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.

3. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).

4. Compare names of medications on labels with MAR at patient's bedside.

Third check for accuracy ensures that right medication is administered.

STEP	RATIONALE
5. Explain procedure to patient; describe positioning and sensations to expect such as burning or eye irritation. Discuss purpose, action, and possible adverse effects of each medication. Ask if patient has any questions.	Patient has right to be informed. Questions may reveal potentially incorrect medication orders. Relieves anxiety about medication being instilled into eye.
6. Arrange supplies at bedside; apply clean gloves.	Ensures organized procedure and reduces transmission of microorganisms.
7. Gently roll eyedrop container between your hands.	Ensures that medication is mixed before administration. Shaking bottle causes bubbles, which makes medication administration difficult.
8. Ask patient to lie supine or sit back in chair with head slightly hyperextended.	Position provides easy access to eye for medication instillation and minimizes drainage of medication through tear duct.

CLINICAL DECISION: *Do not hyperextend the neck of a patient with cervical spine injury.*

STEP	RATIONALE
9. If crusting or drainage is present along eyelid margins or inner canthus, gently wash away. Soak any crusts that are dried and difficult to remove by applying damp washcloth or cotton ball over eye for a few minutes. Always wipe clean from inner to outer canthus.	Crusts or drainage harbors microorganisms. Soaking allows easy removal and prevents pressure from being applied directly over eye. Cleaning from inner to outer canthus avoids entrance of microorganism into lacrimal duct.
10. Hold cotton ball or clean tissue in nondominant hand on patient's cheekbone just below lower eyelid.	Cotton or tissue absorbs medication that escapes eye.
11. With tissue or cotton resting below lower lid, gently press downward with thumb or forefinger against bony orbit.	Technique exposes lower conjunctival sac. Retraction against bony orbit prevents pressure and trauma to eyeball and fingers from touching eye.
12. Ask patient to look at ceiling.	Action retracts sensitive cornea up and away from conjunctival sac and reduces stimulation of blink reflex.
13. Instill ophthalmic drops:	
a. With dominant hand resting on patient's forehead, hold filled medication eyedropper or ophthalmic solution approximately 1 to 2 cm ($\frac{1}{2}$ to $\frac{3}{4}$ inches) above conjunctival sac (see illustration).	Helps prevent accidental contact of eyedropper with eye structures, thus reducing risk of injury to eye and transfer of infection to dropper. Ophthalmic medications are sterile.
b. Drop prescribed number of medication drops into conjunctival sac.	Conjunctival sac normally holds 1 or 2 drops. Provides even distribution of medication across eye.
c. If patient blinks or closes eye or if drops land on outer lid margins, repeat instillation.	Patient obtains therapeutic effect of drug only when drops enter conjunctival sac.
d. After instilling drops, ask patient to close eye gently.	Helps to distribute medication. Squinting or squeezing of eyelids forces medication from conjunctival sac (ASHP, 2013).
e. When administering medications that cause systemic effects, apply gentle pressure with your finger and clean tissue on patient's nasolacrimal duct for 30 to 60 seconds.	Prevents overflow of medication into nasal and pharyngeal passages. Prevents absorption into systemic circulation (ASHP, 2013).
f. If patient receives more than one eye medication to the same eye at the same time, wait at least 5 minutes before administering next medication and use a different cotton ball or tissue with each medication.	Avoids interaction between medications (ASHP, 2013).
14. Instill ophthalmic ointment:	
a. Holding ointment applicator above lower lid margin, apply thin stream of ointment evenly along inner edge of lower eyelid on conjunctiva (see illustration) from inner canthus to outer canthus.	Distributes medication evenly across eye and lid margin.
b. Have patient close eye and rub lid lightly in circular motion with cotton ball if rubbing is not contraindicated.	Distributes medication evenly across eye and lid margin.

STEP 13a Hold eyedropper above conjunctival sac.

STEP 14a Apply ointment along lower eyelid.

SKILL 32-2	ADMINISTERING OPHTHALMIC MEDICATIONS—cont'd

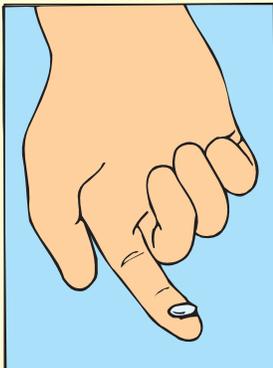
STEP	RATIONALE
15. Administer intraocular disk:	
a. Open package containing disk. Gently press fingertip against disk so it adheres to finger. Position convex side of disk on fingertip (see illustration).	Allows you to inspect disk for damage or deformity.
b. With other hand gently pull patient's lower eyelid away from eye. Ask patient to look up.	Prepares conjunctival sac for receiving medicated disk.
c. Place disk in conjunctival sac so it floats on sclera between iris and lower eyelid (see illustration).	Ensures delivery of medication (Guzman-Aranguez et al., 2013).
d. Pull patient's lower eyelid out and over disk (see illustration). You should not be able to see disk at this time. Repeat Step 15 if you can see disk.	Ensures accurate medication delivery.
16. Removal of intraocular disk:	
a. Perform hand hygiene and apply clean gloves.	Prevents transfer of microorganisms.
b. Explain procedure to patient.	Relieves anxiety about manipulation of disk in eye.
c. Gently pull on patient's lower eyelid with nondominant hand.	Exposes intraocular disk.
d. Using forefinger and thumb of opposite hand, pinch disk, and lift it out of patient's eye (see illustration).	
17. If excess medication is on eyelid, gently wipe it from inner to outer canthus.	Promotes comfort and prevents trauma to eye (ASHP, 2013).
18. If patient had eye patch, apply clean one by placing it over affected eye so entire eye is covered. Tape securely without applying pressure to eye.	Clean eye patch reduces chance of infection.
19. Remove gloves, dispose of soiled supplies in proper receptacle, and perform hand hygiene.	Maintains neat environment at bedside and reduces transmission of microorganisms.

EVALUATION

1. Note patient's immediate response to instillation; ask if patient felt any discomfort.	Determines if procedure performed correctly and safely.
2. Observe response to medication by assessing visual changes and noting any side effects.	Evaluates effects of medication.
3. Use **Teach Back** to determine patient's and family's understanding about eye medications. State, "I want to be sure you understand what I explained about your eyedrops. Can you tell me the name of your eyedrops, why you are taking them, how much to take, and which side effects you might have?" Revise your instruction now or develop plan for revised teaching if patient or family is not able to teach back correctly.	Evaluates what patient and family are able to explain or demonstrate.

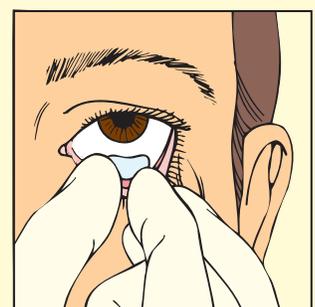
UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Patient cannot instill eyedrops without supervision.
- Reinforce teaching and allow patient to self-administer drops as much as possible to enhance confidence.
- If patient cannot self-administer drops, teach family caregivers to instill them into patient's eye.

2. Patient displays signs of allergic reaction (e.g., tearing, reddened sclera) or systemic response (e.g., bradycardia) to medication.
- Hold medication and speak with health care provider.
- Follow agency policy or guidelines for reporting adverse or allergic reaction to medications.
- Add information about allergy to medical record per agency policy.


STEP 15a Gently position convex side of disk against fingertips.

STEP 15c Place disk in conjunctival sac between iris and lower eyelid.

STEP 15d Gently pull lower eyelid over disk.


STEP 16d Carefully pinch disk to remove it from patient's eye.

RECORDING AND REPORTING

- Record medication, concentration, number of drops, time and date of administration, and eye (left, right, or both) that received medication on MAR.
- Record appearance of eye in nurses' notes.
- Document your evaluation of patient and family learning.

HOME CARE CONSIDERATIONS

- Have patients with chronic health care problems consult with their health care provider before using over-the-counter eye medication.
- When using eyedrops at home, patients should not share medications with other family members because risk of infection transmission is high.

SKILL 32-3	USING METERED-DOSE OR DRY POWDER INHALERS

DELEGATION CONSIDERATIONS

The skill of administering inhaled medications and supervision of patients who self-administer them cannot be delegated to nursing assistive personnel (NAP). Instruct NAP about:

- Potential side effects of medications, changes in patient's respiratory status (e.g., increased coughing, breathing difficulties), and need to report their occurrence.

EQUIPMENT

- Inhaler device with medication canister (metered-dose inhaler [MDI] or dry powder inhaler [DPI])
- Spacer device such as AeroChamber or InspirEase (optional with MDI)
- Facial tissues (optional)
- Wash basin or sink with warm water
- Paper towel
- Medication administration record (MAR) (electronic or printed)
- Stethoscope

STEP	RATIONALE

ASSESSMENT

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name, medication name and dosage (e.g., number of puffs), and route and time for administration. Recopy or reprint any part of MAR that is difficult to read.

   The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives correct medications (Mandrack et al., 2012; Sulosaari et al., 2011). Illegible MARs are a source of medication errors (Alassaad et al, 2013).

2. Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.

   Allows you to anticipate effects of drug and observe patient's response.

3. Assess patient's medical history, history of allergies, and medication history.

   Factors influence how drugs act. Reveals patient's risk for allergic response.

4. Assess patient's respiratory pattern and auscultate breath sounds (Chapter 31).

   Establishes baseline of airway status for comparison during and after treatment.

5. If previously instructed in self-administration, assess patient's ability to use inhaler (e.g., hold, manipulate, and depress canister; strength of inhalation).

   Instruction sometimes requires reinforcement of previous learning. Inability to grasp container, breathe, or coordinate hand movement interferes with patient's ability to use MDI or DPI correctly.

6. Assess patient's readiness and ability to learn: patient asks questions about medication, disease, or complications; requests education in use of inhaler; is mentally alert, not fatigued or in pain, or in respiratory distress; and participates in own care.

   Readiness affects patient's ability to understand explanations and actively participate in instruction. Mental or physical limitations affect patient's ability to learn and methods nurse uses for instruction (Bastable, 2014).

7. Assess patient's knowledge and understanding of disease and purpose and action of prescribed medications.

   Knowledge of disease is essential for patient to realistically understand use of inhaler.

8. Determine medication schedule and number of inhalations prescribed for each dose.

   Influences explanations you provide for inhaler use.

PLANNING

1. Collect appropriate equipment and MAR. Plan preparation to avoid interruptions. Do not take phone calls. Follow agency policy.

   Interruption contributes to medication errors. Use no-interruption zone (NIZ) when possible (Prakash et al., 2014; Yoder et al., 2015).

2. Provide adequate time for teaching session.

   Prevents interruptions and enhances learning (Bastable, 2014).

IMPLEMENTATION

1. Perform hand hygiene and prepare medication (see Skill 32-1, Steps 1a-g). Be sure to compare label of medication with MAR 2 times while preparing the medication.

   Following the same routine when preparing medications, eliminating distractions, and checking the label of the medication with transcribed order reduce error (Murphy and While, 2012). *This is the first and second accuracy check.*

SKILL 32-3	USING METERED-DOSE OR DRY POWDER INHALERS—cont'd

STEP	RATIONALE
2. Take medications to patient at correct time (see agency policy). Medications that require exact timing include STAT, first-time, loading, and 1-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (within 30 minutes before or after scheduled dose). Give non–time-critical scheduled medications within a range of either 1 or 2 hours of scheduled doses (ISMP, 2011). Apply the six rights of medication administration throughout medication administration. Perform hand hygiene.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for the timing of medication administration that considers patient needs, prescribed medication, and specific clinical indications (CMS, 2011; ISMP, 2011). Time-critical scheduled medications are medications in which early or delayed administration of maintenance doses of more than 30 minutes before or after the scheduled dose may cause harm or result in suboptimal therapy or pharmacological effect. Non–time-critical medications are medications in which early or delayed administration of 1-2 hours should not cause harm or result in suboptimal therapy or pharmacological effects (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.
3. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).
4. Compare names of medications on labels with MAR at patient's bedside.	*This is the third accuracy check.*
5. Instruct patient in comfortable environment by sitting in chair in hospital room or at kitchen table in home.	Patient is more likely to remain receptive of your explanations if in a comfortable environment (Bastable, 2014).
6. Allow patient opportunity to manipulate inhaler, canister, and spacer device. Explain and demonstrate how canister fits into inhaler.	Patient needs to be familiar with how to use equipment.

CLINICAL DECISION: *If patient is using an MDI with or without a spacer and the inhaler is new or has not been used for several days, push a "test spray" into the air. You do not need to do this for a DPI.*

STEP	RATIONALE
7. Explain what metered dose is and warn patient about overuse of inhaler, including medication side effects.	Excessive inhalations increase risk of serious side effects. When patient takes medication in recommended doses, side effects are rare.
8. Explain steps for administering squeeze-and-breathe MDI without spacer (demonstrate steps when possible):	Use of simple, step-by-step explanations allows patient to ask questions at any point during procedure (Bastable, 2014).
a. Insert MDI canister into the holder.	
b. Remove mouthpiece cover from inhaler.	

CLINICAL DECISION: *Clean dirt or foreign objects from mouthpiece before using inhaler to avoid inhalation of unwanted material.*

STEP	RATIONALE
c. Shake inhaler vigorously 5 or 6 times. Hold inhaler upright in dominant hand.	Ensures that fine particles are aerosolized.
d. Have patient sit up or stand and take a deep breath and exhale.	Empties lungs and prepares patient's airway to receive medication.
e. Instruct patient to position inhaler in one of two ways.	Proper positioning of inhaler is essential to administering medication correctly.
(1) Close mouth around mouthpiece with opening toward back of throat (see illustration) and lips held tight around it.	Position directs aerosol toward airways.
(2) Alternative technique for using MDI: Position mouthpiece 2 to 4 cm (1 to 2 inches) in front of mouth (see illustration).	
f. With inhaler properly positioned, have patient readjust hold and have thumb at mouthpiece and index and middle fingers at top. This is called a three-point or lateral hand position.	Holding MDI with a three-point or lateral hand position helps patient activate canister effectively.

STEP 8e(1) Patient opens lips and places inhaler in mouth with opening toward back of throat.

STEP 8e(2) Patient positions mouthpiece 1 to 2 inches away from mouth.

STEP	RATIONALE
g. Instruct patient to tilt head back slightly and inhale slowly and deeply through mouth for 3 to 5 seconds while depressing canister fully.	Distributes medication to airways during inhalation. Inhalation through mouth rather than nose draws medication more effectively into airways.
h. Have patient hold breath for about 10 seconds.	Allows tiny drops of aerosol spray to reach deeper branches of airways (MayoClinic.com, 2015b).
i. Remove MDI from mouth and exhale through pursed lips.	Keeps small airways open during exhalation.
9. Explain steps to administer MDI using a spacer such as an Aerochamber (demonstrate when possible):	Use of simple, step-by-step explanations allows patient to ask questions at any point during instruction (Bastable, 2014).
a. Insert canister into holder. Remove mouthpiece cover from MDI and mouthpiece of spacer. Inspect spacer for foreign objects and ensure that valve is intact if spacer has one.	Inhaler fits into end of spacer.
b. Shake MDI inhaler vigorously 5 or 6 times.	Ensures that fine particles are aerosolized.
c. Insert MDI into end of spacer.	Spacer traps medication released from MDI; patient then inhales drug from device. These devices break up and slow down medication particles, increasing amount of medication that goes into patient's lungs (MayoClinic.com, 2015a).
d. Instruct patient to place spacer mouthpiece into mouth and close lips. Do not insert beyond raised lip on mouthpiece. Avoid covering small exhalation slots with lips (see illustration).	Medication should not escape through mouth.
e. Have patient breathe in and exhale completely and then breathe normally through spacer mouthpiece.	Empties lungs and prepares for medication.
f. Have patient depress medication canister, spraying one puff into spacer.	Emits spray that allows finer particles to be inhaled. Large droplets are retained in spacer.
g. Instruct patient to inhale deeply and slowly through mouth for 3 to 5 seconds.	Maximizes amount of medication that enters lung.
h. Have patient hold breath for 10 seconds.	Ensures full medication distribution.
i. Remove MDI and spacer before exhaling.	Allows patient to exhale normally.
10. Explain steps to administer DPI or breath-activated MDI (demonstrate when possible):	
a. Remove cover from mouthpiece. Do not shake inhaler.	
b. Prepare medication as directed by manufacturer (e.g., hold inhaler upright and turn wheel to right and then to left until click is heard; load medication pellet).	Primes inhaler, ensuring that medication is delivered to patient (MayoClinic.com, 2015c).
c. Exhale away from inhaler before inhalation.	Prevents loss of powder.
d. Position mouthpiece between lips (see illustration).	Prevents medication from escaping through mouth.
e. Inhale deeply and forcefully through mouth.	Creates aerosol.
f. Hold breath for 5 to 10 seconds.	Ensures full medication distribution.
11. Instruct patient to wait at least 20 to 30 seconds between inhalations of the same medication and 2 to 5 minutes between inhalations of different medications or as ordered by health care provider.	Medications must be inhaled sequentially. Always give bronchodilators before steroids. First inhalation opens airways. Second or third inhalation reduces inflammation and/or penetrates deeper airways.

CLINICAL DECISION: *If patient uses a corticosteroid, have him or her rinse mouth out with water or salt water or brush teeth after inhalation to reduce risk of fungal infection. Also teach patient to inspect oral cavity daily for redness, sores, or white patches. Report abnormal assessment findings to the patient's health care provider (MayoClinic.com, 2015d).*

STEP 9d Have patient place mouthpiece in mouth and close lips, being careful to keep exhalation slots exposed.

STEP 10d Have patient place mouthpiece of dry powdered inhaler between lips.

SKILL 32-3	USING METERED-DOSE OR DRY POWDER INHALERS—cont'd

STEP	RATIONALE
12. Instruct patient against repeating inhalations before next scheduled dose.	Medications are prescribed at intervals during day to provide constant drug levels and minimize side effects.
13. Explain that patient may feel gagging sensation in throat caused by droplets of medication on pharynx or tongue. Approximately 2 minutes after dose have patient rinse mouth out with warm water.	Results when inhalant is sprayed and inhaled incorrectly.
14. Instruct patient how to clean inhaler:	
a. Once a day remove canister from inhaler. Inhaler and cap need to be rinsed in warm running water. Inhaler needs to be completely dry before using.	Accumulation of spray around mouthpiece interferes with proper distribution during use.
b. Twice a week wash the L-shaped plastic mouthpiece with mild dishwashing soap and warm water. Rinse and dry well before putting canister back inside mouthpiece.	Removes residual medication. Do not place inhalers holding cromolyn, nedocromil, or hydrofluoroalkanes (HFAs) in water.

EVALUATION

1. Observe patient demonstrate a self-inhalation. Ask if patient has any questions.	Clarifies misconceptions or misunderstanding.
2. Use **Teach Back** to determine patient's and family's understanding about inhaled medications. State, "I want to be sure you understand what I explained about how to use your inhaler. Please describe and show me how to use your inhaler." Revise your instruction now or develop plan for revised teaching if patient or family is not able to teach back correctly.	Evaluates what the patient and family are able to explain or demonstrate.
3. Ask patient or family caregiver to calculate how many days inhaler will last.	Helps patient determine when to reorder prescription.
4. Assess patient's respiratory status: ease of respirations, auscultation of lungs, and use of pulse oximetry (see Chapter 31).	Determines status of breathing pattern and adequacy of ventilation.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Patient develops breathing difficulty and needs a bronchodilator more than every 4 hours.
- Indicates respiratory problems; reassessment of type of medication and delivery methods is needed.
- Notify health care provider if respiratory status does not improve.

2. Patient experiences cardiac dysrhythmias, light-headedness, and/or syncope, especially if receiving beta-adrenergics.
- Withhold all further doses of medication.
- Consult with health care provider.

3. Patient is not able to self-administer medication properly.
- Explore alternative delivery routes or methods of medication administration.

RECORDING AND REPORTING

- Document skills taught and patient's ability to perform them.
- Document your evaluation of patient and family learning.
- Record medication, time and date of administration, route, and number of puffs on the MAR.
- Document patient's response to medication in nurses' notes.
- Report any undesirable effects from medication.

HOME CARE CONSIDERATIONS

- Remind patients to carry their prescribed inhalers to use emergently in case of an acute asthma attack.

SKILL 32-4	PREPARING INJECTIONS FROM VIALS AND AMPULES

DELEGATION CONSIDERATIONS

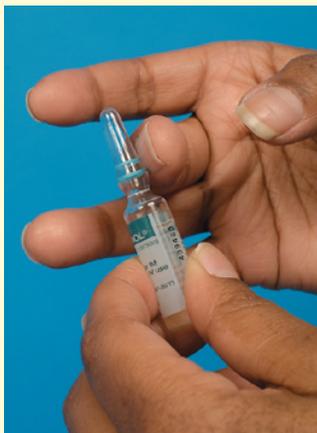
The skill of preparing injections cannot be delegated to nursing assistive personnel (NAP).

EQUIPMENT

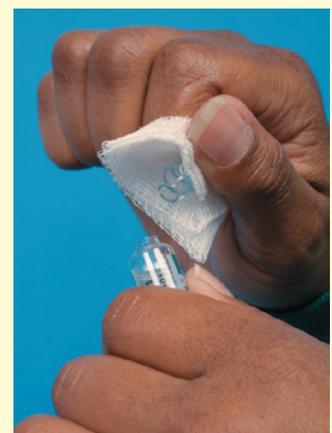
Medication in an ampule
- Safety syringe, needle, and filter needle
- Small, sterile gauze pad or alcohol swab

Medication in a vial
- Safety syringe
- Needles:
  - Needleless blunt tip vial access cannula
  - Filter needle (if indicated)
  - Needle for drawing up medication (if needed)
- Small, sterile gauze pad or alcohol swab
- Diluent (e.g., normal saline or sterile water) (if indicated)

Both
- Medication administration record (MAR) (electronic or printed)
- Medication in vial or ampule
- Puncture-proof container for disposal of syringes, needles, and glass

STEP	RATIONALE
ASSESSMENT	
1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name, medication name and dosage (e.g., number of drops [if a liquid] and eye [right, left, or both eyes]), and route and time of administration. Recopy or reprint any part of MAR that is difficult to read.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives correct medications (Mandrack et al., 2012; Sulosaari et al., 2011). Illegible MARs are a source of medication errors (Alassaad et al, 2013).
2. Review pertinent information related to medication, including action, purpose, dose and route, side effects, and nursing implications.	Medication information is needed to administer medication properly and monitor patient's response.
3. Assess patient's medical history, history of allergies, and medication history.	Knowledge of medical history influences how some medications act. Protects patient from risk for allergic drug response.
4. Assess patient's body build, muscle size, and weight if giving subcutaneous or intramuscular injection.	Determines type and size of syringe and needles for injection.
PLANNING	
1. Collect appropriate equipment and MAR.	Enhances time management and efficiency.
2. Plan preparation to avoid interruptions. Do not take phone calls or talk with others. Follow agency policy.	Interruption contributes to medication errors. Use no-interruption zone (NIZ) when possible (Prakash et al., 2014; Yoder et al., 2015).
IMPLEMENTATION	
1. Perform hand hygiene.	Reduces transmission of microorganisms.
2. Prepare medication (see Skill 32-1, Steps 1a-h). Be sure to check label 2 times while preparing medication. Check expiration date on label to be sure not outdated.	Following the same routine when preparing medications, eliminating distractions, and checking label of medication with transcribed order reduce error (Murphy and While, 2012). *This is the first and second accuracy check.*
a. Ampule preparation	
(1) Tap top of ampule lightly and quickly with finger until fluid moves from neck of ampule (see illustration).	Dislodges any fluid that collects above neck of ampule. All solution moves into lower chamber.
(2) Place small gauze pad or unopened alcohol swab just above neck of ampule (see illustration).	Placing pad around neck of ampule protects your fingers from trauma as glass tip is broken off.
(3) Snap neck of ampule quickly and firmly away from hands (see illustration).	Protects your fingers and face from shattering glass.
(4) Draw up medication quickly, using filter needle long enough to reach bottom of ampule.	System is open to airborne contaminants. Needle needs to be long enough to access medication for preparation. Filter needles filter out any fragments of glass (Alexander et al., 2014).
(5) Hold ampule upside down or set it on flat surface with filter needle in center of ampule opening. Do not allow needle tip or shaft to touch rim of ampule.	Broken rim of ampule is considered contaminated. When ampule is inverted, solution comes out if needle tip or shaft touches rim of ampule.
(6) Aspirate medication into syringe by gently pulling back on plunger (see illustrations).	Withdrawal of plunger creates negative pressure within syringe barrel, which pulls fluid into syringe.


STEP 2a(1) Tapping ampule moves fluid down neck.

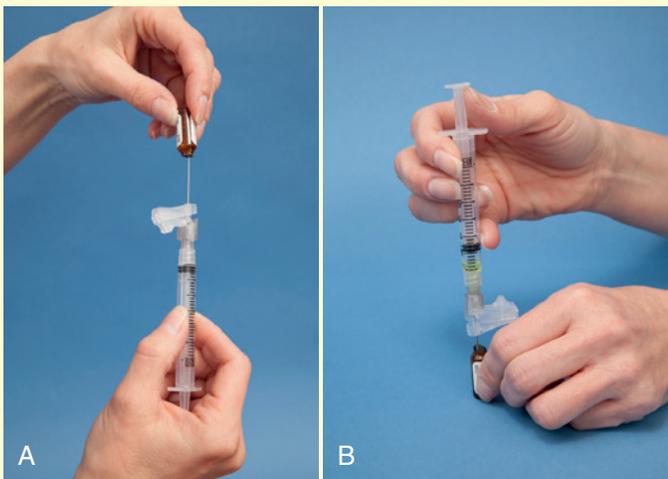
STEP 2a(2) Gauze pad placed just above neck of ampule.


STEP 2a(3) Snapping neck away from hands.

SKILL 32-4	PREPARING INJECTIONS FROM VIALS AND AMPULES—cont'd

STEP	RATIONALE
(7) Keep needle tip under surface of liquid. Tip ampule to bring all fluid within reach of needle.	Prevents aspiration of air bubbles.
(8) If air bubbles are aspirated, do not expel air into ampule.	Air pressure forces liquid out of ampule, and medication is lost.
(9) To expel excess air bubbles, remove needle from ampule. Hold syringe with needle pointing up. Tap side of syringe to cause bubbles to rise toward needle. Draw back slightly on plunger and push plunger upward to eject air. Do not eject fluid.	Withdrawing plunger too far removes it from barrel. Holding syringe vertically allows fluid to settle in bottom of barrel. Pulling back on plunger allows fluid within needle to enter barrel so it is not expelled. Air at top of barrel and within needle is then expelled.
(10) If syringe contains excess fluid, use sink or other specially designated area for medication disposal. Hold syringe vertically with needle tip up and slanted slightly toward sink. Slowly eject excess fluid into sink. Recheck fluid level in syringe by holding it vertically.	Medication dose prepared accurately. Position of needle allows medication to be expelled without flowing down needle shaft. Rechecking fluid level ensures proper dose.
(11) Cover needle with its safety sheath or scoop needle to recap. Replace filter needle with safety needle or needleless access device for injection.	Prevents contamination of needle. Filter needles cannot be used for injection. Scooping technique prevents needlestick injury.
b. Vial containing a solution	
(1) Remove cap covering top of unused vial to expose sterile rubber seal, keeping rubber seal sterile. If a multi-dose vial has been used before, cap is already removed. Firmly and briskly wipe surface of rubber seal with alcohol swab and allow it to dry.	Vial comes packaged with seal that cannot be replaced after cap removal. Not all drug manufacturers guarantee that caps of unused vials are sterile. Therefore swab seals with alcohol before preparing medication. Allowing alcohol to dry prevents needle from being coated with alcohol and mixing with medication.
(2) Pick up syringe and remove needle cap or cap covering needleless vial access device (see illustration). Pull back on plunger to draw amount of air into syringe equal to volume of medication to be aspirated from vial.	Inject air first into vial to prevent buildup of negative pressure in vial when aspirating medication.

CLINICAL DECISION: *Some medications and agencies require use of a filter needle when preparing medications from a vial. See agency policy (Alexander et al., 2014). If you use a filter needle to aspirate the medication, you need to change it to a regular needle of suitable size to administer the medication.*

(3) With vial on flat surface, insert tip of needle with beveled tip entering first or needleless access device through center of rubber seal (see illustration). Apply pressure to tip of needle during insertion.	Center of seal is thinner and easier to penetrate. Injecting beveled tip first and using firm pressure prevent coring of rubber seal, which could enter vial or needle.
(4) Inject air into air space of vial, holding on to plunger. Hold plunger with firm pressure; air pressure within vial sometimes forces plunger backward.	Injecting air before aspirating fluid creates vacuum needed to get medication to flow into syringe. Injecting into air space of vial prevents formation of bubbles and inaccuracy in dose.
(5) Invert vial while keeping firm hold on syringe and plunger (see illustration). Hold vial between thumb and middle fingers of nondominant hand. Grasp end of syringe barrel and plunger with thumb and forefinger of dominant hand to counteract pressure in vial.	Inverting vial allows fluid to settle in lower half of container. Position of hands prevents forceful movement of plunger and permits easy manipulation of syringe.
(6) Keep tip of needle below fluid level.	Prevents aspiration of air.


STEP 2a(6) A, Medication aspirated with ampule inverted.
B, Medication aspirated with ampule on flat surface.

STEP 2b(2) Syringe with needleless adapter.

STEP	RATIONALE

(7) Allow air pressure from vial to fill syringe gradually with medication. If necessary, pull back slightly on plunger to obtain correct amount of solution.

Positive pressure within vial forces fluid into syringe.

(8) When desired volume is obtained, position needle into air space of vial; tap side of syringe barrel carefully to dislodge any air bubbles. Eject any air remaining at top of syringe into vial.

Forcefully striking barrel while needle is inserted in vial bends needle. Accumulation of air displaces medication and causes dose errors.

(9) Remove needle or needleless vial access device from vial by pulling back on barrel of syringe.

Accidentally pulling plunger rather than barrel causes plunger to separate from barrel, resulting in loss of medication.

(10) Hold syringe at eye level at 90-degree angle to ensure correct volume and absence of air bubbles. Remove any remaining air by tapping barrel to dislodge air bubbles (see illustration). Draw back slightly on plunger; push plunger upward to eject air. Do not eject fluid. Recheck volume of medication.

Holding syringe vertically allows fluid to settle in bottom of barrel. Pulling back on plunger allows fluid within needle to enter barrel so it is not expelled. Air at top of barrel and within needle is then expelled.

(11) If medication will be injected into patient's tissue, change needle to appropriate gauge and length according to route of medication.

Inserting needle through rubber stopper dulls beveled tip. New needle is sharper. Because no fluid is along shaft, needle does not track medication through tissues.

(12) For multi-dose vial make label that includes date of mixing, concentration of medication per milliliter, and your initials.

Ensures that future doses will be prepared correctly. Some medications need to be discarded a certain number of days after mixing of vial.

c. Vial containing a powder (reconstituting medications)

(1) Remove cap covering vial of powdered medication and cap covering vial of proper diluent. Firmly swab both seals with alcohol swab and allow to dry.

Not all drug manufacturers guarantee that caps of unused vials are sterile. Therefore seals must be swabbed with alcohol before preparing medication. Allowing alcohol to dry prevents needle from being coated with alcohol and mixing with medication.

(2) Draw up diluent into syringe following Steps 2b(2)-(10).

Prepares diluent for injection into vial containing powdered medication.

(3) Insert tip of safety needle or needleless access device through center of rubber seal of vial of powdered medication. Inject diluent into vial. Remove needle.

Diluent begins to dissolve and reconstitute medication.

(4) Mix medication thoroughly. Roll in palms. Do not shake.

Ensures proper dispersal of medication throughout solution. Shaking produces bubbles.

(5) Reconstituted medication in vial is ready to be drawn into new syringe. Read label carefully to determine dose after reconstitution.

Once diluent is added, concentration of medication (mg/mL) determines dose to be given. Read medication label carefully to avoid medication errors.

(6) Draw up reconstituted medication in syringe following Steps 2b(2)-(12).

CLINICAL DECISION: *Some agencies require prepared parenteral medications to be verified for accuracy by another nurse. Check policies before administering medication.*

---

3. Compare label of medication with MAR for final time at patient's bedside before administering medication.

This is the third accuracy check.

4. Return unused multi-dose medication vial to shelf, drawer, or refrigerator.

5. Dispose of soiled supplies. Place broken ampule and/or used vials and used needle in puncture-proof, leak-proof container. Clean work area and perform hand hygiene.

Proper disposal of glass and needle prevents accidental injury to staff. Controls transmission of infection.

STEP 2b(3) Insert safety needle through center of vial diaphragm (with vial flat on table).

STEP 2b(5) Withdraw fluid with vial inverted.

STEP 2b(10) Hold syringe upright; tap barrel to dislodge air bubbles.

SKILL 32-4	PREPARING INJECTIONS FROM VIALS AND AMPULES—cont'd

STEP	RATIONALE

EVALUATION

1. Compare dose in syringe with desired dose.

Determines that dose is accurate.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Air bubbles remain in syringe.
- Expel air from syringe and add medication to syringe until correct dose is prepared.

2. Incorrect dose is prepared.
- Discard prepared dose and prepare corrected new dose.

SKILL 32-5	ADMINISTERING INJECTIONS

DELEGATION CONSIDERATIONS

The skill of administering injections cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP about:

- Potential medication side effects and the need to report their occurrence along with any changes in patient's vital signs or level of consciousness (e.g., sedation).

EQUIPMENT

- Proper-size safety syringe and sharps with engineered sharps injury protection (SESIP) needle:
  - *Subcutaneous:* Syringe (1 to 3 mL) and needle (25- to 27-gauge, ⅜- to ⅝-inch)
  - *Immunizations:* ⅝-inch, 23- to 25-gauge needle (CDC, 2015)
  - *Subcutaneous U-100 insulin:* Insulin syringe (1 mL) with preattached needle (28- to 31-gauge, ⁵⁄₁₆- to ½-inch)
  - *Subcutaneous U-500 insulin:* 1-mL tuberculin syringe with needle (25- to 27-gauge, ½- to ⅝-inch)
  - *Intramuscular (IM):* Syringe 2 to 3 mL for adult, 0.5 to 1 mL for infants and small children
  - Needle length corresponds to site of injection, age, and size of patient. Refer to guidelines below; length needed may vary outside of these guidelines for patients who are smaller or larger than average.
  - Needle length for immunizations (see below)—based on CDC (2015) guidelines
  - Needle gauge often depends on length of needle. Administer most biologicals and medications in aqueous solutions with 20- to 25-gauge needle. Use 18- to 21-gauge needles for medications in oil-based solutions.
  - *Intradermal (ID):* 1-mL tuberculin syringe with needle (25- to 27-gauge, ½- to ⅝-inch)
  - Small gauze pad
  - Antiseptic swab
  - Vial or ampule of medication or skin test solution
  - Clean gloves
  - Medication administration record (MAR) (electronic or printed)
  - Puncture-proof container

NEEDLE LENGTH FOR SITE AND AGES

SITE	CHILD	ADULT
Ventrogluteal	½- to 1-inch	1½-inch
Vastus lateralis	⅝- to 1-inch	⅝- to 1-inch
Deltoid	½- to 1-inch	1- to 1½-inch

NEEDLE LENGTH FOR IMMUNIZATIONS

GENDER—MALE	GENDER—FEMALE	NEEDLE LENGTH
Less than 130 lbs	Less than 130 lbs	⅝-1-inch
130-152 lbs	130-152 lbs	1-inch
153-260 lbs	153-200 lbs	1-1.5-inches
260+ lbs	200+ lbs	1.5-inches

STEP	RATIONALE

ASSESSMENT

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name, medication name and dosage, and route and time of administration. Recopy or reprint any part of printed MAR that is difficult to read.

The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives correct medications (Mandrack et al., 2012; Sulosaari et al., 2011). Illegible MARs are a source of medication errors (Alassaad et al., 2013).

STEP	RATIONALE
2. Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, nursing implications.	Allows you to anticipate effects of drug and observe patient's response.
3. Assess patient's medical and medication history and history of allergies. Know his or her normal response to an allergy. Assess patient symptoms or condition for which medication has been prescribed.	Reveals need for medication. Allows for early identification of patient risk for allergic response. May require different medication prescription. Do not administer medication to which patient is allergic. Provides baseline for determining patient's drug response.
4. Observe verbal and nonverbal responses toward receiving injection.	Injections are often painful. Some patients have anxiety, which increases pain.
5. Assess for contraindications.	
a. For subcutaneous injections	
(1) Assess for factors such as circulatory shock or reduced local tissue perfusion. Assess adequacy of patient's adipose tissue.	Reduced tissue perfusion interferes with medication absorption and distribution. Physiological changes of aging or patient illness often influence amount of subcutaneous tissue that patient possesses.
b. For IM injections	
(1) Assess for factors such as muscle atrophy, reduced blood flow, or circulatory shock.	Atrophied muscle absorbs medication poorly. Factors interfering with blood flow to muscles impair medication absorption.
6. Assess patient symptoms or condition for which medication has been prescribed.	Provides baseline to determine response to therapy.

CLINICAL DECISION: *Because of documented adverse effects of intramuscular (IM) injections, other routes of medication administration are safer. Verify that IM injection is necessary and explore alternative medication routes if possible (Nicoll and Hesby, 2002; World Health Organization [WHO], 2015).*

STEP	RATIONALE
7. Assess patient's knowledge about medication.	Determines if there is a need for patient education.

PLANNING

STEP	RATIONALE
1. Collect appropriate equipment and MAR.	Enhances time management and efficiency.
2. Plan preparation to avoid interruptions. Do not take phone calls or talk with others. Follow agency policy.	Interruption contributes to medication errors. Use no-interruption zone (NIZ) when possible (Prakash et al., 2014; Yoder et al., 2015).

IMPLEMENTATION

STEP	RATIONALE
1. Perform hand hygiene. Aseptically prepare correct medication dose from ampule or vial (see Skill 32-4). Check label of medication with MAR 2 times while preparing medication.	Ensures that medication is sterile. Following the same routine when preparing medications, eliminating distractions, and checking label of medication with transcribed order reduce error (Murphy and While, 2012). *This is the first and second accuracy check.*
2. Take medications to patient at correct time (see agency policy). Medications that require exact timing include STAT, first-time, loading, and 1-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (within 30 minutes before or after scheduled dose). Give non–time critical scheduled medications within a range of either 1 or 2 hours of scheduled doses (ISMP, 2011). Apply the six rights of medication administration throughout medication administration. Perform hand hygiene.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for the timing of medication administration that considers patient needs, prescribed medication, and specific clinical indications (CMS, 2011; ISMP, 2011). Time-critical scheduled medications are medications in which early or delayed administration of maintenance doses of more than 30 minutes before or after the scheduled dose may cause harm or result in suboptimal therapy or pharmacological effect. Non–time-critical medications are medications in which early or delayed administration of 1-2 hours should not cause harm or result in suboptimal therapy or pharmacological effects (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.
3. Close room curtain or door.	Provides privacy.
4. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).
5. Compare name of medication on label with MAR one more time at patient's bedside.	*This is the third accuracy check.*
6. Explain steps of procedure and tell patient that injection will cause slight burning or sting.	Helps minimize patient's anxiety.
7. Apply clean gloves. NOTE: If patient has latex allergy, use latex-free gloves.	Reduces transfer of microorganisms.
8. Keep sheet or gown draped over body parts not requiring exposure.	Respects dignity of patient while area to be injected is exposed.
9. Select appropriate injection site. Inspect skin surface over sites for bruises, inflammation, or edema.	Injection sites need to be free of abnormalities that interfere with medication absorption. Sites used repeatedly become hardened from lipohypertrophy (increased growth in fatty tissue). Do not use an area that is bruised or has signs associated with infection.

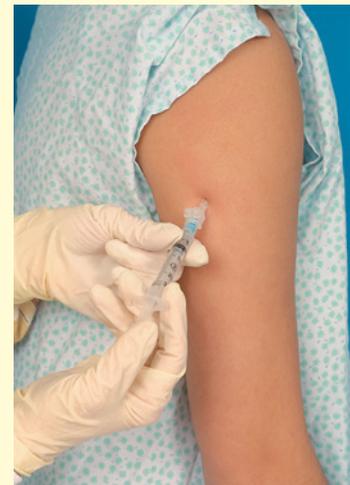
SKILL 32-5	ADMINISTERING INJECTIONS—cont'd

STEP	RATIONALE
a. Subcutaneous: Palpate sites for masses or tenderness. Avoid these areas. For daily insulin, rotate site within anatomical area. Be sure that needle is correct size by grasping skinfold at site with thumb and forefinger. Measure fold from top to bottom. Needle should be one-half length.	Subcutaneous injections are sometimes mistakenly given in muscle, especially in abdomen and thigh sites. Appropriate size of needle and angle of injection ensures that medication is injected in subcutaneous tissue (Hirsch et al., 2012; Hoffman et al., 2010).
b. IM: Note integrity and size of muscle and palpate for tenderness or hardness. Avoid these areas. If injections are given frequently, rotate sites. Use ventrogluteal site if possible.	Ventrogluteal site is preferred site for adults. This site is also preferred for children who are receiving viscous or irritating solutions (Hockenberry and Wilson, 2015; Nicoll and Hesby, 2002; Ogston-Tuck, 2014).
c. Intradermal (ID): Note lesions or discolorations of skin. If possible, select site three to four finger widths below antecubital space and a hand width above wrist. If you cannot use forearm, inspect upper back. If necessary, use sites for subcutaneous injections.	An ID site needs to be clear so you can see results of skin test and interpret them correctly (CDC, 2014a).
10. Help patient to comfortable position:	
a. Subcutaneous: Have patient relax arm, leg, or abdomen, depending on site chosen for injection.	Relaxation of site minimizes discomfort.
b. IM: Position patient depending on site chosen (e.g., sit or lie flat, on side, or prone).	Reduces strain on muscle and minimizes discomfort of injections.
c. ID: Have patient extend elbow and support it and forearm on flat surface.	Stabilizes injection site for easiest accessibility.
d. Have patient talk about subject of interest. Ask open-ended questions.	Distraction reduces anxiety.

CLINICAL DECISION: *Ensure that patient's position is not contraindicated by medical condition.*

STEP	RATIONALE
11. Relocate site using anatomical landmarks.	Injection into correct anatomical site prevents injury to nerves, bones, and blood vessels.
12. Clean site with an antiseptic swab. Apply swab at center of site and rotate outward in circular direction for approximately 5 cm (2 inches) (see illustration).	Mechanical action of swab removes secretions containing microorganisms.
13. Hold swab or gauze between third and fourth fingers of nondominant hand.	Gauze or swab remains readily accessible when needle is withdrawn.
14. Remove needle cap or sheath from needle by pulling it straight off.	Preventing needle from touching sides of cap prevents contamination.
15. Hold syringe between thumb and forefinger of dominant hand.	
a. Subcutaneous: Hold as dart, palm up (see illustration).	Quick, smooth injection requires proper manipulation of syringe parts.
b. IM: Hold as dart, palm down.	
c. ID: Hold bevel of needle pointing up.	With bevel up, medication is less likely to be deposited into tissues below dermis.
16. Administer injection:	
a. Subcutaneous	
(1) For average-size patient, pinch skin with nondominant hand.	Pinching skin elevates subcutaneous tissue and desensitizes area.
(2) Inject needle quickly and firmly at 45- to 90-degree angle. Release skin. Option: Continue to pinch skin and release after injecting medications.	Quick, firm insertion minimizes discomfort. (Injecting medication into compressed tissue irritates nerve fibers.) Correct angle prevents accidental injection into muscle.
(3) For obese patient pinch skin at site and inject needle at 90-degree angle below tissue fold.	Obese patients have fatty layer of tissue above subcutaneous layer.

STEP 12 Clean site with circular motion.

STEP 15a Hold syringe as if grasping a dart.


STEP 16a(4) Inject medication slowly.

STEP	RATIONALE

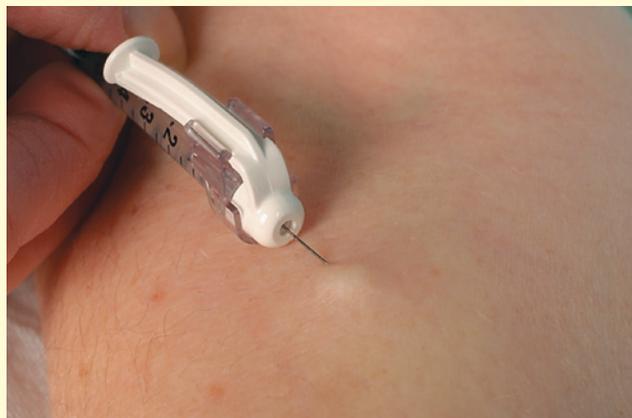
CLINICAL DECISION: *Piercing a blood vessel during a subcutaneous injection is very rare. Therefore aspiration is not necessary when administering subcutaneous injections (Lilley et al., 2011).*

(4) Inject medication slowly (see illustration).	Minimizes discomfort.
b. Intramuscular	
(1) Position ulnar aspect of your nondominant hand just below site and pull skin approximately 2.5 to 3.5 cm (1 to 1.5 inches) down or laterally to administer in a Z-track. Hold position until medication is injected (see Figure 32-22). With dominant hand inject needle quickly at 90-degree angle into muscle.	Z-track creates zigzag path through tissues that seals needle track to avoid tracking of medication. Use Z-track for all IM injections (Hopkins and Arias, 2013; Nicoll and Hesby, 2002; Ogston-Tuck, 2014). A quick, dartlike injection reduces discomfort.
(2) Option: If patient's muscle mass is small, grasp body of muscle between thumb and fingers.	Ensures that medication reaches muscle mass (Hockenberry and Wilson, 2015).

CLINICAL DECISION: *When giving immunizations to adults: to avoid injection into subcutaneous tissue, spread the skin of the selected vaccine administration site taut between the thumb and forefinger, isolating the muscle (CDC, 2015).*

(3) Insert needle into muscle with smooth, steady motion. After needle pierces skin, grasp lower end of syringe barrel with nondominant hand to stabilize syringe. Continue to hold skin tightly with nondominant hand. Move dominant hand to end of plunger. Do not move syringe.	Smooth, steady motion reduces pain at moment of injection. Smooth manipulation of syringe reduces discomfort from needle movement. Skin needs to remain pulled until after injecting medication to ensure Z-track administration.
(4) Pull back on plunger 5 to 10 seconds. If no blood appears, inject medicine slowly, at rate of 1 mL/10 seconds. **NOTE:** Do not aspirate if administering immunizations (CDC, 2015).	This time is necessary to ensure that needle is not in low-flow blood vessel (Nicoll and Hesby, 2002). Aspiration of blood into syringe indicates intravenous (IV) placement of needle. Slow injection rate reduces pain and tissue trauma and the chance of leakage of medication back through needle track (Hockenberry and Wilson, 2015; Nicoll and Hesby, 2002). The CDC (2015) no longer recommends aspiration when administering an immunization.

CLINICAL DECISION: *If blood appears in syringe, remove needle and dispose of medication and syringe properly. Prepare another dose of medication for injection.*

(5) Wait 10 seconds. Then smoothly and steadily withdraw needle and release skin.	Allows for medication to absorb into muscle before removing syringe rather than leaking back out through track that needle created (Hopkins and Arias, 2013; Nicoll and Hesby, 2002).
c. Intradermal	
(1) With nondominant hand stretch skin over site with forefinger or thumb.	Needle pierces tight skin more easily.
(2) With needle almost against patient's skin, insert it slowly with bevel up at 5- to 15-degree angle until resistance is felt. Advance it through epidermis to approximately 3 mm ($\frac{1}{8}$ inch) below skin surface. You will see needle tip through skin.	Ensures that needle tip is in dermis. You obtain inaccurate results if you do not inject needle at correct angle and depth (CDC, 2014b).
(3) Inject medication slowly. Normally you feel resistance. If not, needle is too deep; remove and begin again. Nondominant hand can stabilize needle during the injection.	Slow injection minimizes discomfort at site. Dermal layer is tight and does not expand easily when solution is injected. Stabilizing needle prevents unnecessary movements and decreases patient discomfort.
(4) While injecting medication, notice that small bleb approximately 6 mm ($\frac{1}{4}$ inch) in diameter (resembling mosquito bite) appears on surface of skin (see illustration). Instruct patient that this is normal finding.	Bleb indicates that medication is deposited in dermis.


STEP 16c(4) Injection creates small bleb.

SKILL 32-5	ADMINISTERING INJECTIONS—cont'd

STEP	RATIONALE
17. Withdraw needle while applying alcohol swab or gauze gently over site.	Support of tissue around injection site minimizes discomfort during needle withdrawal. Dry gauze minimizes patient discomfort associated with alcohol on nonintact skin.
18. Apply gentle pressure. Do not massage site. Apply bandage if needed.	Massage causes underlying tissue damage. Massaging ID site disperses medication into underlying tissue layers and alters test results.
19. Help patient to comfortable position.	Gives patient sense of well-being.
20. Discard uncapped needle or needle enclosed in safety shield and attached syringe into puncture-proof, leak-proof receptacle.	Prevents injury to patient and health care personnel. Recapping needles increases risk of needlestick injury (OSHA, n.d.).
21. Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.
22. Stay with patient and observe for any allergic reactions.	Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction, which is life-threatening emergency.

EVALUATION

1. Return to room and ask if patient feels any acute pain, burning, numbness, or tingling at injection site.	Continued discomfort often indicates injury to underlying bones or nerves.
2. Inspect site, noting any bruising or induration. Document bruising or induration if present. Notify health care provider and provide warm compress to site.	Bruising or induration indicates complication associated with injection.
3. Observe patient's response to medication at times that correlate with onset, peak, and duration of medication.	IM medications are absorbed rapidly. Adverse effects of parenteral medications develop rapidly. Nurse's observations determine efficacy of medication action.
4. Use **Teach Back** to determine patient's and family's understanding about injections. State, "I want to be sure you understand what I explained about your injection. Can you explain why you need this injection and the side effects to watch for and report to me if they occur?" Revise your instruction now or develop plan for revised teaching if patient is not able to teach back correctly.	Evaluates what patient and family are able to explain or demonstrate.
5. For ID injections: Use skin pencil and draw circle around perimeter of injection site. Read site within appropriate amount of time, designated by type of medication or skin test administered.	Pencil mark makes site easy to find. Results of skin testing are read at various times on the basis of type of medication used or type of skin testing completed. Refer to manufacturer directions to determine when to read results of test.

> **CLINICAL DECISION:** *Read tuberculin test at 48 to 72 hours. Induration (hard, dense, raised area) of skin around injection site indicates positive reaction, as follows:*
> - *15 mm or more in patients with no known risk factors for tuberculosis (TB)*
> - *10 mm or more in patients who are recent immigrants; injection drug users; residents and employees of high-risk settings; mycobacteriology laboratory personnel; patients with clinical conditions placing them at high risk; children less than 4 years of age; and infants, children, and adolescents exposed to high-risk adults*
> - *5 mm or more in patients who are human immunodeficiency virus (HIV) positive, have fibrotic changes on chest x-ray film consistent with previous TB infection, have had organ transplants, or are immunosuppressed (CDC, 2014b)*

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Raised, reddened, or hard zone (induration) forms around an ID test site.
- Notify patient's health care provider.
- Document sensitivity to injected allergen or positive test if tuberculin skin testing was completed.

2. Hypertrophy of skin develops from repeated subcutaneous injections.
- Do not use this site for future injections.
- Instruct patient not to use site for 6 months.

3. Patient develops signs and symptoms of allergy or side effects.
- Follow agency policy or guidelines for appropriate response to adverse drug reactions.
- Notify patient's health care provider immediately.
- Add allergy information to patient's medical record.

4. Patient complains of localized pain, numbness, tingling, or burning at injection site, indicating possible injury to nerve or tissues.
- Assess injection site.
- Document findings.
- Notify patient's health care provider.

RECORDING AND REPORTING

- Chart medication dose, route, site, and time and date given on MAR immediately after giving medication per agency policy.
- Document if scheduled medication is withheld and record the reason per agency policy.
- Report any undesirable effects from medication to health care provider.
- Record patient's response to medications in nurses' notes and report to health care provider if required.
- Document immunizations in patient's permanent record, including date of administration, vaccine manufacturer and lot number, expiration date, name and title of the person who administered the vaccine and the address of the agency where the permanent record will reside, vaccine information statement (VIS) and date printed on the VIS, and date VIS given to patient or parent/guardian (CDC, 2015).
- Document your evaluation of patient and family learning.

HOME CARE CONSIDERATIONS

- Assess patient's readiness to learn before instructing in self-injections. Some patients are hesitant to self-administer injections; thus relieve anxiety before teaching this skill.
- Some patients prefer to reuse their syringes to save costs. This practice is safe and practical if the needle is not contaminated during the preparation and administration of the injection. Teach patients to recap needles immediately after use.
- Patients can often purchase or obtain sharps boxes for home use. If this is not possible, they can use a hard plastic bottle that they cannot see through (e.g., a fabric softener bottle or detergent bottle) to safely store syringes after use. Disposal of needles used in the home varies among communities. Check with local authorities to verify how to dispose of needles.

SKILL 32-6	ADMINISTERING MEDICATIONS BY INTRAVENOUS BOLUS

DELEGATION CONSIDERATIONS

The skill of administering medications by intravenous (IV) bolus cannot be delegated to nursing assistive personnel (NAP). Inform NAP about:
- Potential side effects of medications and need to report their occurrence.
- The need to report discomfort at infusion site as soon as possible.
- When to obtain required vital signs and report these findings to the nurse.

EQUIPMENT
- Watch with second hand
- Clean gloves
- Antiseptic swab
- Medication in vial or ampule
- Proper-size syringes for medication and saline flush with needleless device or sharps with engineered sharps injury protection (SESIP) needle (21- to 25-gauge)
- Intravenous lock: Vial of normal saline flush solution (recommended [Alexander et al., 2014]); if agency continues to use heparin flush, most common concentration is 10 units/mL; see agency policy)
- Medication administration record (MAR) (electronic or printed)
- Puncture-proof container

STEP	RATIONALE

ASSESSMENT

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name, medication name and dosage, and route and time of administration. Recopy or reprint any part of printed MAR that is difficult to read.

The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives correct medications (Mandrack et al., 2012; Sulosaari et al., 2011). Illegible MARs are a source of medication errors (Alassaad et al., 2013).

CLINICAL DECISION: *Some IV medications can only be pushed safely when a patient is being monitored continuously for dysrhythmias, blood pressure changes, or other adverse effects. Therefore some medications can only be pushed in specific areas within a health care agency. See agency policy for special monitoring requirements before giving medication (Burchum and Rosenthal, 2016).*

2. Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, how slowly to give medication, compatibility with IV fluids, and nursing implications.

Allows you to give medication safely and monitor patient's response to therapy (Burchum and Rosenthal, 2016). Prevents incompatible drug reaction.

3. If pushing medication into an existing IV line, determine compatibility of medication with IV fluids and any additives within IV solution.

IV medications are not always compatible with IV solution and/or additives.

4. Perform hand hygiene. Assess IV or saline lock insertion site for signs of infiltration or phlebitis (see Chapter 42).

Confirming placement of IV catheter and integrity of surrounding tissue ensures that medication is administered safely. Do not administer medication if site is inflamed or edematous.

5. Check patient's medical history, medication history, and history of drug or latex allergies. Assess patient symptoms or condition for which medication has been prescribed.

Knowledge of medical history influences how some medications act. IV bolus delivers medication rapidly. Allergic reactions can be fatal. Provides baseline for determining patient's drug response.

6. Assess patient's understanding of purpose of medication therapy.

Reveals need for patient education.

SKILL 32-6	ADMINISTERING MEDICATIONS BY INTRAVENOUS BOLUS—cont'd

STEP	RATIONALE

PLANNING

1. Collect appropriate equipment and MAR.	Enhances time management and efficiency.

> **CLINICAL DECISION:** *Some IV medications require dilution before administration. Verify with agency policy. If a small amount of medication is given (e.g., less than 1 mL), dilute medication in 5 to 10 mL of normal saline or sterile water so medication does not collect in "dead spaces" (e.g., Y-site injection port, IV cap) of the IV delivery system. Verify that medication can be diluted by consulting medication reference or checking with pharmacist first.*

2. Plan preparation to avoid interruptions. Do not take phone calls or talk with others. Follow agency policy.	Interruption contributes to medication errors. Use no-interruption zone (NIZ) when possible (Prakash et al., 2014; Yoder et al., 2015).

IMPLEMENTATION

1. Perform hand hygiene. Prepare ordered medication from vial or ampule using aseptic technique (see Skill 32-4). Check label of medication carefully with MAR 2 times.	Ensures that medication is sterile. Following the same routine when preparing medications, eliminating distractions, and checking label of medication with transcribed order reduce error (Murphy and While, 2012). *This is the first and second accuracy check.*
2. Take medications to patient at correct time (see agency policy). Medications that require exact timing include STAT, first-time, loading, and 1-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (within 30 minutes before or after scheduled dose). Give non–time-critical scheduled medications within a range of either 1 or 2 hours of scheduled dose (ISMP, 2011). Apply the six rights of medication administration throughout medication administration. Perform hand hygiene.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for the timing of medication administration that considers patient needs, prescribed medication, and specific clinical indications (CMS, 2011; ISMP, 2011). Time-critical scheduled medications are medications in which early or delayed administration of maintenance doses of more than 30 minutes before or after the scheduled dose may cause harm or result in suboptimal therapy or pharmacological effect. Non–time-critical medications are medications in which early or delayed administration of 1-2 hours should not cause harm or result in suboptimal therapy or pharmacological effects (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.
3. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).
4. Compare names of medications on labels with MAR one more time at patient's bedside.	*Third check for accuracy* ensures that right medication is administered.
5. Explain procedure to patient. Encourage patient to report symptoms of discomfort at IV site. Provide instruction on purpose and action of medication and possible side effects.	Keeps patient informed and ensures patient-centered care. Helps identify possible infiltration early.
6. Apply clean gloves. NOTE: If patient has latex allergy, use latex-free gloves.	Reduces transmission of microorganisms. During IV bolus administration there is risk of blood exposure.
7. IV push (existing line):	
a. Select injection port of IV tubing closest to patient. Whenever possible, injection port should accept a needleless syringe. Use IV filter if required by medication reference or agency policy.	Follows provisions of Needle Safety and Prevention Act of 2001 (OSHA, n.d.).

> **CLINICAL DECISION:** *Never administer IV medications through tubing that is infusing blood, blood products, or parenteral nutrition solutions.*

b. Clean injection port with antiseptic swab. Allow to dry.	Prevents introduction of microorganisms during needle insertion. Drying enhances effects of antiseptic.
c. Connect syringe to port of IV line. Insert needleless tip or small-gauge needle of syringe containing prepared drug through center of injection port (see illustration).	Prevents damage to diaphragm of port and subsequent leakage.
d. Occlude IV line by pinching tubing just above injection port (see illustration). Pull back gently on syringe plunger to aspirate blood return.	Final check that medication is being delivered into bloodstream.

> **CLINICAL DECISION:** *In some cases, especially with a smaller-gauge IV needle, blood return is not aspirated, even if IV is patent. If IV site shows no signs of infiltration and IV fluid is infusing without difficulty, proceed with IV push slowly.*

e. Release tubing and inject medication within amount of time recommended by agency policy, pharmacist, or medication reference manual. Use watch to time administration (see illustration). You can pinch IV line while pushing medication and release when not pushing it. Allow IV fluids to infuse when not pushing medication.	Ensures safe medication infusion. Rapid injection of IV medication can be fatal (Burchum and Rosenthal, 2016). Allowing IV fluids to infuse while pushing IV drug enables medications to be delivered to patient at prescribed rate.

STEP	RATIONALE

CLINICAL DECISION: *When IV medication is incompatible with IV fluids, stop the IV fluids, clamp the IV line above the injection site, flush with 10 mL of normal saline or sterile water, give the IV bolus over the appropriate amount of time, flush with another 10 mL of normal saline or sterile water at the same rate as the medication was administered, and restart the IV fluids at the prescribed rate. If IV line that is currently hanging contains a medication (e.g., ranitidine), disconnect it and administer IV push as outlined in Step 8 to avoid giving a sudden bolus of the medication in existing IV line. Some IV medications and fluids cannot be stopped. Verify agency policy regarding temporarily stopping IV fluids or continuous IV medications. If unable to stop IV infusion, start a new IV site (see Chapter 42) and administer medication using the IV lock method.*

f. After injecting medication, release tubing, withdraw syringe, and recheck fluid infusion rate.	Injection of bolus alters rate of fluid infusion. Rapid fluid infusion causes circulatory overload.
8. IV push (IV lock):	
a. Prepare two syringes with 2 to 3 mL of normal saline (0.9%) in syringe.	

CLINICAL DECISION: *Current evidence reflects that saline flushes are effective in maintaining patency of IV lines and do not carry risk of thrombocytopenia associated with heparin flushes.*

STEP 7c Connecting syringe to IV line with blunt needleless cannula tip.

STEP 7d Occluding IV tubing above injection port.

STEP 7e Using watch to time IV push medication.

SKILL 32-6	ADMINISTERING MEDICATIONS BY INTRAVENOUS BOLUS—cont'd

STEP	RATIONALE
b. Administer medication:	
(1) Clean injection port of lock with antiseptic swab. Allow to dry.	Prevents introduction of microorganisms during needle insertion. Drying enhances effects of antiseptic.
(2) Insert syringe containing normal saline (0.9%) into injection port of IV lock (see illustration).	
(3) Pull back gently on syringe plunger and look for blood return.	Determines whether IV needle or catheter is positioned in vein.

CLINICAL DECISION: *At times a blood return is not aspirated even though lock is patent. If IV site does not show signs of infiltration and flushes without difficulty, proceed with IV push.*

(4) Flush IV lock with normal saline by pushing slowly on plunger.	Clears IV lock of blood.

CLINICAL DECISION: *Observe area of skin above IV catheter closely. Note any puffiness or swelling as IV lock is flushed, which indicates infiltration into vein, requiring removal of catheter.*

(5) Remove saline flush syringe.	
(6) Clean injection port of lock with antiseptic swab.	Prevents transmission of infection.
(7) Insert syringe containing prepared medication into injection port of IV lock.	
(8) Inject medication within amount of time recommended by agency policy, pharmacist, or medication reference manual. Use watch to time administration.	Rapid injection of IV medication can result in death. Following guidelines for IV push rates promotes patient safety (Burchum and Rosenthal, 2016).
(9) After administering bolus, withdraw syringe.	
(10) Clean injection port of lock with antiseptic swab.	Prevents transmission of microorganisms.
(11) Flush injection port by attaching syringe with normal saline. Inject normal saline flush at same rate medication was delivered.	Irrigation with saline prevents occlusion of IV access device and ensures that all medication is delivered. Flushing IV site at same rate as medication ensures that any medication remaining within IV needle is delivered at correct rate.
9. Dispose of uncapped needles and syringes in puncture-proof, leak-proof container.	Reduces accidental needlesticks (OSHA, n.d.).
10. Remove and dispose of gloves. Perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1. Observe patient closely for adverse reaction as drug is administered and for several minutes thereafter.	IV medications act rapidly.
2. Observe IV site during injection for sudden swelling.	Swelling indicates infiltration into tissues surrounding vein.
3. Assess patient's status after giving medication to evaluate its effectiveness.	IV bolus medications often cause rapid changes in patient's physiological status. Some medications require careful monitoring and possibly laboratory testing (e.g., vasopressors require monitoring of blood pressure and heart rate).
4. Use **Teach Back** to determine patient's and family's understanding about intravenous medications. State, "I want to be sure you understand what I explained about your intravenous medicine. Can you explain why you need to take this medicine and side effects that you need to watch for and let me know if they occur?" Revise your instruction now or develop plan for revised teaching if patient or family is not able to teach back correctly.	Evaluates what patient and family are able to explain or demonstrate.

STEP 8b(2) **A,** IV catheter with saline lock adapter. **B,** Syringe inserted into injection port.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Patient develops adverse reaction to medication.
   - Stop delivering medication immediately, be sure that IV continues to infuse, and follow agency policy or guidelines for appropriate response and reporting of adverse drug reactions.
   - Add allergy information to patient's medical record.
2. IV site shows symptoms of infiltration or phlebitis (see Chapter 42).
   - Stop infusing medication.
   - Treat IV site as indicated by agency policy.
   - Insert new IV site if continuing IV therapy.
3. Patient is unable to explain medication information.
   - Patient requires reinstruction or is unable to learn at this time.

RECORDING AND REPORTING

- Record medication, dose, time and date, and route of administration.
- Report any adverse reactions immediately to health care provider. Patient's response may indicate need for additional medical therapy.
- Record patient's response to medication in nurses' notes.
- Document your evaluation of patient and family learning.

SKILL 32-7	ADMINISTERING INTRAVENOUS MEDICATIONS BY PIGGYBACK, INTERMITTENT INTRAVENOUS INFUSION SETS, AND SYRINGE PUMPS

DELEGATION CONSIDERATIONS

The skill of administering intravenous (IV) medications by piggyback, intermittent IV infusion sets, and syringe pumps cannot be delegated to nursing assistive personnel (NAP). Instruct NAP about:
- Potential side effects of medications and need to report their occurrence to the nurse immediately.
- Reporting patient's verbalization of discomfort at infusion site.
- Reporting changes in patient's condition or vital signs.

EQUIPMENT
- Adhesive tape (optional)
- Antiseptic swab
- IV pole
- Medication administration record (MAR) (electronic or printed)
- Clean gloves
- Piggyback or mini-infusion pump
  - Medication prepared in 5- to 250-mL labeled infusion bag or syringe
  - Prefilled syringe containing normal saline flush solution (for saline lock)
  - Short microdrip, macrodrip, or mini-infusion IV tubing set, with blunt-end needleless cannula attachment
  - Needleless access device
  - Mini-infusion pump if needed
- Volume-control administration set
  - Buretrol
  - Infusion tubing with blunt-end needleless cannula attachment
  - Syringe (1- to 20-mL)
  - Vial or ampule of ordered medication

STEP	RATIONALE

ASSESSMENT

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name, medication name and dosage, and route and time of administration. Recopy or reprint any part of printed MAR that is difficult to read.

2. Review patient's medical history, medication history, and history of allergies. Assess patient symptoms or condition for which medication has been prescribed.

3. Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, compatibility with existing IV fluids, and nursing implications.

4. Assess patency of patient's existing IV infusion line by noting infusion rate of main IV line (see Chapter 42).

The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives correct medications (Mandrack et al., 2012; Sulosaari et al., 2011). Illegible MARs are a source of medication errors (Alassaad et al., 2013).

Helps you anticipate therapeutic effect of medication. IV bolus delivers medication rapidly. Allergic reactions can be fatal. Provides baseline to determine patient's response to medication.

Allows you to give medication safely and monitor patient's response to therapy.

IV line must be patent, and fluids need to infuse easily for medication to reach venous circulation effectively.

SKILL 32-7	ADMINISTERING INTRAVENOUS MEDICATIONS BY PIGGYBACK, INTERMITTENT INTRAVENOUS INFUSION SETS, AND SYRINGE PUMPS—cont'd

STEP	RATIONALE

CLINICAL DECISION: *If the patient's IV site is saline locked, clean the port with alcohol and assess the patency of the IV line by flushing it with 2 to 3 mL of sterile normal saline. Attach appropriate IV tubing to the saline lock and administer the medication via piggyback, tandem, mini-infusion, or volume-control administration set. When the infusion is completed, disconnect the tubing, clean the port with alcohol, and flush the IV line with 2 to 3 mL of sterile normal saline. Maintain sterility of IV tubing between intermittent infusions.*

STEP	RATIONALE
5. Perform hand hygiene. Assess IV insertion site for signs of infiltration or phlebitis: redness, pallor, swelling, and tenderness on palpation.	Confirmation of placement of IV needle or catheter and integrity of surrounding tissues ensures safe medication administration.
6. Assess patient's understanding of purpose of medication therapy.	Reveals need for education.

PLANNING

STEP	RATIONALE
1. Collect appropriate equipment and MAR.	Enhances time management and efficiency.
2. Plan preparation to avoid interruptions. Do not take phone calls or speak with others. Follow agency policy.	Interruption contributes to medication errors. Use no-interruption zone (NIZ) when possible (Prakash et al., 2014; Yoder et al., 2015).

IMPLEMENTATION

STEP	RATIONALE
1. Perform hand hygiene. Prepare medication from ampule or vial (see Skill 32-4). Be sure to compare label of medication with MAR 2 times while preparing the medication.	Ensures that medication is sterile. Following the same routine when preparing medications, eliminating distractions, and checking label of medication with transcribed order reduce error (Murphy and While, 2012). *This is the first and second accuracy check.*
2. Take medications to patient at correct time (see agency policy). Medications that require exact timing include STAT, first-time, loading, and 1-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (within 30 minutes before or after scheduled dose). Give non–time-critical scheduled medications within a range of either 1 or 2 hours of scheduled doses (ISMP, 2011). Apply the six rights of medication administration throughout medication administration. Perform hand hygiene.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for the timing of medication administration that considers patient needs, prescribed medication, and specific clinical indications (CMS, 2011; ISMP, 2011). Time-critical scheduled medications are medications in which early or delayed administration of maintenance doses of more than 30 minutes before or after the scheduled dose may cause harm or result in suboptimal therapy or pharmacological effect. Non–time-critical medications are medications in which early or delayed administration of 1-2 hours should not cause harm or result in suboptimal therapy or pharmacological effects (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.
3. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).
4. Explain purpose of medication and side effects to patient. Explain that you will give medication through existing IV line. Encourage patient to report symptoms of discomfort at site immediately.	Keeps patient informed of planned therapies, minimizing anxiety. Patients who verbalize pain at IV site help detect infiltrations early.
5. Compare names of medications on labels with MAR one more time at patient's bedside.	*This is the third accuracy check.*
6. Apply clean gloves. NOTE: If patient has latex allergy, use latex-free gloves.	Reduces transmission of microorganisms. During IV administration there is a risk of blood exposure.
7. Administer medications. a. Piggyback infusion	

CLINICAL DECISION: *Never administer IV medications through tubing that is infusing blood, blood products, or parenteral nutrition solutions.*

STEP	RATIONALE
(1) Connect infusion tubing to medication bag (see Chapter 42). Allow solution to fill tubing by opening regulator flow clamp. Once tubing is full, close clamp and cap end of tubing.	Infusion tubing needs to be filled with solution and free of air bubbles to prevent air embolus. Capping keeps line sterile.
(2) Hang piggyback medication bag above level of primary fluid bag (use hook to lower main bag) (see Figure 32-25).	Height of fluid bag affects rate of flow to patient.
(3) Wipe off needleless port of main IV line with antiseptic swab and allow to air dry. Connect tubing of piggyback infusion to appropriate connector on upper Y-port of primary infusion line: (a) Needleless system: Remove cap and insert cannula tip of piggyback infusion tubing to appropriate connector on primary infusion line (see illustration).	Use needleless connections to prevent accidental needlestick injuries (OSHA, n.d.). Establishes route for IV medication to enter main IV line.

STEP	RATIONALE

(b) Saline (IV) lock: Follow Steps 8a(1)-8b(5) in Skill 32-6 to flush and prepare lock. Then wipe off port of lock with antiseptic swab and allow to dry. Remove cap and insert tip of infusion tubing via needless access to port of saline lock. Ensure that end of IV tubing system is sterile. Change tubing if it is not sterile.

Flushing lock ensures patency; IV fluids and medications must be administered aseptically.

(4) Regulate flow rate of medication solution by adjusting regulator clamp or IV pump infusion rate (see Chapter 42). Infusion times vary. Refer to medication reference or agency policy for safe flow rate.

Provides slow, intermittent infusion of medication and maintains therapeutic blood levels.

(5) After medication has infused:

(a) Continuous infusion: Check flow rate of primary infusion. Primary infusion automatically begins to flow after piggyback solution is empty.

Back-check valve on piggyback stops flow of primary infusion until second medication infuses. Checking flow rate ensures proper administration of IV fluids.

(b) Saline lock: Disconnect tubing and apply cap. Cleanse port with antiseptic swab, let dry and flush IV line with 2-3 mL of sterile 0.9% sodium chloride. Maintain sterility of IV tubing between intermittent infusions.

Helps to ensure that lock remains patent.

(6) Regulate main infusion line to desired rate if necessary.

Infusion of piggyback sometimes interferes with main-line infusion rate.

(7) Leave IV piggyback bag and tubing in place for future medication administration or discard in appropriate containers.

Establishment of secondary line produces route for microorganisms to enter main line. Repeated changes in tubing increase risk of infection transmission (see agency policy).

b. Mini-infusion administration

(1) Connect prefilled syringe to mini-infusion tubing.

Special tubing designed to fit syringe delivers medication to main IV line.

(2) Carefully apply pressure to syringe plunger, allowing tubing to fill with medication.

Ensures that tubing is free of air bubbles to prevent air embolus.

(3) Place syringe into mini-infusion pump (follow product directions). Be sure that syringe is secured (see illustration).

(4) Wipe off needleless port of IV tubing with antiseptic swab and allow to dry. Connect mini-infusion tubing to main IV following Step 7a(3)(a or b).

(5) Hang infusion pump with syringe on IV pole alongside main IV bag. Set pump to deliver medication within time recommended by agency policy, pharmacist, or medication reference manual. Use alarm if medication is delivered into heparin/saline lock. Press button on pump to begin infusion.

Pump automatically delivers medication at safe, constant rate on basis of volume in syringe.

STEP 7a(3)(a) For needleless system insert tip of piggyback infusion tubing into port.

STEP 7b(3) Ensure that syringe is secure after placing it into syringe pump.

SKILL 32-7	ADMINISTERING INTRAVENOUS MEDICATIONS BY PIGGYBACK, INTERMITTENT INTRAVENOUS INFUSION SETS, AND SYRINGE PUMPS—cont'd

STEP	RATIONALE
(6) After medication has infused, check flow rate on primary infusion or re-establish saline lock following Steps 7a(5)(a or b).	Maintains patency of primary IV line.
c. Volume-control administration set (e.g., Buretrol)	
(1) Fill Buretrol with desired amount of fluid (50 to 100 mL) by opening clamp between Buretrol and main IV bag (see illustrations).	Small volume of fluid dilutes IV medication and reduces risk of too-rapid infusion.
(2) Close clamp and check to be sure that clamp on air vent of Buretrol chamber is open.	Prevents additional leakage of fluid into Buretrol. Air vent allows fluid in Buretrol to exit at regulated rate.
(3) Clean injection port on top of Buretrol with antiseptic swab and allow to dry.	Prevents introduction of microorganisms during needle insertion.
(4) Remove needle cap or sheath, insert syringe needle through port, and inject medication (see illustrations). Gently rotate Buretrol between hands.	Rotating mixes medication with solution in Buretrol to ensure equal distribution.
(5) If Buretrol tubing is not already connected to patient's IV site, connect it to patient's saline lock following Step 7a(3)(b).	
(6) Regulate IV infusion rate to allow medication to infuse in time recommended by agency policy, pharmacist, or medication reference manual.	For optimal therapeutic effect, medication needs to infuse in prescribed time interval.
(7) Label Buretrol with name of medication, dosage, and total volume, including diluent and time of administration following ISMP (2015b) safe medication label format (see Figure 32-26).	Alerts nurses to medication being infused. Prevents other medications from being added to Buretrol.
(8) After medication has infused, check flow rate on primary infusion or re-establish saline lock following Steps 7a(5)(a or b).	Ensures appropriate fluid balance and maintains IV site.
(9) Dispose of uncapped needle or needle enclosed in safety shield and syringe in proper container.	Prevents accidental needlesticks (OSHA, n.d.).
(10) Discard supplies in appropriate container and perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1. Assess patient's status after administering medication.	Evaluates effect of medication.
2. Observe patient for signs of adverse reactions.	IV medications act rapidly.
3. During infusion periodically check infusion rate and condition of IV site.	IV line needs to remain patent for proper medication administration. Development of infiltration necessitates discontinuing infusion.

STEP 7c(1) Filling volume-control administration device.

STEP 7c(4) **A,** Medication injected into device. **B,** Prepared device.

STEP	RATIONALE
4. Use **Teach Back** to determine patient's and family's understanding about intravenous piggyback medications. State, "I want to be sure you understand what I explained about your IV piggyback medicine. Can you explain why you need to take this IV medicine and any side effects you need to watch for and let me know if they occur?" Revise your instruction now or develop plan for revised teaching if patient or family is not able to teach back correctly.	Evaluates what the patient and family are able to explain or demonstrate.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Patient develops adverse drug reaction.
   - Stop medication infusion immediately. Be sure that main IV line is infusing.
   - Follow agency policy or guidelines for appropriate response and reporting of adverse drug reactions.
   - Document allergy in patient's medical record.
2. Medication does not infuse over desired period.
   - Determine reason (e.g., improper calculation of flow rate, malpositioning of IV needle at insertion site, or infiltration).
   - Take corrective action as indicated (see Chapter 42).
3. IV site shows signs of phlebitis or infiltration (see Chapter 42).
   - See related interventions in Skill 32-6.

RECORDING AND REPORTING

- Record medication, dose, route, and time and date administered on MAR.
- Record volume of fluid in medication bag or Buretrol on intake and output form.
- Report adverse reactions to patient's health care provider.
- Document your evaluation of patient and family learning.

HOME CARE CONSIDERATIONS

- Teach patient and family caregiver how to dispose of needles and contaminated equipment in puncture-proof containers (e.g., coffee can).
- Instruct family caregiver about community resources to obtain supplies.

KEY POINTS

- Learning medication classifications improves understanding of nursing implications for administering medications with similar characteristics.
- All controlled substances are handled according to strict procedures that account for each medication.
- A nurse applies understanding of the physiology of medication action when timing administration, selecting routes, initiating actions to promote medication efficacy, and observing responses to medications.
- The older adult's body undergoes structural and functional changes that alter medication actions and influence the manner in which nurses provide medication therapy.
- Verify medication calculations with another nurse to ensure accuracy.
- Medications given parenterally are absorbed more quickly than those administered by other routes.
- Each medication order needs to include the patient's name, order date, medication name, dosage, route, time of administration, drug indication, and health care provider's signature.
- A medication history reveals allergies, medications a patient is taking, and the patient's adherence to therapy.
- The six rights of medication administration contribute to accurate preparation and administration of medication doses.
- The six rights of medication administration are the right medication, right dose, right patient, right route, right time, and right documentation.
- Nurses need to avoid distractions, use NIZs, and follow the same routine when preparing medications to reduce medication errors.
- Nurses administer only medications they prepare, and prepared medications are never left unattended.
- Document medications immediately after administration.
- A nurse uses clinical judgment regarding a patient's clinical status in determining the best time to administer prn medications.
- A nurse reports a medication error immediately.
- When preparing medications, a nurse checks the medication container label against the MAR 3 times.
- The Z-track method for IM injections protects subcutaneous tissues from irritating parenteral fluids.
- Failure to select injection sites by anatomical landmarks leads to tissue, bone, or nerve damage.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Kyle, a nursing student, is caring for Maria, a 48-year-old who is being treated for multiple fractures after a motorcycle accident. Maria's health care provider writes a new medication order for morphine sulfate liquid suspension 20 mg orally STAT and then q4h as needed for pain. Maria is having difficulty swallowing pills as a result of her trauma; thus her medications are ordered in liquid suspension.

1. What does Kyle need to know about morphine sulfate before administering it?
2. Four unit-dose containers of liquid morphine sulfate arrive on the patient care unit. The labels on the medication say: "10 mg morphine sulfate/5 mL." Using dimensional analysis, how much medication should Kyle administer?
3. Kyle collects the appropriate equipment to administer the medication, performs hand hygiene, prepares the medication, takes it to

Maria at the correct time, and uses two patient identifiers to ensure that she is the right patient. Which step does Kyle need to take next in administering the medication?

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

▌ REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. You are a new graduate nurse completing your orientation on a very busy intensive care unit. You cannot read a health care provider's order for one of your patient's medications. You have heard from more experienced nurses that this health care provider does not like to be called, and you know that another of the health care provider's patients is very unstable. What is the most appropriate next step for you to take?
   1. Call the health care provider to clarify the order
   2. Talk with your preceptor to help you interpret the order
   3. Refer to a medication manual before giving the medication
   4. Use your best judgment and critical thinking and administer the dose you think the health care provider ordered

2. A toddler is to receive 2.5 mL of an antipyretic by mouth. Which equipment is the most appropriate for medication administration for this child?
   1. A medication cup
   2. A teaspoon
   3. A 5-mL syringe
   4. An oral-dosing syringe

3. What statement made by a 2-year-old patient's mother indicates that she understands how to administer her son's eardrops?
   1. "To straighten his ear canal, I need to pull the outside part of his ear down and back."
   2. "I need to straighten his ear canal before administering the medication by pulling his ear upward and outward."
   3. "I need to put my son in a chair and make sure that he's sitting up with his head tilted back before I give him the eardrops."
   4. "After I'm done giving him his eardrops, I need to make sure that my son remains sitting straight up for at least 10 minutes."

4. A health care provider ordered enalapril (Vasotec) 2 mg IV push for a patient with hypertension. The pharmacy sent vials marked 1.25 mg enalapril/mL. How many mL does the nurse administer?
   ___ mL

5. A nurse admits a 72-year-old patient with a medical history of hypertension, heart failure, renal failure, and depression to a general medical patient care unit. The nurse reviews the patient's medication orders and notes that the patient has three health care providers who have ordered a total of 13 medications. What is the most appropriate action for the nurse to take next?
   1. Give the medications after identifying the patient using two patient identifiers
   2. Provide medication education to the patient to help with adherence to the medical plan
   3. Review the list of medications with the health care providers to ensure that the patient needs all 13 medications
   4. Set up a medication schedule for the patient that is least disruptive to the expected treatment schedule in the hospital

6. The nurse is administering an intravenous (IV) push medication to a patient who has a compatible IV fluid running through intravenous tubing. Place the following steps in the appropriate order.

1. Release tubing and inject medication within amount of time recommended by agency policy, pharmacist, or medication reference manual. Use watch to time administration.
2. Select injection port of intravenous (IV) tubing closest to patient. Whenever possible, injection port should accept a needleless syringe. Use IV filter if required by medication reference or agency policy.
3. After injecting medication, release tubing, withdraw syringe, and recheck fluid infusion rate.
4. Connect syringe to port of intravenous (IV) line. Insert needleless tip or small-gauge needle of syringe containing prepared drug through center of injection port.
5. Clean injection port with antiseptic swab. Allow to dry.
6. Occlude intravenous (IV) line by pinching tubing just above injection port. Pull back gently on syringe plunger to aspirate blood return.

7. A nursing student is administering ampicillin PO. The expiration date on the medication wrapper was yesterday. What is the appropriate action for the nursing student to take next?
   1. Ask the nursing professor for advice
   2. Return the medication to pharmacy and get another tablet
   3. Call the health care provider after discussing this situation with the charge nurse
   4. Administer the medication since medications are good for 30 days after their expiration date

8. A nursing student is administering medications to a patient through a gastric tube (G-tube). Which of the following actions taken by the nursing student requires the nursing instructor to intervene?
   1. The nursing student places all the patient's medications in different medicine cups.
   2. The nursing student evaluates each medication and holds the tube feeding before administering a medication that needs to be administered on an empty stomach.
   3. The nursing student flushes the tube with 30 mL of water between each medication.
   4. The nursing student crushes a nifedipine extended-release tablet and mixes it with water before administering it.

9. A pediatric nurse takes a medication to a 12-year-old female patient. The patient tells the nurse to take it away because she is not going to take it. What is the nurse's next action?
   1. Ask the patient's reason for refusal
   2. Consult with the patient's parents for advice
   3. Take the medication away and chart the patient's refusal
   4. Tell the patient that her health care provider knows what is best for her

10. A nurse caring for a patient on a general surgical unit notes the following medication order in the patient's medical record:
    3 March 2016 1415 Administer 25 mg hydrochlorothiazide PO BID D. Anderson, MD
    What should the nurse do next?

11. After receiving an intramuscular (IM) injection in the deltoid, a patient states, "My arm really hurts. It's burning and tingling where I got my injection. What should the nurse do next? (Select all that apply.)
    1. Assess the injection site
    2. Administer an oral medication for pain
    3. Notify the patient's health care provider of assessment findings
    4. Document assessment findings and related interventions in the patient's medical record
    5. This is a normal finding so nothing needs to be done
    6. Apply ice to the site for relief of burning pain

12. You are working in a health clinic on a college campus. You need to administer medroxyprogesterone acetate intramuscularly (IM) to a female patient for birth control. You look up this medication in a reference manual and determine that it is viscous and injections can be painful. On the basis of this information, you plan which of the following when administering this medication? (Select all that apply.)
   1. Inject the medication over 3 minutes to reduce pain associated with the injection
   2. Administer the medication in the ventral gluteal site
   3. Use the Z-track method when administering the medication
   4. Use the deltoid site for medication administration
   5. Ask the patient questions about her major and which classes she is taking during the injection to provide distraction
13. After seeing a patient, the health care provider starts to give a nursing student a verbal order for a new medication. The nursing student first needs to:
   1. Follow ISMP guidelines for safe medication abbreviations.
   2. Explain to the health care provider that the order needs to be given to a registered nurse.
   3. Write down the order on the patient's order sheet and read it back to the health care provider.
   4. Ensure that the six rights of medication administration are followed when giving the medication.
14. A nurse accidently gives a patient the medications that were ordered for the patient's roommate. What is the nurse's first priority?
   1. Complete an occurrence report.
   2. Notify the health care provider.
   3. Inform the charge nurse of the error.
   4. Assess the patient for adverse effects.
15. A child is taking albuterol through a pressurized metered-dose inhaler (pMDI) that contains a total of 64 puffs. The dose is 2 puffs every 6 hours. How many days will the pMDI last? _____ days.

Answers: 1. 1; **2.** 4; **3.** 2; **4.** 1.6 mL; **5.** 3; **6.** 2, 5, 4, 6, 1, 3; **7.** 2; **8.** 4; **9.** 1; **10.** See Evolve; **11.** 1, 3, 4; **12.** 2, 3, 5; **13.** 3; **14.** 4; **15.** 8.

Complementary and Alternative Therapies

The general health of North American people has steadily improved over the course of the last century as evidenced by lower mortality rates and increased life expectancies (CDC, 2014). Changes in science and health care have provided the knowledge and technology to successfully alter the course of many illnesses. Despite the success of **allopathic or biomedicine** (conventional western medicine), many conditions such as chronic back and neck pain, arthritis, gastrointestinal problems, allergies, headache, and anxiety continue to be difficult to treat. As a result, more patients are exploring alternative methods to relieve their symptoms. Researchers estimate that up to 75% of patients seek care from their primary care providers for stress, pain, and health conditions for which there are no known causes or cures (Rakel, 2012). Although biomedicine is quite effective in treating numerous physical ailments (e.g., bacterial infections, chronic diseases, structural abnormalities, and acute illnesses/emergencies), it is generally less effective in decreasing stress-induced illnesses, managing symptoms of chronic disease, caring for the emotional and spiritual needs of individuals, and improving quality of life and general well-being.

The number of patients seeking unconventional treatments has risen considerably over the past decade. In part this increase is caused by (1) a desire for less invasive, less toxic, "more natural" treatments; (2) lack of satisfaction with biomedical treatments; (3) an increasing

desire by patients to take a more active role in their treatment process; (4) beliefs that a combination of treatments (biomedical and complementary) results in better overall results; (5) the increased number of research articles in journals such as *Journal of Alternative and Complementary Medicine* and the *Journal of Holistic Nursing;* and (6) beliefs and values that are consistent with an approach to health that incorporates the mind, body, and spirit or a holistic approach (Koithan, 2009).

COMPLEMENTARY, ALTERNATIVE, AND INTEGRATIVE APPROACHES TO HEALTH

The National Institutes of Health/National Center for Complementary and Integrative Health (NIH/NCCIH, 2015a) defines complementary and alternative medicine (CAM) as "an array of health care approaches with a history of use or origins outside of mainstream medicine." **Complementary therapies** are therapies used in addition to or together with conventional treatment recommended by a person's health care provider. As the name implies, complementary therapies complement conventional treatments. Many of them such as therapeutic touch contain diagnostic and therapeutic methods that require special training. Others such as guided imagery and breathwork are easily learned

and applied. Complementary therapies also include relaxation; exercise; massage; reflexology; prayer; biofeedback; hypnotherapy; creative therapies, including art, music, or dance therapy; meditation; **chiropractic therapy**; and herbs/supplements (Lindquist et al., 2014). Another term that is used to describe interventions used in this fashion, particularly by licensed health care providers, is *integrative therapies*.

Alternative therapies sometimes include the same interventions as complementary therapies; but they become the primary treatment (Table 33-1). For example, a person with chronic pain uses yoga to encourage flexibility and relaxation at the same time that nonsteroidal antiinflammatory or opioid medications are prescribed. Both sets of interventions are based on conventional pathophysiology and anatomy while acknowledging the mind-body connection that contributes to the physiological pain response. In this case yoga is used as a complementary intervention. In contrast, another patient decides that a meditative practice that includes yoga and other lifestyle changes is more helpful than an allopathic approach to chronic pain. This patient studies these practices more deeply, adhering to one of the many schools or traditions, and decides to use them as the primary approach to manage chronic pain. In this case yoga is an alternative treatment. Several therapies are always considered alternative because they are based on completely different philosophies and life systems than those used by allopathic medicine. These are identified by the NIH/NCCIH as **whole medical systems** and include practices such as **traditional Chinese medicine (TCM)**, Ayurveda, and naturopathy (see Table 33-1).

Because of the increased interest in complementary therapies, many health care programs, including medical and nursing schools, have integrated conventional "biomedical" education with programs that incorporate complementary and alternative therapy content. Integrative health care practitioners recommend that patients receive a full spectrum of possible treatments, both biomedical and complementary. **Integrative health care** emphasizes the importance of the relationship between practitioner and patient; focuses on the whole person; is informed by evidence; and makes use of appropriate therapeutic approaches, health care professionals, and disciplines to achieve optimal health (Rakel, 2012). In an integrative health care system consumers are treated by a team of providers consisting of both biomedical and complementary practitioners.

Historically nurses have practiced in an integrative fashion; a review of nursing theory (see Chapter 4) reveals the values of holism, relational care, and informed practice. Until recently nursing identified its practice as holistic rather than integrated. Holistic nursing treats the mind-body-spirit of patients, using interventions such as relaxation therapy, music therapy, touch therapies, and guided imagery (Dossey and Keegan, 2012). The American Holistic Nurses Association (AHNA) maintains Standards of Holistic Nursing Practice, which defines and establishes the scope of holistic practice and describes the level of care expected from a holistic nurse (AHNA/ANA, 2013).

In 2014 Kreitzer and Koithan challenged the nursing profession to embrace its long-standing roots of integrative care, standing alongside our physician colleagues to transform the current health care system and offer whole-person care that is patient centered, relationship based, and supported by evidence, incorporating the best of all possible interventions. Grounded in six principles, **integrative nursing** is defined as "a way of being-knowing-doing that advances the health and well-being of people, families, and communities through caring-healing relationships. Integrative nurses use evidence to inform traditional and emerging interventions that support "whole person/whole systems healing" (Kreitzer and Koithan, 2014, p. 4).

Increasing interest in integrative health care is evident in the increased number of publications in respected health care journals and continued support of research and discovery. The mission of the NIH/NCCIH supports the investigation of the benefits and safety of integrative health solutions. Although the body of evidence about CAM is growing, limited data make it difficult to establish the specific benefits of complementary therapies. Reasons vary but reflect the growing and developing nature of the science. Therefore you need to weigh the risk and benefits of each intervention and consider the following when recommending complementary therapies: (1) the history of each

TABLE 33-1	**Complementary and Integrative Therapies**
Types	**Definitions**
Biologically Based Therapies **(Natural Products)**	
Dietary supplements	Defined by the Dietary Supplement Health and Education Act of 1994 and used to supplement dietary/nutritional intake by mouth; contain one or more dietary ingredients, including vitamins, minerals, herbs, or other botanical products
Herbal medicines	Plant-based therapies used in whole systems of medicine or as individual preparations by allopathic providers and consumers for specific symptoms or issues
Mycotherapies	Fungi-based (mushroom) products
Probiotics	Live microorganisms (in most cases, bacteria) that are similar to beneficial microorganisms found in the human gastrointestinal system; also called *good bacteria*
Energy Therapies **(Use or Manipulation of Energy Fields)**	
Healing touch	Biofield therapy; uses gentle touch directly on or close to body to influence and support the human energy system and bring balance to the whole body (physical, spiritual, emotional, and mental); a formal educational and certification system provides credentials for practitioners
Reiki therapy	Biofield therapy derived from ancient Buddhist rituals; practitioner places hands on or above a body area and transfers "universal life energy," providing strength, harmony, and balance to treat a patient's health disturbances
Therapeutic touch	Biofield therapy involving direction of a practitioner's balanced energies in an intentional manner toward those of a patient; practitioner's hands lay on or close to a patient's body

TABLE 33-1   Complementary and Integrative Therapies—cont'd

Types	Definitions
Manipulative and Body-Based Methods **(Involve Movement of Body with Focus on Body Structures and Systems)**	
Acupressure	Applying digital pressure in a specified way on designated points on the body to relieve pain, produce analgesia, or regulate a body function
Chiropractic medicine	Manipulating the spinal column; includes physiotherapy and diet therapy
Craniosacral therapy	Assessing the craniosacral motion for rate, amplitude, symmetry, and quality and attuning/aligning the spinal column, cerebrospinal fluid, and rhythmic processes, releasing restrictions or abnormal barriers to motion
Massage therapy	Manipulating soft tissue through stroking, rubbing, or kneading to increase circulation, improve muscle tone, and provide relaxation
Mind-Body Interventions **(Honor Connections Between Thoughts and Physiological Functioning Using Emotion to Influence Health and Well-Being)**	
Biofeedback	Process providing a person with visual or auditory information about autonomic physiological functions of the body such as muscle tension, skin temperature, and brain wave activity through the use of instruments
Breathwork	Using a variety of breathing patterns to relax, invigorate, or open emotional channels
Guided imagery	Concentrating on an image or series of images to treat pathological conditions
Meditation	Self-directed practice for relaxing the body and calming the mind with focused rhythmic breathing
Music therapy	Using music to address physical, psychological, cognitive, and social needs of individuals with disabilities and illnesses; improves physical movement and/or communication, develops emotional expression, evokes memories, and distracts people who are in pain.
Tai chi	Incorporating breath, movement, and meditation to cleanse, strengthen, and circulate vital life energy and blood; stimulate the immune system; and maintain external and internal balance
Yoga	Focuses on body musculature, posture, breathing mechanisms, and consciousness; goal is attainment of physical and mental well-being through mastery of body achieved through exercise, holding of postures, proper breathing, and meditation
Movement Therapies **(Eastern or Western Approaches to Promote Well-Being)**	
Dance therapy	Intimate and powerful medium because it is a direct expression of the mind and body; treats people with social, emotional, cognitive, or physical problems
Pilates	Method of body movement used to strengthen, lengthen, and improve the voluntary control of muscles and muscle groups, especially those used for posture and core strengthening
Whole Medical Systems **(Complete Systems of Theory and Practice That Have Evolved Independently from or Parallel to Allopathic [Conventional] Medicine)**	
Ayurvedic medicine	One of the oldest systems of medicine practiced in India since the first century AD. Treatments balance the doshas with a combination of dietary and lifestyle changes, herbal remedies and purgatives, massage, meditation, and exercise.
Homeopathic medicine	Developed in Germany and practiced in the United States since the mid-1800s. It is a system of medical treatments based on the theory that certain diseases can be cured by giving small, highly diluted doses of substances made from naturally occurring plant, animal, or mineral substances that stimulate the vital force of the body so it can heal itself.
Latin American traditional healing	*Curanderismo* is a Latin American traditional healing system that includes a humoral model for classifying food, activity, drugs, and illnesses and a series of folk illnesses. The goal is to create a balance between the patient and his or her environment, thereby sustaining health.
Native American traditional healing	Tribal traditions are individualistic, but similarities across traditions include the use of sweating and purging, herbal remedies, and ceremonies in which a shaman (a spiritual healer) makes contact with spirits to ask their direction in bringing healing to people to promote wholeness and healing.
Naturopathic medicine	A system of therapeutics focused on treating the whole person and promoting health and well-being rather than an individual disease. Therapeutics include herbal medicine, nutritional supplementation, physical medicine, homeopathy, lifestyle counseling, and mind-body therapies with an orientation toward assisting the person's internal capacity for self-healing (vitalism).
Traditional Chinese medicine (TCM)	An ancient healing tradition identified in the first century AD focused on balancing yin/yang energies. It is a set of systematic techniques and methods, including acupuncture, herbal medicines, massage, acupressure, moxibustion (use of heat from burning herbs), Qi gong (balancing energy flow through body movement), cupping, and massage. Fundamental concepts are from Taoism, Confucianism, and Buddhism.

BOX 33-1   EVIDENCE-BASED PRACTICE

Pain in Hospitalized Children

PICO Question: Do complementary therapies safely and effectively reduce pain and discomfort in hospitalized children?

Evidence Summary

Pain is a complex phenomenon for children, involving psychological, biological, and sociological factors. Hospitalization and pain are often linked in the minds of children. Despite advances in pediatric pain management, recent studies demonstrate that many children continue to have uncontrolled moderate-to-severe pain when they are in the hospital. Several systematic analyses focusing on the use of alternative therapies to control pain show that many complementary and nonpharmacological therapies such as relaxation, distraction, focused breathing, imagery, art therapy, and humor are effective in reducing discomfort in children who are hospitalized (Birnie et al., 2014; Thrane, 2013; Uman et al., 2013). Barriers to the use of complementary therapies included nurses' heavy workloads and the need for further education about how to use these techniques.

Application to Nursing Practice

- Children who are hospitalized often respond positively to complementary therapies, experience reduced pain, and need fewer medications to control their pain.
- Instructing parents on specific complimentary therapies used for their child's pain control (e.g., breathing techniques, art therapy) allows the parents to use these techniques.
- Nurses need to learn about and use complementary therapies such as breathing techniques and distraction to alleviate the pain associated with painful and stressful procedures, especially among children.

therapy (many have been used by cultures for thousands of years to support health and reduce suffering); (2) history and experience of nursing with a particular therapy; (3) outcomes and safety data, including case study and qualitative research (Box 33-1); and (4) the cultural influences and context for certain patient populations.

Open communication is essential to ensure safe and effective use of complementary and alternative therapies. People choose these therapies based on many reasons, including personal preference, experience of a family or friend, desire for a more holistic approach to their care, and/or a feeling that traditional medicine alone is not effective. It is important to first assess why the person chose the therapy and his or her understanding of it. For example, if it is an herbal therapy, it is important to determine if the person is taking it correctly and that the side effects or potential interaction with other medicine is known.

This chapter discusses several types of complementary and alternative therapies, including a description, the clinical applications, and the limitations of each therapy. The therapies are organized into two categories. The first are nursing-accessible therapies that you can learn and implement in patient care. The second category includes training-specific therapies such as therapeutic touch or acupressure that a nurse cannot perform without additional training and/or certification.

NURSING-ACCESSIBLE THERAPIES

Some complementary therapies and techniques are general in nature and use natural processes (e.g., breathing, thinking and concentration, presence, movement) to help people feel better and cope with both acute and chronic conditions. Ongoing assessment and evaluation of your patients' responses to these interventions will determine both the appropriateness and usefulness of these complementary therapies. Sometimes changes to physician-prescribed therapies such as medication doses are needed when complementary therapies alter physiological responses and lead to improved therapeutic responses (Kreitzer and Koithan, 2014).

Complementary therapies teach behavioral modifications that often alter physical responses to stress and improve symptoms such as muscle tension, gastrointestinal discomfort, pain, or sleep disturbances. Active involvement is a primary principle for these therapies; individuals achieve better responses if they practice the techniques or exercises daily. Therefore to achieve effective outcomes, therapeutic strategies need to be matched with an individual's lifestyle, beliefs and values, and treatment preferences.

It is important to remember that all therapies have the potential to interact with medication or other therapies currently in use. Patients need to understand what the therapy is, how it is used, and what benefits and side effects can occur. Informed consent is needed for many therapies, and the nurse needs to ensure that institutional policy is followed. Although a therapy may not be invasive, such as an injection of medication, all therapies have potential side effects.

Relaxation Therapy
