Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

STUDENT PREFACE

Fundamentals of Nursing provides you with all of the fundamental nursing concepts and skills you will need as a beginning nurse in a visually appealing, easy-to-use format. We know how busy you are and how precious your time is. As you begin your nursing education, it is very important that you have a resource that includes all the information you need to prepare for lectures, classroom activities, clinical assignments, and exams—and nothing more. We've written this text to meet all of those needs. This book was designed to help you succeed in this course and prepare you for more advanced study. In addition to the readable writing style and abundance of full-color photographs and drawings, we've incorporated numerous features to help you study and learn. We have made it easy for you to pull out important content. **Check out the following special learning aids:**

Learning Objectives begin each chapter to help you focus on the key information that follows.

Key Terms are listed at the beginning of each chapter and are boldfaced in the text. Page numbers help you quickly find where each term is defined.

Evolve Resources sections detail what electronic resources are available to you for every chapter.

32

Medication Administration

OBJECTIVES
- Discuss nursing roles and responsibilities in medication administration.
- Describe the physiological mechanisms of medication action.
- Differentiate among different types of medication actions.
- Discuss developmental factors that influence pharmacokinetics.
- Discuss factors that influence medication actions.
- Discuss methods used to educate patients about prescribed medications.
- Compare and contrast the roles of the health care provider, pharmacist, and nurse in medication administration.
- Implement nursing actions to prevent medication errors.
- Describe factors to consider when choosing routes of medication administration.
- Calculate prescribed medication doses correctly.
- Discuss factors to include in assessing a patient's needs for and response to medication therapy.
- Identify the six rights of medication administration and apply them in clinical settings.
- Correctly and safely prepare and administer medications.

KEY TERMS
Absorption, p. 611
Adverse effects, p. 613
Anaphylactic reactions, p. 613
Biological half-life, p. 614
Biotransformation, p. 612
Buccal, p. 615
Detoxify, p. 612
Idiosyncratic reaction, p. 613
Infusions, p. 614
Injection, p. 611
Instillation, p. 617
Intraarticular, p. 616
Intracardiac, p. 616
Intradermal (ID), p. 615
Intramuscular (IM), p. 615

Intraocular, p. 617
Intravenous (IV), p. 615
Irrigations, p. 618
Medication allergy, p. 613
Medication error, p. 624
Medication interaction, p. 613
Medication reconciliation, p. 625
Metric system, p. 617
Nurse Practice Acts (NPAs), p. 610
Ophthalmic, p. 638
Parenteral administration, p. 615
Peak, p. 614
Pharmacokinetics, p. 611
Polypharmacy, p. 633
Prescriptions, p. 623

Pressurized metered-dose inhalers (pMDIs), p. 638
Side effects, p. 613
Solution, p. 618
Subcutaneous, p. 615
Sublingual, p. 615
Synergistic effect, p. 613
Therapeutic effect, p. 613
Toxic effects, p. 613
Transdermal disk, p. 616
Trough, p. 614
Verbal order, p. 621
Z-track method, p. 650

Patients with health problems use a variety of strategies to restore or maintain their health. One strategy they often use is medication, a substance used in the diagnosis, treatment, cure, relief, or prevention of health problems. No matter where patients receive health care (i.e., hospitals, clinics, or home), nurses play an essential role in preparing, administering, and evaluating the effects of medications. Family members, friends, or home care personnel often administer medications when patients cannot administer them themselves at home. In all settings nurses are responsible for evaluating the effects of medications on the patient's ongoing health status, teaching him or her about medications and side effects, encouraging adherence to the medication regimen, and evaluating the patient's and family caregiver's ability to administer medications.

SCIENTIFIC KNOWLEDGE BASE
Because medication administration and evaluation are a critical part of nursing practice, nurses need to understand the actions and effects of all medications taken by their patients. Administering medications safely requires an understanding of legal aspects of health care,

707

CHAPTER 34 Self-Concept

BOX 34-4 EVIDENCE-BASED PRACTICE
Self-Concept and the Impact on Adolescent Drinking Behaviors

PICO Question: How does self-concept influence drinking behaviors in at-risk adolescents?

Evidence Summary
Low self-concept may precede or perhaps even motivate adolescent drinking (Dudovitz et al., 2013). Because many teens engage in behaviors that increase the potential for morbidity and mortality, helping youth develop a healthy self-concept may prevent health risk behaviors, including teen drinking (CDC, 2014). In 2013 two thirds of high school students reported drinking; 34.9% reported current alcohol use, and 20.8% endorsed binge drinking (CDC, 2014). Overall the prevalence of current drinking in both males and females was higher among white students, followed by Hispanic, and then black students. Identifying risk and protective factors is important when creating drinking-prevention programs. Enhancing opportunities to learn communication skills and engage in alternative behaviors may make drinking less of an adolescent risk behavior.

Application to Nursing Practice
- Drinking-prevention efforts should include stress management and improving self-esteem.
- A priority nursing action is the assessment of child and adolescent coping strategies. Appropriate techniques include effective communication, conflict resolution, and stress management (Dudovitz et al., 2013).
- Families, peers, teachers, and health care providers should instill students' cultural pride, which promotes self-concept and the use of protective factors against risk behaviors such as drinking.
- Family, social, and behavioral factors are important issues to address during preadolescence and adolescence.
- Identifying risk factors for early drug and alcohol use, including genetic predisposition, family environment, and cultural identity, needs to be a priority for health care providers (CDC, 2014).

Patients closely watch the reactions of others to their wounds and scars, and it is very important to be aware of your responses toward the patient. Statements such as, "This wound is healing nicely" or "This tissue looks healthy" are affirmations for the body image of the patient. Nonverbal behaviors convey the level of caring that exists for a patient and affect self-esteem. Anticipate personal reactions, acknowledge them, and focus on the patient instead of the unpleasant task or situation. Nurses who put themselves in the patient's situation incorporate measures to ease embarrassment, frustration, anger, and denial.

Preventive measures, early identification, and appropriate treatment minimize the intensity of self-esteem stressors and the potential effects for a patient and his or her family. Learn to design specific self-concept interventions to fit a patient's profile of risk factors. It is essential to assess a patient's perception of a problem and work collaboratively to resolve self-concept issues. Interventions designed to promote active living and healthy eating may be beneficial for preventing childhood obesity, improving self-esteem, preventing chronic diseases, and improving health outcomes in adulthood.

QSEN: BUILDING COMPETENCY IN PATIENT-CENTERED CARE. You are a third-year nursing student who feels insecure in the clinical setting. You are caring for Mrs. Johnson who had a bilateral mastectomy. This is your first time caring for this type of patient, and you hope that your clinical instructor won't ask you questions about your patient because you "forget" everything when your assigned faculty approaches you. You feel embarrassed that you sometimes "hide" or "look busy" to avoid interacting with your instructor. You wonder, "How can I attend to my patient's physical care and self-concept and self-esteem issues when I can't even deal with my own?" Which actions must you take to improve your self-esteem and self-concept as a student nurse?

Answers to QSEN Activities can be found on the Evolve website.

CRITICAL THINKING
Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients and families, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate information, analyze the data, and make decisions regarding your patient's care. During assessment consider all elements that build toward making an appropriate nursing diagnosis.

In the case of self-concept, it is essential to integrate knowledge from nursing and other disciplines, including self-concept theory, communication principles, and a consideration of cultural and developmental factors. Previous experience in caring for patients with self-concept alterations helps to individualize care. Self-concept profoundly influences a person's response to illness. A critical thinking approach to care is essential.

NURSING PROCESS
Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. Use of the nursing process is continuous until the patient's self-concept is improved, restored, or maintained.

Assessment
During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered

- Ability to convey a nonjudgmental attitude toward patients and families
- Preconceived attitudes toward cultural differences in self-concept and self-esteem

Some patients with a change in body appearance or function are extremely sensitive to the verbal and nonverbal responses of the health care team. A positive, matter-of-fact approach to care provides a model for the patient and family to follow. For example, when you observe a positive change in a patient's behavior, note it and allow the patient to establish its meaning. Nurses have a significant effect on patients by conveying genuine interest and acceptance. Including self-concept issues in the planning and delivery of care can influence patient outcomes positively. Building a trusting nurse-patient relationship that incorporates both the patient and family in the decision-making process enhances self-concept and self-esteem. You can individualize your approach by highlighting a patient's unique needs and incorporating alternative health care practices or methods of spiritual expression into the plan of care. It is important that health care providers understand the degree to which self-esteem and sexuality affect patient outcomes.

Your nursing care significantly affects a patient's body image. For example, the body image of a woman following a mastectomy is positively influenced by showing acceptance of the mastectomy scar. On the other hand, a nurse who has a shocked or disgusted facial expression contributes to the woman developing a negative body image.

Evidence-Based Practice boxes summarize the results of a research study and indicate how that research can be applied to nursing practice.

Building Competency scenario boxes focus on one of the six QSEN key competencies and provide a short case study and question.

The 5-step **Nursing Process** provides a consistent framework for presentation of content in clinical chapters.

Cultural Aspects of Care boxes prepare you to care for patients of diverse populations.

Focus on Older Adults boxes prepare you to address the special needs of older adults.

Patient Teaching boxes emphasize important information to teach patients.

Nursing Assessment Questions boxes help you learn how to properly pose assessment questions when you interview patients.

The unique **Critical Thinking Model** clearly shows how critical thinking is to be applied during steps of the nursing process to help you provide the best care for your patients.

Adolescence is a time of marked maturational changes and shifting levels of self-esteem that set the stage for rises in self-concept in young adulthood (Maldonado et al., 2013).

Erikson's emphasis on the generativity stage (1963) (see Chapter 11) explains the rise in self-esteem and self-concept in adulthood. The individual focuses on being increasingly productive and creative at work while at the same time promoting and guiding the next generation. On the basis of Erikson's stages of development, a decline in self-concept in later adulthood reflects a diminished need for self-promotion and a shift in self-concept to a more modest and balanced view of self. Many report a decline in self-esteem in later adulthood caused in part by physical and emotional changes associated with aging, but older adults with self-concept clarity demonstrate psychological well-being (Diehl and Hay, 2011; Touhy and Jett, 2012). When aging is associated with deterioration of health, nursing interventions must focus on health behavior changes to promote self-care and self-concept (Wurm et al., 2013). Identifying specific nursing interventions to address the unique needs of patients at various life stages is essential.

Components and Interrelated Terms of Self-Concept
A positive self-concept gives a sense of meaning, wholeness, and consistency to a person. A healthy self-concept has a high degree of stability, which generates positive feelings toward self. The components of self-concept are identity, body image, and role performance. How one thinks about oneself (self-concept) affects how one feels about oneself (self-esteem); both concepts need to be evaluated.

Identity. **Identity** involves the internal sense of individuality, wholeness, and consistency of a person over time and in different situations. It implies being distinct and separate from others. Being oneself or living an authentic life is the basis of true identity. Children in culturally accepted values, behaviors, and roles through identification and modeling. They often gain an identity from self-observations from what individuals tell them. An individual first identifies with parenting figures and later with other role models such as teachers or peers. Relationships with parents, teachers, and peers have unique and defined effects on young children's general, academic, and social development (Verschueren et al., 2012). To form an identity, a child must be able to bring together learned behaviors and expectations into a coherent, consistent, and unique whole (Erikson, 1963). The achievement of identity is necessary for intimate relationships (Yu, 2013). Sexuality is a part of identity, and its focus differs across the lifespan. For example, as an adult ages the focus shifts from procreation to companionship, physical and emotional intimacy, and pleasure-seeking (Touhy and Jett, 2014). Gender identity is a person's private view of maleness or femaleness; gender role is the masculine or feminine behavior exhibited. This image and its meaning depend on culturally determined values (see Chapters 9 and 22).

Cultural differences in identity exist (Box 34-2). Cultural identity results from identification and socialization within an established cultural group through the experience of integrating the response of individuals outside the group into one's self-concept. Differences in cultural identity (e.g., Mexican American or Cuban American, homosexual or heterosexual) exist through identification with traditions, customs, and values within one's cultural group (e.g., Hispanic, Latino, gender roles). When cultural identity is central to self-concept and is positive (Rhea, 2013), an individual who experiences discrimination, prejudice, or environmental stressors such as low-income or high-crime

BOX 34-5 Behaviors Suggestive of Altered Self-Concept
- Avoidance of eye contact
- Slumped posture
- Unkempt appearance
- Overly apologetic
- Hesitant speech
- Overly critical or angry
- Frequent or inappropriate crying
- Negative self-evaluation
- Excessively dependent
- Hesitant to express views or opinions
- Lack of interest in what is happening
- Passive attitude
- Difficulty in making decisions
- Self-harm behaviors

BOX 34-6 Nursing Assessment Questions
Nature of the Problem
- How would you describe yourself?
- Which aspects of your appearance do you like?
- Tell me about the things you do that make you feel good about yourself.
- Tell me about your primary roles. How effective are you at carrying out each of these roles?

Onset and Duration
- When did you start to think or feel differently about yourself?
- How long have you struggled with _____ (specify identity, body image, role performance, or self-esteem)?
- Can you remember a time when you felt good about yourself?

Effect on Patient
- Tell me how your self-concept affects your ability to take care of yourself.
- What impact does your self-esteem have on relationships?
- How does your self-esteem affect other areas of your life?
- Have you considered hurting yourself (specify self-mutilation, suicidal gestures)?

clinical decisions required for safe nursing care. In assessing self-concept and self-esteem, first focus on each component of self-concept (identity, body image, and role performance). Assessment needs to include looking for the range of behaviors suggestive of an altered self-concept or self-esteem (Box 34-5), actual and potential self-concept stressors (see Figure 34-4), and coping patterns. Gathering comprehensive assessment data requires the critical synthesis of information from multiple sources (Figure 34-4). In addition to direct questioning (Box 34-6), gather much of the data regarding self-concept through observation of the patient's nonverbal behavior and by paying attention to the content of the patient's conversations. Take note of the manner in which patients talk about the people in their lives because this provides clues to both stressful and supportive relationships and key roles the patient assumes. Use knowledge of developmental stages to determine which areas are likely to be important to the patient and inquire about these aspects of the person's life. For example, ask a 70-year-old patient about his life and what has been important to him. The individual's conversation likely provides data relating to role performance, identity, self-esteem, stressors, and coping patterns.

Through the Patient's Eyes. An important factor in assessing self-concept is the person's viewpoint of his or her health condition and its influence on self-concept. Give patients the opportunity to tell their stories of how they perceive their illness or condition affecting their identity, their image of themselves, and their ability to lead a

---

TABLE 36-2 Religious Dietary Regulations Affecting Health Care

Religion	Dietary Practices
Hinduism	Some sects are vegetarians. The belief is not to kill any living creature.
Buddhism	Some are vegetarians and do not use alcohol. Many fast on Holy Days.
Islam	Consumption of pork and alcohol is prohibited. Followers fast during the month of Ramadan.
Judaism	Some observe the kosher dietary restrictions (e.g., avoid pork and shellfish, do not prepare and eat milk and meat at same time).
Christianity	Some Baptists, Evangelicals, and Pentecostals discourage use of alcohol and caffeine. Some Roman Catholics fast on Ash Wednesday and Good Friday. Some do not eat meat on Fridays during Lent.
Jehovah's Witnesses	Members avoid food prepared with or containing blood.
Mormonism	Members abstain from alcohol and caffeine.
Russian Orthodox Church	Followers observe fast days and a "no-meat" rule on Wednesdays and Fridays. During Lent all animal products, including dairy products and butter, are forbidden.
Native Americans	Individual tribal beliefs influence food practices.

BOX 36-5 FOCUS ON OLDER ADULTS
Spirituality and Spiritual Health
- There is an association between an older adult's spirituality and his or her ability to adjust or cope with illness and other life stressors (Manning, 2014).
- Older adults achieve spiritual resilience through frequent expressions of gratitude (e.g., via prayer, meditation, or discussions with friends) and finding ways to maintain purpose in life (e.g., helping family, volunteering) (Manning, 2014).
- Patients use spiritual rituals, exercise, and complementary medicine to cope with pain and chronic illness.
- Feelings of connectedness are important for the older adult (Anderberg and Berglund, 2010). Enhance connectedness by helping older patients find meaning and purpose in life by listening actively to concerns and being present.
- Beliefs in the afterlife increase as adults age. Make visits from clergy, social workers, lawyers, and financial advisors available so patients feel as though they have completed all unfinished business. Leaving a legacy to leave the world with a sense of meaning and maintains a way to continue connection for the one left behind (Touhy and Jett, 2012).
- Older-adult caregivers use their spirituality and spiritual behaviors or practices to help them deal with crisis and conflict (Strudwick and Morris, 2010).

BOX 36-6 PATIENT TEACHING
Meditation Techniques

Objective
- The patient will verbalize feelings of relaxation and self-transcendence after meditation.

Teaching Strategies
- Give patient a brief description of information and a printed teaching guide that describes how to meditate.
- Help patient identify a quiet room in the home that has no interruptions.
- Explain that peaceful music or the quiet whirring of a fan blocks distractions.
- Teach steps of meditation (i.e., sit in a comfortable position with the spine straight; breathe slowly; and focus on a sound, prayer, or image).
- Encourage patient to meditate for 10 to 20 minutes twice a day.
- Answer questions and reinforce information as needed.

Evaluation
- Have patient describe feelings following meditation.

provide other effective options. Always respect the icons, medals, prayer rugs, or crosses that a patient brings to a health setting and ensure that they are not accidentally lost, damaged, or misplaced. Supporting spiritual rituals is especially important for older adults (Box 36-5).

Restorative and Continuing Care. For patients who are recovering from a long-term illness or disability or who suffer chronic or terminal disease, spiritual care becomes especially important. Many of the nursing interventions applicable in health promotion and acute care apply to this level of health care as well.

Prayer. The act of prayer gives an individual the opportunity to renew personal faith and belief in a higher being in a specific, focused way that is either highly ritualized and formal or quite spontaneous and informal. Prayer is an effective coping resource for physical and psychological symptoms (Oliver and Dutney, 2012). Patients pray in private or participate in group prayer with family, friends, or clergy. Some pray while listening to music. Be supportive of prayer by giving the patient privacy if desired, learning if the patient wishes to have you participate, and suggesting prayer when you know that it is a coping resource for the patient. Delgado (2015) has found that nurses tend to pray for patients rather than with patients; sharing the fact that prayer has been offered gives patients comfort and support. If prayer is not suitable for a patient, alternatives include listening to calming music or reading a book, poetry, or inspirational texts selected by the patient.

Meditation. Meditation creates a relaxation response that reduces daily stress. Patients who meditate often state that they have an increased awareness of their spirituality and of the presence of God or a Supreme Being. Meditation exercises give patients relief from pain,

insomnia, anxiety, and depression and increase coping and the ability to relax (Cole et al., 2012; Williams-Orlando, 2012). Meditation involves sitting quietly in a comfortable position with eyes closed and repeating a sound, phrase, or sacred word in rhythm with breathing while disregarding intrusive thoughts. Individuals who meditate regularly (twice a day for 10 or 20 minutes) experience decreased metabolism and heart rate, easier breathing, and slower brain waves (Box 36-6). Chapter 33 addresses relaxation approaches.

Supporting Grief Work. Patients who experience terminal illness or who have suffered permanent loss of body function because of a

425

BOX 28-7 PROCEDURAL GUIDELINES

Sequential Compression Devices and Applying Elastic Stockings

Delegation Considerations

The skill of applying elastic stockings and sequential compression devices (SCDs) can be delegated to nursing assistive personnel (NAP). The nurse initially determines the size of elastic stockings and assesses the patient's lower extremities for signs and symptoms of DVT or impaired circulation. Instruct NAP to:

- Remove SCD sleeves before allowing patient to get out of bed.
- Notify nurse if patient complains of pain in leg or if discoloration develops in extremities.
- When applying elastic stockings, instruct patient to avoid activities that promote venous stasis (e.g., crossing legs, wearing garters).
- Elevate legs while sitting and before applying stockings to improve venous return.
- Take precautions and **Do Not** massage patient's legs.
- Avoid wrinkles in elastic stockings.

Equipment

Tape measure, powder or cornstarch (optional). Elastic or compression stockings, SCD insufflator with air hoses attached, adjustable Velcro compression stockings/SCD disposable sleeve(s), hygiene supplies

Steps

1. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.
2. Assess for risk factors in Virchow's triad:
   a. Hypercoagulability (e.g., clotting disorders [laboratory test results], fever, dehydration)
   b. Venous wall abnormalities found in patient medical history [i.e., history of orthopedic surgery, atherosclerosis)
   c. Blood stasis (e.g., immobility, obesity, pregnancy)

   CLINICAL DECISION: Clinical signs of thrombophlebitis vary according to the size and location of the thrombus. Signs and symptoms of superficial thrombosis include palpable veins and surrounding areas that are tender to the touch, reddened, and warm. Temperature elevation and edema may or may not be present. Signs and symptoms of deep vein thrombosis (DVT) include swollen extremity; pain; warm, cyanotic skin; and temperature elevation. Homans' sign (pain in the calf on dorsiflexion of the foot) is no longer considered a reliable indicator (Ball et al., 2015; Grinage and Werner, 2013).

3. Assess condition of patient's skin and circulation to the legs (e.g., presence of pedal pulses, edema, discoloration of skin, skin temperature, capillary refill, presence of lesions or cuts). Assess for contraindications for use of elastic stockings or SCDs:
   a. Dermatitis or open skin lesions
   b. Recent skin graft
   c. Decreased arterial circulation in lower extremities as evidenced by cyanotic, cool extremities
4. Obtain health care provider order.
5. When applying elastic stockings, use tape measure to measure patient's legs to determine proper stocking size.
6. Perform hand hygiene. Also provide hygiene to patient's lower extremities as needed.
7. Assemble and prepare equipment.
8. Explain procedure and reason for applying SCDs or elastic stockings.
9. Position patient in supine position. Elevate head of bed to comfortable level.
10. Option: When applying elastic stockings, apply a small amount of powder or cornstarch to legs provided that patient does not have sensitivity to either. Powder eases application of stockings.
11. Apply SCD sleeve(s):
    a. Remove sleeves from plastic cover; unfold and flatten.
    b. Arrange sleeve under patient's leg according to leg position indicated on inner lining of sleeve.
    c. Place patient's leg on SCD sleeve. Back of ankle should line up with ankle marking on inner lining of sleeve.
    d. Position back of knee with popliteal opening on the sleeve (see Illustration).
    e. Wrap SCD sleeve securely around patient's leg. Check fit of SCD sleeve by placing two fingers between patient's leg and sleeve (see illustration).

Continued

STEP 11d Position back of patient's knee with the popliteal opening.

STEP 11e Check fit of SCD sleeve.

Procedural Guidelines provide streamlined, step-by-step instructions for performing the most basic skills.

NURSING CARE PLAN

Readiness for Enhanced Spiritual Well-Being

ASSESSMENT

Lisa Owens is a 61-year-old female who was diagnosed with stage IV breast cancer over 2 years ago. She has undergone numerous rounds of chemotherapy treatment. Her husband, Richard, is 59 years old and a financial assistant at a local bank. The Owens have two children, both adults, with one daughter who is unmarried and living only 2 miles away. The other child, a son, lives out of town. The son is married; he and his wife are about to have their first child. Lisa has numerous side effects from her advancing disease and chemotherapy. She has ongoing hip pain from the cancer having spread to the bone. She also has reduced sensation in her feet, chronic fatigue, and difficulty sleeping at night. Her husband provides most of her support at home, but this sometimes interferes with his ability to do the work that he brings home. Lisa is coming to the outpatient chemotherapy infusion center to begin yet another course of chemotherapy. The nurse who has been seeing Lisa in the center knows that the patient regularly attends church with her husband.

Assessment Activities	Findings/Defining Characteristics[*]
Ask Lisa to describe what it is about her cancer that frightens her most.	Lisa explains, "I have found it makes me appreciate what I have with my family. That being said, I worry that I will not see my grandchild born, **but I hope the chemotherapy will give me some time and it will make me feel a bit better.**"
Have Lisa tell you who she finds to be the greatest source of support since she has been taking chemotherapy.	Lisa has received support from her husband and daughter. **She wants to be able to show them her love, "I still want to be there for them."**
Ask Lisa if she feels satisfaction with her life.	Lisa responds, "We always want more, don't we? **I have been blessed, but I think God gave me this illness so I can show others what life means.**"

[*]**Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Readiness for Enhanced Spiritual Well-Being

PLANNING

Goals	Expected Outcomes (NOC)[†]
	Hope
Lisa will express her will to live with family members.	Lisa participates in worship with her family and shares spiritual readings.
	Lisa connects with members of her church.
	Lisa interacts with family members and discusses their future.
	Spiritual Health
Lisa will describe a feeling of peacefulness to her family.	Lisa engages in regular prayer and meditation.
Lisa will express a personal sense of spiritual well-being.	Lisa expresses her feelings through writing.

[†]Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC)*, ed 5, St Louis, 2013, Mosby.

INTERVENTIONS (NIC)[‡]	**RATIONALE**
Spiritual Growth Facilitation	
Plan discussions with Lisa during treatment and listen, allowing her to sort out concerns she might have about her future. Include Lisa's husband if she desires.	Listening provides support or comfort in spiritual care (Delgado, 2015). Family caregivers engage in "meaning making" activities by expressing important values such as hope, dignity, and togetherness (Delgado-Guay, 2014).
Offer to pray with Lisa as she describes what hopes for.	One study found that cancer patients commonly used prayer and meditation to reduce their side effects (Huebner et al., 2014)
Introduce Lisa to journaling. Encourage her to begin by writing what is meaningful to her about her illness and family	Use of journaling helps individuals facing a crisis deal with the unknown; find meaning and spiritual connection; and physically, emotionally, and spiritually heal (Harvey et al., 2013; Sealy, 2013).
Spiritual Support	
Discuss with Lisa the likely times that her chemotherapy will affect her most and how she can schedule involvement in church activities around those times.	Chemotherapy can cause severe fatigue. Faith communities such as a church play an important role in fostering belief systems of compassion (Delgado-Guay, 2014).
Teach Lisa methods of relaxation, meditation, and guided imagery.	Relaxation methods help promote quality of life and enhance serenity and dignity. Relaxation responses have been associated with improved physiological (blood pressure, exercise capacity, and cardiac symptoms) and psychological (depression and anxiety) outcomes (Horowitz, 2010; Sheeba et al., 2013).

[‡]Intervention classification labels from Bulechek GM et al: *Nursing interventions classification (NIC)*, ed 6, St Louis, 2013, Mosby.

EVALUATION

Nursing Actions	Patient Response/Finding	Achievement of Outcome
Ask Lisa to describe in what way relaxation exercises have helped her.	Lisa reported using relaxation daily after being at clinic. She states, "I feel calm. It allows me to connect with God, and know I have my loving family to help me."	Lisa's story reflects spiritual well-being and peacefulness. She needs to share with family.
Have Lisa review her discussions with family and/or church members.	Lisa reports, "We have been talking more. My family knows that I see each day as a blessing and that my hope is to see my son's baby. My church really keeps me connected."	Lisa is connecting with family and church members. She is able to express a sense of hope.

Nursing Care Plans demonstrate how comprehensive a plan of care should be for a patient. Each plan helps you understand the process of assessment, the association of assessment findings with defining characteristics in the formation of nursing diagnoses, the identification of goals and outcomes, the selection of nursing interventions, and the process for evaluating care.

Nursing Interventions Classification (NIC) and **Nursing Outcomes Classification (NOC)** terminologies are used in the care plans to build your knowledge of nursing concepts.

Rationales for each of the interventions in the care plans demonstrate the evidence to support nursing care approaches.

Evaluation section explains how to evaluate and determine whether patient outcomes have been achieved.

Concept Maps help you see the connections between your patient's medical problems and your plan of care.

Nursing Skills are presented in a clear, two-column format that includes Steps and Rationales to help you learn how and why a skill is performed. Each skill begins with a **Safety Guidelines** section that will help you focus on safe and effective skill performance.

Delegation Considerations guide you in delegating tasks to assistive personnel.

Equipment lists show specific items needed for each skill.

Video Icons indicate video clips associated with specific skills that are available on the free Evolve Student Resources website.

Clinical Decisions alert you to important information within a skill to consider to ensure safe and effective patient care.

Clear, close-up **photos** and **illustrations** show you how to perform important skill procedures.

CHAPTER 34 Self-Concept   711

individual and key critical thinking elements (see the Nursing Care Plan). Professional standards are especially important to consider when developing a plan of care. These standards often establish ethical or evidence-based practice guidelines for selecting effective nursing interventions.

Another method to help plan care is a concept map. An example of an illustrative concept map (Figure 34-6) shows the relationship of a primary health problem (postoperative bilateral radical mastectomy) and four nursing diagnoses and several interventions. The concept map shows how the nursing diagnoses are interrelated. It also helps to show the interrelationships among nursing interventions. A single nursing intervention can be effective for more than one diagnosis.

Goals and Outcomes. Develop an individualized plan of care for each nursing diagnosis. Work collaboratively with the patient to set realistic expectations for care. Make sure that goals are individualized and realistic with measurable outcomes. In establishing goals consult with the patient about whether they are achievable. Consultation with significant others, mental health clinicians, and community resources results in a more comprehensive and workable plan. When you set goals, consider the data necessary to demonstrate that the patient's problem would change if the nursing diagnosis were managed. The outcome criteria should reflect these changes. For example, a patient is diagnosed with *Situational Low Self-Esteem related to a recent job layoff*. Establish a goal: "Patient's self-esteem and self-concept will

CONCEPT MAP

Nursing diagnosis: Disturbed body image
- Does not touch her chest
- Unable to look in mirror
- Avoids new social interactions
- Fears husband's response to loss of breasts

Interventions
- Assist patient to develop a realistic perception of image
- ... her feelings are similar to feelings ... me situation
- ... when providing care

Nursing diagnosis: Acute pain
- Rates postoperative pain as a 9 on a scale of 0 to 10
- States "no relief from pain" with PCA
- Has poor sleeping patterns
- Has a lack of appetite
- Has decreased nutritional intake

Interventions
- Ask patient to describe past methods used to control pain
- Explore the need for opioid and nonnarcotic analgesics
- Discuss patient's fears of undertreated pain and addiction

... generative bilateral radical ... ears on

---

432   UNIT V   Foundations for Nursing Practice

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with the members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient-centered care.

- Determine the amount and type of assistance required for safe positioning, including any transfer equipment and the number of personnel to safely transfer and prevent harm to patient and health care providers.

SKILL 28-1   MOVING AND POSITIONING PATIENTS IN BED

DELEGATION CONSIDERATIONS

The skill of moving and positioning patients in bed can be delegated to nursing assistive personnel (NAP). The nurse is responsible for assessing the patient's level of comfort and for any hazards of immobility. Instruct NAP about:

- Any moving and positioning limitations unique to patient.
- Individual needs for body alignment (e.g., patient with spinal cord injury).
- Scheduled times to reposition patient through the shift.
- When to request assistance (e.g., if the patient has a spinal cord injury, is confused).

- Raise the side rail on the side of the bed opposite of where you are standing to prevent the patient from falling out of bed on that side.
- Arrange equipment (e.g., intravenous lines, feeding tube, indwelling catheter) so it does not interfere with the positioning process.
- Evaluate the patient for correct body alignment and pressure risks after repositioning.

EQUIPMENT
- Pillows, drawsheet
- Therapeutic boots, splints if needed
- Trochanter roll
- Hand rolls
- Side rails
- Appropriate safe patient-handling assistive device (e.g., friction-reducing device)

STEP

ASSESSMENT

1. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.
2. Assess patient's body alignment and comfort level while he or she is lying down.
3. Assess for risk factors that contribute to complications of immobility:
   a. Paralysis, hemiparesis ... from a cerebrovascular accident (CVA); decreased ...

RATIONALE

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2016).

Provides baseline data for later comparison. Determines ways to improve positioning and alignment.

Increased risk factors require more frequent repositioning.

Paralysis impairs movement; muscle ... bone change ...

Because of difficulty in moving ... patient is unable to protect ...

Traction or arthritis ... motion ...

... contributing disease ...

CHAPTER 28   Immobility   433

STEP	RATIONALE
8. Assess condition of patient's skin (see Chapter 31).	Provides baseline to determine effects of positioning.
9. Assess ability and motivation of patient and family caregivers to participate in moving and positioning patient in bed in anticipation of discharge to home.	Determines ability of patient and caregivers to help with positioning.

PLANNING

1. Collect appropriate equipment. Get extra help as needed. Close door to room or bedside curtains.	Having appropriate number of people to position patient prevents patient and nurse injury. Provides for patient privacy.
2. Perform hand hygiene.	Reduces transfer of microorganisms.
3. Raise level of bed to comfortable working height. Remove all pillows and devices used for positioning.	Raises work toward nurse's center of gravity. Reduces any interference during positioning.
4. Explain procedure to patient.	Helps to relieve anxiety and allows patient to participate more actively.

IMPLEMENTATION

1. Assist Patient in Moving Up in Bed	Determines degree of risk in repositioning patient and technique required to safely assist patient.
a. *Can patient assist?*	
(1) Fully able to assist, nurse assistance not needed; nurse stands by to assist.	
(2) Partially able to assist; patient can assist with nurse using positioning cues or aids (e.g., drawsheet or friction-reducing device).	

CLINICAL DECISION: Before lowering head of bed to flatten bed, account for all tubing, drains, and equipment to prevent dislodgement or tipping if caught in mattress or bedframe as bed is lowered.

b. *Assist patient moving up in bed, using a drawsheet (two or three nurses).*	This is not a one-person task. Helping a patient move up in bed without help from other co-workers or without the aid of an assistive device (i.e., friction-reducing pad) is not recommended or considered safe for the patient or nurse (ANA, 2010; CDC, 2009).
(1) Place patient supine with head of bed flat. A nurse stands on each side of bed.	Enables nurse to assess body alignment. Reduces pull of gravity on patient's upper body.
(2) Remove pillow from under head and shoulders and place it at head of bed.	Prevents striking patient's head against head of bed.
(3) Turn patient side to side to place drawsheet under patient, extending from shoulders to thighs.	Supports patient's body weight and reduces friction during movement.
(4) Return patient to supine position.	Even distribution of patient's weight makes lifting and positioning easier.
(5) Fanfold drawsheet on both sides, with each nurse grasping firmly near patient.	Provides strong handles to grip drawsheet without slipping.

CLINICAL DECISION: Protect patient's heels from shearing force by having a third nurse lift heels while moving patient up in bed.

(6) Nurses place their feet apart with forward-backward stance. Flex knees and hips. On the count of three, shift weight from front to back leg and move patient and drawsheet to desired position in bed (see illustration).	Facing direction of movement ensures proper balance. Shifting weight reduces force needed to move load. Flexing knees lowers center of gravity and uses thigh muscles instead of back muscles.

STEP 1b(6) A and **B,** Moving immobile patient up in bed with drawsheet.

Unexpected Outcomes and Related Interventions identify possible undesired results and provide guidelines for appropriate nursing responses.

Recording and Reporting provides guidelines for what to chart and report with each skill.

Key Points and **Clinical Application Questions** sections help you review and apply essential content from the chapter.

The **Review Questions** at the end of each chapter, with the answer key included, help you evaluate learning and prepare for the examination.

Home Care Considerations explain how to adapt skills for the home setting.

KEY POINTS

- Use findings from evidence-based nursing research about safe patient handling to prevent injuries to nurses and patients when moving and transferring.
- Coordination and regulation of muscle groups depend on muscle tone; activity of antagonistic, synergistic, and antigravity muscles; and neural input to muscles.
- Body alignment is the condition of joints, tendons, ligaments, and muscles in various body positions.
- Balance occurs when there is a wide base of support, the center of gravity falls within the base of support, and a vertical line falls from the center of gravity through the base of support.
- Developmental stages influence body alignment and mobility; the greatest impact of physiological changes on the musculoskeletal system is observed in children and older adults.
- The risk of disabilities related to immobilization depends on the extent and duration of immobilization and the patient's overall level of health.
- Immobility presents hazards in the physiological, psychological, and developmental dimensions.
- The nursing process and critical thinking assist you in providing care for patients who are experiencing or are at risk for the adverse effects of impaired body alignment and immobility.
- Patients with impaired body alignment require nursing care to maintain correct positioning such as the supported Fowler's, supine, prone, side-lying, and Sims' positions.
- Patient movement algorithms serve as assessment tools and guide safe patient handling and movement.
- Appropriate friction-reducing assistive devices and mechanical lifts need to be used for patient transfers when applicable.
- No-lift policies benefit all members of the health care system: patients, nurses, and administration.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Ms. Cavallo, 97 years of age, has been a resident at the rehabilitation unit for 6 weeks. She has been receiving rehabilitation therapy following the repair of her fractured left hip. The nursing assistive personnel (NAP) tells you that Ms. Cavallo has not been finishing her meals over the past 2 days because of poor appetite. As you enter her room with a food tray today, she states, "Go away and take that tray of food with you. I'm tired of all of this, and I just want to stay in bed today." You explore why she feels this way. You discover that she does not like the foods that are being prepared for her and she does not feel strong enough to use her walker. She states, "I'm afraid that I'm going to fall because I don't feel strong enough to get out of bed and use my walker."

1. On the basis of these data, you develop a nursing diagnosis of *Deficient Knowledge (Imbalanced Nutrition: Less Than Body Requirements) related to lack of information*. Identify one goal, two expected outcomes, and three related nursing interventions with rationales that will help her meet the identified goal and outcomes.

2. You finish teaching Ms. Cavallo about the importance of a balanced diet and how it will help her regain strength to ambulate. As you are doing her morning assessment, you notice that she has a reddened area on her coccyx.
   a. Which risk factors contribute to this finding?
   b. In addition to a balanced diet, which other nursing interventions would be good to include in her plan of care?

3. You convince Ms. Cavallo to eat a balanced diet of three meals and two snacks high in protein. Describe the decision-making process you use to ensure that Ms. Cavallo continues to recognize the importance of a balanced diet. Include essential assessment data that you need to ensure that she continues to have an intake of proper foods.

Answers to Clinical Application Questions can be found on the Evolve website.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. An older adult has limited mobility as a result of a total knee replacement. During assessment you note that the patient has difficulty breathing while lying flat. Which of the following assessment data support a possible pulmonary problem related to impaired mobility? (Select all that apply.)
   1. B/P = 128/84
   2. Respirations 26/min on room air
   3. HR 114
   4. Crackles over lower lobes heard on auscultation
   5. Pain reported as 3 on scale of 0 to 10 after medication

2. A patient has been on bed rest for over 4 days. On assessment, the nurse identifies the following as a sign associated with immobility:
   1. Decreased peristalsis
   2. Decreased heart rate
   3. Increased blood pressure
   4. Increased urinary output

3. The nurse puts elastic stockings on a patient following major abdominal surgery. The nurse teaches the patient that the stockings are used after a surgical procedure to _____.

4. A nurse is teaching a community group about ways to minimize the risk of developing osteoporosis. Which of the following statements reflect understanding of what was taught? (Select all that apply.)
   1. "I usually go swimming with my family at the YMCA 3 times a week."
   2. "I need to ask my doctor if I should have a bone mineral density check this year."
   3. "If I don't drink milk at dinner, I'll eat broccoli or cabbage to get the calcium that I need in my diet."
   4. "I'll check the label of my multivitamin. If it has calcium, I can save money by not taking another pill."
   5. "My lactose intolerance should not be a concern when considering my calcium intake."

5. A nurse is caring for an older adult who has had a fractured hip repaired. In the first few postoperative days, which of the following nursing measures will best facilitate the resumption of activities of daily living for this patient?
   1. Encouraging use of an overhead trapeze for positioning and transfer
   2. Frequent family visits
   3. Assisting the patient to a wheelchair once per day
   4. Ensuring that there is an order for physical therapy

6. An older-adult patient has been bedridden for 2 weeks. Which of the following complaints by the patient indicates to the nurse that he or she is developing a complication of immobility?
   1. Loss of appetite
   2. Gum soreness

The nursing profession is always responding to dynamic change and continual challenges. Today nurses need a broad knowledge base from which to provide care. More important, nurses require the ability to know how to apply best evidence in practice to ensure the best outcomes for their patients. The role of the nurse includes assuming the lead in preserving nursing practice and demonstrating its contribution to the health care of our nation. Nurses of tomorrow, therefore, need to become critical thinkers, patient advocates, clinical decision makers, and patient educators within a broad spectrum of care services.

The ninth edition of *Fundamentals of Nursing* was revised to prepare today's students for the challenges of tomorrow. This textbook is designed for beginning students in all types of professional nursing programs. The comprehensive coverage provides fundamental nursing concepts, skills, and techniques of nursing practice and a firm foundation for more advanced areas of study.

Fundamentals of Nursing provides a contemporary approach to nursing practice, discussing the entire scope of primary, acute, and restorative care. This new edition continues to address a number of key current practice issues, including an emphasis on patient-centered care and evidence-based practice. Evidence-based practice is one of the most important initiatives in health care today. The increased focus on applying current evidence in skills and patient care plans helps students understand how the latest research findings should guide their clinical decision making.

KEY FEATURES

We have carefully developed this ninth edition with the student in mind. We have designed this text to welcome the new student to nursing, communicate our own love for the profession, and promote learning and understanding. Key features of the text include the following:

- Students will appreciate the **clear, engaging writing style.** The narrative actually addresses the reader, making this textbook more of an active instructional tool than a passive reference. Students will find that even complex technical and theoretical concepts are presented in a language that is easy to understand.
- **Comprehensive** coverage and readability of all fundamental nursing content.
- The **attractive, functional design** will appeal to today's visual learner. The clear, readable type and bold headings make the content easy to read and follow. Each special element is consistently color-keyed so students can readily identify important information.
- Hundreds of **large, clear, full-color photographs and drawings** reinforce and clarify key concepts and techniques.
- The **nursing process** format provides a consistent organizational framework for clinical chapters.
- **Learning aids** help students identify, review, and apply important content in each chapter and include Objectives, Key Terms, Key Points, Clinical Application Questions, and Review Questions.
- **Evolve Resources** lists at the beginning of every chapter detail the electronic resources available for the student.
- **Health promotion and acute and continuing care** are covered to address today's practice in various settings.
- A **health promotion/wellness** thread is used consistently throughout the text.

- **Cultural awareness**, care of the **older adult,** and **patient teaching** are stressed throughout chapter narratives and are highlighted in special boxes.
- **Procedural Guidelines** boxes provide more streamlined, step-by-step instructions for performing very basic skills.
- **Concept Maps** in each clinical chapter show you the association between multiple nursing diagnoses for a patient with a selected medical diagnosis and the relationship between nursing interventions.
- **Nursing Care Plans** guide students on how to conduct an assessment and analyze the defining characteristics that indicate nursing diagnoses. The plans include NIC and NOC classifications to familiarize students with this important nomenclature. The evaluation sections of the plans show students how to evaluate and then determine the outcomes of care.
- A **critical thinking model provides a framework** for all clinical chapters and show how elements of critical thinking, including knowledge, critical thinking attitudes, intellectual and professional standards, and experience are integrated throughout the nursing process for making clinical decisions.
- **More than 50 nursing skills** are presented in a clear, two-column format with steps and supporting rationales that are often supported with current, evidence-based research.
- **Delegation Considerations** guide when it is appropriate to delegate tasks to assistive personnel.
- **Unexpected Outcomes and Related Interventions** are highlighted within nursing skills to help students anticipate and appropriately respond to possible problems faced while performing skills.
- **Video Icons** indicate video clips associated with specific skills that are available online in the Evolve Student Resources.
- **Printed endpapers** on the inside back cover help students locate specific assets in the book, including Skills, Procedural Guidelines, Nursing Care Plans, and Concept Maps.

NEW TO THIS EDITION

- Information related to the **Quality and Safety Education for Nurses** (**QSEN**) initiative is highlighted by headings that coordinate with the key competencies. Building Competency scenarios in each chapter incorporate one of the six key competencies in QSEN. Answers to these activities can be found online in the Evolve Student Resources.
- The latest **NANDA 2015-2017** diagnoses are included for up-to-date content.
- **A new skill** covers Fall Prevention in Health Care Settings.
- **Review Questions** have been updated in each chapter, with a minimum of four alternate-item type questions. Answers are provided with questions and rationales on Evolve.
- **Evidence-Based Practice** boxes in each chapter have been updated to reflect current research topics and trends.
- Both *Healthy People 2020* and The Joint Commission's **2016 National Patient Safety Goals** are covered in this new edition, promoting the importance of current research.
- **Chapter 28: Immobility** and **Chapter 39: Activity and Exercise** have been completely reorganized to reduce redundancy, improve clarity, and increase the clinical focus of both chapters.
- **Chapter 9: Cultural Awareness** has been completely rewritten and revised to better address this topic for fundamentals students.

LEARNING SUPPLEMENTS FOR STUDENTS

- The **Evolve Student Resources** are available online at http://evolve.elsevier.com/Potter/fundamentals/ and include the following valuable learning aids organized by chapter:
  - Chapter Review Questions from the book in an interactive format! Includes hundreds of questions to prepare for examinations.
  - Answers and rationales to Chapter Review Questions
  - Answers and rationales to Clinical Application Questions
  - Answers and rationales to Building Competency scenario questions
  - Video clips to highlight common skills and procedural guidelines
  - Concept Map Creator (included in each clinical chapter)
  - Conceptual Care Map (included in each clinical chapter)
  - Case Study with Questions
  - Audio Glossary
  - Fluids & Electrolytes Tutorial
  - Calculation Tutorial
  - Printable versions of Chapter Key Points
  - Interactive Skills Performance Checklists (included for each skill in the text)
- A thorough *Study Guide* by Geralyn Ochs provides an ideal supplement to help students understand and apply the content of the text. Each chapter includes multiple sections:
  - Preliminary Reading includes a chapter assignment from the text.
  - Comprehensive Understanding provides a variety of activities to reinforce the topics and main ideas from the text.
  - Review Questions are NCLEX®-style multiple-choice questions that require students to provide rationales for their answers. Answers and rationales are provided in the answer key.
  - Clinical chapters include an Application of Critical Thinking Synthesis Model that expands the case study from the chapter's Care Plan and asks students to develop a step in the synthesis model based on the nurse and patient in the scenario. This helps students learn to apply both content learned and the critical thinking synthesis model.
- The handy *Clinical Companion: Just the Facts* complements, rather than abbreviates, the textbook. Content is presented in a tabular, list, and outline format that equips your students with a concise, portable guide to all the facts and figures they'll need to know in their early clinical experiences.
- **Virtual Clinical Excursions** is an exciting workbook and CD-ROM experience that brings learning to life in a virtual hospital setting. The workbook guides students as they care for patients, providing ongoing challenges and learning opportunities. Each lesson in *Virtual Clinical Excursions* complements the textbook content and provides an environment for students to practice what they are learning. This CD/workbook is available separately or packaged at a special price with the textbook.

TEACHING SUPPLEMENTS FOR INSTRUCTORS

The **Evolve Instructor Resources** (available online at http://evolve.elsevier.com/Potter/fundamentals) are a comprehensive collection of the most important tools instructors need, including the following:
- **TEACH for Nurses** ties together every chapter resource you need for the most effective class presentations, with sections dedicated to objectives, teaching focus, nursing curriculum standards (including QSEN, BSN Essentials, and Concepts), instructor chapter resources, student chapter resources, answers to chapter questions, and an in-class case study discussion. Teaching Strategies include relations between the textbook content and discussion items. Examples of student activities, online activities, new health promotion-focused activities, and large group activities are provided for more "hands-on" learning.
- The **Test Bank** contains 1500 questions with text page references and answers coded for NCLEX Client Needs category, nursing process, and cognitive level. Each question was involved in an instructor piloting process to ensure the best possible exam for students. The ExamView software allows instructors to create new tests; edit, add, and delete test questions; sort questions by NCLEX category, cognitive level, nursing process step, and question type; and administer/grade online tests.
- Completely revised **PowerPoint Presentations** include more than 1500 slides for use in lectures. Art is included within the slides, and progressive case studies include discussion questions and answers.
- The **Image Collection** contains more than 1150 illustrations from the text for use in lectures.
- **Simulation Learning System** is an online toolkit that helps instructors and facilitators effectively incorporate medium- to high-fidelity simulation into their nursing curriculum. Detailed patient scenarios promote and enhance the clinical decision-making skills of students at all levels. The system provides detailed instructions for preparation and implementation of the simulation experience, debriefing questions that encourage critical thinking, and learning resources to reinforce student comprehension. Each scenario in *Simulation Learning System* complements the textbook content and helps bridge the gap between lectures and clinicals. This system provides the perfect environment for students to practice what they are learning in the text for a true-to-life, hands-on learning experience.

MULTIMEDIA SUPPLEMENTS FOR INSTRUCTORS AND STUDENTS

- **Nursing Skills Online 3.0** contains 18 modules rich with animations, videos, interactive activities, and exercises to help students prepare for their clinical lab experience. The instructionally designed lessons focus on topics that are difficult to master and pose a high risk to the patient if done incorrectly. Lesson quizzes allow students to check their learning curve and review as needed, and the module exams feed out to an instructor grade book. Modules cover Airway Management, Blood Therapy, Bowel Elimination/Ostomy Care, Chest Tubes, Enteral Nutrition, Infection Control, Injections, IV Fluid Administration, IV Fluid Therapy Management, IV Medication Administration, Nonparenteral Medication Administration, Safe Medication Administration, Safety, Specimen Collection, Urinary Catheterization, Vascular Access, Vital Signs, and Wound Care. Available alone or packaged with the text.
- **Mosby's Nursing Video Skills: Basic, Intermediate, Advanced, 4th edition** provides 126 skills with overview information covering skill purpose, safety, and delegation guides; equipment lists; preparation procedures; procedure videos with printable step-by-step guidelines; appropriate follow-up care; documentation guidelines; and interactive review questions. Available online, as a student DVD set, or as a networkable DVD set for the institution.

Nursing Today

Nursing is an art and a science. As a professional nurse you will learn to deliver care artfully with compassion, caring, and respect for each patient's dignity and personhood. As a science, nursing practice is based on a body of knowledge that is continually changing with new discoveries and innovations. When you integrate the art and science of nursing into your practice, the quality of care you provide to your patients is at a level of excellence that benefits patients and their families.

NURSING AS A PROFESSION

A variety of career opportunities are available in nursing, including clinical practice, education, research, management, administration, and even entrepreneurship. As a student it is important for you to understand the scope of professional nursing practice and how nursing influences the lives of your patients, their families, and their communities.

The patient is the center of your practice. Your patient includes individuals, families, and/or communities. Patients have a wide variety of health care needs, knowledge, experiences, vulnerabilities, and expectations; but this is what makes nursing both challenging and rewarding. Making a difference in your patients' lives is fulfilling (e.g., helping a dying patient find relief from pain, helping a young mother learn parenting skills, and finding ways for older adults to remain independent in their homes). Nursing offers personal and professional rewards every day. This chapter presents a contemporary view of the evolution of nursing and nursing practice and the historical, practical, social, and political influences on the discipline of nursing.

Nursing is not simply a collection of specific skills, and you are not simply a person trained to perform specific tasks. Nursing is a profession. No one factor absolutely differentiates a job from a profession, but the difference is important in terms of how you practice. To act professionally you administer quality patient-centered care in a safe, prudent, and knowledgeable manner. You are responsible and accountable to yourself, your patients, and your peers.

Health care advocacy groups recognize the importance of the role quality professional nursing has on the nations' health care. One such program is the Robert Wood Johnson Foundation (RWJF) *Future of Nursing: Campaign for Action* (RWJF, 2014a). This program is a multifaceted campaign to transform health care through nursing, and it is a response to the Institute of Medicine (IOM) publication on *The Future of Nursing* (IOM, 2010). Together these initiatives prepare a professional workforce to meet health promotion, illness prevention, and complex care needs of the population in a changing health care system.

Science and Art of Nursing Practice

Because nursing is both an art and a science, nursing practice requires a blend of the most current knowledge and practice standards with an insightful and compassionate approach to patient care. Your patients' health care needs are multidimensional and constantly changing. Thus your care will reflect the needs and values of society and professional standards of care and performance, meet the needs of each patient, and integrate evidence-based findings to provide the highest level of care.

Nursing has a specific body of knowledge; however, it is essential that you socialize within the profession and practice to fully

BOX 1-1   Benner: From Novice to Expert

- **Novice:** Beginning nursing student or any nurse entering a situation in which there is no previous level of experience (e.g., an experienced operating room nurse chooses to now practice in home health). The learner learns via a specific set of rules or procedures, which are usually stepwise and linear.
- **Advanced Beginner:** A nurse who has had some level of experience with the situation. This experience may only be observational in nature, but the nurse is able to identify meaningful aspects or principles of nursing care.
- **Competent:** A nurse who has been in the same clinical position for 2 to 3 years. This nurse understands the organization and specific care required by the type of patients (e.g., surgical, oncology, or orthopedic patients). He or she is a competent practitioner who is able to anticipate nursing care and establish long-range goals. In this phase the nurse has usually had experience with all types of psychomotor skills required by this specific group of patients.
- **Proficient:** A nurse with more than 2 to 3 years of experience in the same clinical position. This nurse perceives a patient's clinical situation as a whole, is able to assess an entire situation, and can readily transfer knowledge gained from multiple previous experiences to a situation. This nurse focuses on managing care as opposed to managing and performing skills.
- **Expert:** A nurse with diverse experience who has an intuitive grasp of an existing or potential clinical problem. This nurse is able to zero in on the problem and focus on multiple dimensions of the situation. He or she is skilled at identifying both patient-centered problems and problems related to the health care system or perhaps the needs of the novice nurse.

Data from Benner P: *From novice to expert: excellence and power in clinical nursing practice,* Menlo Park, CA, 1984, Addison-Wesley.

BOX 1-2   ANA Standards of Nursing Practice

1. **Assessment:** The registered nurse collects comprehensive data pertinent to the patient's health and/or the situation.
2. **Diagnosis:** The registered nurse analyzes the assessment data to determine the diagnoses or issues.
3. **Outcomes Identification:** The registered nurse identifies expected outcomes for a plan individualized to the patient or the situation.
4. **Planning:** The registered nurse develops a plan that prescribes strategies and alternatives to attain expected outcomes.
5. **Implementation:** The registered nurse implements the identified plan.
   - 5a. **Coordination of Care:** The registered nurse coordinates care delivery.
   - 5b. **Health Teaching and Health Promotion:** The registered nurse uses strategies to promote health and a safe environment.
   - 5c. **Consultation:** The graduate level–prepared specialty nurse or advanced practice registered nurse provides consultation to influence the identified plan, enhance the abilities of others, and effect change.
   - 5d. **Prescriptive Authority and Treatment:** The advanced practice registered nurse uses prescriptive authority, procedures, referrals, treatment, and therapies in accordance with state and federal laws and regulations.
6. **Evaluation:** The registered nurse evaluates progress toward attainment of outcomes.

understand and apply this knowledge and develop professional expertise. Clinical expertise takes time and commitment. According to Benner (1984), an expert nurse passes through five levels of proficiency when acquiring and developing generalist or specialized nursing skills (Box 1-1).

Expert clinical nursing practice is a commitment to the application of knowledge, ethics, aesthetics, and clinical experience. Your ability to interpret clinical situations and make complex decisions is the foundation for your nursing care and the basis for the advancement of nursing practice and the development of nursing science (Benner, 1984; Benner et al., 1997, 2010). Critical thinking skills are essential to nursing (see Chapter 15). When providing nursing care, you need to make clinical judgments and decisions about your patients' health care needs based on knowledge, experience, critical-thinking attitudes, and standards of care. Use critical thinking skills and reflections to help you gain and interpret scientific knowledge, integrate knowledge from clinical experiences, and become a lifelong learner (Benner et al., 2010).

Use the competencies of critical thinking in your practice. This includes integrating knowledge from the basic sciences and nursing, applying knowledge from past and present experiences, applying critical thinking attitudes to a clinical situation, and implementing intellectual and professional standards. When you provide well–thought out care with compassion and caring, you provide each patient the best of the science and art of nursing care (see Chapter 7).

Scope and Standards of Practice

When giving care, it is essential to provide a specified service according to standards of practice and to follow a code of ethics (ANA, 2015). Professional practice includes knowledge from social and behavioral sciences, biological and physiological sciences, and nursing theories.

In addition, nursing practice incorporates ethical and social values, professional autonomy, and a sense of commitment and community (ANA, 2010b). The following definition from the **American Nurses Association (ANA)** illustrates the consistent commitment of nurses to provide care that promotes the well-being of their patients and communities (ANA, 2010a). **Nursing** is *the protection, promotion, and optimization of health and abilities; prevention of illness and injury; alleviation of suffering through the diagnosis and treatment of human response; and advocacy in the care of individuals, families, communities, and populations* (ANA, 2010b). The **International Council of Nurses** (ICN, 2014) has another definition: *Nursing encompasses autonomous and collaborative care of individuals of all ages, families, groups, and communities, sick or well, and in all settings. Nursing includes the promotion of health; prevention of illness; and the care of ill, disabled, and dying people. Advocacy, promotion of a safe environment, research, participation in shaping health policy and in patient and health systems management, and education are also key nursing roles.* Both of these definitions support the prominence and importance that nursing holds in providing safe, patient-centered health care to the global community.

Since 1960 the ANA has defined the scope of nursing and developed Standards of Practice and Standards of Professional Performance (ANA, 2010b). It is important that you know and apply these standards in your practice (Box 1-2). Most schools of nursing and practice settings have published copies of the scope and standards of nursing practice. The scope and standards of practice guide nurses to make significant and visible contributions that improve the health and well-being of all individuals, communities, and populations (ANA, 2010b).

Standards of Practice. The Standards of Practice describe a competent level of nursing care. The levels of care are demonstrated by a critical thinking model known as the nursing process: assessment,

BOX 1-3 ANA Standards of Professional Performance

1. **Ethics:** The registered nurse practices ethically.
2. **Education:** The registered nurse attains knowledge and competency that reflects current nursing practice.
3. **Evidence-Based Practice and Research:** The registered nurse integrates evidence and research findings into practice.
4. **Quality of Practice:** The registered nurse contributes to quality nursing practice.
5. **Communication:** The registered nurse communicates effectively in all areas of practice.
6. **Leadership:** The registered nurse demonstrates leadership in the professional practice setting and the profession.
7. **Collaboration:** The registered nurse collaborates with health care consumer, family, and others in the conduct of nursing practice.
8. **Professional Practice Evaluation:** The registered nurse evaluates her or his own nursing practice in relation to professional practice standards and guidelines, relevant statutes, rules, and regulations.
9. **Resources:** The registered nurse uses appropriate resources to plan and provide nursing services that are safe, effective, and financially responsible.
10. **Environmental Health:** The registered nurse practices in an environmentally safe and healthy manner.

diagnosis, outcomes identification and planning, implementation, and evaluation (ANA, 2010b). The nursing process is the foundation of clinical decision making and includes all significant actions taken by nurses in providing care to patients (see Unit III).

Standards of Professional Performance. The ANA Standards of Professional Performance (Box 1-3) describe a competent level of behavior in the professional role (ANA, 2010b). The standards provide a method to assure patients that they are receiving high-quality care, that the nurses must know exactly what is necessary to provide nursing care, and that measures are in place to determine whether nursing care meets the standards.

Code of Ethics. The **code of ethics** is the philosophical ideals of right and wrong that define the principles you will use to provide care to your patients. It is important for you to also incorporate your own values and ethics into your practice. As you incorporate these values, you explore what type of nurse you will be and how you will function within the discipline (ANA, 2015). Ask yourself how your ethics, values, and practice compare with established standards. The ANA has a number of publications that address ethics and human rights in nursing. *The Code of Ethics for Nurses With Interpretive Statements* is a guide for carrying out nursing responsibilities that provide quality nursing care; it also outlines the ethical obligations of the profession (ANA, 2015). Chapter 22 provides a review of the nursing code of ethics and ethical principles for everyday practice.

Professional Responsibilities and Roles

You are responsible for obtaining and maintaining specific knowledge and skills for a variety of professional roles and responsibilities. Nurses provide care and comfort for patients in all health care settings. Nurses' concern for meeting their patient's needs remains the same whether care focuses on health promotion and illness prevention, disease and symptom management, family support, or end-of-life care.

Autonomy and Accountability. Autonomy is an essential element of professional nursing that involves the initiation of independent nursing interventions without medical orders. Although the nursing profession regulates accountability through nursing audits and standards of practice, you also need to develop a commitment to personal professional accountability. For example, you independently implement coughing and deep-breathing exercises for a patient who recently had surgery. As you continue to care for this patient, a complication arises. You note that the patient has a fever and the surgical wound has a yellow-green discharge. You collaborate with other health professionals to develop the best treatment plan for this patient's surgical wound infection. With increased autonomy comes greater responsibility and accountability. Accountability means that you are responsible professionally and legally for the type and quality of nursing care provided. You must remain current and competent in nursing and scientific knowledge and technical skills.

Caregiver. As a **caregiver** you help patients maintain and regain health, manage disease and symptoms, and attain a maximal level of function and independence through the healing process. You provide healing through psychomotor and interpersonal skills. Healing involves more than achieving improved physical well-being. You need to meet all health care needs of a patient by providing measures to restore a patient's emotional, spiritual, and social well-being. As a caregiver you help patients and families set realistic goals and meet them.

Advocate. As a **patient advocate** you protect your patient's human and legal rights and provide assistance in asserting these rights if the need arises. As an advocate you act on behalf of your patient and secure your patient's health care rights (Emrich et al., 2013). For example, you provide additional information to help a patient decide whether or not to accept a treatment, or you find an interpreter to help family members communicate their concerns. You sometimes need to defend patients' rights to make health care decisions in a general way by speaking out against policies or actions that put patients in danger or conflict with their rights (Wilson et al., 2013).

Educator. As an educator you explain concepts and facts about health, describe the reason for routine care activities, demonstrate procedures such as self-care activities, reinforce learning or patient behavior, and evaluate the patient's progress in learning. Some of your patient teaching is unplanned and informal. For example, during a casual conversation you respond to questions about the reason for an intravenous infusion, a health issue such as smoking cessation, or necessary lifestyle changes. Other teaching activities are planned and more formal such as when you teach your patient how to self-administer insulin injections. Always use teaching methods that match your patient's capabilities and needs and incorporate other resources such as the family in teaching plans (see Chapter 25).

Communicator. Your effectiveness as a communicator is central to the nurse-patient relationship. It allows you to know your patients, including their strengths, weaknesses, and needs. Communication is essential for all nursing roles and activities. You will routinely communicate with patients and families, other nurses and health care professionals, resource people, and the community. Without clear communication it is impossible to advocate for your patients or to give comfort and emotional support, give care effectively, make decisions with patients and families, protect patients from threats to well-being,

coordinate and manage patient care, assist patients in rehabilitation, or provide patient education (Emrich et al., 2013). Quality communication is a critical factor in meeting the needs of individuals, families, and communities (see Chapter 24).

Manager. Today's health care environment is fast paced and complex. Nurse managers need to establish an environment for collaborative patient-centered care to provide safe, quality care with positive patient outcomes. A manager coordinates the activities of members of the nursing staff in delivering nursing care and has personnel, policy, and budgetary responsibility for a specific nursing unit or agency. A manager uses appropriate leadership styles to create a nursing environment for patients and staff that reflects the mission and values of the health care organization (see Chapter 21).

Career Development

Innovations in health care, expanding health care systems and practice settings, and the increasing needs of patients have created new nursing roles. Today the majority of nurses practice in hospital settings, followed by community-based care, ambulatory care, and nursing homes/extended care settings.

Nursing provides an opportunity for you to commit to lifelong learning and career development. Because of increasing educational opportunities for nurses, the growth of nursing as a profession, and a greater concern for job enrichment, the nursing profession offers different career opportunities. Your career path is limitless. You will probably switch career roles more than once. Take advantage of the different clinical practice and professional opportunities. Examples of these career opportunities include advanced practice registered nurses (APRNs), nurse researchers, nurse risk managers, quality improvement nurses, consultants, and even business owners.

Provider of Care. Most nurses provide direct patient care in an acute care setting. However, as changes in health care services and reimbursement continue, there will be an increase in the direct care activities provided in the home care setting and an increased need for community-based health promotion activities.

Educate your patients and families how to maintain their health and implement self-care activities. While collaborating with other health care team members, focus your care on returning a patient to his or her home at an optimal functional status.

In the hospital you may choose to practice in a medical-surgical setting or concentrate on a specific area of specialty practice such as pediatrics, critical care, or emergency care. Most specialty care areas require some experience as a medical-surgical nurse and additional continuing or in-service education. Many intensive care unit and emergency department nurses are required to have certification in advanced cardiac life support and critical care, emergency nursing, or trauma nursing.

Advanced Practice Registered Nurses. The **advanced practice registered nurse (APRN)** is the most independently functioning nurse. An APRN has advanced education in pathophysiology, pharmacology, and physical assessment and certification and expertise in a specialized area of practice (AACN, 2011). There are four core roles for the APRN: clinical nurse specialist (CNS), certified nurse practitioner (CNP), certified nurse midwife (CNM), and certified RN anesthetist (CRNA). The educational preparation for the four roles is in at least one of the following six populations: adult-gerontology, pediatrics, neonatology, women's health/gender related, family/individual across the life span, and psychiatric mental health. APRNs function

FIGURE 1-1 Nurse specialist consults on a difficult patient case. (iStock.com/Sturti.)

as clinicians, educators, case managers, consultants, and researchers within their area of practice to plan or improve the quality of nursing care for patients and families.

Clinical Nurse Specialist. A **clinical nurse specialist (CNS)** is an APRN who is an expert clinician in a specialized area of practice (Figure 1-1). The specialty may be identified by a population (e.g., geriatrics), a setting (e.g., critical care), a disease specialty (e.g., diabetes), a type of care (e.g., rehabilitation), or a type of problem (e.g., pain) (National CNS Competency Task Force, 2010). Some examples of CNS practice settings include community, acute care, restorative, and palliative.

Nurse Practitioner. A **nurse practitioner (NP)** is an APRN who provides health care to a group of patients, usually in an outpatient, ambulatory care, or community-based setting. NPs provide care for patients with complex problems and a more holistic approach than physicians. The NP provides comprehensive care, directly managing the nursing and medical care of patients who are healthy or who have chronic conditions. An NP establishes a collaborative provider-patient relationship and works with a specific group of patients or with patients of all ages and health care needs.

Certified Nurse-Midwife. A **certified nurse-midwife (CNM)** is an APRN who is also educated in midwifery and is certified by the American College of Nurse-Midwives. The practice of nurse-midwifery involves providing independent care for women during normal pregnancy, labor, and delivery and care for the newborn. It includes some gynecological services such as routine Papanicolaou (Pap) smears, family planning, and treatment for minor vaginal infections.

Certified Registered Nurse Anesthetist. A **certified registered nurse anesthetist (CRNA)** is an APRN with advanced education from a nurse anesthesia–accredited program. Before applying to a nurse anesthesia program, a nurse must have at least 1 year of critical care or emergency experience. Nurse anesthetists provide surgical anesthesia under the guidance and supervision of an anesthesiologist who is a physician with advanced knowledge of surgical anesthesia.

Nurse Educator. A **nurse educator** works primarily in schools of nursing, staff development departments of health care agencies, and patient education departments. Nurse educators need experience in clinical practice to provide them with practical skills and theoretical knowledge. A faculty member in a nursing program educates students to become professional nurses. Nursing faculty members are responsible for teaching current nursing practice; trends; theory; and

necessary skills in classroom, laboratories, and clinical settings. Nursing faculty usually have graduate degrees such as a master's degree in nursing or an earned doctorate in nursing or related field. Generally they have a specific clinical, administrative, or research specialty and advanced clinical experience.

Nurse educators in staff development departments of health care institutions provide educational programs for nurses within their institution. These programs include orientation of new personnel, critical care nursing courses, assisting with clinical skill competency, safety training, and instruction about new equipment or procedures. These nursing educators often participate in the development of nursing policies and procedures.

The primary focus of the nurse educator in a patient education department of an agency such as a wound treatment clinic is to teach and coach patients and their families how to self-manage their illness or disability and make positive choices or change their behaviors to promote their health. These nurse educators are usually specialized and hold a certification such as a certified diabetes educator (CDE) or an ostomy care nurse and see only a specific population of patients.

Nurse Administrator. A **nurse administrator** manages patient care and the delivery of specific nursing services within a health care agency. Nursing administration begins with positions such as clinical care coordinators. Experience and additional education sometimes lead to a middle-management position such as nurse manager of a specific patient care area or house supervisor or to an upper-management position such as an associate director or director of nursing services.

Nurse manager positions usually require at least a baccalaureate degree in nursing, and director and nurse executive positions generally require a master's degree. Chief nurse executive and vice president positions in large health care organizations often require preparation at the doctoral level. Nurse administrators often have advanced degrees such as a master's degree in nursing administration, hospital administration (MHA), public health (MPH), or an MBA.

In today's health care organizations directors have responsibility for more than one nursing unit. They often manage a particular service or product line such as medicine or cardiology. Vice presidents of nursing or chief nurse executives often have responsibilities for all clinical functions within the hospital. This may include all ancillary personnel who provide and support patient care services. The nurse administrator needs to be skilled in business and management and understand all aspects of nursing and patient care. Functions of administrators include budgeting, staffing, strategic planning of programs and services, employee evaluation, and employee development.

Nurse Researcher. The **nurse researcher** conducts evidence-based practice and research to improve nursing care and further define and expand the scope of nursing practice (see Chapter 5). She or he often works in an academic setting, hospital, or independent professional or community service agency. The preferred educational requirement is a doctoral degree, with at least a master's degree in nursing.

Nursing Shortage

There is an ongoing shortage of qualified RNs to fill vacant positions (AACN, 2014; IOM, 2010). This shortage affects all aspects of nursing, including patient care, administration, and nursing education; but it also represents challenges and opportunities for the profession (Tanner and Bellack, 2010). Many health care dollars are invested in strategies aimed at recruiting and retaining a well-educated, critically thinking, motivated, and dedicated nursing workforce (Benner et al., 2010). There is a direct link between direct care by an RN and positive patient outcomes, reduced complication rates, and a more rapid return of the patient to an optimal functional status (Aiken, 2010, 2013a,b).

Professional nursing organizations predict that the number of nurses will continue to diminish (AACN, 2011; Aiken, 2010, 2013a). With fewer available nurses, it is important for you to learn to use your patient contact time efficiently and professionally. Time management, therapeutic communication, patient education, and compassionate implementation of bedside skills are just a few of the essential skills you need. It is important for your patients to leave the health care setting with a positive image of nursing and a feeling that they received quality care. Your patients should never feel rushed. They need to feel that they are important and are involved in decisions and that their needs are met. If a certain aspect of patient care requires 15 minutes of contact, it takes you the same time to deliver organized and compassionate care as it does if you rushed through your nursing care.

HISTORICAL INFLUENCES

Nurses have responded and always will respond to the needs of their patients. In times of war they responded by meeting the needs of the wounded in combat zones and military hospitals in the United States and abroad. When communities face health care crises such as disease outbreaks or insufficient health care resources, nurses establish community-based immunization and screening programs, treatment clinics, and health promotion activities. Our patients are most vulnerable when they are injured, sick, or dying.

Today nurses are active in determining best practices in a variety of areas such as skin care management, pain control, nutritional management, and care of individuals across the life span. Nurse researchers are leaders in expanding knowledge in nursing and other health care disciplines. Their work provides evidence for practice to ensure that nurses have the best available evidence to support their practices (see Chapter 5).

Knowledge of the history of the nursing profession increases your ability to understand the social and intellectual origins of the discipline. Although it is not practical to describe all of the historical aspects of professional nursing, some of the more significant nursing leaders and milestones are described in the following paragraphs.

Florence Nightingale

In *Notes on Nursing: What It Is and What It Is Not,* Florence Nightingale established the first nursing philosophy based on health maintenance and restoration (Nightingale, 1860). She saw the role of nursing as having "charge of somebody's health" based on the knowledge of "how to put the body in such a state to be free of disease or to recover from disease" (Nightingale, 1860). During the same year she developed the first organized program for training nurses, the Nightingale Training School for Nurses at St. Thomas' Hospital in London.

Nightingale was the first practicing nurse epidemiologist. Her statistical analyses connected poor sanitation with cholera and dysentery. She volunteered during the Crimean War in 1853 and traveled the battlefield hospitals at night carrying her lamp; thus she was known as the "lady with the lamp." The sanitary, nutrition, and basic facilities in the battlefield hospitals were poor at best. Eventually she was tasked with organizing and improving the quality of sanitation facilities. As a result, the mortality rate at the Barracks Hospital in Scutari, Turkey, was reduced from 42.7% to 2.2% in 6 months (Donahue, 2011).

The Civil War to the Beginning of the Twentieth Century

The Civil War (1860 to 1865) stimulated the growth of nursing in the United States. Clara Barton, founder of the American Red Cross, tended soldiers on the battlefields, cleansing their wounds, meeting their basic needs, and comforting them in death. Mother Bickerdyke organized ambulance services and walked abandoned battlefields at night, looking for wounded soldiers. Harriet Tubman was active in the Underground Railroad movement and helped to lead over 300 slaves to freedom (Donahue, 2011). The first professionally trained African-American nurse was Mary Mahoney. She was concerned with the effect culture had on health care, and as a noted nursing leader she brought forth an awareness of cultural diversity and respect for the individual, regardless of background, race, color, or religion.

Nursing in hospitals expanded in the late nineteenth century. However, nursing in the community did not increase significantly until 1893, when Lillian Wald and Mary Brewster opened the Henry Street Settlement, which focused on the health needs of poor people who lived in tenements in New York City (Donahue, 2011).

Twentieth Century

In the early twentieth century a movement toward developing a scientific, research-based defined body of nursing knowledge and practice evolved. Nurses began to assume expanded and advanced practice roles. Mary Adelaide Nutting, who became the first nursing professor at Columbia Teacher's College in 1906, was instrumental in moving nursing education into universities (Donahue, 2011).

As nursing education developed, nursing practice also expanded, and the Army and Navy Nurse Corps were established. By the 1920s nursing specialization began. Graduate nurse-midwifery programs began; in the last half of the century specialty-nursing organizations were created.

Twenty-First Century

Today the profession faces multiple challenges. Nurses and nurse educators are revising nursing practice and school curricula to meet the ever-changing needs of society, including an aging population, bioterrorism, emerging infections, and disaster management. Advances in technology and informatics (see Chapter 26), the high acuity level of care of hospitalized patients, and early discharge from health care institutions require nurses in all settings to have a strong and current knowledge base from which to practice.

Nursing organizations and the RWJF are currently involved in programs to support nursing scholars, decrease the nursing shortage, and improve the health of the nation's population (RWJF, 2014a,b). Nursing is taking a leadership role in developing standards and policies to address the needs of the population now and in the future.

CONTEMPORARY INFLUENCES

Multiple external forces affect nursing, including the need for nurses' self-care, the Affordable Care Act (ACA) and rising health care costs, demographic changes of the population, human rights, and increasing numbers of medically underserved.

Importance of Nurses' Self-Care

You cannot give fully engaged, compassionate care to others when you feel depleted or do not feel cared for yourself. Nurses experience grief and loss too. Many times, even before a nurse has a chance to recover from an emotionally draining situation, he or she encounters another difficult human story. Nurses in acute care settings often witness prolonged, concentrated suffering on a daily basis, leading to feelings of frustration, anger, guilt, sadness, or anxiety. Nursing students report feeling initially hesitant and uncomfortable with their first encounters with a dying patient and identify feelings of sadness, anxiety, and discomfort.

Frequent, intense, or prolonged exposure to grief and loss places nurses at risk for developing compassion fatigue. *Compassion fatigue* is a term used to describe a state of burnout and secondary traumatic stress (Potter et al., 2013a). It occurs without warning and often results from giving high levels of energy and compassion over a prolonged period to those who are suffering, often without experiencing improved patient outcomes (Potter et al., 2010). Secondary traumatic stress is the trauma that health care providers experience when witnessing and caring for others suffering trauma. Examples include an oncology nurse who cares for patients undergoing surgery and chemotherapy over the long term for their cancer or a spouse who witnesses his wife deteriorating over the years from Alzheimer's disease.

Burnout is the condition that occurs when perceived demands outweigh perceived resources (Potter et al., 2013a). It is a state of physical and mental exhaustion that often affects health care providers because of the nature of their work environment. Over time, giving of oneself in often intense caring environments sometimes results in emotional exhaustion, leaving a nurse feeling irritable, restless, and unable to focus and engage with patients (Potter et al., 2013b). This often occurs in situations in which there is a lack of social support, organizational pressures influencing staffing, and the inability of the nurse to practice self-care. Compassion fatigue typically results in feelings of hopelessness, a decrease in the ability to take pleasure from previously enjoyable activities, a state of hypervigilance, and anxiety.

Compassion fatigue impacts the health and wellness of nurses and the quality of care provided to patients. Nurses experience changes in job performance and in their personal lives, increased demands, and a desire to leave the profession or their specialty. In addition, these factors affect an agency's ability to maintain a caring, competent staff and patient satisfaction.

When health care agencies develop interventions to help nurses manage compassion fatigue, nurse retention and job satisfaction rates improve. Agency-based programs that provide opportunities to validate the caregiver's experiences and an opportunity to talk about the challenges of the type of care nurses give are basic interventions to begin to manage these factors and their implication for professional nursing care. More complex interventions include specific programs that teach nurses how to more effectively cope with the challenges of care to offset the stress related to the care (Potter et al., 2010).

When a nurse experiences ongoing stressful patient relationships, he or she often disengages (Slatten et al., 2011). This disengagement can also occur when perceived stress comes from nurse-physician or nurse-nurse relationships. It is not uncommon for nurses who are experiencing compassion fatigue to become angry or cynical and have difficulty relating with patients and co-workers (Young et al., 2011).

Compassion fatigue may contribute to what is described as *lateral violence.* Health care providers do not always voice concerns about patients and actively avoid conflict in clinical settings (Lyndon et al., 2011). However, lateral violence sometimes occurs in nurse-nurse interactions and includes behaviors such as withholding information, making snide remarks, and demonstrating nonverbal expressions of disapproval such as raising eyebrows or making faces. New graduates and nurses new to a unit are most likely to face problems with lateral or horizontal violence (Lachman, 2014).

All nurses require resiliency skills to better manage the stressors that contribute to compassion fatigue and lateral violence. Skills such as

managing stress and conflict, building connections with colleagues to share difficult stories, and self-care are helpful in dealing with difficult situations and contribute to safe and effective care (Mahon and Nicotera, 2011).

However, interventions in the health care agency alone are not enough. Nurses need to be self-aware, allowing them to identify their own vulnerability to secondary traumatic stress and burnout (see Chapter 38). Participating in health promotion activities is also effective in identifying and managing the stressors that lead to compassion fatigue. Chapter 6 provides a guide to identify effective interventions that help nurses identify and manage health-related risk factors from prolonged caregiver stress.

The Affordable Care Act and Rising Health Care Costs

The ACA affects how health care is paid for and delivered (see Chapter 2). There will be greater emphasis on health promotion, disease prevention, and illness management in the future. The ACA impacts how and where nursing care is provided. More nursing services will be in community-based care settings. As a result, more nurses will be needed to practice in community care centers, schools, and senior centers. This will require nurses to be better able to assess for resources, identify service gaps, and help patients adapt to safely return to their community.

Skyrocketing health care costs present challenges to the nursing profession, consumer, and health care delivery system. As a nurse you are responsible for providing patients with the best-quality care in an efficient and economically sound manner. The challenge is to use health care and patient resources wisely. Chapter 2 summarizes reasons for the rise in health care costs and its implications for nursing

Demographic Changes

The U.S. Census Bureau (2014) continues to predict a continuing rise in the population, with an increase in the population over 65. This change alone requires expanded health care resources. To effectively meet all the health care needs of the expanding and aging population, changes need to occur as to how care is provided, especially in the areas of outpatient-, community-, and home-based services (see Chapters 2 and 3). The population is still shifting from rural areas to urban centers, and more people are living with chronic and long-term illness (RWJF, 2014b).

Medically Underserved

Unemployment, underemployment and low-paying jobs, mental illness, homelessness, and rising health care costs all contribute to increases in the medically underserved population. Caring for this population is a global issue; the social, political, and economic factors of a country affect both access to care and resources to provide and pay for these services (Huicho et al., 2010). In addition, the number of underserved patients who require home-based palliative care services is increasing. This is a group of patients whose physical status does not improve and health care needs increase. As a result, the cost for home-based care continues to rise, to the point that some patients opt out of all palliative services because of costs (Fernandes et al., 2010).

TRENDS IN NURSING

Nursing is a dynamic profession that grows and evolves as society and lifestyles change, as health care priorities and technologies change, and as nurses themselves change. The current philosophies and definitions of nursing have a holistic focus, which addresses the needs of the whole person in all dimensions, in health and illness, and in interaction with the family and community. In addition, there continues to be an increasing awareness for patient safety in all care settings.

Evidence-Based Practice

Today the general public is more informed about their health care needs, the cost of health care, and the incidence of medical errors within health care institutions. Your practice needs to be based on current evidence, not just according to your education and experiences and the policies and procedures of health care facilities (see Chapter 5). Health care organizations can show their commitment to each health care stakeholder (e.g., patients, insurance companies, and governmental agencies) to reduce health care errors and improve patient safety by implementing evidence-based practices (National Quality Forum, 2010). In addition, many hospitals are achieving Magnet Recognition, which recognizes excellence in nursing practice (ANCC, 2014). A component of excellence in practice is quality of care, which is achieved by implementing evidenced-based practice (see Chapter 2).

Quality and Safety Education for Nurses

The RWJF sponsored the **Quality and Safety Education for Nurses (QSEN)** initiative to respond to reports about safety and quality patient care by the IOM (Barton et al., 2009). QSEN addresses the challenge to prepare nurses with the competencies needed to continuously improve the quality of care in their work environments (Table 1-1). The QSEN initiative encompasses the competencies of patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics (Cronenwett et al., 2007). For each competency there are targeted knowledge, skills, and attitudes (KSAs). The KSAs are elements that are integrated in a nursing prelicensure program (Jarzemsky et al., 2010). As you gain experience in clinical practice, you will encounter situations in which your education helps you to make a difference in improving patient care (Box 1-4).

Whether that difference in care is to provide evidence for implementing care at the bedside, identifying a safety issue, or reviewing patient data to identify trends in outcomes, each of these situations requires competence in patient-centered care, safety, or informatics. Although it is not within the scope of this textbook to present the QSEN initiative in its entirety, subsequent clinical chapters will provide you an opportunity to address how to build competencies in one or more of these areas.

QSEN **QSEN: BUILDING COMPETENCY IN PATIENT-CENTERED CARE** You are caring for Kitty, a 10-year-old with severe delayed development. Kitty, an only child, lives with her parents and goes to a school that is able to meet her needs. Her mom gives her seizure medicine each day, and her seizures are well controlled. Kitty has very little independent function. She needs assistance with all of her activities of daily living (e.g., bathing, toileting, eating, and hygiene). Up to now Kitty's parents are able to provide all of her care and meet her needs. As Kitty gets older and bigger, it will be difficult for her mom and dad to provide this care. They want to keep Kitty in her current school as long as possible. They are looking at in-home physical care assistance and anticipate needing to make decisions about Kitty's home care within the next 2 years. After thinking about this scenario, which questions do you need to ask to determine how best to guide the family to establish a comprehensive home care team? How would you help Kitty's parents ask these questions when they interview home care services?

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

TABLE 1-1   **Quality and Safety Education for Nurses**

Competency	Definition with Examples
Patient-Centered Care	Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs. Examples: Involve family and friends in care. Elicit patient values and preferences. Provide care with respect for diversity of the human experience.
Teamwork and Collaboration	Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality patient care. Examples: Recognize the contributions of other health team members and patient's family members. Discuss effective strategies for communicating and resolving conflict. Participate in designing methods to support effective teamwork.
Evidence-Based Practice	Integrate best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal health care. Examples: Demonstrate knowledge of basic scientific methods. Appreciate strengths and weaknesses of scientific bases for practice. Appreciate the importance of regularly reading relevant journals.
Quality Improvement	Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems. Examples: Use tools such as flow charts and diagrams to make process of care explicit. Appreciate how unwanted variation in outcomes affects care. Identify gaps between local and best practices.
Safety	Minimize risk of harm to patients and providers through both system effectiveness and individual performance. Examples: Examine human factors and basic safety design principles and commonly used unsafe practices. Value own role in preventing errors.
Informatics	Use information and technology to communicate, manage knowledge, mitigate error, and support decision making. Examples: Navigate an electronic health record. Protect confidentiality of protected health information in electronic health records.

Adapted from Cronenwett L et al: Quality and safety education for nurses, *Nurs Outlook* 57:122, 2007.

BOX 1-4   **EVIDENCE-BASED PRACTICE**

Safety Competencies and Patient-Centered Care

PICO Question: Do teaching strategies targeted at interprofessional communication develop competencies in teamwork and collaboration in new graduates?

Evidence Summary
Patient care needs are increasingly complex, and this trend is expected to continue well into the future. The American Association of Colleges of Nursing (AACN) (AACN, 2008) endorsed a new set of guidelines that parallel the QSEN competencies to direct the preparation of baccalaureate nurses to provide safe, high-quality patient care (Barton et al., 2009). Health professions education must prepare all students for "deliberately working together" toward a safer and better health care system. Collaboration and teamwork are essential competencies in delivering safe, effective patient-centered care (Headrick et al., 2012).

Students need more than classroom and clinical experiences to understand the intricacies of effective teamwork and collaboration. Institution of QSEN content into schools' curricula enables students to practice teamwork and collaboration in safe, clinical simulations (Barnsteiner et al., 2013). For teamwork and collaboration to be successful, there must be strong and clear communication between and among all health care professions. Adverse events, omission of care, and confusion are serious events in today's health care environments.

An academic/clinical partnership provides consistent class and clinical environments for students to safely incorporate teamwork and collaboration early in the clinical practicum (Didion et al., 2013). Inaccurate communication among health care providers leads to serious events (Barnsteiner et al., 2013). Teaching effective communication strategies across the disciplines is an effective method to help bridge this gap (Robinson et al., 2010).

Application to Nursing Practice
- Communicate with clarity and precision when designing multidisciplinary plans of care (Robinson et al., 2010).
- Create a safety huddle so all health care staff are aware of the clinical objectives (Didion et al., 2013).
- Set up communication simulations to increase caregiver's knowledge about the expertise of other health care disciplines (Headrick et al., 2012; Didion et al., 2013).
- Recognize that electronic communication may be quick but in some situations may not be effective (Robinson et al., 2010). When patient care issues are at stake, a focused, well-organized interdisciplinary meeting is more effective than a series of "round-robin" e-mails (Robinson et al., 2010).
- It usually takes the same amount of time to communicate and collaborate ineffectively as it does to do it effectively.

Impact of Emerging Technologies

Many emerging technologies have the potential to rapidly change nursing practice. Some of these help nurses use noninvasive, more accurate assessment tools; implement evidence-based practices; collect and trend patient outcome data; and use clinical decision support systems. The electronic health record (EHR) offers an efficient method to record and manage patient health care information (see Chapter 26). In addition, computerized physician/provider order entry (CPOE) is a key patient safety initiative (Houston, 2014).

Three skills sets are needed to respond to these emerging technologies (Houston, 2013). First, you need to use technology to facilitate mobility, communication, and relationships. Telehealth and telemedicine functions, video conferencing, and simulations provide opportunities for nurses, health care professionals, and patients and families to communicate about specific health care issues. Second, you need to develop an expertise to acquire and distribute knowledge. Evidence-based practice, clinical decision support systems, and case-based reasoning are all methods to increase information acquisition and distribution. Last, you need to understand and use genomics. Effective use of genomic information in a confidential, ethical, and culturally appropriate manner helps health care providers and patients make informed care decisions (Houston, 2013).

Genomics

Genetics is the study of inheritance, or the way traits are passed down from one generation to another. Genes carry the instructions for making proteins, which in turn direct the activities of cells and functions of the body that influence traits such as hair and eye color. **Genomics** is a newer term that describes the study of all the genes in a person and interactions of these genes with one another and with that person's environment (CDC, 2015). Using genomic information allows health care providers to determine how genomic changes contribute to patient conditions and influence treatment decisions (Miaskowski and Aouizerat, 2012). For example, when a family member has colon cancer before the age of 50, it is likely that other family members are at risk for developing this cancer. Knowing this information is important for family members who will need a colonoscopy before the age of 50 and repeat colonoscopies more often than the patient who is not at risk. In this case nurses are essential in identifying the patients' risk factors through assessment and counseling patients about what this genomic finding means to them personally and to their family.

Public Perception of Nursing

Nursing is a pivotal health care profession. As frontline health care providers, nurses practice in all health care settings and constitute the largest number of health care professionals. They are essential to providing skilled, specialized, knowledgeable care; improving the health status of the public; and ensuring safe, effective quality care (ANA, 2010b).

Consumers of health care are more informed than ever; with the Internet consumers have access to more health care and treatment information. For example, *Hospital Compare* is a consumer-oriented website that allows people to select multiple hospitals and directly compare performance measure information on specific diseases such as health attack, heart failure, pneumonia, and surgery (CMS, 2014). This information can help consumers make informed decisions about health care.

Consumers can also access *Hospital Consumer Assessment of Healthcare Providers Systems* (HCAHPS) to obtain information about patients' perspectives on hospital care. Although many hospitals collect information on patient satisfaction, HCAHPS helps consumers obtain valid comparisons about patient perspectives across all hospitals. This information is intended to allow consumers to make "apples to apples" comparisons to support their choice (HCAHPS, 2015).

Publications such as *To Err Is Human* (IOM, 2000) describe strategies for government, health care providers, industry, and consumers to reduce preventable medical errors. When you care for patients, realize how your approach to care influences public opinion. Always act in a competent professional manner.

Impact of Nursing on Politics and Health Policy

Political power or influence is known as the ability to influence or persuade an individual holding a government office to exert the power of that office to affect a desired outcome. Nurses' involvement in politics is receiving greater emphasis in nursing curricula, professional organizations, and health care settings. Professional nursing organizations and state nursing boards employ lobbyists to urge state legislatures and the U.S. Congress to improve the quality of health care (Mason et al., 2012).

The ANA works for the improvement of health standards and the availability of health care services for all people, fosters high standards of nursing, stimulates and promotes the professional development of nurses, and advances their economic and general welfare. The ANA's

purposes are unrestricted by considerations of nationality, race, creed, lifestyle, color, gender, or age.

Nurses are active in social policy and political arenas. Nurses and their professional organizations lobby for health care legislation to meet the needs of patients, particularly the medically underserved. For example, nurses in communities provide home visits to newborns of high-risk mothers (e.g., adolescent, poorly educated, or medically underserved). These visits result in fewer emergency department visits, fewer newborn infections, fewer developmental delays, and reduced infant mortality (Mason et al., 2012).

You can influence policy decisions at all governmental levels. One way to get involved is by participating in local and national efforts (Mason et al., 2012). This effort is critical to exerting nurses' influence early in the political process. When nurses become serious students of social needs, activists in influencing policy to meet those needs, and generous contributors of time and money to nursing organizations and to candidates working for universal good health care, the future is bright indeed (Mason et al., 2012).

PROFESSIONAL REGISTERED NURSE EDUCATION

Nursing requires a significant amount of formal education. The issues of standardization of nursing education and entry into practice remain a major controversy. Most nurses agree that nursing education is important to practice and that education needs to respond to changes in health care created by scientific and technological advances. Various education preparations are available for an individual intending to be an RN. In addition, graduate nurse education and continuing and in-service education are available for practicing nurses.

Currently in the United States the most frequent way to become a **registered nurse (RN)** is through completion of either an associate or baccalaureate degree program. Graduates of both programs are eligible to take the National Council Licensure Examination for Registered Nurses (NCLEX-RN®) to become RNs in the state in which they will practice.

The associate degree program in the United States is a 2-year program that is usually offered by a university or community college. This program focuses on the basic sciences and theoretical and clinical courses related to the practice of nursing.

The baccalaureate degree program usually includes 4 years of study in a college or university. It focuses on the basic sciences; theoretical and clinical courses; and courses in the social sciences, arts, and humanities to support nursing theory. In Canada the degree of Bachelor of Science in Nursing (BScN) or Bachelor in Nursing (BN) is equivalent to the degree of Bachelor of Science in Nursing (BSN) in the United States. The *Essentials of Baccalaureate Education for Professional Nursing* (AACN, 2008) delineates essential knowledge, practice and values, attitudes, personal qualities, and professional behavior for the baccalaureate-prepared nurse and guides faculty on the structure and evaluation of the curriculum. Standards published by nursing program accrediting organizations typically specify core competencies for the professional nurse that should be in the nursing curriculum. In addition, one of the IOM recommendations is that 80% of nurses be prepared with a baccalaureate in nursing by 2020 (IOM, 2010) (see Chapter 2). Thus nurses with associate degrees often return to school to earn their baccalaureate degree.

Graduate Education

After obtaining a baccalaureate degree in nursing, you can pursue graduate education leading to a master's or doctoral degree in any number of graduate fields, including nursing. A nurse completing a graduate program can receive a master's degree in nursing. The

graduate degree provides the advanced clinician with strong skills in nursing science and theory. Graduate education emphasizes advance knowledge in the basic sciences and research-based clinical practice. A master's degree in nursing is important for the roles of nurse educator and nurse administrator, and it is required for an APRN.

   Doctoral Preparation. Professional doctoral programs in nursing (DSN or DNSc) prepare graduates to apply research findings to clinical nursing. Other doctoral programs prepare nurses for more rigorous research and theory development and award the research-oriented Doctor of Philosophy (PhD) in nursing. Recently the AACN recommended the Doctor of Nursing Practice (DNP) as the terminal practice degree and required preparation for all APRNs. The DNP is a practice-focused doctorate. It provides skills in obtaining expanded knowledge through the formulation and interpretations of evidence-based practice (Chism, 2010).

   The need for nurses with doctoral degrees is increasing. Expanding clinical roles and continuing demand for well-educated nursing faculty, nurse administrators, and APRNs in the clinical settings and new areas of nursing specialties such as nursing informatics are just a few reasons for increasing the number of doctoral-prepared nurses.

Continuing and In-Service Education

Nursing is a knowledge-based profession, and technological expertise and clinical decision making are qualities that our health care consumers demand and expect. Continuing education programs help nurses maintain current nursing skills, gain new knowledge and theory, and obtain new skills reflecting the changes in the health care delivery system (Hale et al., 2010). **Continuing education** involves formal, organized educational programs offered by universities, hospitals, state nurses associations, professional nursing organizations, and educational and health care institutions. An example is a program on caring for older adults with dementia offered by a university or a program on safe medication practices offered by a hospital. Continuing education updates your knowledge about the latest research and practice developments, helps you to specialize in a particular area of practice, and teaches you new skills and techniques (Hale et al., 2010). In some states continuing education is required for RNs to keep their licenses.

   In-service education programs are instruction or training provided by a health care agency or institution. An in-service program is held in the institution and is designed to increase the knowledge, skills, and competencies of nurses and other health care professionals employed by the institution. Often in-service programs are focused on new technologies such as how to correctly use the newest safety syringes. Many in-service programs are designed to fulfill required competencies of an organization. For example, a hospital might offer an in-service program on safe principles for administering chemotherapy or a program on cultural sensitivity.

NURSING PRACTICE

You will have an opportunity to practice in a variety of settings, in many roles within those settings, and with caregivers in other related health professions. The ANA standards of practice, standards of performance, and code of ethics for nurses are part of the public recognition of the significance of nursing practice to health care and implications for nursing practice regarding trends in health care. State and provincial nurse practice acts (NPAs) establish specific legal regulations for practice, and professional organizations establish standards of practice as criteria for nursing care.

Nurse Practice Acts

In the United States the State Boards of Nursing oversee NPAs. NPAs regulate the scope of nursing practice and protect public health, safety, and welfare. This protection includes shielding the public from unqualified and unsafe nurses. Although each state defines for itself the scope of nursing practice, most have similar NPAs. The definition of nursing practice published by the ANA is representative of the scope of nursing practice as defined in most states. However, in the last decade many states have revised their NPAs to reflect the growing autonomy of nursing and the expanded roles of nurses in practice. For example, NPAs expanded their scope to include minimum education requirements, required certifications, and practice guidelines for APRNs such as nurse practitioners and certified RN anesthetists. The expansion of scope of practice includes skills unique to the advanced practice role (e.g., advanced assessment, prescriptive authority for certain medications and diagnostic procedures, and some invasive procedures).

Licensure and Certification

   Licensure. In the United States all boards of nursing require RN candidates to pass the NCLEX-RN®. Regardless of educational preparation, the examination for RN licensure is exactly the same in every state in the United States. This provides a standardized minimum knowledge base for nurses. Other requirements for licensure such as criminal background checks vary from state to state.

   Certification. Beyond the NCLEX-RN®, the nurse may choose to work toward certification in a specific area of nursing practice. Minimum practice requirements are set, based on the certification the nurse seeks. National nursing organizations such as the ANA have many types of certification to enhance your career such as certification in medical surgical or geriatric nursing. After passing the initial examination, you maintain your certification by ongoing continuing education and clinical or administrative practice.

PROFESSIONAL NURSING ORGANIZATIONS

A **professional organization** deals with issues of concern to those practicing in the profession. In addition to the educational organizations previously discussed, a variety of specialty organizations exist. For example, some organizations focus on specific areas such as critical care, advanced practice, maternal-child nursing, and nursing research. These organizations seek to improve the standards of practice, expand nursing roles, and foster the welfare of nurses within the specialty areas. In addition, professional organizations present educational programs and publish journals.

   As a student you have the opportunity to take part in organizations such as the National Student Nurses Association (NSNA) in the United States and the Canadian Student Nurses Association (CSNA) in Canada. These organizations consider issues of importance to nursing students such as career development and preparation for licensing. The NSNA often cooperates in activities and programs with the professional organizations.

█ **KEY POINTS**

- Nursing responds to the health care needs of society, which are influenced by economic, social, and cultural variables of a specific era.

- Changes in society such as increased technology, new demographic patterns, consumerism, health promotion, and the women's and human rights movements lead to changes in nursing.
- Nursing definitions reflect changes in the practice of nursing and help bring about changes by identifying the domain of nursing practice and guiding research, practice, and education.
- Nursing standards provide the guidelines for implementing and evaluating nursing care.
- Professional nursing organizations deal with issues of concern to specialist groups within the nursing profession.
- Nurses are becoming more politically sophisticated and, as a result, are able to increase the influence of nursing on health care policy and practice.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. You are on the patient safety committee at your hospital. Your assignment is to identify two sources related to safety. One resource must relate to the individual nurse, and the second must relate to the practice and work environment. Identify the ANA website and use this site to identify the resources.
2. Mrs. Langman is in the hospital recovering from hip replacement surgery. Her surgery involved insertion of a new type of hip replacement prosthesis and newer postsurgical care. The advanced practice registered nurse (APRN) is preparing her discharge medication and rehabilitation prescriptions. The staff nurse is preparing to transfer Mrs. Langman to a rehabilitation facility. The nurse educator is conducting bedside rounds to explain the new prosthesis and related postoperative care.
   a. Discuss the roles of the staff nurse, APRN, and nurse educator.
   b. What is the educational preparation for each role?

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. You are preparing a presentation for your classmates regarding the clinical care coordination conference for a patient with terminal cancer. As part of the preparation you have your classmates read the Nursing Code of Ethics for Professional Registered Nurses. Your instructor asks the class why this document is important. Which of the following statements best describes this code?
   1. Improves self–health care
   2. Protects the patient's confidentiality
   3. Ensures identical care to all patients
   4. Defines the principles of right and wrong to provide patient care
2. An 18-year-old woman is in the emergency department with fever and cough. The nurse obtains her vital signs, listens to her lung and heart sounds, determines her level of comfort, and collects blood and sputum samples for analysis. Which standard of practice is performed?
   1. Diagnosis
   2. Evaluation
   3. Assessment
   4. Implementation
3. A patient in the emergency department has developed wheezing and shortness of breath. The nurse gives the ordered medicated nebulizer treatment now and in 4 hours. Which standard of practice is performed?
   1. Planning
   2. Evaluation
   3. Assessment
   4. Implementation
4. A nurse is caring for a patient with end-stage lung disease. The patient wants to go home on oxygen and be comfortable. The family wants the patient to have a new surgical procedure. The nurse explains the risk and benefits of the surgery to the family and discusses the patient's wishes with them. The nurse is acting as the patient's:
   1. Educator.
   2. Advocate.
   3. Caregiver.
   4. Case manager.
5. The nurse spends time with the patient and family reviewing the dressing change procedure for the patient's wound. The patient's spouse demonstrates how to change the dressing. The nurse is acting in which professional role?
   1. Educator
   2. Advocate
   3. Caregiver
   4. Case manager
6. The examination for registered nurse (RN) licensure is exactly the same in every state in the United States. This examination:
   1. Guarantees safe nursing care for all patients.
   2. Ensures standard nursing care for all patients.
   3. Ensures that honest and ethical care is provided.
   4. Provides a minimal standard of knowledge for an RN in practice.
7. Contemporary nursing requires that the nurse has knowledge and skills for a variety of professional roles and responsibilities. Which of the following are examples? (Select all that apply.)
   1. Caregiver
   2. Autonomy and accountability
   3. Patient advocate
   4. Health promotion
   5. Lobbyist
8. Match the advanced practice nurse specialty with the statement about the role.
   1. Clinical nurse specialist
   2. Nurse anesthetist
   3. Nurse practitioner
   4. Nurse-midwife

   a. Provides independent care, including pregnancy and gynecological services
   b. Expert clinician in a specialized area of practice such as adult diabetes care
   c. Provides comprehensive care, usually in a primary care setting, directly managing the medical care of patients who are healthy or have chronic conditions
   d. Provides care and services under the supervision of an anesthesiologist
9. Health care reform will bring changes in the emphasis of care. Which of the following models is expected from health care reform?

1. Moving from an acute illness to a health promotion, illness prevention model
2. Moving from an illness prevention to a health promotion model
3. Moving from an acute illness to a disease management model
4. Moving from a chronic care to an illness prevention model

10. A nurse meets with the registered dietitian and physical therapist to develop a plan of care that focuses on improving nutrition and mobility for a patient. This is an example of which Quality and Safety in the Education of Nurses (QSEN) competency?
    1. Patient-centered care
    2. Safety
    3. Teamwork and collaboration
    4. Informatics

11. A critical care nurse is using a computerized decision support system to correctly position her ventilated patients to reduce pneumonia caused by accumulated respiratory secretions. This is an example of which Quality and Safety in the Education of Nurses (QSEN) competency?
    1. Patient-centered care
    2. Safety
    3. Teamwork and collaboration
    4. Informatics

12. How does knowledge of genomics affect patient treatment decisions?

13. The nurses on an acute care medical floor notice an increase in pressure ulcer formation in their patients. A nurse consultant decides to compare two types of treatment. The first is the procedure currently used to assess for pressure ulcer risk. The second uses a new assessment instrument to identify at-risk patients. Given this information, the nurse consultant exemplifies which career?
    1. Clinical nurse specialist
    2. Nurse administrator
    3. Nurse educator
    4. Nurse researcher

14. Nurses in an acute care hospital are attending a unit-based education program to learn how to use a new pressure-relieving device for patients at risk for pressure ulcers. This is which type of education?
    1. Continuing education
    2. Graduate education
    3. In-service education
    4. Professional Registered Nurse Education

15. Which of the following Internet resources can help consumers compare quality care measures? (Select all that apply.)
    1. WebMD
    2. Hospital Compare
    3. Magnet Recognition Program
    4. Hospital Consumer Assessment of Healthcare
    5. The American Hospital Association's webpage.

The Health Care Delivery System

The U.S. health care system is complex and constantly changing. A broad variety of services are available from different disciplines of health professionals, but gaining access to services is often very difficult for those with limited health care insurance. Uninsured patients present a challenge to health care and nursing because they are more likely to skip or delay treatment for acute and chronic illnesses and die prematurely (Kovner and Knickman, 2011). The continuing development of new technologies and medications, which shortens length of stay (LOS), also causes health care costs to increase. Thus health care institutions are managing health care more as businesses than as service organizations. Challenges to health care leaders today include reducing health care costs while maintaining high-quality care for patients, improving access and coverage for more people, and encouraging healthy behaviors (Kovner and Knickman, 2011). Health care providers are discharging patients sooner from hospitals, resulting in more patients needing nursing homes or home care. Often families provide care for their loved ones in the home setting. As a nurse you

face major challenges to prevent gaps in health care across health care settings so individuals remain healthy and well within their own homes and communities.

Nursing is a caring discipline. Values of the nursing profession are rooted in helping people to regain, maintain, or improve health; prevent illness; and find comfort and dignity. The health care system of the new millennium is less service oriented and more business oriented because of cost-saving initiatives, which often causes tension between the caring and business aspects of health care (Kovner and Knickman, 2011). The Institute of Medicine (IOM) calls for a health care delivery system that is safe, effective, patient centered, timely, efficient, and equitable (IOM, 2001). The National Priorities Partnership is a group of 52 organizations from a variety of health care disciplines that have joined together to work toward transforming health care with the aims of healthy people and healthy communities and better and affordable care (National Priorities Partnership, 2014). The group set the following national priorities:

- Work with communities to promote wide use of best practices to enable healthy living and well-being.
- Promote the most effective prevention, treatment, and intervention practices for the leading causes of mortality, starting with cardiovascular disease.
- Ensure person- and family-centered care.
- Make care safer.
- Promote effective communication and care coordination.
- Make quality care affordable for people, families, employers, and governments.

The IOM (2011) put forth a vision for a transformed health care delivery system. The health care system of the future makes quality care accessible to all populations, focuses on wellness and disease prevention, improves health outcomes, and provides compassionate care across the life span. Transformations in health care are changing the practice of nursing. Nursing continues to lead the way in change and retain values for patient care while meeting the challenges of new roles and responsibilities. These changes challenge nurses to provide evidence-based, compassionate care and continue in the role as patient advocate (Singleton, 2010). According to the IOM report (IOM, 2011), nurses need to be transformed by:

- Practicing to the full extent of their education and training.
- Achieving higher levels of education and training through an improved education system that provides seamless progression.
- Becoming full partners with physicians and other health care providers in redesigning the health care system.
- Improving data collection and information infrastructure for effective workforce planning and policy making.

HEALTH CARE REGULATION AND REFORM

Through most of the twentieth century, few incentives existed for controlling health care costs. Insurers or third-party payers paid for whatever the health care providers ordered for a patient's care and treatment. As health care costs continued to rise out of control, regulatory and competitive approaches had to control health care spending. The federal government, the biggest consumer of health care, which paid for **Medicare** and **Medicaid**, created **professional standards review organizations (PSROs)** to review the quality, quantity, and cost of hospital care. Medicare-qualified hospitals had physician-supervised **utilization review (UR) committees** to review the admissions and identify and eliminate overuse of diagnostic and treatment services ordered by physicians caring for patients on Medicare.

One of the most significant factors that influenced payment for health care was the **prospective payment system (PPS).** Established by Congress in 1983, the PPS eliminated cost-based reimbursement. Hospitals serving patients who received Medicare benefits were no longer able to charge whatever a patient's care cost. Instead the PPS grouped inpatient hospital services for Medicare patients into **diagnosis-related groups (DRGs).** Each group has a fixed reimbursement amount with adjustments based on case severity, rural/urban/regional costs, and teaching costs. Hospitals receive a set dollar amount for each patient based on the assigned DRG, regardless of the patient's LOS or use of services. Most health care providers (e.g., health care networks or managed care organizations) now receive capitated payments. **Capitation** means that the providers receive a fixed amount per patient or enrollee of a health care plan (Sultz and Young, 2014). Capitation aims to build a payment plan for select diagnoses or surgical procedures that consists of the best standards of care at the lowest cost.

Capitation and prospective payment influence the way health care providers deliver care in all types of settings. Many now use DRGs in the rehabilitation setting and **resource utilization groups (RUGs)** in long-term care. In all settings health care providers try to manage costs so the organizations remain profitable. For example, when patients are hospitalized for lengthy periods, hospitals have to absorb the portion of costs that are not reimbursed. This simply adds more pressure to ensure that patients are managed effectively and discharged as soon as is reasonably possible. Thus hospitals started to increase discharge planning activities, and hospital lengths of stay began to shorten. Because patients are discharged home as soon as possible, home care agencies now provide complex technological care, including mechanical ventilation and long-term parenteral nutrition.

Managed care describes health care systems in which a provider or health care system receives a predetermined capitated payment for each patient enrolled in the program. In this case the managed care organization assumes financial risk in addition to providing patient care. The focus of care of the organization shifts from individual illness care to prevention, early intervention, and outpatient care. If people stay healthy, the cost of medical care declines. Systems of managed care focus on containing or reducing costs, increasing patient satisfaction, and improving the health or functional status of individuals (Sultz and Young, 2014). Table 2-1 summarizes the most common types of health care insurance plans.

In 2011 the National Quality Forum (NQF) revised and defined a list of 29 "Never Events" that are devastating and preventable. The "Never Events" are organized in seven categories: surgical, product or device, patient protection, care management, environmental, radiological, and critical. The Joint Commission (TJC) labels "Never Events" as sentinel events and requires a root cause analysis following the event. Many states now require mandatory reporting of these events when they occur (AHRQ PSNet, 2012). In 2007 Medicare ruled that it would no longer pay for medical costs associated with these errors. In the current culture of patient safety and quality, health care organizations are implementing processes to eliminate "Never Events."

Major health care reform came in 2010 with the signing into law of the Patient Protection and Affordable Care Act (PPACA) (Public Law No. 111-148). Health care reform of this magnitude has not occurred in the United States since the 1960s when Medicare and Medicaid were signed into law. It is predicted that implementing the proposed changes with PPACA will be a lengthy process and will change the current health care system (Kovner and Knickman, 2011). The PPACA focused on the major goals of increasing access to health care services for all, reducing health care costs, and improving health care quality. Examples of key provisions in the law include (Kovner and Knickman, 2011; Sultz and Young, 2014):

- All individuals are required to have some form of health insurance by 2014 or pay a penalty through the tax code.
- Public program eligibility, including state Medicaid and Children's Health Insurance, is expanded. Primary care physician payments for Medicaid services increased to equal Medicare payments.
- States will create health insurance exchanges whereby individuals and small business owners can purchase more affordable health insurance. The exchanges will also provide individuals and small employers with consumer information to aid them in making decisions regarding alternative health insurance policies.
- Insurance regulations that prevent private insurance companies from denying insurance coverage for any reason and from charging higher premiums based on health status and gender will be implemented.

TABLE 2-1   Examples of Health Care Plans

Type	Definition	Characteristics
Managed care organization (MCO)	Provides comprehensive preventive and treatment services to a specific group of voluntarily enrolled people. Structures include a variety of models.	Focuses health maintenance, primary care. All care is provided by a primary care physician. Referral is needed for access to specialist and hospitalization. May use capitated payments.
Preferred provider organization (PPO)	Type of managed care plan that limits an enrollee's choice to a list of "preferred" hospitals, physicians, and providers. An enrollee pays more out-of-pocket expenses for using a provider not on the list.	Contractual agreement exists between a set of providers and one or more purchasers (self-insured employers or insurance plans). Comprehensive health services are at a discount to companies under contract. Focus is on health maintenance.
Medicare	A federally administered program by the Commonwealth Fund or the Centers for Medicare and Medicaid Services (CMS); a funded national health insurance program in the United States for people 65 years and older. Part A provides basic protection for medical, surgical, and psychiatric care costs based on diagnosis-related groups (DRGs); also provides limited skilled nursing facility care, hospice, and home health care. Part B is a voluntary medical insurance; covers physician, certain other specified health professional services, and certain outpatient services. Part C is a managed care provision that provides a choice of three insurance plans. Part D is a voluntary Prescription Drug Improvement (Sultz and Young, 2014).	Payment for plan is deducted from monthly individual Social Security check. Covers services of nurse practitioners. Does not pay full cost of certain services such as skilled nursing facilities. Supplemental insurance is encouraged.
Medicaid	Federally funded, state-operated program that provides: (1) health insurance to low-income families; (2) health assistance to low-income people with long-term care (LTC) disabilities; and (3) supplemental coverage and LTC assistance to older adults and Medicare beneficiaries in nursing homes. Individual states determine eligibility and benefits.	Finances a large portion of care for poor children, their parents, pregnant women, and disabled very poor adults. Reimburses for nurse-midwifery and other advanced practice nurses (varies by state). Reimburses nursing home funding.
Private insurance	Traditional fee-for-service plan. Payment is computed after patient receives services on basis of number of services used.	Policies are typically expensive. Most policies have deductibles that patients have to meet before insurance pays.
Long-Term Care (LTC) insurance	Supplemental insurance for coverage of LTC services. Policies provide a set amount of dollars for an unlimited time or for as little as 2 years.	Very expensive. Often has a minimum waiting period for eligibility; payment for skilled nursing, intermediate, or custodial care and home care.
State Children's Health Insurance Program (SCHIP)	Federally funded, state-operated program to provide health coverage for uninsured children. Individual states determine participation eligibility and benefits.	Covers children not poor enough for Medicaid.

- A financial penalty will be assessed to employers of more than 50 employees if they do not offer health insurance coverage to employees.
- Adult children up to the age of 26, regardless of student status, are allowed to be covered under their parents' health insurance plan.

EMPHASIS ON POPULATION WELLNESS

The United States health care delivery system faces many issues such as rising costs, increased access to services, a growing population, and improved quality of health outcomes. As a result, the emphasis of the health care industry today is shifting from managing illness to managing health of a community and the environment.

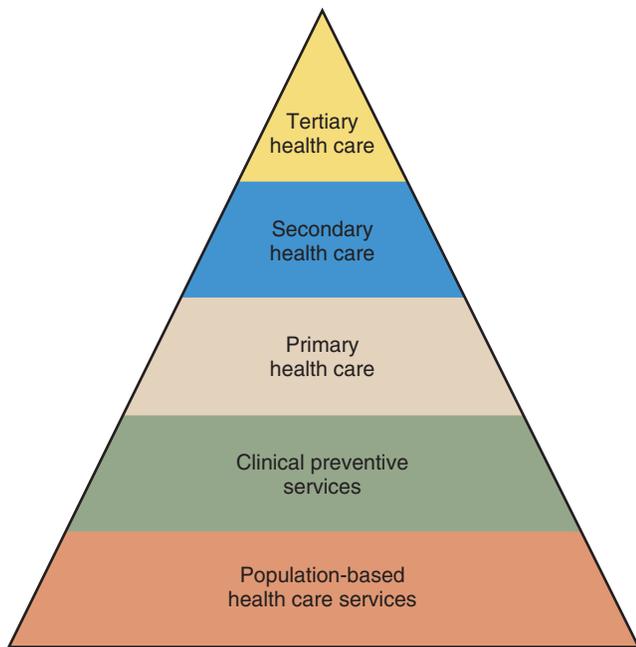
The Health Services Pyramid developed by the Core Functions Project serves as a model for improving the health care of U.S. citizens (Figure 2-1). The pyramid shows that population-based health care services provide the basis for preventive services. These services include primary, secondary, and tertiary health care. Achievements in the lower tiers of the pyramid contribute to the improvement of health care delivered by the higher tiers. Health care in the United States is moving toward practices that emphasize managing health rather than managing illness. This emphasis on wellness and health of populations and the environment enhances quality of life (Stanhope and Lancaster, 2012). The premise is that in the long term health promotion reduces health care costs. A wellness perspective focuses on the health of populations and the communities in which they live rather than just on finding a cure for an individual's disease. Life expectancy for Americans is 78.7 years, which has shown a steady increase in the past century. Along with increased life expectancy, adult deaths related to coronary heart disease and stroke continue a long-term decreasing trend, and there is a decreasing trend in deaths of children since 1900 (Murphy et al., 2013). The reduction in mortality rates has been credited to advancements in sanitation and prevention of infectious diseases (e.g., water, sewage, immunization, and crowded living conditions); patient teaching (e.g., dietary habits, decrease in tobacco use, and blood pressure control); and injury prevention programs (e.g., seat belt restraints, child seats, and helmet laws).


FIGURE 2-1 Health services pyramid. US Public Health Service: *The core functions project,* Washington, DC, 1994/update 2000, Office of Disease Prevention and Health Promotion. (From Stanhope M, Lancaster J: *Public health nursing: population-centered health care in the community, revised reprint,* ed 8, St Louis, 2014, Mosby.)

HEALTH CARE SETTINGS AND SERVICES

Currently the U.S. health care system has five levels of care for which health care providers offer services: disease prevention; health promotion; and primary, secondary, and tertiary health care. The health care settings within which the levels of care are provided include preventive, primary, secondary, tertiary, restorative, and continuing care settings (Box 2-1). Larger health care systems have **integrated delivery networks (IDNs)** that include a network of facilities, providers, and services organized to deliver a continuum of care to a population of patients at a capitated cost in a particular setting. An integrated system reduces duplication of services across levels or settings of care to ensure that patients receive care in the most appropriate settings.

Changes unique to each setting of care have developed because of health care reform. For example, many health care providers now place greater emphasis on wellness, directing more resources toward primary and preventive care services. Nurses are especially important as patient advocates in maintaining continuity of care throughout the levels of care. They have the opportunity to provide leadership to communities and health care systems. The ability to find strategies that better address patient needs at all levels of care is critical to improving the health care delivery system.

Health care agencies seek accreditation and certification as a way to demonstrate quality and safety in the delivery of care and to evaluate the performance of the organization based on established standards. Accreditation is earned by the entire organization; specific programs or services within an organization earn certifications (TJC, 2013). TJC accredits health care organizations across the continuum of care, including hospitals and ambulatory care, long-term care, home care, and behavioral health agencies. Other accrediting agencies have a specific focus such as the Commission on Accreditation of Rehabilitation Facilities (CARF) and the Community Health Accrediting Program (CHAP). Disease-specific certifications are available in most chronic

diseases. Accreditation and certification survey processes help organizations identify problems and develop solutions to improve the safety and quality of delivered care and services.

Preventive and Primary Health Care

Primary health care focuses on improved health outcomes for an entire population. It includes primary care and health education, proper nutrition, maternal/child health care, family planning, immunizations, and control of diseases. Primary health care requires collaboration among health professionals, health care leaders, and community members. This collaboration needs to focus on improving health care equity, making health care systems person centered, developing reliable and accountable health care leaders, and promoting and protecting the health of communities (WHO, 2015). In settings in which patients receive preventive and primary care such as schools, physician's offices, occupational health clinics, community health centers, and nursing centers, health promotion is a major theme (Table 2-2). Health promotion programs lower the overall costs of health care by reducing the incidence of disease, minimizing complications, and thus reducing the need to use more expensive health care resources. In contrast, preventive care is more disease oriented and focused on reducing and controlling risk factors for disease through activities such as immunization and occupational health programs. Chapter 3 provides a more comprehensive discussion of primary health care in the community.

BOX 2-1 Examples of Health Care Services

Primary Care (Health Promotion)
- Prenatal and well-baby care
- Nutrition counseling
- Family planning
- Exercise, yoga, and mediation classes

Preventive Care
- Blood pressure and cancer screenings
- Immunizations
- Mental health counseling and crisis prevention
- Community legislation (e.g., seat belts, air bags, bike helmets, no texting while driving)

Secondary Acute Care
- Emergency care
- Acute medical-surgical care
- Radiological procedures for acute problems (e.g., x-rays, computed tomography [CT] scans)

Tertiary Care
- Intensive care
- Subacute care

Restorative Care
- Cardiovascular and pulmonary rehabilitation
- Orthopedic rehabilitation
- Sports medicine
- Spinal cord injury programs
- Home care

Continuing Care
- Assisted living
- Psychiatric and older adult day care

TABLE 2-2 **Preventive and Primary Care Services**		
Type of Service	**Purpose**	**Available Programs/Services**
School health	These are comprehensive programs that include health promotion principles throughout a school curriculum. They emphasize program management, interdisciplinary collaboration, and community health principles.	Positive life skills Nutritional planning Health screening Physical fitness Counseling Communicable disease prevention Crisis intervention
Occupational health	This is a comprehensive program designed for health promotion and accident or illness prevention in the workplace setting. It aims to increase worker productivity, decrease absenteeism, and reduce use of expensive medical care	Environmental surveillance Physical assessment Health screening Health education Communicable disease control Counseling
Physicians' offices	They provide primary health care (diagnosis and treatment). Many focus on health promotion practices. Nurse practitioners often partner with a physician in managing a patient population (e.g., diabetes, arthritis).	Routine physical examination Health screening Diagnostics Treatment of acute and chronic ailments
Nurse-managed clinics	These clinics provide nursing services with a focus on health promotion and education, chronic disease assessment management, and support for self-care and caregivers.	Day care Health risk appraisal Wellness counseling Employment readiness Acute and chronic care management
Block and parish nursing	Nurses living within a neighborhood provide services to older patients or those unable to leave their homes. It fills in gaps not available in traditional health care system.	Running errands Transportation Respite care Homemaker aides Spiritual health
Community health centers	These are outpatient clinics that provide primary care to a specific patient population (e.g., well-baby, mental health, diabetes) that lives in a specific community. They are often associated with a hospital, medical school, church, or other community organization.	Physical assessment Health screening Disease management Health education Counseling

Secondary and Tertiary Care

In secondary and tertiary care the diagnosis and treatment of illnesses are traditionally the most common services. With managed care, these services are now delivered in primary care settings. For example, many surgeons now perform simple surgeries in office surgical suites. Disease management is the most common and expensive service of the health care delivery system. Chronic illness causes disability, decreased quality of life, and increased health care costs (CDC, 2015). Often patients with chronic illnesses need care from a specialist, leading to increased health care costs.

People who do not have health care insurance often wait longer before presenting for treatment; thus they are usually sicker and need more health care. As a result, secondary and tertiary care (also called **acute care**) are more costly. Young adults turning 19 years of age are in danger of being uninsured because of the inability to attend college, instability with financial independence, and challenges finding employment with health care benefits (Kirzinger et al., 2013). With the passage of the PPACA in 2010, the number of young adults with either private health insurance coverage or employer-sponsored health insurance has increased (Kirzinger et al., 2013). People in this age-group are also less likely to see a doctor on a regular basis and follow up on a problem if they do not have health insurance. With the arrival of more advanced

technology and managed care, physicians now perform simple surgeries in office surgical suites instead of in the hospital. Cost to the patient is lower in the office because the general overhead cost of the facility is lower.

Hospitals. Hospital emergency departments, urgent care centers, critical care units, and inpatient medical-surgical units provide secondary and tertiary levels of care. Quality, safe care is the focus of most acute care organizations, and patient satisfaction with the health care services provided is important. Patient satisfaction becomes a priority in a busy, stressful location such as the inpatient nursing unit. Patients expect to receive courteous and respectful treatment, and they want to be involved in daily care decisions. As a nurse you play a key role in bringing respect and dignity to a patient. Acute care nurses need to be responsive to learning patient needs and expectations early to form effective partnerships that ultimately enhance the level of nursing care given.

Because of managed care, the number of days patients can expect to be hospitalized is limited based on their DRGs on admission. Therefore you need to use resources efficiently to help patients successfully recover and return home. To contain costs, many hospitals have redesigned nursing units. Because of **work redesign,** more

services are available on nursing units, thus minimizing the need to transfer and transport patients across multiple diagnostic and treatment areas.

Hospitalized patients are acutely ill and need comprehensive and specialized tertiary health care. The services provided by hospitals vary considerably. Some small rural hospitals offer only limited emergency and diagnostic services and general inpatient services. In comparison, large urban medical centers offer comprehensive, up-to-date diagnostic services, trauma and emergency care, surgical intervention, intensive care units (ICUs), inpatient services, and rehabilitation facilities. Larger hospitals also offer professional staff from a variety of specialties such as social service, respiratory therapy, physical and occupational therapy, and speech therapy. The focus in hospitals is to provide the highest quality of care possible so patients are discharged early but safely to home or another health care facility that will adequately manage remaining health care needs.

Discharge planning begins the moment a patient is admitted to a health care facility. You play an important role in **discharge planning** in the hospital, where continuity of care is important. To achieve continuity of care, use critical thinking skills and apply the nursing process (see Unit III). To anticipate and identify a patient's needs, work with all members of the interdisciplinary health care team. They take the lead to develop a plan of care that moves a patient from the hospital to another level of health care such as the patient's home or a nursing home. Discharge planning is a centralized, coordinated, interdisciplinary process that ensures that a patient has a plan for continuing care after leaving a health care agency.

Because patients leave hospitals as soon as their physical conditions allow, they often have continuing health care needs when they go home or to another facility. For example, a surgical patient requires wound care at home after surgery. A patient who has had a stroke requires ambulation training. Patients and families worry about how they will care for unmet needs and manage over the long term. Help by anticipating and identifying patients' continuing needs before the actual time of discharge and by coordinating health care team members in achieving an appropriate discharge plan.

Some patients are more in need of discharge planning because of the risks they present (e.g., patients with limited financial resources, limited family support, and long-term disabilities or chronic illness). However, any patient who is being discharged from a health care facility with remaining functional limitations or who has to follow certain restrictions or therapies for recovery needs discharge planning. All caregivers who care for a patient with a specific health problem participate in discharge planning. The process is truly interdisciplinary. For example, patients with diabetes visiting a diabetes management center require the group effort of a diabetes nurse educator, dietitian, and physician to ensure that they return home with the right information to manage their condition. A patient who has experienced a stroke will not be discharged from a hospital until the team has established plans with physical and occupational therapists to begin a program of rehabilitation.

Effective discharge planning often requires referrals to various health care disciplines. In many agencies a health care provider's order is necessary for a referral, especially when planning specific therapies (e.g., physical therapy). It is best to have patients and families participate in referral processes so they are involved early in any necessary decision making. Some tips on making the referral process successful include the following:

- Make a referral as soon as possible.
- Provide the care provider receiving the referral as much information about the patient as possible. This avoids duplication of effort and exclusion of important information.

- Involve the patient and family caregiver in the referral process, including selecting the necessary referral. Explain the service that the referral will provide, the reason for the referral, and what to expect from the services of the referral.
- Determine what the care provider receiving the referral recommends for the patient's care and include this in the treatment plan as soon as possible.

Provide information about community resources available to improve the long-term outcomes of patients with limitations. Discharge planning depends on comprehensive patient and family education (see Chapter 25). Patients and family caregivers need to know what to do when they get home, how to do it, and for what to observe when problems develop. Patients require the following instruction before they leave health care facilities:

- Safe and effective administration of medications
- Safe and proper use of medical equipment
- Instruction in potential food-drug interactions and counseling on nutrition and modified diets
- Rehabilitation techniques to support adaptation to and/or functional independence in the environment
- Access to available and appropriate community resources
- When and how to obtain further treatment
- The patient's and family's responsibilities in the patient's ongoing health care needs and the knowledge and skills needed to carry out those responsibilities
- When to notify their health care provider for changes in functioning or new symptoms

Intensive Care. An ICU or critical care unit is a hospital unit in which patients receive close monitoring and intensive medical care. ICUs have advanced technologies such as computerized cardiac monitors and mechanical ventilators. Although many of these devices are on regular nursing units, patients hospitalized within ICUs are monitored and maintained on multiple devices. Nursing and medical staff have special knowledge about critical care principles and techniques. An ICU is the most expensive health care delivery site because each nurse usually cares for only one or two patients at a time and because of all the treatments and procedures the patients in the ICU require.

Psychiatric Facilities. Patients who suffer emotional and behavioral problems such as depression, violent behavior, and eating disorders often require special counseling and treatment in psychiatric facilities. Located in hospitals, independent outpatient clinics, or private mental health hospitals, psychiatric facilities offer inpatient and outpatient services, depending on the seriousness of the problem. Patients enter these facilities voluntarily or involuntarily. Hospitalization involves relatively short stays with the purpose of stabilizing patients before transfer to outpatient treatment centers. Patients with psychiatric problems receive a comprehensive interdisciplinary treatment plan that involves them and their families. Medicine, nursing, social work, and activity therapy work together to develop a plan of care that enables patients to return to functional states within the community. At discharge from inpatient facilities, patients usually receive a referral for follow-up care at clinics or with counselors.

Rural Hospitals. Access to health care in rural areas has been a serious problem. Most rural hospitals have experienced a severe shortage of primary care providers. Many have closed because of economic failure. In 1989 the Omnibus Budget Reconciliation Act (OBRA) directed the U.S. Department of Health and Human Services (USDHHS) to create a new health care organization, the rural primary care hospital (RPCH). The Balanced Budget Act of 1997 changed

the designation for rural hospitals to Critical Access Hospital (CAH) if certain criteria were met (DHHS CMS, 2012). A CAH is located in a rural area and provides 24-hour emergency care, with no more than 25 inpatient beds for providing temporary care for 96 hours or less to acutely ill or injured patients needing stabilization before transfer to a larger, better-equipped facility. Basic radiological and laboratory services are also available. Physicians, nurse practitioners, or physician assistants staff a CAH.

With health care reform, more big-city health care systems are branching out and establishing connections or merging with rural hospitals. The rural hospitals provide a referral base to the larger tertiary care medical centers. With the development of advanced technologies such as telemedicine, rural hospitals have increased access to specialist consultations. Nurses who work in rural hospitals or clinics require competence in physical assessment, clinical decision making, and emergency care. Having a culture of evidence-based practice (EBP) is important in rural hospitals so nurses practice using the best evidence to achieve optimal patient outcomes and an environment of quality and safety (Newhouse and Morlock, 2011). Advanced practice nurses (e.g., nurse practitioners and clinical nurse specialists) use medical protocols and establish collaborative agreements with staff physicians to ensure that they provide safe, evidence-based care.

Restorative Care

Patients recovering from an acute or chronic illness or disability often require additional services to return to their previous level of function or reach a new level of function limited by their illness or disability. The goals of **restorative care** are to help individuals regain maximal functional status and enhance quality of life through promotion of independence and self-care. With the emphasis on early discharge from hospitals, patients usually require some level of restorative care. For example, some patients require ongoing wound care and activity and exercise management until they have recovered enough following surgery to independently resume normal activities of daily living.

The intensity of care has increased in restorative care settings because patients leave hospitals earlier. The restorative health care team is an interdisciplinary group of health professionals and includes a patient and family or significant others. In restorative settings nurses recognize that success depends on effective and early collaboration with patients and their families. Patients and families require a clear understanding of goals for physical recovery, the rationale for any physical limitations, and the purpose and potential risks associated with therapies. Patients and families are more likely to follow treatment plans and achieve optimal functioning when they are involved in restorative care.

Home Care. **Home care** is the provision of medically related professional and paraprofessional services and equipment to patients and families in their homes for health maintenance, education, illness prevention, diagnosis and treatment of disease, palliation, and rehabilitation. Nursing is one service that most patients use in home care. However, home care also includes medical and social services; physical, occupational, speech, and respiratory therapy; and nutritional therapy. A home care service also coordinates the access to and delivery of home health equipment, or durable medical equipment, which is a medical product adapted for home use.

Health promotion and education are traditionally the primary objectives of home care, yet at present most patients receive home care because they need nursing care. Examples of home nursing care include monitoring vital signs; assessment; administering parenteral or enteral nutrition, medications, and intravenous (IV) or blood therapy; and wound or respiratory care. The focus is on patient and family independence. Nurses address recovery and stabilization of illness in the home and identify problems related to lifestyle, safety, environment, family dynamics, and health care practices.

Approved home care agencies usually receive reimbursement for services from the government (such as Medicare and Medicaid in the United States), private insurance, and private pay. The government has strict regulations that govern reimbursement for home care services. An agency cannot simply charge whatever it wants for a service and expect to receive full reimbursement. Government programs set the cost of reimbursement for most professional services.

Nurses in home care provide individualized care. They have a caseload and help patients adapt to permanent or temporary physical limitations so they are able to assume a more normal daily home routine. Home care requires a strong knowledge base in many areas such as family dynamics (see Chapter 10), cultural practices (see Chapter 9), spiritual values (see Chapter 36), and communication principles (see Chapter 24).

Rehabilitation. **Rehabilitation** restores a person to the fullest physical, mental, social, vocational, and economic potential possible. Patients require rehabilitation after a physical or mental illness, injury, or chemical addiction. Specialized rehabilitation services such as cardiovascular, neurological, musculoskeletal, pulmonary, and mental health rehabilitation programs help patients and families adjust to necessary changes in lifestyle and learn to function with the limitations of their disease. Drug rehabilitation centers help patients become free from drug dependence and return to the community.

Rehabilitation services include physical, occupational, and speech therapy and social services. Ideally rehabilitation begins the moment a patient enters a health care setting for treatment. For example, some orthopedic programs now have patients perform physical therapy exercises before major joint repair to enhance their recovery after surgery. Initially rehabilitation usually focuses on preventing complications related to an illness or injury. As the condition stabilizes, it helps to maximize a patient's functioning and level of independence.

Rehabilitation occurs in many health care settings, including special rehabilitation agencies, outpatient settings, and the home. Frequently patients needing long-term rehabilitation (e.g., patients who have had strokes and spinal cord injuries) have severe disabilities affecting their ability to carry out the activities of daily living. When rehabilitation services occur in outpatient settings, patients receive treatment at specified times during the week but live at home the rest of the time. Health care providers use rehabilitation strategies specific to the home environment. Nurses and other members of the health care team visit homes and help patients and families learn to adapt to illness or injury.

Extended Care Facilities. An **extended care facility** provides intermediate medical, nursing, or custodial care for patients recovering from acute illness or those with chronic illnesses or disabilities. Extended care facilities include intermediate care and skilled nursing facilities. Some include long-term care and assisted-living facilities. At one point extended care facilities primarily cared for older adults. However, because hospitals discharge their patients sooner, there is a greater need for intermediate care settings for patients of all ages. For example, health care providers transfer a young patient who has experienced a traumatic brain injury resulting from a car accident to an extended care facility for rehabilitative or supportive care until discharge to the home becomes a safe option.

An intermediate care or **skilled nursing facility** offers skilled care from a licensed nursing staff. This often includes administration of IV fluids, wound care, long-term ventilator management, and physical rehabilitation. Patients receive extensive supportive care until they

are able to move back into the community or into residential care. Extended care facilities provide around-the-clock nursing coverage. Nurses who work in a skilled nursing facility need nursing expertise similar to that of nurses working in acute care inpatient settings, along with a background in gerontological nursing principles (see Chapter 14).

Continuing Care

Continuing care describes a variety of health, personal, and social services provided over a prolonged period. These services are for people who are disabled, who were never functionally independent, or who suffer a terminal disease. The need for continuing health care services is growing in the United States. People are living longer, and many of those with continuing health care needs have no immediate family members to care for them. A decline in the number of children families choose to have, the aging of care providers, and the increasing rates of divorce and remarriage complicate this problem. Continuing care is available within institutional settings (e.g., nursing centers or nursing homes, group homes, and retirement communities), communities (e.g., adult day care and senior centers), or the home (e.g., home care, home-delivered meals, and hospice) (Meiner, 2011).

Nursing Centers or Facilities. The language of long-term care is confusing and constantly changing. The nursing home has been the dominant setting for long-term care (Meiner, 2011). With the 1987 OBRA, *nursing facility* became the term for nursing homes and other facilities that provided long-term care. Now *nursing center* is the most appropriate term. A nursing center typically provides 24-hour intermediate and custodial care such as nursing, rehabilitation, dietary, recreational, social, and religious services for residents of any age with chronic or debilitating illnesses. In some cases patients stay in nursing centers for room, food, and laundry services only. The majority of people living in nursing centers are older adults. A nursing center is a resident's temporary or permanent home, with surroundings made as homelike as possible (Sorrentino and Remmert, 2012). The philosophy of care is to provide a planned, systematic, and interdisciplinary approach to nursing care to help residents reach and maintain their highest level of function.

The nursing center industry is one of the most highly regulated industries in the United States. These regulations raised the standard of services that nursing centers are required to provide (Box 2-2). One regulatory area that deserves special mention is that of resident rights.

Nursing facilities have to recognize residents as active participants and decision makers in their care and life in institutional settings (Meiner, 2011). This also means that family members are active partners in planning residents' care.

Interdisciplinary functional assessment of residents is the cornerstone of clinical practice within nursing centers (Meiner, 2011). Government regulations require that staff comprehensively assess each resident and make care planning decisions within a prescribed period. A resident's functional ability (e.g., ability to perform activities of daily living) and long-term physical and psychosocial well-being are the focus. Staff must complete the Resident Assessment Instrument (RAI) on all residents. The RAI consists of the **Minimum Data Set (MDS)** (Box 2-3), Resident Assessment Protocols, and utilization guidelines of each state. The collected information provides a national database for nursing facilities so policy makers will better understand the health care needs of the long-term care population. The MDS is a rich resource for nurses in determining the best interventions to support the health care needs of this growing population.

Assisted Living. Assisted living is one of the fastest growing industries within the United States. There are approximately 31,000 assisted-living facilities that house more than 971,000 people in the United States (NCAL, 2014). **Assisted living** offers an attractive long-term care setting with an environment more like home and greater resident autonomy. Residents require some assistance with activities of daily living but remain relatively independent within a partially protective setting. A group of residents live together, but each resident has his or her own room and shares dining and social activity areas. Usually people keep all of their personal possessions in their residences. Facilities range from hotel-like buildings with hundreds of units to modest group homes that house a handful of seniors. Assisted living provides independence, security, and privacy all at the same time (Touhy and Jett, 2012). These facilities promote physical and psychosocial health (Figure 2-2). Services in an assisted-living facility include laundry, assistance with meals and personal care, 24-hour oversight, and housekeeping (NCAL, 2014). Some facilities provide assistance with medication administration. Nursing care services are not always directly available, although home care nurses can visit patients in

BOX 2-2 Major Regulatory Requirements Defined by the 1987 Omnibus Budget Reconciliation Act

- Resident rights
- Admission, transfer, and discharge rights
- Resident behavior and facility practices
- Quality of life
- Resident assessment
- Quality of care
- Nursing services
- Dietary services
- Physician services
- Specialized rehabilitative services
- Dental services
- Pharmacy services
- Infection control
- Physical environment
- Administration

From Health Care Financing Administration, Department of Health and Human Services: *Requirements for states and long-term care facilities,* 42 CFR 483 Subpart B (483.1-75), 2014, http://www.gpo .gov/fdsys/pkg/CFR-2011-title42-vol5/pdf/CFR-2011-title42-vol5-part483 .pdf. Accessed July 9, 2015.

BOX 2-3 Minimum Data Set and Examples of Resident Assessment Protocols

Minimum Data Set
- Resident's background
- Cognitive, communication/hearing, and vision patterns
- Physical functioning and structural problems
- Mood, behavior, and activity patterns
- Psychosocial well-being
- Bowel and bladder continence
- Health conditions
- Disease diagnoses
- Oral/nutritional and dental status
- Skin condition
- Medication use
- Special treatments and procedures

Resident Assessment Protocols (Examples)
- Delirium
- Falls
- Pressure ulcers
- Psychotropic drug use

FIGURE 2-2 Providing nursing services in assisted-living facilities promotes physical and psychosocial health.

assisted-living facilities. Unfortunately most residents of assisted-living facilities pay privately. The national median monthly fee is $3500 for a private unit (NCAL, 2014). With no government fee caps and little regulation, assisted living is not always an option for individuals with limited financial resources.

Respite Care. The need to care for family members within the home creates great physical and emotional problems for family caregivers, especially if the people for whom they care have either physical or cognitive limitations. A family caregiver not only has the responsibility for providing care to a loved one, but usually needs to maintain a full-time job, raise a family, and manage the routines of daily living as well. **Respite care** is a service that provides short-term relief or "time off" for people providing home care to an individual who is ill, disabled, or frail (Meiner, 2011). Respite care is offered in the home, a day care setting, or a health care institution that provides overnight care. The family caregiver is able to leave the home for errands or some social time while a responsible person stays in the home to care for the loved one. There are few formal respite care programs in the United States because of cost. Currently Medicare does not cover respite care, and Medicaid has strict requirements for services and eligibility (Sultz and Young, 2014).

Adult Day Care Centers. **Adult day care centers** provide a variety of health and social services to specific patient populations who live alone or with family in the community. Services offered during the day allow family members to maintain their lifestyles and employment and still provide home care for their relatives (Meiner, 2011). Day care centers are associated with a hospital or nursing home or exist as independent centers. Frequently the patients need continuous health care services (e.g., physical therapy or counseling) while their families or support people work. The centers usually operate 5 days per week during typical business hours and usually charge on a daily basis. Adult day care centers allow patients to retain more independence by living at home, thus potentially reducing the costs of health care by avoiding or delaying an older adult's admission to a nursing center. Nurses working in day care centers provide continuity between care delivered in the home and the center. For example, nurses ensure that patients continue to take prescribed medication and administer specific treatments. Knowledge of community needs and resources is essential in providing adequate patient support (Touhy and Jett, 2012).

Hospice. A **hospice** is a system of family-centered care that allows patients to live with comfort, independence, and dignity while easing the pains of terminal illness. The focus of hospice care is palliative care,

not curative treatment (see Chapters 37 and 44). Hospice care can be provided in the patient's home, an inpatient hospice unit or a free-standing hospice home. The interdisciplinary team in the hospice works continuously with a patient's health care provider to develop and maintain a patient-directed individualized plan of care. Many hospice programs provide respite care, which is important in maintaining the health of the primary caregiver and family.

Care Coordination

A problem that many patients face in today's complex health care delivery system is lack of coordination of care and services. Health care reform has stimulated the development of two models focused on coordinating medical care for patients and families. The first, accountable care organizations (ACOs) were developed to coordinate medical care by primary care and specialty physicians, hospitals, and other health care providers, with the goal of providing high-quality coordinated care (Colpas, 2013). An ACO strives to ensure that patients receive the right care at the right time, without duplication of services or incidence of medical errors (CMS, 2012). In an ACO, all health care providers are accountable for the quality and cost of care delivered to patients. Nurses are a key part of the ACO, acting as leaders and care coordinators (Amara et al., 2013).

The second model of care developed to improve coordination of care is the patient-centered medical home (PCMH). The goal of a PCMH is to make care for patients more efficient, effective, continuous, comprehensive, patient centered, and coordinated (Kovner and Knickman, 2011; NCQA, 2014). The PCMH uses technology, teamwork, and effective communication with patients to make care culturally sensitive and accessible, gather clinical data, promote patient participation in decision-making, and monitor patient outcomes (NCQA, 2014). The primary care health provider functions as the "hub" of the PCMH (Sultz and Young, 2014). Reports indicate that patients in a PCMH have increased access to care and that the PCMH helps to decrease disparities for lower-income patients (NCQA, 2014).

ISSUES AND CHANGES IN HEALTH CARE DELIVERY

The climate in health care today influences both health care professionals and consumers. Because those who provide patient care are the most qualified to make changes in the health care delivery system, you need to participate fully and effectively within all aspects of health care. As you face issues of how to maintain health care quality while reducing costs, you need to acquire the knowledge, skills, and values necessary to practice competently and effectively. It is also more important than ever to collaborate with other health care professionals to design new approaches for patient care delivery.

Nursing Shortage

There are more than 3.1 million nurses in the United States, making nursing the largest health care profession in the country (American Association of Colleges of Nursing [AACN], 2011). Although nearly 57% of the nurses work in medical-surgical hospitals, they are involved in delivering health care at all levels, including primary and preventive care (AACN, 2011). In spite of the large number of practicing nurses, a critical shortage of nurses is projected in the United States. It is expected that this shortage will worsen with increased need for health care services by the aging baby-boomer generation (AACN, 2014). The U.S. Department of Labor (2013) lists nursing as one of the top job growth professions through 2022, predicting that by 2022 there will be 1.05 million job openings for nurses. The age of the nursing workforce is increasing, with over 55% of the workforce over the age of 50 years (AACN, 2014). One factor contributing to the shortage is the slow

growth in nursing school enrollments, often because of nursing faculty shortages, space limitations, and clinical site availability (AACN, 2014).

Competency

The Pew Health Professions Commission, a national and interdisciplinary group of health care leaders, recommended 21 competencies for health care professionals in the twenty-first century (Pew Health Professions Commission, 1998). The competencies emphasize the importance of public service, caring for the health of communities, and developing ethically responsible behaviors. In addressing the continued challenge facing the health care system, the IOM (2001) identified five interrelated competencies that are essential for all health care workers in the twenty-first century (Box 2-4). Shifting the emphasis on prevention and management places increased importance on the competencies of care management and coordination, patient education, public health, and transitional care (IOM, 2011). The IOM also identified 10 important rules of performance for a health care system to follow to better meet patient needs (Box 2-5) (IOM, 2003).

The health care practitioner competencies are an excellent tool for measuring how well a nurse practices nursing and serve as a guide for the development of a professional nursing career. A consumer of health care expects that the standards of nursing care and practice in any health care setting are appropriate, safe, and effective. Health care organizations ensure quality care by establishing policies, procedures, and protocols that are evidence based and follow national accrediting standards. Your responsibility is to follow policies and procedures and know the most current practice standards. Ongoing competency is

your responsibility. You are also responsible for obtaining necessary continuing education, following an established code of ethics, and earning certifications in specialty areas.

Quality and Safety in Health Care

Nursing plays an important role in quality and safety in health care (Box 2-6). Quality health care is the "degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge" (IOM, 2001). Safety is a critical part of quality health care. The

BOX 2-5 Ten Rules of Performance in a Redesigned Health Care System

1. Care is based on continuous healing relationships.
2. Care is individualized based on patient needs and values.
3. The patient is the source of control, participating in shared decision making.
4. Knowledge is shared, and information flows freely.
5. Decision making is evidence based, with care based on the best available scientific knowledge.
6. Safety is a system property and focused on reducing errors.
7. Transparency is necessary through sharing information with patients and families.
8. Patient needs are anticipated through planning.
9. Waste is continuously decreased.
10. Cooperation and communication among clinicians are priorities.

Adapted from Institute of Medicine (IOM): *Crossing the quality chasm: a new health system for the 21st century,* Washington DC, 2001, National Academies Press; and Institute of Medicine: *Health professions education: a bridge to quality,* Washington, DC, 2003, National Academies Press.

BOX 2-4 Institute of Medicine Competencies for the Twenty-First Century

Provide Patient-Centered Care
- Recognize and respect differences in patients' values, preferences, and needs.
- Relieve pain and suffering.
- Coordinate continuous care.
- Effectively communicate with and educate patients.
- Share decision making and management.
- Advocate for disease prevention and health promotion.

Work in Interdisciplinary Teams
- Cooperate, collaborate, and communicate.
- Integrate care to ensure that it is continuous and reliable.

Use Evidence-Based Practice
- Integrate best research with clinical practice and patient values.
- Participate in research activities as possible.

Apply Quality Improvement
- Identify errors and hazards in care.
- Practice using basic safety design principles.
- Measure quality in relation to structure, process, and outcomes.
- Design and test interventions to change processes.

Use Informatics
- Use information technology to communicate, manage knowledge, reduce error, and support decision-making.

Adapted from Institute of Medicine (IOM): *Crossing the quality chasm: a new health system for the 21st century,* Washington DC, 2001, National Academies Press; and Institute of Medicine: *Health professions education: a bridge to quality,* Washington, DC, 2003, National Academies Press.

BOX 2-6 EVIDENCE-BASED PRACTICE

End-of-Shift Reporting Practices and Patient Satisfaction

PICO Question: Does the practice of bedside shift-to-shift report versus traditional report improve patient satisfaction in hospitalized adults?

Evidence Summary

Shift-to-shift report is an important nursing activity that allows nurses to share information about patients so nursing care can be delivered safely and competently. Historically shift-to-shift report occurred at the nurses' station or in a conference room and did not include patients (Radtke, 2013). In efforts to improve nursing communication, nursing report has moved to the bedside and includes the patient. Bedside shift report or hand-off allows patients to receive information about their care and ask questions (Dempsey et al., 2014). Patient satisfaction with nurse-patient communication is a key factor in patient satisfaction surveys. Bedside shift report is recognized by patients as an activity that enhances nurse-patient communication and involves the patient in decision making related to his or her care (Cairns et al., 2013; Dempsey et al., 2014; Radtke, 2013). Improvement of nurse-patient communication has a direct effect on improving patient satisfaction (Dempsey et al., 2014).

Application to Nursing Practice
- Use a standardized report to ensure that all pertinent patient information is communicated to the next shift nurse.
- Respond to all patient questions during bedside shift report.
- Use bedside shift report as a time to provide information to patients related to discharge (Dempsey et al., 2014).
- Encourage patients to participate in making decisions related to their care.

NQF (2014) endorsed performance measures to improve health care transparency related to safety and quality; ensure that health care is safer; ensure accountability of health care providers; and generate information to help individuals make informed health care decisions. Examples of NQF practices include hand hygiene, teamwork, training, influenza prevention, central line–associated bloodstream infection prevention, catheter-associated urinary tract infection prevention, pressure ulcer prevention, fall prevention, and medication reconciliation (NQF, 2010). Health care providers define the quality of their services by measuring health care outcomes that show how a patient's health status has changed. Examples of outcomes that are monitored are readmission rates for patients who have had surgery, functional health status of patients after discharge (e.g., ability and time frame for returning to work), and the rate of infection after surgery. You play an important role in gathering and analyzing quality outcome data.

Pay for performance programs and public reporting of hospital quality data are designed to promote quality, effective, and safe patient care by physicians and health care organizations. These programs are quality improvement strategies that reward excellence through financial incentives to motivate change to achieve measurable improvements. Nurses play an important role in helping hospitals meet measures for quality, efficiency, and patient satisfaction. You are often the health care provider who ensures that performance measures occur. Some health care organizations use balanced scorecards to report data on their key performance indicators. These scorecards are reported publicly so health care consumers can use the information when choosing health care services.

More and more health care institutions are focused on improving processes as a way to improve quality and safety. Many use strategies such as Six Sigma, Lean Six Sigma, or Value Stream Analysis. Six Sigma is a data-driven approach to process improvement that reduces variation in process. For example, a nursing unit sets up a project to collect data on the process of administering the first dose of an ordered chemotherapy. The audit reveals delays in getting the drug from the pharmacy to the nursing unit. Using Six Sigma, the collected data are analyzed, and unnecessary steps in the process are identified. On the basis of this analysis the process is streamlined to decrease time from ordering to administration. Lean Six Sigma and value stream analysis are two other methods that focus on improvement of processes through studying each step of a process to determine if the step adds value and reduces the time, costs, and resources of the health care organization (Carey, 2010). The aim of both is to eliminate unnecessary, non–value-added costly steps to reduce waste.

Health plans throughout the United States rely on the Healthcare Effectiveness Data and Information Set (HEDIS) as a quality measure. The National Committee for Quality Assurance (NCQA) created HEDIS to collect various data to measure the quality of care and services provided by different health plans. It is the database of choice for the Centers for Medicare and Medicaid Services (CMS). HEDIS compares how well health plans perform on measures across eight domains of care in the key areas of quality and effectiveness of care, access to care, and patient satisfaction with the health plan and doctors (NCQA, 2015). For accreditation purposes TJC requires health care organizations to determine how well an organization meets patient needs and expectations. Organizations are using outcomes such as patient satisfaction to redesign how they manage and deliver care in hopes of improving quality in the long term.

Patient Satisfaction.   Every major health care organization measures certain aspects of patient satisfaction. The Hospital Consumer of Assessment of Healthcare Providers and Systems (HCAHPS) is a standardized survey developed to measure patient perceptions of their hospital experience (HCAHPS, 2013). HCAHPS was developed by the CMS and the Agency for Healthcare Research and Quality (AHRQ) as a way for hospitals to collect and report data publicly for comparison purposes. The survey is administered to a randomly selected sample of adults who were discharged from a hospital between 48 hours and 6 weeks ago. The telephone survey asks patients questions about communication with nurses and physicians, responsiveness of hospital staff, pain management, communication about medications, discharge planning, cleanliness and quietness of the environment, overall satisfaction, and willingness to recommend the hospital (HCAHPS, 2013).

Patient- and family-centered health care is an approach to health care delivery that builds relationships among the health care provider, patients, and families. This approach leads to improved outcomes and greater patient and family satisfaction (IPFCC, 2010). Identifying patient and family expectations, knowledge, preferences, cultural beliefs, and values is an important part of patient-centered care (IPFCC, 2010; QSEN, 2014). Concepts of **patient-centered care** include respect and dignity, sharing of information, participation in care and care decisions, and collaboration (IPFCC, 2010). By learning early what a patient expects with regard to information, comfort, and availability of family and friends, you are able to better plan care. Ask about a patient's expectations when a patient first enters a health care setting, while care continues, and when the patient is discharged. Research often helps explain the relationship between patient expectations and patient satisfaction. Enhancing relationships through nursing actions such as asking about patient expectations, explaining care, being caring and compassionate, involving patients in care, and providing timely care improves patient satisfaction (Jeffs et al., 2013; Reck, 2013). A Patient and Family Advisory Council is one strategy that is effective in obtaining patient and family feedback to develop patient- and family-centered care (IPFCC, 2010).

> **QSEN**   **QSEN: BUILDING COMPETENCY IN PATIENT-CENTERED CARE**   Nathan, a new graduate nurse, is assigned to care for a patient of the Muslim faith who had surgery yesterday for cancer. The patient tells Nathan that his pain is an 8 on the 0 to 10 pain scale. Identify strategies that Nathan can use to meet his patient's expectations.

Magnet Recognition Program

The American Nurses Credentialing Center (ANCC) established the Magnet Recognition Program to recognize health care organizations that achieve excellence in nursing practice (ANCC, 2014b). In the United States approximately 7% of health care organizations have achieved Magnet status (ANCC, 2013). Health care organizations that apply for Magnet status must demonstrate quality patient care, nursing excellence, and innovations in professional practice. The professional work environment needs to allow nurses to practice with a sense of empowerment and autonomy to deliver quality nursing care. The revised Magnet model has five components affected by global issues that are challenging nursing today (ANCC, 2014a). The five components are Transformational Leadership; Structural Empowerment; Exemplary Professional Practice; New Knowledge, Innovation, and Improvements; and Empirical Quality Results (Box 2-7). Institutions achieve Magnet status through an appraisal process that requires them to present evidence showing achievement of the 14 forces of magnetism. Magnet status requires nurses to collect data on specific nursing-sensitive quality indicators or outcomes and compare their outcomes against a national, state, or regional database to demonstrate quality of care.

BOX 2-7 Model and Forces of Magnetism

Magnet Model Components	Forces of Magnetism
Transformational Leadership—A vision for the future and the systems and resources to achieve the vision are created by nursing leaders.	• Quality of Nursing Leadership • Management Style
Structural Empowerment—Structures and processes provide an innovative environment in which staff are developed and empowered and professional practice flourishes.	• Organizational Structure • Personnel Policies and Programs • Community and the Health Organization • Image of Nursing • Professional Development
Exemplary Professional Practice—Strong professional practice is established, and accomplishments of the practice are demonstrated.	• Professional Models of Care • Consultation and Resources • Autonomy • Nurses As Teachers • Interdisciplinary Relationships
New Knowledge, Innovations, and Improvements—Contributions are made to the profession in the form of new models of care, use of existing knowledge, generation of new knowledge, and contributions to the science of nursing.	• Quality Improvement
Empirical Quality Outcomes—Focus is on structure and processes and demonstration of positive clinical, workforce, and patient and organizational outcomes.	• Quality of Care

Adapted from American Nurses Credentialing Center (ANCC): *Magnet program overview,* 2014b, http://www.nursecredentialing.org/Magnet/ProgramOverview. July 1, 2015.

BOX 2-8 Nursing Quality Indicators

- Patient falls/falls with injuries
- Falls in ambulatory settings
- Pressure ulcers—hospital acquired, unit acquired
- Pressure ulcer incidence rates from electronic health record (EHR)
- Skill mix (registered nurse [RN], licensed practical nurse [LPN], unlicensed assistive personnel [UAP])—hospital units, emergency department (ED), perioperative and perinatal units
- Nursing hours per patient day
- Nursing care hours in ED, perioperative and perinatal units
- RN surveys on job satisfaction and practice environment scale
- RN education and certification
- Pain assessment intervention/reassessment cycle
- Hospital readmission rates
- Physical/sexual assault
- Physical restraints
- Nurse turnover
- Hospital-acquired infections of ventilator-associated pneumonia and events, central line–associated bloodstream infection, catheter-associated urinary tract infection

Data from National Database of Nursing Quality Indicators (NDNQI): *Turn nursing quality insights into improved patient experiences,* 2015. http://pressganey.com/ourSolutions/performance-and-advanced-analytics/clinical-business-performance/nursing-quality-ndnqi. Accessed July 1, 2015.

minutes of RN staffing per patient day greatly reduced the incidence of pneumonia in patients following surgery. These studies also found that increased levels of nurse staffing positively impacted nurse satisfaction. Future studies will examine how nurses' workloads affect patient safety and how their working conditions affect medication safety. Measuring and monitoring nursing-sensitive outcomes reveal the interventions that improve patients' outcomes. Nurses and health care facilities use nursing-sensitive outcomes to improve nurses' workloads, enhance patient safety, and develop sound policies related to nursing practice and health care.

Nursing Informatics and Technological Advancements

Quality and Safety Education for Nurses (QSEN) identified informatics as a competency for nurses (QSEN, 2014). **Nursing informatics** "uses information and technology to communicate, manage knowledge, mitigate error, and support decision-making" (QSEN, 2014). Data are individually distinct pieces of reality. Examples of data that nurses collect and use to deliver safe patient care include a patient's blood pressure or the measurement of a patient's wound. Nurses gain or use *information* when they organize, structure, or interpret data. You use information when looking at trends in a patient's blood pressure readings over the past 24 hours or when evaluating the changes in the size of a wound over the past 3 weeks. Knowledge develops when you combine and identify relationships between different pieces of information. For example, you know that diet plays an important role in blood pressure control and wound healing. You use this knowledge to teach patients at risk for developing high blood pressure to limit their salt intake and to teach patients who have wounds the importance of eating a well-rounded diet that includes adequate protein, vitamins, and minerals. Knowledge and skills in informatics also provides the ability to access quality electronic sources of health care information to plan and coordinate patient care (QSEN, 2014). The focus of nursing informatics is not on the technology or the computer; rather, its focus is on the organization, analysis, and dissemination of information

Nursing-Sensitive Outcomes. Nursing-sensitive outcomes are patient outcomes and nursing workforce characteristics that are directly related to nursing care such as changes in patients' symptom experiences, functional status, safety, psychological distress, registered nurse (RN) job satisfaction, total nursing hours per patient day, and costs. As a nurse you assume accountability and responsibility for achieving and accepting the consequences of these outcomes. The American Nurses Association developed the National Database of Nursing Quality Indicators (NDNQI) to measure and evaluate nursing-sensitive outcomes with the purpose of improving patient safety and quality care (NDNQI, 2015) (Box 2-8). The NDNQI reports quarterly results on nursing outcomes at the nursing unit level. This provides a database for individual hospitals to compare their performance against nursing performance nationally. The evaluation of patient outcomes and nursing workforce characteristics remains important to nursing and the health care delivery system. Chapter 5 describes approaches for measuring outcomes.

Because of the importance of nursing-sensitive outcomes, AHRQ funded several nursing research studies that looked at the relationship of nurse staffing levels to adverse patient outcomes. These studies found a connection between higher levels of staffing by registered nurses (RNs) in hospitals and fewer negative patient outcomes. For example, the incidence of hospital-acquired pneumonia was highly sensitive to RN staffing levels (AHRQ/USDHHS, 2008). Adding just 30

(ANA, 2008). Chapter 26 provides a thorough review of how nursing informatics improves the way nurses provide health care through use of the electronic health record.

Advances in technology are constantly evolving. People work, play, and view the world much differently because of these advances. Technological advancements influence where and how you provide care to patients and help you deliver evidence-based care (Simpson, 2012). Sophisticated equipment such as electronic IV infusion devices, cardiac telemetry (a device that monitors a patient's heart rate wherever the patient is on a nursing unit), and computerized medication dispensation systems (see Chapter 32) are just a few examples that have changed health care. In many ways technology makes your work easier, but it does not replace nursing judgment. For example, it is your responsibility when managing a patient's IV therapy to monitor the infusion to be sure that it infuses on time and without complications. An electronic infusion device provides a constant rate of infusion, but you need to be sure that you calculate the rate correctly. The device sets off an alarm if the infusion slows, making it important for you to respond to the alarm and troubleshoot the problem. Technology does not replace your critical eye and clinical judgment. Challenges arise when technologies create inefficient delivery systems or uses or need repairs.

Telemedicine or telehealth is an emerging technology that is used to improve patient outcomes. In telemedicine electronic medical records and video teleconferencing are used by health care providers and nurses to provide care from a remote location (Mullen-Fortino et al., 2012). Vital signs and other types of physiological assessment findings are transmitted to monitor patient status (Radhakrishanan and Jacelon, 2012). Patient and family education and building of the patient's self-care abilities are other interventions used in telehealth or telemedicine. Telehealth has been found to be an effective tool in promoting self-care in patients with heart failure (Radhakrishanan and Jacelon, 2012) and improved survival rates in patients in ICUs (Mullen-Fortino et al., 2012).

Technology also affects the way we communicate with others. Personal computers, cell phones, and tablets allow us to communicate and share information or data with others in a variety of formats around the world. People expect accurate information to be delivered to them as it develops. Managing communication, information, and data is challenging in health care. Health care agencies use data to measure their outcomes and improve patient care. Accrediting bodies, insurance companies, and Medicare/Medicaid all require collection and reporting of accurate data. Furthermore, you need accurate, up-to-date information to make the best decisions about patient care. Therefore it is crucial that you help health care agencies develop an effective way to manage the collection, interpretation, and distribution of information.

Nurses need to play a role in evaluating and implementing new technological advances. You use technology and informatics to improve the effectiveness of nursing care, enhance safety, and improve patient outcomes. Most important, it is essential for you to remember that the focus of nursing care is not the machine or the technology; it is the patient. Therefore you need to constantly attend to and connect with your patients and ensure that their dignity and rights are preserved at all levels of care.

Globalization of Health Care

Globalization, the increasing connectedness of the world's economy, culture, and technology, is one of the forces reshaping the health care delivery system (Oulton, 2012). Advances in communication, primarily through the Internet, allow nurses, patients, and other health care providers to talk with others worldwide about health care issues.

Improved communication, easier air travel, and easing of trade restrictions are making it easier for people to engage in "health tourism." Health tourism is the travel to other nations to seek out health care.

Many problems affect the health status of people around the world. For example, poverty is still deadlier than any disease and is the most frequent reason for death in the world today. It increases the disparities in health care services among vulnerable populations (Finkelman and Kenner, 2010). Nations and communities that experience poverty have limited access to vaccines, clean water, and standard medical care. The growth of urbanization also currently is affecting global health. As cities become more densely populated, problems with pollution, noise, crowding, inadequate water, improper waste disposal, and other environmental hazards become more apparent. Children, women, and older adults are **vulnerable populations** most threatened by urbanization. Nurses work toward improving the health of all populations (Finkelman and Kenner, 2010). Although globalization of trade, travel, and culture improves the availability of health care services, the spread of communicable diseases such as Ebola, tuberculosis, and severe acute respiratory syndrome has become more common. Finally, the results of global environmental changes and disasters affect health. Changes in climate and natural disasters threaten food supplies and often allow infectious diseases to spread more rapidly.

You need to understand how worldwide communication and globalization of health care influence nursing practice. Health care consumers demand quality and service and have become more knowledgeable. They often have searched the Internet about their health concerns and medical conditions. They also use the Internet to select their health care providers. As a result of globalization, health care providers have to make their services more accessible. Because of advances in communication, nurses and other health care providers practice across state and national boundaries. In response to the nursing shortage in the early 2000s, health care institutions recruited nurses from around the world to work in the United States. This was an effort to continue to provide quality, safe patient care. This trend is expected to continue to fill vacant nursing positions. The migration of nurses from their home countries to other countries often leaves the home country with insufficient resources to meet their own health needs (Nichols et al., 2010). The hiring of nurses from other nations has required American hospitals to better understand and work with nurses from different cultures and with different needs.

As a leader in health care, remain aware of what is happening in your community, nation, and around the world. The International Council of Nurses (ICN), based in Switzerland, represents nursing worldwide. The mission of the ICN is to represent nursing worldwide, advancing the professions and influencing health policy. It does this by enhancing the health of individuals, populations, and societies (ICN, 2015). The goals of ICN are to bring nursing together, advance the nursing profession, and influence health policy worldwide (ICN, 2015). The unique focus of nursing on caring helps nurses address the issues presented by globalization. Nurses and the nursing profession are able to help overcome these issues by working together to improve nursing education throughout the world, retaining nurses and recruiting people to be nurses, and being advocates for changes that will improve the delivery of health care. Be prepared for future health care issues. Globalization has influenced many other industries. As a leader, nursing has to take control and be proactive in developing solutions before someone outside of nursing takes control.

QUALITY AND PERFORMANCE IMPROVEMENT

Every health care organization gathers data on a number of health outcome measures as a way to gauge and improve its quality of care.

This is the focus of outcomes management. Examples of quality data include fall rates, number of medication errors, incidence of pressure ulcers, and infection rates. Health care organizations actively promote efforts for improving patient care and outcomes, particularly with respect to reducing medical errors and enhancing patient safety. Quality data are the outcome of both quality improvement (QI) and performance improvement (PI) initiatives. **Quality improvement (QI)** is an approach to the continuous study and improvement of the processes of providing health care services to meet the needs of patients and others and inform health care policy. The QI program of an institution focuses on improvement of health care–related processes (e.g., medication delivery or fall prevention). Performance measurement analyzes what an institution does and how well it does it. In **performance improvement (PI)** an organization analyzes and evaluates current performance and uses the results to develop focused improvement actions. PI activities are typically clinical projects conceived in response to identified clinical problems and designed to use research findings to improve clinical practice (Melnyk and Fineout-Overholt, 2014).

QI data inform you about how processes work within an organization and thus offer information about how to make EBP changes (see Chapter 5). When implementing a research project, EBP and QI can inform opportunities for research. Rapid-cycle improvements measured through QI often identify gaps in evidence. Similarly EBP literature reviews often identify gaps in scientific evidence. When implementing a QI project, you consider information from research and EBP that aims to improve or better understand practice, thus helping to identify worthy processes to evaluate. Here is an example of how the three processes can merge to improve nursing practice. A nursing unit has an increase in the number of patient falls over the last several months. QI data identifies the type of patients who fall, time of day of falls, and possible precipitating factors (e.g., efforts to reach the bathroom, multiple medications, or patient confusion). A thorough analysis of QI data then leads clinicians to conduct a literature review and implement the best evidence available to prevent patient falls for the type of patients on the unit. Once the staff apply the evidence in a fall-prevention protocol, they implement the protocol (in this case, focusing efforts on care approaches during evening hours) and evaluate its results. Recurrent problems with falls lead staff to conduct a research study specific to the problem.

Quality Improvement Programs

A well-organized QI program focuses on processes or systems that contribute to patient, staff, or system outcomes. A systematic approach ensures that all employees support a continuous QI philosophy. An organizational culture in which all staff members understand their responsibility toward maintaining and improving quality is essential. Typically in health care many individuals are involved in single processes of care. For example, medication delivery involves the nurse who prepares and administers the drugs, the health care provider who prescribes medications, the pharmacist who prepares the dosage, the secretary who communicates about new orders, and the transporter who delivers medications. All members of the health care team collaborate together in QI activities. As a member of the nursing team, you participate in recognizing trends in practice, identifying when recurrent problems develop, and initiating opportunities to improve the quality of care.

The QI process begins at the staff level, where problems are defined by the staff. This requires staff members to know the practice standards or guidelines that define quality. Unit QI committees review activities or services considered to be most important in providing quality care to patients. To identify the greatest opportunity for improving quality,

the committees consider activities that are high-volume (greater than 50% of the activity of a unit), high-risk (potential for trauma or death), and problem areas (potential for patient, staff, or institution). TJC's annual National Patient Safety Goals provide another focus for QI committees to explore and identify problem areas (TJC, 2015). Sometimes the problem is presented to a committee in the form of a sentinel event (i.e., an unexpected occurrence involving death or serious physical or psychological injury). Once a committee defines the problem, it applies a formal model for exploring and resolving quality concerns. There are many models for QI and PI. One model is the PDSA cycle:

*P*lan—Review available data to understand existing practice conditions or problems to identify the need for change.

*D*o—Select an intervention on the basis of the data reviewed and implement the change.

*S*tudy—Study (evaluate) the results of the change.

*A*ct—If the process change is successful with positive outcomes, act on the practices by incorporating them into daily unit performance.

Six Sigma or Lean is another QI model. In this model organizations carefully evaluate processes to reduce costs, enhance quality and revenue, and improve teamwork while using the talents of existing employees and the fewest resources. In a lean organization all employees are responsible and accountable for integrating QI methodologies and tools into daily work (DelliFraine et al., 2014; Kimsey, 2010).

Some organizations use a QI model called rapid-cycle improvement or rapid-improvement event (RIE). RIEs are very intense, usually week-long events, in which a group gets together to evaluate a problem with the intent of making radical changes to current processes (Kimsey, 2010). Changes are made within a very short time. The effects of the changes are measured quickly, results are evaluated, and further changes are made when necessary. An RIE is appropriate to use when a serious problem exists that greatly affects patient safety and needs to be solved quickly (DelliFraine et al., 2014).

Once a QI committee makes a practice change, it is important to communicate results to staff in all appropriate organizational departments. Practice changes will likely not last when QI committees fail to report findings and results of interventions. Regular discussions of QI activities through staff meetings, newsletters, and memos are good communication strategies. Often a QI study reveals information that prompts organization-wide change. An organization is responsible for responding to the problem with the appropriate resources. Revision of policies and procedures, modification of standards of care, and implementation of new support services are examples of ways an organization responds.

THE FUTURE OF HEALTH CARE

Any discussion of the health care delivery system must begin with the issue of change. Change is often threatening, but it also opens up opportunities for improvement. The ultimate issue in designing and delivering health care is ensuring the health and welfare of the population. Health care in the United States and around the world is not perfect. Often patients are uninsured or underinsured and do not have access to necessary services. However, health care organizations are trying to become better prepared to deal with the challenges. Increasingly they are changing how they provide their services, reducing unnecessary costs, improving access to care, and trying to provide high-quality patient care. Professional nursing is an important player in the future of health care delivery. The solutions necessary to improve the quality of health care depend largely on the active participation of nurses.

KEY POINTS

- Increasing costs and decreasing reimbursement are forcing health care institutions to deliver care more efficiently without sacrificing quality.
- The Medicare prospective reimbursement system is based on payment calculated on the basis of DRG assignment.
- Levels of health care describe the range of services and settings in which health care is available to patients in all stages of health and illness.
- Health promotion occurs in home, work, and community settings.
- Nurses are facing the challenge of keeping populations healthy and well within their own homes and communities.
- Successful community-based health programs involve building relationships with the community and incorporating cultural and environmental factors.
- Hospitalized patients are acutely ill, requiring better coordination of services before discharge.
- The goal of rehabilitation is to allow individuals to return to a level of normal or near-normal function after a physical or mental illness, injury, or chemical dependency.
- Home care agencies provide a wide variety of health care services with an emphasis on patient and family independence.
- Discharge planning begins at admission to a health care facility and helps in the transition of a patient's care from one environment to another.
- Health care organizations are evaluated on the basis of outcomes such as prevention of complications, patients' functional outcomes, and patient satisfaction.
- Nurses need to remain knowledgeable and proactive about issues in the health care delivery system to provide quality patient care and positively affect health.
- Providing patient- and family-centered care is a key component to patient satisfaction.
- A thorough analysis of QI data leads clinicians to understand work processes and the need to change practice.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Community Hospital is a 400-bed urban hospital, one of six hospitals in a health care system. The nursing department of the hospital is applying to the American Nurses Credentialing Center for Magnet status. Nursing units are working on a number of projects to prepare for the Magnet application process.

1. You are a staff nurse on a medical-surgical floor at the hospital. The unit is trying to improve its culture in patient safety. How would you go about helping to improve the culture of safety on the unit?
2. Discuss four strategies that the nursing unit can use to deliver patient- and family-centered care.
3. You are asked by a newly hired nurse what the nursing-sensitive outcomes mean and why it is important that the unit measure the outcomes. What is your response?

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A community center is presenting a nurse-led program on the Patient Protection and Affordable Care Act. Which statement made by a participant indicates a need for further teaching?
   1. "My small company will now have to offer the 75 employees health insurance or pay a penalty."
   2. "As long as my son is a full-time student in college, I will be able to keep him on my health insurance until he is 26 years old."
   3. "I signed up for the state health insurance exchange before the designated deadline to make sure I had health insurance."
   4. "Since I have now been diagnosed with diabetes, my health insurance plan cannot charge me higher premiums."

2. Which activity performed by a nurse is related to maintaining competency in nursing practice?
   1. Asking another nurse about how to change the settings on a medication pump
   2. Regularly attending unit staff meetings
   3. Participating as a member of the professional nursing council
   4. Attending a review course in preparation for a certification examination

3. A patient tells a nurse that she is enrolled in a preferred provider organization (PPO) but does not understand what this is. What is the nurse's best explanation of a PPO?
   1. This health plan is for people who cannot afford their own health insurance.
   2. This health plan is operated by the government to provide health care to older adults.
   3. This health plan gives you a list of physicians and hospitals from which you can choose.
   4. This is a fee-for-service plan in which you can choose any physician or hospital.

4. Which of the following are examples of a nurse participating in primary care activities? (Select all that apply.)
   1. Providing prenatal teaching on nutrition to a pregnant woman during the first trimester
   2. Assessing the nutritional status of older adults who come to the community center for lunch
   3. Working with patients in a cardiac rehabilitation program
   4. Providing home wound care to a patient
   5. Teaching a class to parents at the local grade school about the importance of immunizations

5. Nurses on a nursing unit are discussing the processes that led up to a near-miss error on the clinical unit. They are outlining strategies that will prevent this in the future. This is an example of nurses working on what issue in the health care system?
   1. Patient safety
   2. Evidence-based practice
   3. Patient satisfaction
   4. Maintenance of competency

6. Which of the following statements is true regarding Magnet status recognition for a hospital?
   1. Nursing is run by a Magnet manager who makes decisions for the nursing units.
   2. Nurses in Magnet hospitals make all of the decisions on the clinical units.
   3. Magnet is a term that is used to describe hospitals that are able to hire the nurses they need.
   4. Magnet is a special designation for hospitals that achieve excellence in nursing practice.

7. A group of staff nurses notice an increased incidence of medication errors on their unit. After further investigation it is determined that the nurses are not consistently identifying the patient

correctly. A change is needed quickly. What type of quality improvement method would be most appropriate?
1. PDSA
2. Six Sigma
3. Rapid-improvement event (RIE)
4. A randomized controlled trial

8. Which of the following are characteristics of managed care systems? (Select all that apply.)
   1. Provider receives a predetermined payment for each patient in the program.
   2. Payment is based on a set fee for each service provided.
   3. System includes a voluntary prescription drug program for an additional cost.
   4. System tries to reduce costs while keeping patients healthy.
   5. Focus of care is on prevention and early intervention.

9. Which of the following nursing activities is provided in a secondary health care environment?
   1. Conducting blood pressure screenings for older adults at the Senior Center
   2. Teaching a clinic patient with chronic obstructive pulmonary disease purse-lipped breathing techniques
   3. Changing the postoperative dressing for a patient on a medical-surgical unit
   4. Doing endotracheal suctioning for a patient on a ventilator in the medical intensive care unit

10. A nurse is using the Plan-Do-Study-Act (PDSA) strategy to do a quality improvement project to decrease patient falls on a nursing unit. Place the steps in the correct sequence for PDSA.
    1. Bedside change of shift report is piloted on two medical-surgical units.
    2. Patient satisfaction levels after implementation of the bedside report are compared to patient satisfaction levels before the change.
    3. The nursing council develops a strategy for bedside change of shift report.
    4. After modifications are made in the shift report elements, bedside shift report is implemented on all nursing units.

11. The nursing staff is developing a quality program. Which of the following are nursing-sensitive indicators from the National Database of Nursing Quality Indicators (NDNQI) that the nurses can use to measure patient safety and quality for the unit? (Select all that apply.)
    1. Use of physical restraints
    2. Pain assessment, intervention, and reassessment

3. Patient satisfaction with food preparation
4. Registered nurse (RN) education and certification
5. Number of outpatient surgical cases per year

12. A nurse is providing restorative care to a patient following an extended hospitalization for an acute illness. Which of the following is an appropriate goal for restorative care?
    1. Patient will be able to walk 200 feet without shortness of breath.
    2. Wound will heal without signs of infection.
    3. Patient will express concerns related to return to home.
    4. Patient will identify strategies to improve sleep habits.

13. A nurse is presenting information to a management class of nursing students on the topic of financial reimbursement for achievement of established, measurable patient outcomes. The nurse is presenting information to the class on which topic?
    1. Prospective payment system
    2. Pay for performance
    3. Capitation payment system
    4. Managed care systems

14. A nurse is using data collected from the unit to monitor the incidence of falls after the unit implemented a new fall protocol. The nurse is working in which area?
    1. Quality improvement (QI)
    2. Health care patient system
    3. Nursing informatics
    4. Computerized nursing network

15. The nurses on a medical unit have seen an increase in the number of pressure ulcers that develop in their patients. They decide to initiate a quality improvement project using the Plan-Do-Study-Act (PDSA) model. Which of the following is an example of "Do" from that model?
    1. Implementing the new skin care protocol on all medicine units
    2. Reviewing the data collected on patients cared for using the protocol
    3. Reviewing the quality improvement reports on the six patients who developed ulcers over the last 3 months
    4. Based on findings from patients who developed ulcers, implementing an evidence-based skin care protocol

Community-Based Nursing Practice

OBJECTIVES

- Explain the relationship between public health and community health nursing.
- Differentiate community health nursing from community-based nursing.
- Discuss the role of the community health nurse.
- Discuss the role of the nurse in community-based practice.

- Identify characteristics of patients from vulnerable populations that influence the community-based nurse's approach to care.
- Describe the competencies important for success in community-based nursing practice.
- Describe elements of a community assessment.

KEY TERMS

Community-based nursing, p. 33

Community health nursing, p. 33

Health disparities, p. 33

Incident rates, p. 32

Population, p. 33

Public health nursing, p. 33

Social determinants of health, p. 32

Vulnerable populations, p. 34

Community-based care focuses on health promotion, disease prevention, and restorative care. Because patients are often discharged quickly from acute care settings, there is a growing need to provide health care delivery services where people live, work, socialize, and learn. One way to achieve this goal is through a community-based health care model. Community-based health care is a collaborative, evidence-based model designed to meet the health care needs of a community (Olson et al., 2011). A healthy community includes elements that maintain a high quality of life and productivity. For example, safety and access to health care services are elements that enable people to function productively in their community (U.S. Department of Health and Human Services [USDHHS], 2015). As more community health care partnerships develop, nurses are in a strategic position to play an important role in health care delivery and improve the health of the community.

The focus of health promotion and disease prevention continues to be essential for the holistic practice of professional nursing. The history of nursing documents the roles of nurses in establishing and meeting the public health needs of their patients. Within community health settings, nurses are leaders in assessing, diagnosing, planning, implementing, and evaluating the types of public and community health services needed. Community health nursing and community-based nursing are components of a health care delivery system that improve the health of the general public.

COMMUNITY-BASED HEALTH CARE

It is important to understand the focus of community-based health care. Community-based health care is a model of care that reaches everyone in a community (including the poor and underinsured),

focuses on primary rather than institutional or acute care, and provides knowledge about health and health promotion and models of care to the community. Community-based health care occurs outside traditional health care institutions such as hospitals. It provides services to individuals and families within the community for acute and chronic conditions (Stanhope and Lancaster, 2014).

Today the challenges in community-based health care are numerous. Political policy and the Affordable Care Act (ACA); social determinants of health, increases in health disparities, and economics all influence public health problems and subsequent health care services. Some of these problems include a lack of adequate health insurance, chronic illnesses such as heart disease and diabetes, an increase in sexually transmitted infections, and underimmunization of infants and children (USDHHS, 2015). More than ever before, the health care system must commit to reform and bring attention and health care services to all communities.

Achieving Healthy Populations and Communities

The USDHHS Public Health Service designed a program to improve the overall health status of people living in this country. The *Healthy People Initiative* was created to establish ongoing health care goals (see Chapter 6). The 2020 document strives to ensure that *Healthy People 2020* is relevant to diverse public health needs and seizes opportunities to achieve its goals. Since its inception, *Healthy People* has become a broad-based, public engagement initiative with thousands of citizens helping to shape it at every step along the way. The overall goals of *Healthy People 2020* are to increase life expectancy and quality of life and eliminate health disparities through improved delivery of health care services (USDHHS, 2015).

Improved delivery of health care occurs through assessment of health care needs of individuals, families, and communities; development and implementation of public health policies; and improved access to care. For example, assessment includes systematic data collection on the population, monitoring the health status of the population, and accessing available information about the health of the community (Stanhope and Lancaster, 2014). A comprehensive community assessment sometimes leads to community health programs such as adolescent smoking prevention, sex education, and proper nutrition. Some examples of assessment include gathering information on **incident rates** such as identifying and reporting new infections or diseases, determining adolescent pregnancy rates, and reporting the number of motor vehicle accidents caused by teenage drivers.

Health professionals provide leadership in developing public policies to support the health of the population (Stanhope and Lancaster, 2014). Strong policies are driven by community assessment. For example, assessing the level of lead poisoning in young children often leads to a lead cleanup program to reduce the incidence of lead poisoning. Identifying evidence-based practices to help more people manage chronic illnesses in the home and the community addresses the needs of nurses and their patients (Kirkpatrick et al., 2012) (Box 3-1).

Improved access to care ensures that essential community-wide health services are available and accessible to the entire community (Stanhope and Lancaster, 2014). Community development, social capital, and capacity are essential in establishing community-wide health promotion and health maintenance activities. As a result the community is empowered to be part of the health care agenda (Piper, 2011). Examples include prenatal care programs and programs focusing on disease prevention, health protection, and health promotion. The five-level health services pyramid is an example of how to provide community-based services within existing health care services in a community. In this population-focused health care services model, the goals of disease prevention, health protection, and health promotion provide a foundation for primary, secondary, and tertiary health care services (see Figure 2-1 on p. 17).

A rural community does not always have a hospital to meet the acute care needs of its citizens. However, a community assessment might reveal which services are available to meet the needs of expectant mothers, reduce teenage smoking, or provide nutritional support for older adults. In addition, this same community assessment identifies the health care gaps for a specific community. Community-based programs provide these services and are effective in improving the health of the community. In other situations a community has the resources for providing childhood immunizations, flu vaccines, and primary preventive care services and is able to focus on child developmental problems and child safety.

Public health services aim at achieving a healthy environment for all individuals. Health care providers apply these principles for individuals, families, and the communities in which they live. Nursing plays a role in all levels of the health services pyramid. By using public health principles you are better able to understand the types of environments in which patients live and the types of interventions necessary to help keep them healthy.

Social Determinants of Health

Our health is also determined in part by access to social and economic opportunities; the resources and support systems available in our homes, neighborhoods, and communities; the quality of our schooling; the safety of our workplaces; the cleanliness of our water, food, and air; and the nature of our social interactions and relationships.

Health starts in our homes, schools, workplaces, neighborhoods, and communities. We know that taking care of ourselves by eating well

---

BOX 3-1   EVIDENCE-BASED PRACTICE

Promoting Informed Decision Making in a Community Setting

PICO Question: Do community centers that provide informed decision making for prostate cancer screening (PCS) have better outcomes than those centers that do not provide informed decision making?

Evidence Summary

Often a community health center is the first, if not only, health care resource for some of the population. Social determinants of health, health disparities, and inequalities in health care all contribute to a population's level of health. Cultural beliefs, experiences with health care services, and health literacy all impact how patients access health care and make health care decisions (Chan et al., 2011). Translating research evidence and creating an evidence-based community nursing practice also impact health care outcomes (Kirkpatrick et al., 2012).

Health promotion and related health screenings are essential in maintaining an individual and community level of health. Health practices related to PCS are often lacking in ethnically diverse communities. For example, both Hispanic and African-American men tend to have lower participation in PCS when compared with Caucasian men (Chan et al., 2011; Gash & McIntosh, 2013). This most likely happens for many reasons, such as limited knowledge about PCS, poor access to health care, and mistrust of the health care system. Lower participation in PCS often leads to a diagnosis of cancer at a later, more aggressive stage and poorer health outcomes in these populations (Gash & McIntosh, 2013).

Chan et al. (2011) found that community centers that provide culturally appropriate information related to PCS improves knowledge and promotes more active involvement in decision making about PCS screening activities. Including the spouse or significant other in educational interventions may be especially helpful because men's decision making about health screening and their coping patterns often includes family or friends (Gash & McIntosh, 2013). Thus patients who seek health care at community centers that provide gender neutral, culturally appropriate, and targeted education regarding decision making about PCS may experience better health outcomes when compared with community centers that do not provide this type of educational interventions.

Application to Nursing Practice
- Help increase patients knowledge about appropriate screening practices.
- Reinforce patients' decision-making rights.
- Understand the social and cultural dynamics of the community.
- Use community resources and leadership to develop culturally appropriate educational interventions (Chan et al., 2011).
- Include spouses and significant others in educational sessions when appropriate to enhance patients' involvement in their decision making about health screenings (Gash & McIntosh, 2013).

---

and staying active, not smoking, getting the recommended immunizations and screening tests, and seeing a doctor when we are sick all influence our health. However there are also social determinants of health. **Social determinants of health** are factors that contribute to a person's current state of health. These factors may be biological, socioeconomic, psychosocial, behavioral, or social in nature. Scientists generally recognize five determinants of health: biology and genetics (sex and age), individual behavior (such as alcohol, injection drug use, unprotected sex, and smoking), social environment (such as discrimination, income, and gender), physical environment (where a person

lives or crowding conditions), and health services (such as access to quality health care and having health insurance) (CDC, 2014b). Whether these factors affect a single family or the community, they impact the overall health and wellness of that community.

Health Disparities

Health disparities negatively affect groups of people who have systematically experienced social or economic obstacles to health. These obstacles stem from characteristics historically linked to discrimination or exclusion such as race or ethnicity, religion, socioeconomic status, gender, mental health, sexual orientation, or geographic location. Other characteristics include cognitive, sensory, or physical disability.

Health disparities are preventable differences in the burden of disease, injury, violence, or opportunities to achieve optimal health that are experienced by socially disadvantaged populations. Populations can be defined by factors such as race or ethnicity, gender, education or income, disability, geographic location (e.g., rural or urban), or sexual orientation. Health disparities are inequitable and are directly related to the historical and current unequal distribution of social, political, economic, and environmental resources. They result from multiple factors, including poverty, environmental threats, inadequate access to health care, individual and behavioral factors, and educational inequalities (CDC, 2014a).

COMMUNITY HEALTH NURSING

Frequently the terms *community health nursing* and *public health nursing* are used interchangeably, although they are different. A **public health nursing** focus requires understanding the needs of a **population** or a collection of individuals who have one or more personal or environmental characteristics in common (Stanhope and Lancaster, 2014). Examples of populations include high-risk infants, older adults, or an ethnic group such as Native Americans. A public health nurse understands factors that influence health promotion and health maintenance, the trends and patterns influencing the incidence of disease within populations, environmental factors contributing to health and illness, and the political processes used to affect public policy. For example, a nurse uses data on increased incidence of playground injuries to lobby for a policy to use shock-absorbing material rather than concrete for new public playgrounds.

Public health nursing requires preparation at the basic entry level and sometimes requires a baccalaureate degree in nursing that includes educational preparation and clinical practice in public health nursing. A specialist in public health has a graduate level education with a focus in the public health sciences (American Nurses Association [ANA], 2013).

Community health nursing is nursing practice in the community, with the primary focus on the health care of individuals, families, and groups within the community. The goal is to preserve, protect, promote, or maintain health (Stanhope and Lancaster, 2014). The emphasis of such nursing care is to improve the quality of health and life within that community. In addition, the community health nurse provides direct care services to subpopulations within a community. These subpopulations often have a clinical focus in which the nurse has expertise. For example, a case manager follows older adults recovering from stroke and sees the need for community rehabilitation services, or a nurse practitioner gives immunizations to patients with the objective of managing communicable disease within the community. By focusing on subpopulations, a community health nurse cares for the community as a whole and considers an individual or family as only one member of a group at risk.

Competence as a community health nurse requires the ability to use interventions that include the broad social and political context of the community (Stanhope and Lancaster, 2014). The educational requirements for entry-level nurses practicing in community health nursing roles are not as clear as those for public health nurses. Not all hiring agencies require an advanced degree. However, nurses with a graduate degree in nursing who practice in community settings are considered community health nurse specialists, regardless of their public health experience (Stanhope and Lancaster, 2014).

Nursing Practice in Community Health

Community health nursing practice requires a unique set of skills and knowledge. In the health care delivery system nurses who become experts in community health practice usually have advanced nursing degrees, yet the baccalaureate-prepared nurse generalist is also able to formulate and apply population-focused assessments and interventions. The expert community health nurse understands the needs of a population or community through experience with individual families, which includes working through their social and health care issues. In this context, critical thinking involves applying knowledge of public health principles, community health nursing, family theory, and communication in finding the best approaches to partner with families.

Successful community health nursing practice involves building relationships with the community and being responsive to changes within the community. For example, when there is an increase in the incidence of grandparents assuming child care responsibilities, a community health nurse becomes an active part of a community by establishing an educational program in cooperation with local schools to assist and support grandparents in this caregiving role. The nurse knows the community members, along with their needs and resources, and then works in collaboration with community leaders to establish effective health promotion and disease prevention programs. This requires working with highly resistant systems (e.g., welfare system) and trying to encourage them to be more responsive to the needs of a population. Skills of patient advocacy, communicating people's concerns, and designing new systems in cooperation with existing systems help to make community nursing practice effective.

COMMUNITY-BASED NURSING

Community-based nursing care takes place in community settings such as a home or clinic, where nurses focus on the needs of an individual or family. It involves the safety needs and acute and chronic care of individuals and families, enhances their capacity for self-care, and promotes autonomy in decision making (Stanhope and Lancaster, 2014). It requires critical thinking and decision making for the individual patient and family—assessing health status, diagnosing health problems, planning care, implementing interventions, and evaluating outcomes of care. Because nurses provide direct care services where patients live, work, and play, it is important that they place the perspectives of the community members first and foremost when planning care (Jackson et al., 2012).

Community-based nursing centers function as the first level of contact between members of a community and the health care delivery system (Figure 3-1). Ideally health care services are provided near where patients live. This approach helps to reduce the cost of health care for the patient and the stress associated with the financial burdens of care. In addition, these centers offer direct access to nurses and patient-centered health services and readily incorporate the patient and the patient's family or friends into a plan of care. Community-based nursing centers often care for the most vulnerable of the population (Olson et al., 2011).

FIGURE 3-1 Patient and family receiving care in a community-based care center. (Courtesy Mass Communication Specialist 2nd Class Daniel Viramontes.)

With the individual and family as the patients, the context of community-based nursing is family-centered care within the community. This focus requires a strong knowledge base in family theory (see Chapter 10), principles of communication (see Chapter 24), group dynamics, and cultural diversity (see Chapter 9). Nurses partner with their patients and families to enable them to ultimately assume responsibility for their health care decisions.

Vulnerable Populations

In a community setting nurses care for patients from diverse cultures and backgrounds and with various health conditions. However, changes in the health care delivery system have made high-risk groups the principal patients. For example, you are not likely to visit low-risk mothers and babies. Instead, you are more likely to visit adolescent mothers or mothers with drug addiction. **Vulnerable populations** are groups of patients who are more likely to develop health problems as a result of excess health risks, who are limited in access to health care services, or who depend on others for care. Individuals living in poverty, older adults, people who are homeless, immigrant populations, individuals in abusive relationships, substance abusers, and people with severe mental illnesses are examples of vulnerable populations. These vulnerabilities are often associated with the individual's/community's social determinants of health or individual health disparities.

Public and community health nursing and primary care providers share health care responsibility for health promotion, screening, and early detection and disease prevention for vulnerable populations. These patients have intense health care needs that are unmet or ignored or require more care than can be provided in outpatient or hospital settings. Individuals and their families who are vulnerable often belong to more than one of these groups. In addition, health care vulnerability affects all age-groups (Sebastian, 2014).

Patients who are vulnerable often come from varied cultures, have different beliefs and values, face language and literacy barriers, and have few sources of social support. Their special needs will be a challenge for you as you care for increasingly complex acute and chronic health conditions.

To provide competent care for vulnerable populations, you need to assess these patients accurately (Box 3-2). In addition, you need to evaluate and understand a patient's and family's cultural beliefs, values, and practices to determine their specific needs and the interventions that will be most successful in improving their state of health (see Chapter 9). It is important not to judge or evaluate your patient's

Setting the Stage
- Create a comfortable, nonthreatening environment.
- Obtain information about a patient's culture so you understand the practices, beliefs, and values that affect the patient's health care.
- If the patient speaks a different language, use a professional interpreter and observe nonverbal behavior to complete a culturally competent assessment (Chapter 9).
- Be sensitive to the fact that patients often have priorities other than their health care (e.g., financial, legal, or social issues). Help them with these concerns before beginning a health assessment. If a patient needs financial assistance, consult a social worker. If there are legal issues, provide the patient with a resource. Do not attempt to provide financial or legal advice yourself.

Nursing History of an Individual or Family
- Because you often have only one opportunity to conduct a nursing history, you need to obtain an organized history of all of essential information to help an individual or family during that visit.
- Collect data on a comprehensive form that focuses on the specific needs of the vulnerable population with whom you work. However, be flexible so as not to overlook important health information. For example, when with an adolescent mother, obtain a nutritional history on both the mother and baby. Be aware of the developmental needs of the adolescent mom and listen to her social needs as well.
- Identify both developmental and health care needs. Remember, the goal is to collect enough information to provide family-centered care.
- Identify any risks to the patient's immune system. This is especially important for vulnerable patients who are homeless and sleep in shelters.

Physical Examination and Home Assessment
- Complete as thorough a physical and/or home assessment as possible. However, only collect data that are relevant to providing care to the patient and family.
- Be alert for signs of physical or substance abuse (e.g., inadequately clothed to hide bruising, underweight, runny nose).
- When assessing a patient's home, observe: Is there adequate water and plumbing? What is the status of the utilities? Are foods and perishables stored properly? Are there signs of insects or vermin? Is the paint peeling? Are the windows and doors adequate? Are there water stains on the ceiling, evidence of a leaky roof? What is the temperature? Is it comfortable? What does the outside environment look like: Are there vacant houses/lots nearby? Is there a busy intersection? What is the crime level?

Modified from Stanhope M, Lancaster J: *Foundations of nursing in the community: community oriented practice,* ed 4, St Louis, 2014, Mosby.

beliefs and values about health in terms of your own culture, beliefs, and values. Communication and caring practices are critical in learning a patient's perceptions of his or her problems and then planning health care strategies that will be meaningful, culturally appropriate, and successful.

Barriers to access and use of services often lead to adverse health outcomes for vulnerable populations (Jackson and Saltman, 2011; Rew et al., 2009). Because of these poorer outcomes, vulnerable populations have shorter life spans and higher morbidity rates. Members of vulnerable groups frequently have multiple risks, which make them more sensitive to the cumulative effects of individual risk factors. It is essential for community-based nurses to assess members of vulnerable populations by taking into account the multiple stressors that affect their patients' lives. It is also important to learn patients' strengths and

resources for coping with stressors. Complete assessment of vulnerable populations enables a community-based nurse to design interventions within the context of the patient's community (Sebastian, 2014).

Immigrant Population. Researchers predict a continued increase in immigrant population (Camarota, 2012). This continued growth creates many social and health care needs. Immigrant populations face multiple diverse health issues that cities, counties, and states need to address. These health care needs pose significant legal and policy issues. For some immigrants access to health care is limited because of language barriers and lack of benefits, resources, and transportation. Immigrant populations often have higher rates of hypertension, diabetes mellitus, and infectious diseases; decreased outcomes of care; and shorter life expectancies (Stanhope and Lancaster, 2014).

Frequently the immigrant population practices nontraditional healing practices (see Chapter 9). Although many of these healing practices are effective and complement traditional therapies, it is important that you know and understand your patient's health beliefs about these healing practices.

Certain immigrant populations left their homes as a result of oppression, war, or natural disaster (e.g., Afghans, Bosnians, and Somalis). Be sensitive to these physical and psychological stressors and consequences and identify the appropriate resources to help understand your patients and their health care needs (Stanhope and Lancaster, 2014).

Effects of Poverty and Homelessness. People who live in poverty are more likely to have more health disparities because they often live in hazardous environments, work at high-risk jobs, eat less nutritious diets, have multiple stressors in their lives, have poor or unavailable transportation, and are at risk for homelessness.

Patients who are homeless have even fewer resources than the poor. They are often jobless, do not have the advantage of a permanent shelter, and must continually cope with finding food and a place to sleep at night. Chronic health problems tend to worsen because of poor nutrition and the inability to store nutritional foods. In addition, people who are homeless usually walk the streets and neighborhoods to seek shelter, leading to an imbalance of rest and activity (Jackson et al., 2012).

Patients Who Are Abused. Physical, emotional, and sexual abuse and neglect are major public health problems affecting older adults, women, and children. Risk factors for abusive relationships include mental health problems, substance abuse, socioeconomic stressors, and dysfunctional family relationships (Landenburger and Campbell, 2014). For some, risk factors may not be present. When dealing with patients at risk for or who have suffered abuse, it is important to provide protection. Interview a patient you suspect is abused at a time when the patient has privacy and the individual suspected of being the abuser is not present. Patients who are abused may fear retribution if they discuss their problems with a health care provider. Most states have abuse hot lines that nurses and other health care providers must notify when they identify an individual as being at risk.

Patients with Mental Illness. When a patient has a severe mental illness such as schizophrenia or bipolar disorder, you need to explore multiple health and socioeconomic problems. Many patients with severe mental illnesses are homeless or live in poverty. Others lack the ability to remain employed or even to care for themselves on a daily basis (Prochaska et al., 2012). Patients who have a mental illness often require medication therapy, counseling, housing, and vocational assistance. In addition, they are at a greater risk for abuse and assault.

Patients with mental illnesses are no longer routinely hospitalized in long-term psychiatric institutions. Instead resources are offered within the community. Although comprehensive service networks are in every community, many patients still go untreated. Many are left with fewer and more fragmented services, with little skill in surviving and functioning within the community (Happell and Cleary, 2012).

Older Adults. With the increasing older-adult population, simultaneous increases in the number of patients suffering from chronic diseases and a greater demand for health care services are seen. Take time to understand what health means to an older adult and which assessment findings to expect; view health promotion in the older adult within a broad context (see Chapter 14). Help older adults and their families understand which steps they need to take to maintain their health and improve their level of function (Piper, 2011). Design appropriate community-based interventions that provide an opportunity to improve the lifestyle and quality of life of older adults (Table 3-1).

Competency in Community-Based Nursing

A nurse in community-based practice needs a variety of skills and talents to be successful. In addition to assisting patients with their health care needs and developing relationships within the community, the community-based nurse needs skills in health promotion and disease prevention. The nurse uses the nursing process and critical thinking (see Unit III) to ensure individualized nursing care for specific patients and their families. Students' clinical practice in a community-based care setting will probably be in partnership with a community nurse.

Caregiver. First and foremost is the role of caregiver (see Chapter 1). In the community setting you manage and care for the health of patients and families in the community. Use a critical thinking approach to apply the nursing process (see Unit III) and ensure appropriate, individualized nursing care for specific patients and their families.

Historically well-baby and child care were integral to community nursing practices. Because of changes in the health care delivery system, changing economics, homelessness, and the medically underinsured, community child care services are increasing. Community nurses are undertaking more complex and expanded child health services for increasingly diverse client populations (Borrow et al., 2011).

In addition, you individualize care within the context of a patient's community so long-term success is more likely. Together with the patient and family you develop a caring partnership to recognize actual and potential health care needs and identify needed community resources. As a caregiver, you also help build a healthy community, which is one that is safe and includes elements to enable people to achieve and maintain a high quality of life and function.

QSEN **QSEN: BUILDING COMPETENCY IN SAFETY** Jan Carrel is a 30-year-old single woman who has multiple sclerosis (MS). She owns a condo and is an executive for a car rental firm. Her MS has progressed to the point that she needs ambulatory assistive devices. Depending on her level of mobility, these devices range from a walker to a motorized chair; and the amount of assistance Jan requires changes during the week. She is able to stand to transfer to the toilet or to her handicapped-accessible vehicle or to reach items in the kitchen. However, because of her muscle weakness, her activity intolerance, and imbalance, she cannot stand for long periods of time. Both she and her doctor have requested a home safety assessment. What information do you need to begin this assessment?

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

TABLE 3-1 Major Health Problems in Older Adults and Community-Based Nursing Roles and Interventions

Problem	Community-Based Nursing Roles and Interventions
Hypertension	Monitor blood pressure and weight; educate about nutrition and antihypertensive drugs; teach stress management techniques; promote a good balance between rest and activity; establish blood pressure screening programs; assess patient's current lifestyle and promote lifestyle changes; promote dietary modifications by using techniques such as a diet diary.
Cancer	Obtain health history; promote monthly breast self-examinations and annual Papanicolaou (Pap) smears and mammograms for older women; promote regular physical examinations; encourage smokers to stop smoking; correct misconceptions about processes of aging; provide emotional support and quality of care during diagnostic and treatment procedures.
Arthritis	Educate adult about management of activities, correct body mechanics, availability of mechanical appliances, and adequate rest; promote stress management; counsel and assist the family to improve communication, role negotiation, and use of community resources; help adult avoid the false hope and expense of arthritis fraud.
Visual impairment (e.g., loss of visual acuity, eyelid disorders, opacity of the lens)	Provide support in a well-lighted, glare-free environment; use printed aids with large, well-spaced letters; help adult clean eyeglasses; help make arrangements for vision examinations and obtain necessary prostheses; teach adult to be cautious of false advertisements.
Hearing impairment (e.g., presbycusis)	Speak with clarity at a moderate volume and pace and face audience when performing health teaching; help make arrangements for hearing examination and obtain necessary prostheses; teach adult to be cautious of false advertisements.
Cognitive impairment	Provide complete assessment; correct underlying causes of disease (if possible); provide for a protective environment; promote activities that reinforce reality; help with personal hygiene, nutrition, and hydration; provide emotional support to the family; recommend applicable community resources such as adult day care, home care aides, and homemaker services.
Alzheimer's disease	Maintain high-level functioning, protection, and safety; encourage human dignity; demonstrate to the primary family caregiver techniques to dress, feed, and toilet adult; provide frequent encouragement and emotional support to caregiver; act as an advocate for patient when dealing with respite care and support groups; protect the patient's rights; provide support to maintain family members' physical and mental health; maintain family stability; recommend financial services if needed.
Dental problems	Perform oral assessment and refer to dentist as necessary; emphasize regular brushing and flossing, proper nutrition, and dental examinations; encourage patients with dentures to wear and take care of them; calm fears about dentist; help provide access to financial services (if necessary) and dental care facilities.
Substance and alcohol abuse	Get drug use history; educate adult about safe storage, risks for drug, drug-drug, drug-alcohol, and drug-food interactions; give general information about drug (e.g., drug name, purpose, side effects, dosage); instruct adult about presorting techniques (using small containers with one dose of drug that are labeled with specific times to take drug). Counsel adults about substance abuse; promote stress management to avoid need for drugs or alcohol and arrange for and monitor detoxification if appropriate.
Sexually transmitted infections	Perform a full sexual risk assessment and bring awareness regarding risk factors and susceptibility to human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS). Educate about safe sexual practices such as abstinence, use of condoms and refer as necessary for HIV testing.

Data from Stanhope M, and Lancaster J: *Foundations of nursing in the community: community-oriented practice,* ed 4, St Louis, 2014, Mosby; Goodman C et al: Activity promotion for community-dwelling older people: a survey of the contribution of primary care nurses, *Br J Community Nurs* 16(1):12, 2011; Baym-Williams J, Salyer J: Factors influencing the health-related lifestyles of community-dwelling older adults, *Home Health Care Nurse* (28)115–121, 2010; Jacobson SA: HIV/AIDS interventions in an aging US population, *Health Soc Work*: 2(36):149, 2011.

Case Manager. In community-based practice case management is an important competency (see Chapter 2). It is the ability to establish an appropriate plan of care based on assessment of patients and families and to coordinate needed resources and services for a patient's well-being across a continuum of care. Generally a community-based case manager assumes responsibility for the case management of multiple patients. The greatest challenge is coordinating the activities of multiple providers and payers in different settings throughout a patient's continuum of care. An effective case manager eventually learns the obstacles, limits, and even the opportunities that exist within the community that influence the ability to find solutions for patients' health care needs.

Change Agent. A community-based nurse is also a change agent. This involves identifying and implementing new and more effective approaches to problems. You act as a change agent within a family system or as a mediator for problems within a patient's community.

You identify any number of problems (e.g., quality of community child care services, availability of older-adult day care services, or the status of neighborhood violence). As a change agent you empower individuals and their families to creatively solve problems or become instrumental in creating change within a health care agency. For example, if your patient has difficulty keeping regular health care visits, you determine why. Maybe the health clinic is too far and difficult to reach, or perhaps the hours of service are incompatible with a patient's transportation resources. You work with the patient to solve the problem and help identify an alternative site such as a nursing clinic that is closer and has more convenient hours.

To effect change you gather and analyze facts before you implement the program. This requires you to be very familiar with the community itself. Many communities resist change, preferring to provide services in the established manner. Before analyzing facts, it is often necessary to manage conflict among the health care providers, clarify their roles, and clearly identify the needs of the patients. If the community has a

history of poor problem solving, you will have to focus on developing problem-solving capabilities (Stanhope and Lancaster, 2014).

Patient Advocate. Patient advocacy is more important today in community-based practice because of the confusion surrounding access to health care services. Your patients often need someone to help them walk through the system and identify where to go for services, how to reach individuals with the appropriate authority, which services to request, and how to follow through with the information they receive. It is important to provide the information necessary for patients to make informed decisions in choosing and using services appropriately. In addition, it is important for you to support and at times defend your patients' decisions.

Collaborator. In community-based nursing practice you need to be competent in working not only with individuals and their families but also with other related health care disciplines. Collaboration, or working in a combined effort with all those involved in care delivery, is necessary to develop a mutually acceptable plan that will achieve common goals (Stanhope and Lancaster, 2014). For example, when your patient is discharged home with terminal cancer, you collaborate with hospice staff, social workers, and pastoral care to initiate a plan to support end-of-life care for the patient in the home and support the family. For collaboration to be effective, you need mutual trust and respect for each professional's roles, abilities, and contributions.

Counselor. Knowing community resources is a critical factor in becoming an effective patient counselor. A counselor helps patients identify and clarify health problems and choose appropriate courses of action to solve those problems. For example, in employee assistance programs or women's shelters, a major amount of nurse-patient interaction is through counseling. As a counselor you are responsible for providing information; listening objectively; and being supportive, caring, and trustworthy. You do not make decisions but rather help your patients reach decisions that are best for them (Stanhope and Lancaster, 2014). Patients and families often require assistance in first identifying and clarifying health problems. For example, a patient who repeatedly reports a problem in following a prescribed diet is actually unable to afford nutritious foods or has family members who do not support good eating habits. You need to discuss with your patient factors that block or aid problem resolution, identify a range of solutions, and then discuss which solutions are most likely to be successful. You also encourage your patient to make decisions and express your confidence in the choice the patient makes.

Educator. In a community-based setting you work with single individuals and groups of patients. Establishing relationships with community service organizations offers educational support to a wide range of patient groups. Prenatal classes, infant care, child safety, and cancer screening are just some of the health education programs provided in a community practice setting.

When the goal is to help your patients assume responsibility for their own health care, your role as an educator takes on greater importance (Stanhope and Lancaster, 2014). Patients and families need to gain skills and knowledge to care for themselves. Assess your patient's learning needs and readiness to learn within the context of the individual, the systems with which the individual interacts (e.g., family, business, and school), and the resources available for support. Adapt your teaching skills so you can instruct a patient within the home setting and make the learning process meaningful. In this practice setting you have the opportunity to follow patients over time. Planning for return demonstration of skills, using follow-up phone calls, and referring to community support and self-help groups give you an

opportunity to provide continuity of instruction and reinforce important instructional topics and learned behaviors (see Chapter 25).

Epidemiologist. As a community-based nurse, you also apply principles of epidemiology. Your contacts with families, community groups such as schools and industries, and health care agencies place you in a unique position to initiate epidemiological activities. As an epidemiologist, you are involved in case finding, health teaching, and tracking incident rates of an illness. For example, a cafeteria worker in the local high school is diagnosed with active tuberculosis (TB). As a community health nurse, you help find new TB exposures or active disease within the worker's home, employment network, and community.

Nurse epidemiologists are responsible for community surveillance for risk factors (e.g., tracking incidence of elevated lead levels in children and identifying increased fetal and infant mortality rates, increases in adolescent pregnancy, presence of infectious and communicable diseases, and outbreaks of head lice). Nurse epidemiologists protect the level of health of the community, develop sensitivity to changes in the health status of the community, and help identify the cause of these changes.

COMMUNITY ASSESSMENT

When practicing in a community setting, you need to learn how to assess the community at large, especially in community health nursing. Community assessment is the systematic data collection on the population, monitoring the health status of the population, and making information available about the health of the community (Stanhope and Lancaster, 2014). This is the environment in which patients live and work. Without an adequate understanding of that environment, any effort to promote a patient's health and bring about necessary change is unlikely to be successful. The community has three components: structure or locale, the people, and the social systems. To develop a complete community assessment, take a careful look at each of the three components to identify needs for health policy, health programs, and needed health services (Box 3-3).

When assessing the structure or locale, you travel around the neighborhood or community and observe its design, the location of services, and the locations where residents meet. You obtain the demographics of the population by accessing statistics on the community from a local public health department or public library. You acquire information about existing social systems such as schools or health care facilities by visiting various sites and learning about their services.

Once you have a good understanding of the community, you can perform all individual patient assessments against that background. For example, when assessing a patient's home for safety, you consider the following: does the patient have secure locks on doors? Are windows secure and intact? Is lighting along walkways and entryways operational? As you conduct a patient assessment, it is important to know the level of community violence and the resources available when help is necessary. Always assess an individual in the context of the community.

CHANGING PATIENTS' HEALTH

In community-based practice nurses care for patients from diverse backgrounds and in diverse settings. It is relatively easy over time to become familiar with the available resources within a particular community practice setting. Likewise, with practice you learn how to identify the unique needs of individual patients. Similarly, nurses bring together the resources necessary to improve a patient's continuity of care. When you collaborate with your patients and their health care providers, you help to reduce duplication of health care services.

BOX 3-3   Community Assessment

Structure
- Name of community or neighborhood
- Geographical boundaries
- Emergency services
- Water and sanitation
- Housing
- Economic status (e.g., average household income, number of residents on public assistance)
- Transportation

Population
- Age distribution
- Sex distribution
- Growth trends
- Density
- Education level
- Predominant ethnic groups
- Predominant religious groups

Social System
- Education system
- Government
- Communication system
- Welfare system
- Volunteer programs
- Health system

For example, when caring for a patient with a healing wound, it is important to coordinate wound care services and help the patient and family locate cost-effective dressing materials.

However, the challenge is promoting and protecting a patient's health within the context of the community using an evidence-based practice approach when possible. For example, can nurses help men in an ethnic community change their decision-making processes regarding prostate cancer screening (Chan et al., 2011; Gash & McIntosh, 2013; see Box 3-1)? Kirkpatrick et al. (2012) investigated the effect of an evidence-based approach used by community health nurses to develop strategies to support patients with chronic obstructive pulmonary disease (COPD) in the community setting. Patients improved their self-care practices, managed panic attacks, and improved their medication compliance in this study.

Perhaps the most important theme to consider is how well you understand your patients' lives. This begins by establishing strong, caring relationships with patients and their families (see Chapter 7). As you gain experience and are accepted by a patient's family, you are able to advise, counsel, and teach effectively and understand what truly makes a patient unique. The day-to-day activities of family life are the variables that influence how you will adapt nursing interventions. The time of day a patient goes to work, the availability of the spouse and patient's parents to provide child care, and the family values that shape views about health are just a few examples of the many factors you will consider in community-based practice. Once you acquire a picture of a patient's life, you then design interventions to promote health and prevent disease within the community-based practice setting.

KEY POINTS

- Principles of public health nursing practice focus on helping individuals and communities achieve and maintain a healthy living environment.

- Essential public health functions include community assessment, policy development, and access to resources.
- When population-based health care services are effective, there is a greater likelihood that higher levels of services will contribute efficiently to health improvement of the population.
- A community health nurse cares for a community as a whole and assesses individuals or families within the context of the community.
- Successful community health nursing practice involves building relationships with a community and being responsive to changes within the community.
- A community-based nurse's competence is based on decision making at the level of the individual patient.
- The special needs of vulnerable populations are a challenge that nurses face in caring for these patients' increasingly complex acute and chronic health conditions.
- A community-based nurse is competent as a caregiver, collaborator, educator, counselor, change agent, patient advocate, case manager, and epidemiologist.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You are managing community care for Katie, age 17, who has cerebral palsy and is severely disabled. Because of the impact of this adolescent's disability, you are also providing care to her mother, Monica, age 50, who is a single parent. Monica has cardiac disease, and all three of her siblings died in their late 50s. She is not able to work and is on public health insurance; Katie is covered through her state insurance program. Katie attends special education programs through the school district, and she will remain eligible for this education until she is 21.

Katie's two siblings, Josh (22) and Marilyn (19), both have cardiac disease and follow strict health promotion activities, which include diet and exercise. Both are in college and currently live at home. Monica is encouraging them to live in their own apartment when they graduate and have a job.

1. Identify some of the social determinants of health for this family. Use the following reference to assist you: Centers for Disease Control and Prevention (CDC): *Social Determinants of Health, Definitions,* 2014b, http://www.cdc.gov/socialdeterminants/Definitions.html.
2. Which resources do you need to identify for the family?
3. How would you help the family begin to envision the new family structure as Josh and Marilyn move out of the home?

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A community nurse in a diverse community is working with health care professionals to provide prenatal care for underemployed and underinsured South African women. Which overall goal of *Healthy People 2020* does this represent?
   1. Assess the health care needs of individuals, families, or communities.
   2. Develop and implement public health policies and improve access to care.

3. Gather information on incident rates of certain diseases and social problems.
4. Increase life expectancy and quality of life and to eliminate health disparities.

2. Using *Healthy People 2020* as a guide, which of the following would improve delivery of care to a community? (Select all that apply.)
   1. Community assessment
   2. Implementation of public health policies
   3. Home safety assessment
   4. Increased access to care
   5. Determining rates of specific illnesses

3. A nursing student in the last semester of a baccalaureate nursing program is beginning the community health practicum and will be working in a clinic with a focus on asthma and allergies. What is the primary focus of the community health nurse in this clinic setting? (Select all that apply.)
   1. Decrease the incidence of asthma attacks in the community
   2. Increase patients' ability to self-manage their asthma
   3. Treat acute asthma attack in the hospital
   4. Provide asthma education programs for the teachers in the local schools
   5. Provide scheduled immunizations to people who come to the clinic

4. The nurse caring for a Bosnian community identifies that the children are undervaccinated and the community is unaware of resources. The nurse assesses the community and determines that there is a health clinic within a 5-mile radius. The nurse meets with the community leaders and explains the need for immunizations, the location of the clinic, and the process of accessing health care resources. Which of the following practices is the nurse providing? (Select all that apply.)
   1. Providing community resources for the children
   2. Teaching the community about health promotion and illness prevention
   3. Promoting autonomy in decision-making about health practices
   4. Improving the health care of the community's children
   5. Participating in professional development activities to maintain nursing competency

5. Vulnerable populations of patients are those who are more likely to develop health problems as a result of:
   1. Chronic diseases, homelessness, and poverty
   2. Poverty and limits in access to health care services
   3. Lack of transportation, dependence on others for care, and homelessness
   4. Excess risks, limits in access to health care services, and dependency on others for care

6. Which of the following are major public health problems commonly affecting older adults? (Select all that apply.)
   1. Substance abuse
   2. Confusional states
   3. Financial limitations
   4. Communicable diseases
   5. Acute and chronic physical illnesses

7. Some nurses are collecting data to determine how many adolescents attempt suicide in a community. This is an example of what type of community assessment data?

8. Many older homes in a neighborhood are undergoing a lot of restoration. Lead paint was used. The community clinic in the neighborhood is initiating a lead screening program. This activity is based on which social determinant of health?

9. Following a community assessment that focused on adolescent health behaviors, a nurse determines that a large number of adolescents smoke and designs a smoking cessation program at the youth community center. This is an example of which nursing role:
   1. Educator
   2. Counselor
   3. Collaborator
   4. Case manager

10. A nurse in a community health clinic noticed an increase in the number of positive tuberculosis (TB) skin tests from students in a local high school during the most recent academic year. After comparing these numbers to the previous years, 10% increase in positive tests was found. The nurse contacts the school nurse and the director of the health department. Together they begin to expand their assessment to all students and employees of the school district. The community nurse was acting in which nursing role(s)? (Select all that apply.)
    1. Epidemiologist
    2. Counselor
    3. Collaborator
    4. Case manager
    5. Caregiver

11. A nursing student is giving a presentation to a group of other nursing students about the needs of patients with mental illnesses in the community. The nursing professor needs to clarify the student's presentation when the student states:
    1. "Many patients with mental illness do not have a permanent home."
    2. "Unemployment is a common problem experienced by people with a mental illness."
    3. "The majority of patients with mental illnesses live in long-term care settings."
    4. "Patients with mental illnesses are often at a higher risk for abuse and assault."

12. The nurse in a new community-based clinic is requested to complete a community assessment. Order the steps for completing this assessment.
    1. Structure or locale
    2. Social systems
    3. Population

13. On the basis of an assessment, the nurse identifies an increase in the immigrant population group in the community. How would the nurse determine the health needs of this population? (Select all that apply.)
    1. Identify what the immigrant population views as the two most important health needs.
    2. Apply information from *Healthy People 2020*.
    3. Determine how the population uses available health care resources.
    4. Determine which health care agencies will accept immigrant populations.
    5. Identify perceived barriers for health care.

14. A patient is worried about her 76-year-old grandmother who is in very good health and wants to live at home. The patient's concerns are related to her grandmother's safety. The neighborhood does not have a lot of crime. Using this scenario, which of the following are the most relevant to assess for safety?
    1. Crime rate, locks, lighting, neighborhood traffic
    2. Lighting, locks, clutter, medications
    3. Crime rate, medications, support system, clutter
    4. Locks, lighting, neighborhood traffic, crime rate

15. The public health nurse is working with the county health department on a task force to fully integrate the goals of *Healthy People 2020*. In the immigrant community most of the population does not have a primary care provider, nor do they participate in health promotion activities; the unemployment rate in the community is 25%. How does the nurse determine which goals need to be included or updated? (Select all that apply.)

   1. Assess the health care resources within the community.

   2. Assess the existing health care programs offered by the county health department.

   3. Compare existing resources and programs with *Healthy People 2020* goals.

   4. Initiate new programs to meet *Healthy People 2020* goals.

   5. Implement educational sessions in the schools to focus on nutritional needs of the children.

Answers: 1. 4; **2.** 1, 2, 4, 5; **3.** 3; **4.** 1, 2, 4; **5.** 4; **6.** 1, 2, 3, 5; **7.** Incident rates; **8.** Physical environment; **9.** 2; **10.** 1, 3; **11.** 3; **12.** 1, 3, 2; **13.** 1, 2, 3, 5; **14.** 2; **15.** 1, 2, 3.

Theoretical Foundations of Nursing Practice

OBJECTIVES

- Explain the influence of nursing theory on a nurse's approach to practice.
- Describe types of nursing theories.
- Describe the relationship among nursing theory, the nursing process, and patient needs.

- Review selected nursing theories.
- Review selected shared theories from other disciplines.
- Describe theory-based nursing practice.

Providing patient-centered nursing care is an expectation for all nurses. As you progress through your nursing classes, you will learn to apply knowledge from nursing; social, physical and biobehavioral sciences; ethics; and health policy. Theory-based nursing practice helps you to design and implement nursing interventions that address individual and family responses to health problems. Some nurses find nursing theory difficult to understand or appreciate. However, as your knowledge about theories improves, you will find that they help to describe, explain, predict, and/or prescribe nursing care measures. Common questions nurses have about theory include: What is theory? How are nursing theories created? Why is theory important to the nursing profession? This chapter answers these questions and will help you understand how to use theory in your nursing practice.

Imagine that you are building a house. You need to complete the foundation before you start building the walls. Without a strong foundation, the house will not stand. Such is the case with nursing practice. Theory serves as the foundation for the art and science of nursing. Nurses use theory every day but are not always aware of it. For example, when a nurse ensures that a patient's room is free of clutter, excess noise, and soiled linens, she or he is using Florence Nightingale's environmental theory to promote healing and comfort. When encouraging a patient to set goals for his recovery, a nurse is using Imogene King's theory of goal attainment. A nurse uses Dorothea Orem's self-care deficit theory when feeding or bathing a patient until the patient is able to do this independently. Even though the term *theory* may sound

intimidating, you will find that it is a standard part of everyday nursing practice.

The scientific work used to develop theories expands the scientific knowledge of the profession. Theories offer well-grounded rationales for how and why nurses perform specific interventions and for predicting patient behaviors and outcomes. Expertise in nursing is a result of knowledge and clinical experience. Nursing knowledge improves nursing practice by connecting theory and research. Theory, research, and practice are bound together in a continuous interactive relationship (Figure 4-1). Nurses develop theories to explain the relationship among variables by testing the theory through research and applying it in practice. Throughout this process new information often comes to light that indicates the need to revise a theory, and the cycle repeats (McEwen and Wills, 2014). Throughout your nursing career you need to reflect and learn from your experiences to grow professionally and use well-developed theories as a basis for your approach to patient care.

THEORY

What is theory? A **theory** helps explain an event by defining ideas or concepts, explaining relationships among the concepts, and predicting outcomes (McEwen and Wills, 2014). In the case of nursing, theories are designed to explain a phenomenon such as self-care or caring.

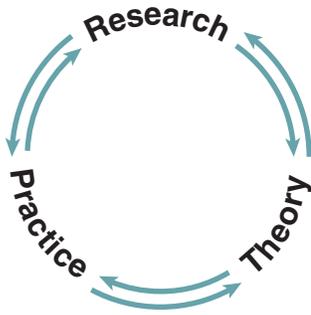
A **nursing theory** conceptualizes an aspect of nursing to describe, explain, predict, or prescribe nursing care (Meleis, 2012). Theories


FIGURE 4-1 Cyclical relationship among theory, research, and practice. (Adapted from McEwen M, Wills EM: *Theoretical basis for nursing,* ed 4, Philadelphia, 2014, Wolters Kluwer Health.)
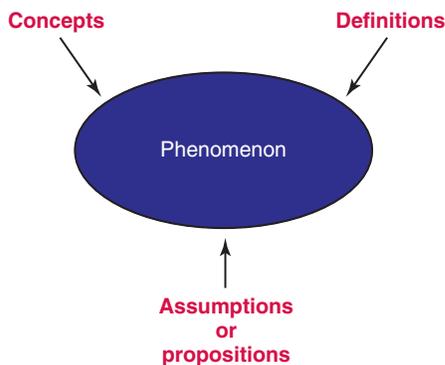

FIGURE 4-2 Components of a nursing theory.

offer a perspective for assessing your patients' situations. They also help you organize, analyze, and interpret data. For example, if you use Orem's theory in practice, you assess and interpret data to determine patients' self-care needs, deficits, and abilities in the management of their disease. Orem's theory then guides your development of patient-centered nursing interventions.

Nursing is both a science and an art. The *science* of nursing is based on data obtained from current research, whereas the *art* of nursing stems from a nurse's experience and the unique caring relationship that a nurse develops with a patient (McEwen and Wills, 2014). A nursing theory helps to identify the focus, means, and goals of practice. Nursing theories enhance communication and accountability for patient care (Meleis, 2012).

Components of a Theory

A theory contains a set of concepts, definitions, and assumptions or propositions that explain a phenomenon. It explains how these elements are uniquely related in the phenomenon (Figure 4-2). These components provide a foundation of knowledge for nurses to direct and deliver caring nursing practices. Researchers test theories, and as a result they gain a clearer perspective and understanding of all parts of a phenomenon.

Phenomenon. Nursing theories focus on the phenomena of nursing and nursing care. A **phenomenon** is the term, description, or label given to describe an idea or responses about an event, a situation, a process, a group of events, or a group of situations (Meleis, 2012). Phenomena may be temporary or permanent. Examples of phenomena of nursing include caring, self-care, and patient responses to stress.

Concepts. A theory also consists of interrelated concepts that help describe or label phenomena. "Concepts are the words or phrases that identify, define, and establish structure and boundaries for ideas generated about a particular phenomenon" (Johnson and Webber, 2014, p. 18). Think of **concepts** as ideas and mental images. They can be abstract such as emotions or concrete such as physical objects (McEwen and Wills, 2014). For example, in Watson's transpersonal theory of caring (see Chapter 7), concepts include meeting human needs and instilling faith-hope (Watson, 2010). Theories use concepts to communicate meaning.

Definitions. Theorists use definitions to communicate the general meaning of the concepts of a theory. Definitions may be *theoretical/conceptual* or *operational*. Theoretical or conceptual definitions simply define a particular concept, much like what can be found in a dictionary, based on the theorist's perspective (Meleis, 2012; McEwen and Wills, 2014). Operational definitions state how concepts are measured (Johnson and Webber, 2014). For example, a nursing concept *conceptually* defines pain as physical discomfort and *operationally* as a patient reporting a score of three or above on a pain scale of zero to ten.

Assumptions. **Assumptions** are the "taken-for-granted" statements that explain the nature of the concepts, definitions, purpose, relationships, and structure of a theory. Assumptions are accepted as *truths* and are based on values and beliefs (Masters, 2015; Meleis, 2012). For example, Watson's transpersonal caring theory has the assumption that a conscious intention to care promotes healing and wholeness (Watson, 2010).

The Domain of Nursing

The **domain** is the perspective or territory of a profession or discipline (Meleis, 2012). It provides the subject, central concepts, values and beliefs, phenomena of interest, and central problems of a discipline. The domain of nursing provides both a practical and theoretical aspect of the discipline. It is the knowledge of nursing practice and nursing history, nursing theory, education, and research. The domain of nursing gives nurses a comprehensive perspective that allows you to identify and treat patients' health care needs in all health care settings.

A **paradigm** is a pattern of beliefs used to describe the domain of a discipline. It links the concepts, theories, beliefs, values, and assumptions accepted and applied by the discipline (McEwen and Wills, 2014). Often used synonymously with paradigm is the term **conceptual framework**. A conceptual framework provides a way to organize major concepts and visualize the relationship among phenomena. Different frameworks provide alternative ways to view the subject matter of a discipline and represent the perspective of the author. For example, the grand theorists all address similar concepts in their respective theories, but each theorist defines and describes the concepts in a different way on the basis of the theorist's own ideas and experiences (Fawcett and DeSanto-Mayeda, 2013).

The **nursing metaparadigm** allows nurses to understand and explain what nursing *is*, what nursing *does*, and *why* nurses do what they do (Fawcett and DeSanto-Mayeda, 2013). The nursing metaparadigm includes the four concepts of person (or human beings), health, environment/situation, and nursing. **Person** is the recipient of nursing care, including individual patients, groups, cultures, families, and communities. The person is central to the nursing care you provide. Because each person's needs are often complex, it is important to provide individualized patient-centered care. **Health** has different meanings for each patient, the clinical setting, and the health care profession (see Chapter 6). It is a state of being that people define in relation to their own values, personality, and lifestyle. It is dynamic and

continuously changing. Your challenge as a nurse is to provide the best possible care based on a patient's level of health and health care needs at the time of care delivery.

Environment/situation includes all possible conditions affecting patients and the settings where they go for their health care. There is a continuous interaction between a patient and the environment. This interaction has positive and negative effects on a person's level of health and health care needs. Factors in the home, school, workplace, or community all influence the level of these needs. For example, an adolescent girl with type 1 diabetes needs to adapt her treatment plan to adjust for physical activities of school, the demands of a part-time job, and the timing of social events such as her prom.

Nursing is the "… protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations" (ANA, 2014). The scope of nursing is broad. For example, a nurse does not medically diagnose a patient's health condition as heart failure. However, he or she assesses a patient's response to the decrease in activity tolerance as a result of the disease and develops *nursing diagnoses* of fatigue, activity intolerance, and ineffective coping (see Chapter 17). From these nursing diagnoses the nurse creates a patient-centered plan of care for each of the patient's health problems (see Chapter 18). Use critical thinking skills to integrate knowledge, experience, attitudes, and standards into the individualized plan of care for each of your patients (see Chapter 15).

Evolution of Nursing Theory.   How are theories created? Nursing theories often build on the works of prior theories. Florence Nightingale is generally regarded as the first nursing theorist; her theory was founded on her belief that nursing could improve a patient's environment to facilitate recovery and prevent complications. In the Nightingale era nurses were trained to observe each patient's condition and report changes to the doctor, thus beginning the status of nursing as subservient to the physician—a sign of the Victorian era in which Nightingale lived (Warelow, 2013).

With the twentieth century approaching, nursing began to transition from a vocation to a profession, which prompted American nurses to standardize nursing education in diploma programs and encouraged more nurses to seek academic degrees. The first national gathering of nurses occurred at the World's Fair in Chicago in 1893,

and the first edition of the *American Journal of Nursing* (AJN) was published in 1900 (Alligood, 2014). The "curriculum era" of nursing spanned the 1900s to the 1940s. During this period nursing education expanded beyond basic anatomy and physiology courses to include courses in the social sciences, pharmacology, and "nursing arts" that addressed nursing actions, skills, and procedures (Alligood, 2014).

The "research era" encompassed the 1950s, '60s, and '70s, during which nurses became increasingly involved in conducting studies and sharing their findings. However, the earliest research studies had a psycho-social, anthropological, or educational focus. Nurses studied their own attitudes, their relationships with other disciplines, and their functions in work and political settings. In the early years, nursing research did not explore clinical questions based on the medical model of research because the discipline was attempting to show its uniqueness from medicine. At this same time the "graduate education era" began, and early versions of nursing theories were developed that offered more structure to nursing research. The renowned theorists of this time period included Johnson, King, Levine, Neuman, Orem, Rogers, and Roy (Alligood, 2014).

The *theory* era, which included the 1980s and 1990s, significantly contributed to knowledge development, and the nursing metaparadigm was proposed by Fawcett. This era resulted in the publication of several nursing journals, the development of nursing conferences, and the offering of more doctoral programs in nursing (Alligood, 2014).

The twenty-first century is considered the era of *theory utilization*. Today nurses strive to provide evidence-based practice (EBP), which stems from theory, research, and experience. The focus of EBP is safe, comprehensive, individualized, quality health care (see Chapter 5). The original *grand* theories served as springboards for the development of the more modern *middle-range* theories, which, through testing in research studies, provided "evidence" for EBP and promoted the translation of research into practice. Theory use is congruent with current national goals for quality health care (Alligood, 2014).

Historical eras of knowledge development in nursing are represented in Table 4-1. Nursing theories have changed over time in response to changes in society and the world. The environment of war was a primary factor in developing Nightingale's theory. At the other end of the nursing spectrum Rogers' vision of aerospace nursing was developed during the 1980s when the advent of the space shuttle program made the concept of space travel a possible reality for everyone (Warelow, 2013).

TABLE 4-1   Historical Eras of Knowledge Development in Nursing

Historical Areas	Major Question	Emphasis	Outcomes	Emerging Goal
Curriculum era: 1900 to the 1940s	What curriculum content should student nurses study?	Courses taught in nursing programs	Standardized curricula for diploma programs	Specialized knowledge and higher education
Research era: 1950 to the 1970s	What is focus for nursing research?	Role for nurses and what to research	Problem studies and studies of nurses	Theory-based studies for unified knowledge
Graduate education era: 1950 to the 1970s	What knowledge is needed for nursing practice?	Carving out an advanced role and basis for nursing pracice	Nurses have an important role in quality health care	Focus graduate education on knowledge development
Theory era: 1980 to the 1990s	How do these frameworks guide research and practice?	The many ways to think about nursing	Nursing theoretical works clearly focus on the patient	Guide nursing research and practice
Theory utilization era: twenty-first century	Which new theories are needed as evidence for quality care?	Nursing theory as a guide for research, practice, education, and administration	Middle-range theories are from quanititative or qualitative approaches	Nursing frameworks as the knowledge (evidence) for quality care

From Alligood MR: *Nursing theory: utilization and application,* ed 5, St Louis, 2014, Mosby.

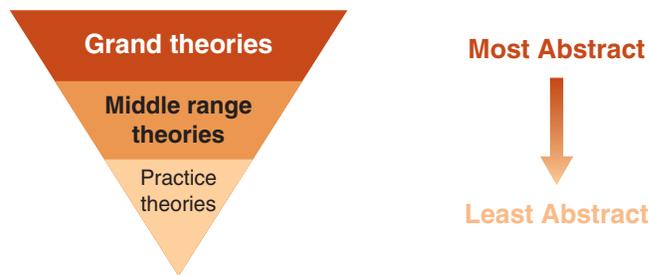
FIGURE 4-3 Correlation of theory category with level of abstraction. (Adapted from McEwen M, Wills EM: *Theoretical basis for nursing,* ed 4, Philadelphia, 2014, Wolters Kluwer Health.)

Theorists developed their theories from their own experiences in nursing education and nursing practice and from knowledge gained from the disciplines of philosophy, sociology, psychology, and anthropology. Many nursing theorists revise their theories over time to remain current with health care changes. Such evolution shows that theories are not stagnant; rather they are dynamic and responsive to the changing environment in which we live (Warelow, 2013).

Types of Theory

The unique theories of a discipline help to distinguish the discipline from other professions. Before the development of nursing theories, nursing was considered to be a task-oriented occupation that functioned under the direction of the medical profession (McEwen and Wills, 2014). "The primary use of theory is to provide insights about nursing practice situations and guide research" and to provide a guideline or explanation of why nurses do what they do (Meleis, 2012, p. 35). Theories have different purposes and are sometimes classified by levels of abstraction (grand versus middle-range versus practice theories) or the goals of the theory (descriptive or prescriptive). For example, a descriptive theory describes a phenomenon such as grief or caring and also identifies conditions or factors that predict a phenomenon. A prescriptive theory details nursing interventions for a specific phenomenon and the expected outcome of the care. Box 4-1 summarizes goals of theoretical nursing models.

Grand theories are abstract, broad in scope, and complex; therefore they require further clarification through research so they can be applied to nursing practice. A grand theory does not provide guidance for *specific* nursing interventions; but it provides the structural framework for general, global ideas about nursing. Grand theories intend to answer the question, "What is nursing" and focus on the *whole* of nursing rather than on a *specific* type of nursing. The grand theorists developed their works based on their own experiences and the time in which they were living, which helps to explain why there is so much variation among the theories. Grand theories address the nursing metaparadigm components of person, nursing, health, and environment.

Middle-range theories are more limited in scope and less abstract. They address a specific phenomenon and reflect practice (administration, clinical, or teaching). A middle-range theory tends to focus on a concept found in a specific field of nursing such as uncertainty, incontinence, social support, quality of life, and caring rather than reflect on a wide variety of nursing care situations as the grand theories do (Meleis, 2012). For example, Kolcaba's theory of comfort encourages nurses to meet patients' needs for comfort in physical, psychospiritual, environmental, and sociocultural realms (Krinsky et al, 2014). Like many middle-range theories, Kolcaba's theory was based on the works of a grand theorist—in this case, Nightingale. Middle-range theories


are also sometimes developed from research, nursing practice, or the theories of other disciplines (McEwen and Wills, 2014; Meleis, 2012).

Practice theories, also known as situation-specific theories, bring theory to the bedside. Narrow in scope and focus, these theories guide the nursing care of a *specific* patient population at a *specific* time (Meleis, 2012). An example of a practice theory is a pain-management protocol for patients recovering from cardiac surgery. "Practice theories have had the benefit of trial and error through clinical practice" and are often easier to understand and apply than the grand and middle-range theories (Warelow, 2013, p. 41). Figure 4-3 demonstrates the level of abstraction for each of the grand, middle-range, and practice theory categories.

Descriptive theories are the first level of theory development. They describe phenomena and identify circumstances in which the phenomena occur (Meleis, 2012). For example, theories of growth and development describe the maturation processes of an individual at various ages (see Chapter 11). Descriptive theories do not direct specific nursing activities or attempt to produce change but rather help to explain patient assessments.

Prescriptive theories address nursing interventions for a phenomenon, guide practice change, and predict the consequences. Nurses use prescriptive theories to anticipate the outcomes of nursing interventions (McEwen and Wills, 2014).

Theory-Based Nursing Practice

Why is theory important to the nursing profession? Nursing knowledge is derived from basic and nursing sciences, experience, aesthetics, nurses' attitudes, and standards of practice. As nursing continues to grow as a practice-oriented profession, new knowledge is needed to prescribe specific interventions to improve patient outcomes. Nursing theories and related concepts continue to evolve. Florence Nightingale spoke with firm conviction about the "nature of nursing as a profession that requires knowledge distinct from medical knowledge" (Nightingale, 1860). The overall goal of nursing knowledge is to explain the practice of nursing as different and distinct from the practice of medicine, psychology, and other health care disciplines. Theory generates nursing knowledge for use in practice, thus supporting EBP (see Chapter 5). The integration of theory into practice leads to coordinated care delivery and therefore serves as the basis for nursing (McEwen and Wills, 2014).

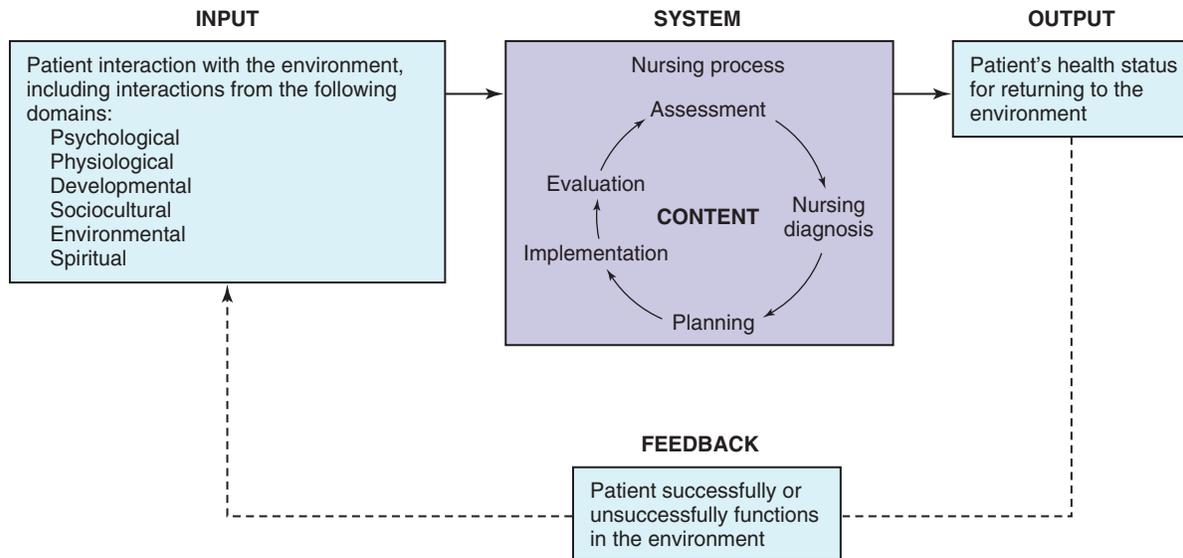
The nursing process is used in clinical settings to determine individual patient needs (see Unit III). Although the nursing process is central to nursing, it is not a theory. It provides a systematic process for the delivery of nursing care, not the knowledge component of the discipline. However, nurses use theory to provide direction in how to *use* the nursing process. For example, the theory of caring influences what nurses need to assess, how to determine patient needs, how to


FIGURE 4-4 Providing nursing services in assisted-living facilities promotes physical and psychosocial health.

plan care, how to select individualized nursing interventions, and how to evaluate patient outcomes.

SHARED THEORIES

To practice in today's health care systems, nurses need a strong scientific knowledge base from nursing and other disciplines such as the biomedical, sociological, and behavioral sciences. Also known as a *borrowed* or *interdisciplinary* theory, a **shared theory** explains a phenomenon specific to the discipline that developed the theory (McEwen and Wills, 2014). For example, Piaget's theory of cognitive development helps to explain how children think, reason, and perceive the world (see Chapter 11). Knowledge and use of this theory help pediatric nurses design appropriate therapeutic play interventions for ill toddlers or school-age children. Knowles's adult learning theory helps a nurse plan and provide appropriate discharge teaching for a patient who is recovering from surgery. Several nursing theories are based on systems theory, and the nursing process is also a system (Figure 4-4). Like all systems, the nursing process has a specific purpose or goal (see Unit III). The goal of the nursing process is to organize and deliver patient-centered care. As a system the nursing process has the following components: input, output, feedback, and content. **Input** for the nursing process is the data or information that comes from a patient's assessment. **Output** is the end product of a system; and in the case of the nursing process it is whether the patient's health status improves, declines, or remains stable as a result of nursing care.

Feedback serves to inform a system about how it functions. For example, in the nursing process the outcomes reflect the patient's responses to nursing interventions. The outcomes are part of the feedback system to refine the plan of care. Other forms of feedback in the nursing process include responses from family members and consultation from other health care professionals.

The **content** is the product and information obtained from the system. For example, patients with impaired bed mobility have common skin care needs and interventions (e.g., hygiene and scheduled positioning changes) that are very successful in reducing the risk for pressure ulcers. Table 4-2 provides an overview of additional select shared theories that are often used in nursing practice.

SELECT NURSING THEORIES

Definitions and theories of nursing can help you understand the practice of nursing. The following sections describe select theories and their concepts. See Table 4-3 for a review of additional grand and middle-range nursing theories.

Nightingale's Environmental Theory

Known as the founder of modern nursing, Florence Nightingale is credited with developing the first nursing theory. The focus of Nightingale's grand theory is a patient's environment, which Nightingale believed nurses should manipulate (e.g., ventilation, light, decreased noise, hygiene, nutrition) so nature is able to restore a patient to health (McEwen and Wills, 2014). Through observation and data collection, she linked the patient's health status with environmental factors and initiated improved hygiene and sanitary conditions during the Crimean War. Nightingale taught and used the nursing process, noting that "vital observation [assessment] … is not for the sake of piling up miscellaneous information or curious facts, but for the sake of saving life and increasing health and comfort" (Nightingale, 1860).

Peplau's Interpersonal Theory

Hildegard Peplau is considered to be the mother of psychiatric nursing; the focus of her middle-range theory includes interpersonal relations among a nurse, a patient, and a patient's family and developing the nurse-patient relationship (McEwen and Wills, 2014). According to Peplau, nurses help patients reduce anxiety by converting it into constructive actions (McEwen and Wills, 2014). They develop therapeutic relationships with patients that are respectful, empathetic, and nonjudgmental (Senn, 2013). The following phases characterize the nurse-patient interpersonal relationship: preorientation (data gathering), orientation (defining issue), working phase (therapeutic activity), and resolution (termination of relationship). In developing a nurse-patient relationship, the nurse serves as a resource person, counselor, and surrogate. For example, when a patient seeks help, the nurse and patient first discuss the nature of any problems, and the nurse explains the services available. As the nurse-patient relationship develops, the nurse and patient mutually define the problems and potential solutions.

TABLE 4-2   Overview of Select Shared Theories

Theory Categories	Focus	Application to Nursing
Human needs	Need motivates human behavior. Maslow's hierarchy of basic human needs includes five levels of priority (e.g., physiological, safety and security, love and belonging, self-esteem, and self-actualization) (see Figure 6-3, p. 68.).	Basic physiological and safety needs are usually a patient's first priority, especially when he or she is severely dependent physically. When a patient has no emergent physical or safety needs, the nurse gives high priority to his or her psychological, sociocultural, developmental, or spiritual needs. Patients entering the health care system generally have unmet needs. A patient in pain after surgery (basic need) is not ready for discharge teaching (higher level need) until the pain is relieved. The hierarchy of needs is a way to plan for individualized patient care (McEwen and Wills, 2014).
Stress/adaptation	Humans respond to actual or perceived threats by adapting to maintain function and life.	Patients demonstrate a similar pattern of reacting to stress through physiological and psychological responses. Failure to adapt to stress can lead to exhaustion and decline in health. Nurses need to understand the reaction of body and mind to stress and intervene to help patients develop methods of coping/adapting to prevent or manage illness and disease (Master's, 2015).
Developmental	Humans have a common pattern of growth and development.	Human growth and development are orderly, predictive processes that begin with conception and continue through death. Varieties of well-tested theories describe and predict behavior and development at various phases of the life continuum (McEwen and Wills, 2014).
Biomedical	Theory explains causes of disease; principles related to physiology.	Nurses must have knowledge of theories from the fields of biology, medicine, public health, physiology, and pharmacology to provide holistic patient care, promote health, and prevent illness (McEwen and Wills, 2014).
Psychosocial	Theory explains and/or predicts human responses within the physiological, psychological, sociocultural, developmental, and spiritual domains	Nursing is a diverse discipline that strives to meet holistic needs of patients. Chapter 9 discusses models for understanding cultural diversity and implementing care to meet the diverse needs of the patient. Chapter 10 describes family theory and how to meet the needs of the family when the family is the patient or the caregiver. Chapter 37 discusses several models of grieving and demonstrates how to help patients through loss, death, and grief.
Educational	Theory explains the teaching-learning process by examining behavioral, cognitive, and adult learning principles.	Nurses provide education to patients, families, community groups, and members of the health care team. A basic understanding of various teaching-learning theories is critical for this aspect of the professional nursing role (Butts and Rich, 2015).
Leadership/ management	Theory promotes organization, change, power/empowerment, motivation, conflict management, and decision-making.	Nurses often assume leadership positions in the health care realm and as such are expected to effectively manage individuals and groups to promote change and improve quality care and outcomes (McEwen and Wills, 2014).

TABLE 4-3   Overview of Select Grand and Middle-Range Nursing Theories

Theory Category	Theorist	Focus	Application
Grand theory	Henderson	Principles and practice of nursing	Nurses assist patients with 14 activities (breathing, eating/drinking, elimination, movement/positioning, sleep/rest, clothing, body temperature, hygiene, safety, communication/socialization/play, practice of faith, learning) until patients can meet these needs for themselves; or they help patients have a peaceful death (Butts and Rich, 2015; McEwen and Wills, 2014).
	Johnson	Behavioral system	Nurses perceive patients as being more important than their disease; a patient is viewed as a collection of subsystems that form an overall behavioral system focused on meeting basic drives of achievement, affiliation, aggression/protection, dependence, elimination, ingestion, sex, and restoration. The goal of nursing is to help the patient attain/maintain balance, function, and stability in each of the subsystems (Butts and Rich, 2015).
	Neuman	Systems	Nurses view a patient (physical, psychological, sociocultural, developmental, and spiritual) as being an open system that is in constant energy exchange with both internal and external environments. Nurses help a patient/client (individual, group, family, or community) cope with intrapersonal, interpersonal, and extra-personal *stressors* that can break through the patient's line of defense and cause illness. The role of nursing is to stabilize a patient or situation, and the focus is on *wellness* and *prevention* of disease (McEwen and Wills, 2014).

TABLE 4-3   Overview of Select Grand and Middle-Range Nursing Theories—cont'd

Theory Category	Theorist	Focus	Application
	Abdellah	Patient-centered care	Nurses address 21 "nursing problems" to meet patients' physical, psychological, and social needs and should strive to *know* each patient. Nurses use knowledge constructed from previous experiences to determine a general plan of care and then personalizes the plan to the patient to provide *patient-centered care*. A nurse should involve a patient's family in the plan of care (McEwen and Wills, 2014).
	Levine	Conservation	Nurses promote *balance* between nursing interventions and patient participation to help patients *conserve energy* needed for healing; *conserve structural integrity* by limiting the extent of tissue involvement/damage; *conserve personal integrity* by involving them in their care decisions; and *conserve social integrity* by facilitating patient interactions with family and loved ones (Johnson and Webber, 2014).
	King	Goal attainment	Nurses view a patient as a unique personal system that is constantly interacting/transacting with other systems (e.g., nurse, family, friends); nurses help patients become active participants in their care by working *with* them to establish goals for attaining, restoring, or maintaining health (Johnson and Webber, 2014; McEwen and Wills, 2014).
	Roy	Adaptation	Nurses help a patient cope with or adapt to changes in physiological, self-concept, role function, and interdependence domains (Masters, 2015).
	Erickson-Tomlin-Swain	Modeling/role modeling	Nurses understand a patient's *model of the world* or world view (e.g., how the patient thinks, acts, feels, communicates) and help a patient use internal and external resources to make appropriate changes *(role modeling)* to attain optimal health (McEwen and Wills, 2014).
	Watson	Caring	Nurses understand that caring is a fundamental component of professional nursing practice and is based on 10 *carative factors* (see Chapter 7). The purpose of nursing is to understand the interrelationship among health, illness, and human behavior rather than focus on the disease-cure model. Caring occurs when a nurse and patient engage in a *transpersonal relationship* that facilitates the patient's ability for self-healing (Johnson and Webber, 2014).
	Rogers/Parse/Newman	Unitary beings/human becoming/expanding consciousness	Nurses view a patient as a unique, dynamic energy field in constant energy exchange with the environment; nursing care focuses on helping a patient use his or her *own* potential to identify and alter personal rhythms/patterns (e.g., eating, breathing, sleeping, communicating, touching) to promote and maintain health. Nurses understand that patients are responsible for their own health and that health stems from how patients live their lives in accordance with their own values; the nurse's role is to be truly *present* with the patient and accepting of his or her view of reality while providing guidance to the patient in making health-related choices in accordance with his or her belief system (Johnson and Webber, 2014; McEwen and Wills, 2014).
Middle-range theory	Benner	Skill acquisition	Nurses progress through five stages of skill acquisition: novice, advanced beginner, competent, proficient, and expert (Butts and Rich, 2015).
	Kolcaba	Comfort	Nurses facilitate health-seeking behaviors in patients by striving to relieve physical, emotional, social, environmental, and/or spiritual distress (McEwen and Wills, 2014).
	Pender	Health promotion	Nurses understand that a patient's personal characteristics, experiences, and beliefs affect his or her motivation for adopting healthy behaviors (see Chapter 6) (McEwen and Wills, 2014).
	American Association of Critical-Care Nurses	Synergy	Matching nurse competencies to patient needs in the critical care environment improves patient outcomes (McEwen and Wills, 2014).
	Mishel	Uncertainty in illness	Nurses facilitate patient coping and adaptation by performing interventions aimed at helping patients process and find meaning related to their illness (Adelstein et al., 2014).
	Eakes, Burke, and Hainsworth	Chronic sorrow	Nurses understand that the disparity between *desired* and *actual* reality often leads to continuous cycles of grief. For example, chronic sorrow sometimes occurs in parents of children with disabilities or in individuals diagnosed with a chronic illness (Vitale and Falco, 2014).

When the patient's original needs are resolved, new needs sometimes emerge. This middle-range theory is useful in establishing effective nurse-patient communication when obtaining a nursing history, providing patient education, or counseling patients and their families (see Chapter 24).

Orem's Self-Care Deficit Nursing Theory

Dorothea Orem's theory is commonly used in nursing practice (Alligood, 2014). When applying this grand theory, a nurse continually assesses a patient's ability to perform self-care and intervenes as needed to ensure that the patients meets physical, psychological,

sociological, and developmental needs. According to Orem, people who participate in self-care activities are more likely to improve their health outcomes (Rustøen et al., 2014). Nursing care becomes necessary when patients are unable to fulfill biological, psychological, developmental, or social needs. Nurses continually assess and determine why patients are unable to meet these needs, identify goals to help them, intervene to help them perform self-care, and evaluate how much   self-care they are able to perform. For example, a patient may need a nurse to bathe or feed him or her while acutely ill; but as his or her condition improves, the nurse encourages the patient to begin doing these activities independently.

Leininger's Culture Care Theory

As early as the 1950s Madeleine Leininger recognized the need to focus on culture in nursing as she predicted that nursing and health care would become more global. She blended her background in anthropology with nursing to form her middle-range theory of cultural care diversity and universality (Alligood, 2014). Human caring varies among cultures in its expressions, processes, and patterns. Social structure factors such as a patient's politics, culture, and traditions are significant forces affecting care and influencing the patient's health and illness patterns. Think about the diversity of patients and their nursing care needs (see Chapter 9). The major concept of Leininger's theory is cultural diversity, and the goal of nursing care is to provide a patient with culturally specific nursing care (Alligood, 2014). To provide care to patients of unique cultures, nurses safely integrate their cultural traditions, values, and beliefs into a plan of care. Leininger's theory recognizes the importance of culture and its influence on everything that involves a patient, including health beliefs, the role of family and community, and dietary practices (Alligood, 2014). For example, some cultures believe that the leader of the community needs to be present during health care decisions. As a result, a health care team needs to reschedule when rounds occur to include the community leader. In addition, symptom expression also differs among cultures. A person with an Irish background might be stoic and not complain about pain, whereas a person from a Middle Eastern culture might be very vocal about pain. In both cases a nurse needs to skillfully incorporate the patient's cultural practices in assessing his or her level of pain (e.g., is the pain getting worse or remaining the same?).

> **QSEN** **QSEN: BUILDING COMPETENCY IN PATIENT-CENTERED CARE** You are caring for a patient from India who is visiting family in the United States. On entering this patient's room, you notice that he has not eaten any of the food on his tray. When you ask if he wasn't hungry, he replies, "I am very hungry, but I cannot eat this food." How could you use *Leininger's culture care theory* to respond to this patient?

LINK BETWEEN THEORY AND KNOWLEDGE DEVELOPMENT IN NURSING

Nursing has its own body of knowledge that is both theoretical and experiential. You acquire theoretical knowledge through "reading, observing, or discussing" concepts (Alligood, 2014, p. 123). Theoretical knowledge stimulates thinking and creates a broad understanding of nursing science and practice. Experiential, or clinical, knowledge, often called the *art* of nursing, is formed from nurses' clinical experience. Both types of knowledge are needed to provide safe, comprehensive nursing care.

Nursing theories guide nursing practice (McEwen and Wills, 2014). When using theory-based nursing practice, you apply the principles of a theory in delivering nursing interventions. Grand theories help shape and define your practice; middle-range theories continue to advance nursing knowledge through nursing research; and practice theories help you provide specific care for individuals and groups of diverse populations and situations (Im and Chang, 2012).

Relationship Between Nursing Theory and Nursing Research

Research validates, refutes, supports, and/or modifies theory; and theory stimulates nurse scientists to explore significant issues in nursing practice, leading to the improvement of nursing care (McEwen and Wills, 2014; Meleis, 2012). The relationship between nursing theory and nursing research builds the scientific knowledge base of nursing, which is then applied to practice. Nurses better understand the appropriate use of a theory to improve patient care as more research is conducted. The relationships between the components of a theory often help identify research questions and determine the overall design of a study. For example, nurse researchers used Peplau's interpersonal theory as the framework for a study about standardized shift report as a means of improving nurse-to-nurse communication. The results showed improved patient satisfaction with nursing care (Radtke, 2013).

Sometimes research is used to develop new theories (Meleis, 2012). *Theory-generating* research uses logic to explore relationships among phenomena (McEwen and Wills, 2014). In theory-generating research an investigator makes observations (*without* any preconceived ideas) to view a phenomenon in a new way. Middle-range theories are often developed in this manner. For example, the middle-range theory of chronic sorrow stemmed from a researcher's initial observations of cyclic periods of sadness in parents of children with intellectual or developmental disabilities (Vitale and Falco, 2014).

Theory-testing research determines how accurately a theory describes a nursing phenomenon. Testing develops the evidence for describing or predicting patient outcomes. A researcher has *some* preconceived idea as to how patients describe or respond to a phenomenon and generates research questions or hypotheses to test the assumptions of the theory. No one study tests *all* components of a theory; researchers test the theory through a variety of research activities. For example, nurse researchers studied Kolcaba's middle-range nursing theory of comfort in relation to the pain and discomfort experienced by patients with heart disease. The researchers explored the specific intervention of "quiet time" as a comfort measure in this patient population (Krinsky et al, 2014).

Theory-generating or theory-testing research refines the knowledge base of nursing. As a result, nurses incorporate research-based interventions into theory-based practice (Box 4-2). As research activities continue, not only does the knowledge and science of nursing increase, but patients receive high-quality evidence-based nursing practice (see Chapter 5). As an art, nursing relies on knowledge gained from practice and reflection on past experiences. The "expert nurse" translates both the art and science of nursing into the realm of *creative caring*, which takes the extra step of individualizing care to the specific needs of each patient. For example, a nurse provides creative caring when arranging for a hospitalized patient to visit with a beloved pet or finding a way to honor a patient's wish to die at home.

As you progress in your nursing education and practice, you will use theory in a variety of ways. Keep in mind that these theories are not only applicable to patient care but are also useful in communicating with other members of the health care team. Theory is the

foundation of nursing; it defines our unique profession and sets it apart from other disciplines. Theory provides a basis for research and practice and serves as a guide in providing safe, comprehensive, individualized care, which is the hallmark of nursing.

KEY POINTS

- A nursing theory conceptualizes an aspect of nursing to describe, explain, predict, and/or prescribe nursing care.
- Grand theories provide complex structural frameworks for broad, abstract ideas.
- Middle-range theories address specific phenomena or concepts and reflect practice. Thus they are more limited in scope and less abstract.
- Practice or situation-specific theories bring theory to the bedside by focusing on specific types of patients in specific situations.

- The metaparadigm of nursing identifies four concepts of interest to the profession: the person, health, environment/situation, and nursing. These four components are essential to the development of nursing theory.
- Theory generates nursing knowledge used in practice. Nurses use the nursing process to apply the theory or knowledge. The integration of theory and nursing process is the basis for professional nursing.
- Theory-generating research discovers and describes relationships without imposing preconceived notions (e.g., hypotheses) of what the phenomenon under study means.
- Theory-testing research determines how accurately a theory describes nursing phenomena.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Your nursing class is debating the issue of the usefulness of grand theories in current practice. Make a case for the applicability of grand theories in modern nursing and describe how nurses can use the original nursing theory—Nightingale's environmental theory—in the following settings:
   a. Critical Care Unit
   b. Emergency Department (ED)
   c. Home Health
2. You are providing care to a patient with chronic obstructive pulmonary disease (COPD) who has been readmitted 3 times within the past month for difficulty breathing. Explain how you would apply Peplau's interpersonal theory to help this patient prevent complications and promote self-management of his disease.
3. For the same patient described previously, how would you apply Orem's self-care deficit theory to help the patient? Compare and contrast the use of Peplau's and Orem's theories for this patient.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The components of the nursing metaparadigm include:
   1. Person, health, environment, and theory
   2. Health, theory, concepts, and environment
   3. Nurses, physicians, health, and patient needs
   4. Person, health, environment, and nursing
2. Theory is essential to nursing practice because it: (Select all that apply.)
   1. Contributes to nursing knowledge.
   2. Predicts patient behaviors in situations.
   3. Provides a means of assessing patient vital signs.
   4. Guides nursing practice.
   5. Formulates health care legislation.
   6. Explains relationships between concepts.
3. A nurse ensures that each patient's room is clean; well ventilated; and free from clutter, excessive noise, and extremes in temperature. Which theorist's work is the nurse practicing in this example?
   1. Henderson
   2. Orem
   3. King
   4. Nightingale

4. The nurse is caring for a patient admitted to the neurological unit with the diagnosis of a stroke and right-sided weakness. The nurse assumes responsibility for bathing and feeding the patient until the patient is able to begin performing these activities. The nurse in this situation is applying the theory developed by:
   1. Neuman.
   2. Orem.
   3. Roy.
   4. Peplau.

5. Match the following types of theory with the appropriate description.
   1. Middle-range theory
   2. Shared theory
   3. Grand theory
   4. Practice theory

   a. Very abstract; attempts to describe nursing in a global context
   b. Specific to a particular situation; brings theory to the bedside
   c. Applies theory from other disciplines to nursing practice
   d. Addresses a specific phenomenon and reflects practice

6. Match the following descriptions to the appropriate grand theorist.
   1. King
   2. Henderson
   3. Orem
   4. Neuman

   a. Based on the theory that focuses on *wellness* and *prevention* of disease
   b. Based on the belief that people who participate in self-care activities are more likely to improve their health outcomes
   c. Based on 14 activities, the belief that the nurse should assist patients with meeting needs until they are able to do so independently
   d. Based on the belief that nurses should work with patients to develop goals for care

7. Match the following description to the appropriate middle-range theory.
   1. Benner's Skill Acquisition
   2. AACN's Synergy Model
   3. Mishel's Uncertainty in Illness
   4. Kolcaba's Theory of Comfort

   a. The nurse strives to relieve patients' distress.
   b. The nurse progresses through five stages of expertise.
   c. The nurse helps the patient to process and find meaning related to his or her illness.
   d. Matching nurse competencies to patient needs can improve patient outcomes.

8. Which of the following statements related to theory-based nursing practice are correct? (Select all that apply.)
   1. Nursing theory differentiates nursing from other disciplines.
   2. Nursing theories are standardized and do not change over time.
   3. Integrating theory into practice promotes coordinated care delivery.
   4. Nursing knowledge is generated by theory.
   5. The theory of nursing process is used in planning patient care.
   6. Evidence-based practice results from theory-testing research.

9. A nurse is caring for a patient who recently lost a leg in a motor vehicle accident. The nurse best assists the patient to cope with this situation by applying which of the following theories?
   1. Roy
   2. Levine
   3. Watson
   4. Johnson

10. Using Maslow's hierarchy of needs, identify the priority for a patient who is experiencing chest pain and difficulty breathing.
   1. Self-actualization
   2. Air, water, and nutrition
   3. Safety
   4. Esteem and self-esteem needs

11. Which of the following categories of shared theories would be most appropriate for a patient who is grieving the loss of a spouse?
   1. Biomedical
   2. Leadership
   3. Psychosocial
   4. Developmental

12. While working in a rehabilitation facility, it is important to obtain nursing histories and develop a therapeutic nurse-patient relationship. List in correct order the phases of Peplau's theory as applied in this setting. The nurse:
   1. Ensures that the patient has access to appropriate community resources for long-term care.
   2. Collaborates with the patient to identify specific patient needs.
   3. Collects essential information from the patient's health record.
   4. Works with the patient to develop a plan for resolving patient issues.

13. Nurses have developed theories in response to: (Select all that apply.)
   1. Changes in health care.
   2. Prior nursing theories.
   3. Changes in nursing practice.
   4. Research findings.
   5. Government regulations.
   6. Theories from other disciplines.
   7. Physician opinions.

14. Which of the following types of theory influence the "evidence" in current "evidence-based practice (EBP)"?
   1. Grand theory
   2. Middle-range theory
   3. Practice theory
   4. Shared theory

15. A nurse is preparing to begin intravenous fluid therapy for a patient. Which category of theory would be most helpful to the nurse at this time?
   1. Grand theory
   2. Middle-range theory
   3. Practice theory
   4. Shared theory

Answers: 1. 4; **2.** 1, 2, 4, 6; **3.** 4; **4.** 2; **5.** 1d, 2c, 3a, 4b; **6.** 1d, 2c, 3a, 4b, 4a; **7.** 1b, 2d, 3c, 4a; **8.** 1, 3, 4, 6; **9.** 1; **10.** 2; **11.** 3; **12.** 3, 2, 4, 1; **13.** 1, 2, 3, 4, 6; **14.** 2; **15.** 3.

Evidence-Based Practice

Rick is a registered nurse (RN) on a general surgical unit. Since he started working there 5 years ago, standard nursing care includes significant patient education, administration of pain medications, and promoting a quiet environment to manage anxiety and pain for patients after surgery. Rick notices that many patients are experiencing higher levels of anxiety and pain, which is interfering with their recovery and delaying their discharge. Rick raises the question with other RNs in the department, "What if we had our patients listen to music after they have surgery? Is it possible that music will help better manage our patients' anxiety and pain?"

Most nurses like Rick practice nursing according to what they learn in nursing school, their experiences in practice, and the policies and procedures of their health care agency. This approach to practice does not guarantee that nursing practice is always based on up-to-date scientific information. Sometimes it is based on tradition and not on current evidence. If Rick went to the scientific literature for articles about how listening music affects postsurgical pain and anxiety, he would find some studies that show having patients listen to music following surgery sometimes helps them recover more quickly. The evidence from research and the opinions of nursing experts provide a basis for Rick and his colleagues to make evidence-based changes to their care of patients following surgery. The use of evidence in practice enables clinicians like Rick to provide the highest quality of care to their patients and families.

THE NEED FOR EVIDENCE-BASED PRACTICE

Quality and cost issues drive the direction of the current health care environment (Garner et al., 2013). As a professional nurse you are accountable and responsible for providing the best nursing care possible. People are more informed about their own health and the incidence of medical errors within health care institutions across the country. Evidence-based care improves quality, safety, patient outcomes, and nurse satisfaction while reducing costs (Melnyk and Fineout-Overholt, 2014). Thus implementing **evidence-based practice (EBP)** helps you make effective, timely, and appropriate clinical decisions in response to the broad political, professional, and societal forces present in today's health care environment (Peterson et al., 2014).

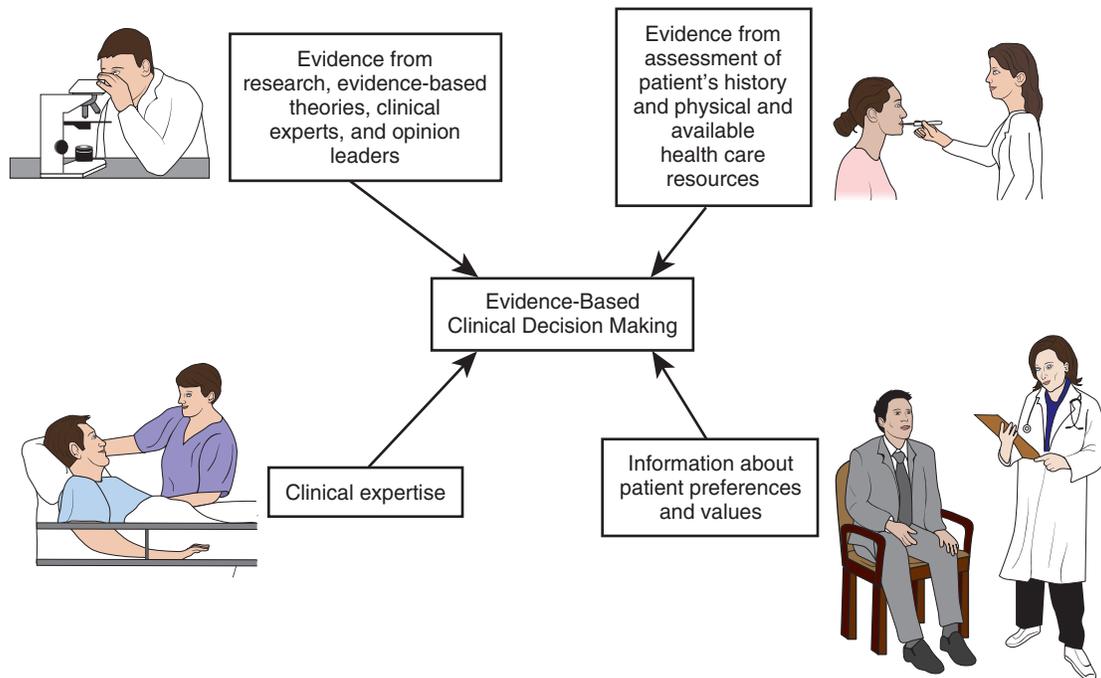
Nurses make important clinical decisions when caring for patients (e.g., what to assess in a patient and which interventions are best to use). It is important to translate best evidence into best practices at a patient's bedside. For example, changing how patients' pain is managed after surgery is one way that Rick uses evidence at the bedside (see previous case study). EBP is a problem-solving approach to clinical practice that integrates the conscientious use of best evidence in combination with a clinician's expertise and patient preferences and values in making decisions about patient care (Figure 5-1) (Melnyk and Fineout-Overholt, 2014). Today EBP is an expectation of all health care institutions and professional nurses (Peterson et al., 2014).


FIGURE 5-1 Model for evidence-based clinical decision making.

There are many sources of evidence. A good textbook incorporates evidence into the information, practice guidelines, and procedures it includes. Articles from nursing and health care literature are available on almost any topic involving nursing practice in either journals or on the Internet. Although the scientific basis of nursing practice has grown, some nursing care practices do not have adequate research to guide practice decisions. The challenge is to obtain the very best, most relevant, current, and accurate information at the right time, when you need it for patient care.

The best information is evidence that comes from well-designed, systematically conducted research studies, mostly found in scientific journals. Unfortunately much of that evidence never reaches the bedside. Nurses in practice settings, unlike in educational settings, do not always have easy access to databases for scientific literature. Instead they often care for patients on the basis of tradition or convenience (Flynn-Makic et al., 2014). Other sources of evidence come from quality improvement and risk management data; international, national, and local standards of care; infection control data; benchmarking, retrospective, or concurrent chart reviews; and clinicians' expertise. It is important to rely more on research evidence rather than solely on evidence that is not research based. When you face a clinical problem, always ask yourself where you can find the best evidence to help you find the best solution in caring for patients.

Even when you use the best evidence available, application and outcomes will differ on the basis of your patient's values, preferences, concerns, and/or expectations (Sherwood and Zomorodi, 2014). As a nurse you develop critical thinking skills to determine whether evidence is relevant and appropriate to your patients and to a clinical situation. For example, a single research article suggests that using medical clowns is an effective intervention for reducing fear and anxiety in children (Tener et al., 2012). However, if your patient is afraid of clowns, you will need to search for a better evidence-based therapy that he or she will accept. Using your clinical expertise and considering patient values and preferences ensures that you apply the evidence available in practice both safely and appropriately.

Steps of Evidence-Based Practice

EBP is a systematic, problem-solving process that facilitates achievement of best practices. Consistently following a step-by-step approach ensures that you obtain the strongest available evidence to apply in patient care. There are seven steps of EBP, which are numbered from zero to six (Melnyk and Fineout-Overholt, 2014):

0. Cultivate a spirit of inquiry.
1. Ask a clinical question in PICOT format.
2. Search for the most relevant and best evidence.
3. Critically appraise the evidence you gather.
4. Integrate all evidence with your clinical expertise and patient preferences and values.
5. Evaluate the outcomes of practice decisions or changes using evidence.
6. Share the outcomes of EBP changes with others.

Cultivate a Spirit of Inquiry. Changes in health care are often made slowly because of multiple barriers that often prevent the implementation of EBP. Gaps between what is known to improve patient care and what we actually do when caring for patients sometimes lead to inappropriate or unnecessary care (Holmes et al., 2012). When your care is not evidence based, your patients will sometimes experience poor outcomes. To be an effective change agent and foster optimal patient care, you need to have a never-ending spirit of inquiry. Constantly questioning current clinical practices and believing in the value of EBP leads to the consistent use of EBP in clinical nursing practice. You need to gain knowledge and skills associated with EBP and maintain a commitment to provide the best care possible to your patients and their families. In addition, health care agencies need to adopt a culture that supports EBP (e.g., through staff-led practice councils and journal clubs) and provide essential resources and tools to promote evidence-based care (Melnyk and Fineout-Overholt, 2014).

Ask a Clinical Question. Always think about your practice when caring for patients. Question what does not make sense to you and

what needs to be clarified. Think about a problem or area of interest that is time consuming, costly, or not logical (Stilwell et al., 2010). Use problem- and knowledge-focused triggers to think critically about clinical and operational nursing unit issues (Titler et al., 2001). A problem-focused trigger is one you face while caring for a patient or a trend you see on a nursing unit. For example, while Rick is caring for patients following abdominal surgery, he wonders, "If we changed our patients' activity levels after surgery, would they experience fewer episodes of postoperative ileus?" Other examples of problem-focused trends include the increasing number of patient falls or incidence of urinary tract infections on a nursing unit. Such trends lead you to ask, "How can I reduce falls on my unit?" or "What is the best way to prevent urinary tract infections in postoperative patients?"

A knowledge-focused trigger is a question regarding new information available on a topic. For example, "What current evidence exists to improve pain management in patients with migraine headaches?" Important sources of this type of information are standards and practice guidelines available from national agencies such as the Agency for Healthcare Research and Quality (AHRQ), the American Pain Society (APS), or the American Association of Critical Care Nurses (AACN). Other sources of knowledge-focused triggers include recent research publications and nurse experts within an organization.

Sometimes you use data gathered from a health care setting to examine clinical trends when developing clinical questions. For example, most hospitals keep monthly records on key quality of care or performance indicators such as medication errors or infection rates. All magnet-designated hospitals maintain the National Database of Nursing Quality Improvement (NDNQI) (see Chapter 2). The database includes information on falls, falls with injuries, pressure ulcer incidence, and nurse satisfaction. You use quality and risk-management data to help you understand the nature or severity of problems that then allow you to form practice questions. The questions you ask eventually lead you to the evidence for an answer. When you ask a question and then go to the scientific literature, you don't want to read 100 articles to find the handful that are most helpful. You want to be able to read the best four-to-six articles that specifically address your practice question. Melnyk and Fineout-Overholt (2014) suggest using a PICOT format to state your question. Box 5-1 summarizes the five elements of a **PICOT question**. The more focused your question is, the easier it becomes to search for evidence in the scientific literature. For example, Rick is a member of the evidence-based council committee of his unit. The nurses on the committee develop the following PICOT question: Do patients (P) who listen to music (I) achieve better control of their anxiety and pain (O) after surgery (T) when compared with patients who receive standard nursing care following surgery (C)? Another example is: Is an adult patient's (P) blood pressure more accurate (O) when measuring with the patient's legs crossed (I) versus *with* the patient's feet flat on the floor (C)?

Proper question formatting allows you to identify key words to use when conducting your literature search. Note that a well-designed PICOT question does not have to follow the sequence of P, I, C, O, and T. In addition, intervention (I), comparison (C), and time (T) are not appropriate to be used in every question. The aim is to ask a question that contains as many of the PICOT elements as possible. For example, here is a meaningful question that contains only a P and O: How do patients with cystic fibrosis (P) rate their quality of life (O)?

Inappropriately formed questions are background questions that will likely lead to many irrelevant sources of information, making it difficult to find the best evidence (e.g., What is the best way to reduce wandering? What is the best way to improve family's satisfaction with patient care?). Sometimes a background question is needed to identify a more specific PICOT question. The PICOT format allows you to ask questions that are intervention focused. For questions that are not intervention focused, the meaning of the letter I can be an area of interest (Melnyk and Fineout-Overholt, 2014). For example, What is the difference in retention (O) of new nursing graduates (P) who go through a nurse residency program (I) versus those who do not (C) *2 years post hire date* (T)?

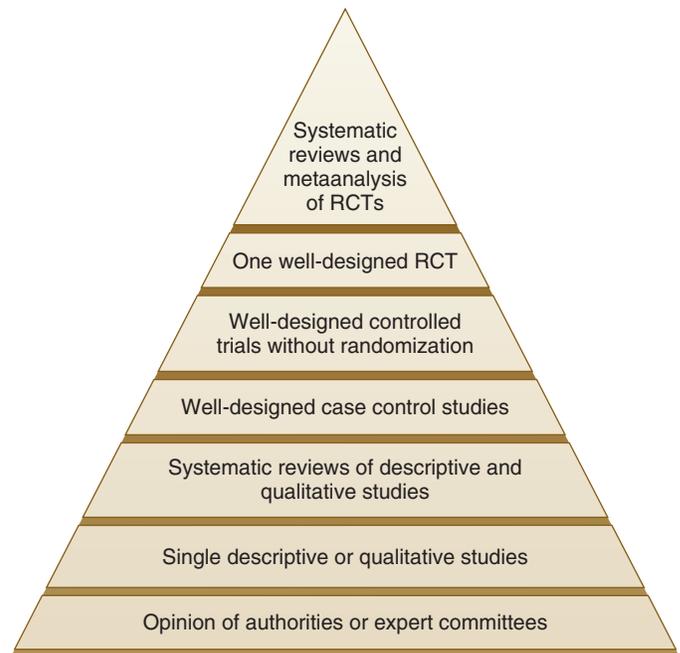
The questions you ask using a PICOT format help to identify knowledge gaps within a clinical situation. Asking well–thought out questions allows you to identify evidence needed to guide clinical practice. Remember: do not be satisfied with clinical routines. Always question and use critical thinking to consider better ways to provide patient care.

BOX 5-1   Developing a PICOT Question

P = Patient population of interest
  Identify patients by age, gender, ethnicity, and disease or health problem.
I = Intervention of interest
  Which intervention is worthwhile to use in practice (e.g., a treatment, diagnostic test, prognostic factor)?
C = Comparison of interest
  What is the usual standard of care or current intervention used now in practice?
O = Outcome
  What result do you wish to achieve or observe as a result of an intervention (e.g., change in patient behavior, physical finding, or patient perception)?
T = Time
  What amount of time is needed for an intervention to achieve an outcome (e.g., the amount of time needed to change quality of life or patient behavior)?

QSEN   **QSEN: BUILDING COMPETENCY IN EVIDENCE-BASED PRACTICE** While attending a professional nursing conference about the care of surgical patients, Rick hears a report about common nursing practices that are not supported by research. One practice is the size or gauge of an intravenous (IV) needle that nurses need to use when infusing packed red blood cells (PRBCs). Traditionally nurses were taught that it is necessary to insert the largest IV needle possible and to use at least a 20-gauge IV needle when administering PRBCs to minimize destruction of the blood. However, current evidence indicates that PRBCs are not damaged by small IV needles. Rather it is high pressure during PRBC administration that damages blood cells. The evidence presented at the conference indicated that it is safe and effective to use IV needles as small as 22 gauge in adults and 24 gauge in infants and toddlers when administering PRBCs. Using this information, develop a PICOT question that Rick could use to further investigate this intervention. Identify each part of the PICOT question.

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

Collect the Best Evidence.   Once you have a clear and concise PICOT question, you are ready to search for evidence. A variety of sources will provide the evidence needed to answer your question such as agency policy and procedure manuals, quality improvement data, existing clinical practice guidelines, and journal articles. Do not hesitate to ask for help to find appropriate evidence. Key resources include nursing faculty, librarians, advanced practice nurses, staff educators, risk managers, and infection control nurses.


When using scientific literature for evidence, seek the assistance of a medical librarian who knows the various online databases that are

TABLE 5-1   Searchable Scientific Literature Databases and Sources

Databases	Sources
AHRQ	Agency for Healthcare Research and Quality; includes clinical guidelines and evidence summaries http://www.ahrq.gov
CINAHL	Cumulative Index of Nursing and Allied Health Literature; includes studies in nursing, allied health, and biomedicine http://www.cinahl.com
MEDLINE	Includes studies in medicine, nursing, dentistry, psychiatry, veterinary medicine, and allied health http://www.ncbi.nim.nih.gov
EMBASE	Biomedical and pharmaceutical studies http://www.embase.com
PsycINFO	Psychology and related health care disciplines http://www.apa.org/psycinfo/
Cochrane Database of Systematic Reviews	Full text of regularly updated systematic reviews prepared by the Cochrane Collaboration; includes completed reviews and protocols http://www.cochrane.org/reviews
National Guidelines Clearinghouse	Repository for structured abstracts (summaries) about clinical guidelines and their development; also includes condensed version of guideline for viewing http://www.guideline.gov
PubMed	Health science library at the National Library of Medicine; offers free access to journal articles http://www.nlm.nih.gov
World Views on Evidence-Based Nursing	Electronic journal containing articles that provide a synthesis of research and an annotated bibliography for selected references

FIGURE 5-2 Hierarchy of evidence. *RCT,* Randomized controlled trial. (Data from Guyatt G, Rennie D: User's guide to the medical literature, Chicago, 2002, American Medical Association; Harris RP et al: Current methods of the US Prevention Services Task Force: a review of the process, *Am J Prev Med* 20:21, 2001; Melnyk BM, Fineout-Overholt E: *Evidence-based practice in nursing and healthcare: a guide to best practice,* ed 3, Philadelphia, 2014, Lippincott Williams & Wilkins.)

available to you (Table 5-1). The databases contain large collections of published scientific studies, including peer-reviewed research. A **peer-reviewed** article is reviewed for accuracy, validity, and rigor and approved for publication by experts before it is published. MEDLINE and the Cumulative Index of Nursing and Allied Health Literature (CINAHL) are among the best-known online databases to search for scientific knowledge in health care (Melnyk and Fineout-Overholt, 2014). Some databases are available through vendors at a cost, some are free of charge, and some offer both options. Students typically have access to an institutional subscription through a vendor purchased by their school. One of the more common vendors is OVID, which offers several different databases. Databases are also available on the Internet free of charge. The Cochrane Database of Systematic Reviews is a valuable source of high-quality evidence. It includes the full text of regularly updated systematic reviews and protocols for reviews currently under way. Collaborative review groups prepare and maintain the reviews. The protocols provide the background, objectives, and methods for reviews in progress (Melnyk and Fineout-Overholt, 2014).

The National Guidelines Clearinghouse (NGC) is a database supported by the AHRQ. It contains **clinical guidelines**, which are systematically developed statements about a plan of care for a specific set of clinical circumstances involving a specific patient population. Examples of clinical guidelines on NGC include care of children and adolescents with type 1 diabetes and practice guidelines for the treatment of adults

with low back pain. The NGC is invaluable when developing a plan of care for a patient (see Chapter 18).

Seek the help of a librarian to identify the appropriate databases and key words that will provide the best evidence to answer your PICOT question. When conducting a search, you need to enter and manipulate different key words until you get the combination of terms that provides the best articles that will help answer your question. It usually takes several searches before you find the most appropriate articles. The key words you select often have one meaning to one author and a very different meaning to another. Be patient and persistent and keep trying different words and different combinations of words until you find the evidence you need.

Figure 5-2 represents the hierarchy of available evidence. The level of rigor or amount of confidence you can have in the findings of a study decreases as you move down the pyramid. At this point in your nursing career, you cannot be an expert on all aspects of the types of studies conducted. But you can learn enough about the types of studies to help you know which ones have the best scientific evidence. At the top of the pyramid are systematic reviews or meta-analyses, which are state-of-the-art summaries from an individual researcher or panel of experts. Meta-analyses and systematic reviews are the perfect answers to PICOT questions because they rigorously summarize current evidence.

During either a meta-analysis or a systematic review, a researcher asks a PICOT question, reviews the highest level of evidence available (e.g., randomized controlled trials [RCTs]), summarizes what is currently known about the topic, and reports if current evidence supports a change in practice or if further study is needed. The main difference is that in a meta-analysis the researcher uses statistics to show the effect of an intervention on an outcome. In a systematic review no statistics are used to draw conclusions about the evidence. In the Cochrane Library all entries include information on meta-analyses and

systematic reviews. If you use MEDLINE or CINAHL, enter a text word such as *meta-analysis, systematic reviews,* or *evidence-based medicine* to obtain scientific reviews on your PICOT question.

RCTs are the most precise forms of experimental study and therefore are the gold standard for research. A single RCT is not as conclusive as a review of several RCTs on the same question. However, a single RCT that tests the intervention included in your question yields very useful evidence. If RCTs are not available, you can use results from other research studies such as descriptive or qualitative studies to help answer your PICOT question. The use of clinical experts is at the bottom of the evidence pyramid, but do not consider clinical experts to be a poor source of evidence. Expert clinicians use evidence frequently as they build their own practice, and they are rich sources of information for clinical problems.

When the members of Rick's EBP council committee search for evidence to answer their PICOT question, they ask for help from a medical librarian. The medical librarian helps the committee members learn how to choose key terms to identify articles that will help answer their question. During their search they identify two research articles (Acquillo, 2007; Miller and Schlueter, 2004) and one clinical article (Makic et al., 2013) published since 2004 that address the effects of IV needle size on the effectiveness of blood transfusions. Other articles they found about this question were published in the 1980s and 1990s.

Critically Appraise the Evidence. Perhaps the most difficult step in the EBP process is critiquing or analyzing the available evidence. Critiquing evidence involves evaluating it, which includes determining the value, feasibility, and usefulness of evidence for making a practice change (ONS, n.d.). When critiquing evidence, first evaluate the scientific merit and clinical applicability of the findings of each study. Then with a group of studies and expert opinion determine which findings have a strong enough basis for use in practice. After critiquing the evidence you will be able to answer the following questions. Do the articles offer evidence to explain or answer my PICOT question? Do the articles show support for the reliability and validity of the evidence? Can I use the evidence in practice?

It takes time to develop skills needed to critique the evidence like an expert. When you read an article, do not put it down and walk away because of the statistics and technical language. Know the elements of an article and use a careful approach when reviewing each one. Evidence-based articles include the following elements:

- *Abstract.* An abstract is a brief summary that quickly tells you if the article is research or clinically based. An abstract summarizes the purpose of the article. It also includes the major themes or findings and the implications for nursing practice.
- *Introduction.* The introduction contains more information about the purpose of the article. There is usually brief supporting evidence as to why the topic is important. Together the abstract and introduction help you decide if you want to continue to read the entire article. You will know if the topic of the article is similar to your PICOT question or related closely enough to provide useful information. If you decide that an article will most likely help answer your question, continue to read the next elements of the article.
- *Literature review or background.* A good author offers a detailed background of the level of science or clinical information about the topic. The literature review offers an argument about what led the author to conduct a study or report on a clinical topic. This section of an article is very valuable. Even if the article itself does not address your PICOT question the way you desire, the literature review may lead you to other more useful articles.

After reading a literature review, you should have a good idea of how past research led to the researcher's question. For example, a study designed to test an educational intervention for older-adult family caregivers reviews literature that describes characteristics of caregivers, the type of factors influencing caregivers' ability to cope with stressors of caregiving, and previous educational interventions used with families.

- *Manuscript narrative.* The "middle section" or narrative of an article differs according to the type of evidence-based article it is (Melnyk and Fineout-Overholt, 2014). A clinical article describes a clinical topic, which often includes a description of a patient population, the nature of a certain disease or health alteration, how patients are affected, and the appropriate nursing therapies. An author sometimes writes a clinical article to explain how to use a therapy or new technology. A research article contains several subsections within the narrative, including the following:
  - *Purpose statement:* Explains the focus or intent of a study. It includes research questions or **hypotheses**—predictions made about the relationship or difference among study **variables** (concepts, characteristics, or traits that vary within or among subjects). An example of a research question is: Does music therapy reduce a patient's pain and anxiety?
  - *Methods or design:* Explains how a research study was organized and conducted to answer the research question or test the hypothesis. This section explains the type of study that was conducted (e.g., RCT, case control study, or qualitative study) and the amount of subjects or people who participated in the study. In health care research, subjects often include patients, family members, or health care staff. The methods section is sometimes confusing because it explains details about how the researcher designed the study to obtain the most accurate results possible. Use your faculty member as a resource to help interpret this section.
  - *Results or conclusions:* Clinical and research articles have a summary section. In a clinical article the author explains the clinical implications for the topic presented. In a research article the author details the results of the study and explains whether a hypothesis is supported or how a research question is answered. This section includes a statistical analysis if it is a quantitative research study. A qualitative study summarizes the descriptive themes and ideas that arise from the researcher's analysis of data. Do not let the statistical analysis in an article overwhelm you. Read carefully and ask these questions: Does the researcher describe the results? Were the results significant? A good author also discusses limitations to a study in this section. The information on limitations is valuable in helping you decide if you want to use the evidence with your patients. Have a faculty member or an expert nurse help you interpret statistical results.
  - *Clinical implications:* A research article includes a section that explains if the findings from the study have clinical implications. The researcher explains how to apply findings in a practice setting for the type of subjects studied.

After Rick's EBP council critiques each article for their PICOT question, they combine the findings from the three articles he found about the IV needle gauge needed to safely administer a blood transfusion. They use critical thinking to consider the settings where the studies were performed, the scientific rigor of the evidence, the number of patients involved, and how well the evidence answers their PICOT question. They also consider the evidence in light of surgical patients' typical concerns and preferences. As nurses, the committee judges

whether to use the evidence for patients who usually are admitted on the surgical unit. Patients frequently have complex medical histories and patterns of responses (Melnyk and Fineout-Overholt, 2014). Ethically it is important for the committee to consider evidence that will benefit patients and do no harm. They need to decide if the evidence is relevant, is easily applicable in this setting of practice, and has the potential for improving patient outcomes.

Integrate the Evidence. If you decide that the evidence is strong and applicable to your patients and clinical situation, you begin to identify how to incorporate it into practice. Your first step is simply to apply the research in your plan of care for a patient (see Chapter 18). Use the evidence you find as a rationale for an intervention you plan to try. For instance, you learned about an approach to bathe older adults who are confused and decide to use the technique during your next clinical assignment. If you find that the bathing technique is successful with your own assigned patients, you may begin to work with a group of other students or nurses to revise the policy and procedure for bathing patients or develop a new clinical protocol.

The literature that Rick's committee found reveals that using a 22-gauge IV needle may be safe and effective when administering a blood transfusion. However, they only found two research articles, both of which used small sample sizes (Acquillo, 2007; Miller and Schlueter, 2004). Because this is not enough evidence to support a practice change at this time, the committee members meet with their colleagues on the hospital-wide nursing practice committee to recommend further investigation into this practice issue. The nursing practice committee decides to consult with advanced practice nurses on the IV therapy team to search for professional guidelines that address the IV needle size needed when infusing blood.

Evidence is integrated in a variety of ways through teaching tools, clinical practice guidelines, policies and procedures, and new assessment or documentation tools. Depending on the amount of change needed to apply evidence in practice, it becomes necessary to involve a number of staff from a given nursing unit. It is important to consider the setting where you want to apply the evidence. Is there support from all staff? Does the practice change fit with the scope of practice in the clinical setting? Are resources (time, secretarial support, and staff) available to make a change? When evidence is not strong enough to apply in practice, your next option is to conduct a pilot study to investigate your PICOT question. A pilot study is a small-scale research study or one that includes a quality or **performance improvement (PI)** project.

Evaluate the Practice Decision or Change. After applying evidence in your practice, your next step is to evaluate the outcome. How does the intervention work? How effective was the clinical decision for your patient or practice setting? Sometimes your evaluation is as simple as determining if the expected outcomes you set for an intervention are met (see Chapters 18 and 20). For example, after the use of a transparent IV dressing, does the IV dislodge, or does the patient develop the complication of phlebitis? When using a new approach to preoperative teaching, do patients learn what to expect after surgery?

When an EBP change occurs on a larger scale, an evaluation is more formal. For example, evidence showing factors that contribute to pressure ulcers lead a nursing unit to adopt a new skin care protocol. To evaluate the protocol, nurses track the incidence of pressure ulcers over a course of time (e.g., 6 months to a year). In addition, they collect data to describe patients who develop ulcers and those who do not. This comparative information is valuable in determining the effects of the protocol and whether modifications are necessary.

When evaluating an EBP change, determine if the change was effective, if modifications in the change are needed, or if the change needs to be discontinued. Events or results that you do not expect may occur. For example, a hospital that implements a new method of cleaning IV line puncture sites discovers an increased rate of IV line infections and reevaluates the new cleaning method to determine why infections have increased. If the hospital does not evaluate this change in practice, more patients will develop IV site infections. Never implement a practice change without evaluating its effects.

In Rick's case nurses from the EBP committee of the unit, the hospital-wide nursing practice committee, and the IV therapy team decide to collect data to determine how many patients on surgical units require a blood transfusion and how many require multiple IV sticks to start at least a 20-gauge IV needle. After completing chart reviews, the nurses discover that patients who need blood transfusions and who require multiple IV sticks to start a 20-gauge or larger IV tend to be elderly and experience an increase in complications associated with their IV sites. Since the evidence does not provide a clear answer to their PICOT question, the nurses decide to present this information during the hospital grand rounds to gather more expert opinions from physicians and continue researching this issue. The physicians decide to join the nurses. They work together to conduct a pilot study evaluating the efficacy of using 22-gauge IV needles for blood transfusions in adults who cannot have larger IVs started.

Share the Outcomes with Others. After implementing an EBP change, it is important to communicate the results. If you implement an evidence-based intervention with one patient, you and the patient determine the effectiveness of that intervention. When a practice change occurs on a nursing unit level, the first group to discuss the outcomes of the change is often the clinical staff on that unit. To enhance professional development and promote positive patient outcomes beyond the unit level, share the results with various groups of nurses or other care providers such as the nursing practice council or the research council. Clinicians enjoy and appreciate seeing the results of a practice change. In addition, the practice change will more likely be sustainable and remain in place when staff are able to see the benefits of an EBP change.

As a professional nurse it is critical to contribute to the growing knowledge of nursing practice. Nurses often communicate the outcomes of EBP changes at professional conferences and meetings. Being involved in professional organizations allows them to present EBP changes in scientific abstracts, poster presentations, or even podium presentations.

After completing the pilot study, Rick presents the outcomes to the nursing research committee at his hospital. The chief nursing officer hears Rick's presentation and encourages him to submit an abstract about his study to a national professional nursing conference. Rick submits his abstract for consideration as a poster presentation at the annual Midwest Nursing Research Society conference, and it is accepted. During the conference Rick tells other nurses about the findings of this study and is contacted after the conference by several nurses who are interested in studying this problem further.

NURSING RESEARCH

After completing a thorough review and critique of the scientific literature, you might not have enough strong evidence to make a practice change. Instead you may find a gap in knowledge that makes your PICOT question go unanswered. When this happens, the best way to answer your PICOT question is to conduct a research study. At this time in your career you will not be conducting research. However, you

may observe more senior nurses performing research within the hospital. It is important for you to understand the process of nursing research and how it generates new knowledge.

Nursing research improves the health and welfare of people (NINR, n.d.). **Nursing research** is a way to identify new knowledge, improve professional education and practice, and use nursing and health care resources effectively. Research means to search again or to examine carefully. It is a systematic process that asks and answers questions to generate knowledge. The knowledge provides a scientific basis for nursing practice and validates the effectiveness of nursing interventions. Nursing research improves professional education and practice and helps nurses use resources effectively (e.g., how to best use human resources by determining the best practice mix of nurses and unlicensed assistive personnel on a nursing unit). The scientific knowledge base of nursing continues to grow today, thus furnishing evidence that nurses can use to provide safe and effective patient care. Many professional and specialty nursing organizations support the conduct of research for advancing nursing science.

An example of how research can expand our practice can be seen in the work of Dr. Norma Metheny who has spent many years asking questions about how to prevent the aspiration of tube feeding in patients who receive feeding through nasogastric tubes (Metheny et al., 1988, 1989, 1990, 1994, 2000, 2007, 2010, and 2012; Metheny, 2006; Metheny and Meert, 2014). Through her program of research she has identified factors that increase the risk for aspiration and approaches to use in determining tube feeding placement. Dr. Metheny's findings are incorporated into this textbook and have changed the way nurses administer tube feedings to patients. Through research Dr. Metheny has contributed to the scientific body of knowledge that has saved patients' lives and helped to prevent the serious complication of pulmonary aspiration.

Outcomes Research

In today's health care delivery system it is more important than ever to understand the results of health care practices. Outcomes research helps patients, health care providers, and those in health care policy make informed decisions on the basis of current evidence (PCORI, 2015). Outcomes research typically focuses on the benefits, risks, costs, and holistic effects of a treatment on patients. For example, researchers are conducting outcomes research when they study the effects of managing Parkinson disease in patients using videoconferencing and telemedicine to increase access to health care.

Care delivery outcomes are the observable or measurable effects of health care interventions (Melnyk and Fineout-Overholt, 2014). Similar to the expected outcomes you develop in a plan of care (see Chapter 18), a care-delivery outcome focuses on the recipients of service (e.g., patient, family, or community) and not the providers (e.g., nurse or physician). For example, an outcome of a diabetes education program is that patients are able to self-administer insulin, not the nurses' success in instructing patients newly diagnosed with diabetes.

A problem in outcomes research is the clear definition or selection of measurable outcomes. Components of an outcome include the outcome itself, how it is observed (the indicator), its critical characteristics (how it is measured), and its range of parameters (Melnyk and Fineout-Overholt, 2014). For example, health care settings commonly measure the outcome of patient satisfaction when they introduce new services (e.g., new care delivery model or outpatient clinic). The outcome is patient satisfaction, observed through patients' responses to a patient satisfaction instrument, including characteristics such as nursing care, physician care, support services, and the environment. Patients complete the instrument, responding to a scale (parameter) designed to measure their degree of satisfaction (e.g., scale of 1 to 5).

The combined score on the instrument yields a measure of patient satisfaction, an outcome that the facility can track over time.

Nurse-sensitive indicators are outcomes that are sensitive to nursing practice (Press Gainey Associates, 2015) (see Box 2-8). Although it is important to research the effects of nursing care on nurse-sensitive indicators, some researchers choose outcomes that do not measure a direct effect of nursing care such as length of stay, mortality, quality of life, and patient satisfaction. Researchers need to select appropriate outcomes to measure when designing their studies. For example, if a nurse researcher intends to measure the success of a nurse-initiated protocol to manage blood glucose levels in patients who are critically ill, the researcher will not likely measure mortality because it is too broad and susceptible to many factors outside of the control of the nurse-initiated protocol (e.g., the selection of medical therapies, the patients' acuity of illness). Instead the nurse researcher will have a better idea of the effects of the protocol by measuring the outcome of patients' blood glucose ranges. He or she obtains the blood glucose level of patients placed on the protocol and compares them to a desired range that represents good blood glucose control.

Scientific Method

The **scientific method** is the foundation of research and the most reliable and objective of all methods of gaining knowledge. This method is an advanced, objective means of acquiring and testing knowledge. Aspects of the method guide you in applying evidence gained from research in practice and conducting future research. When using research evidence to change practice, you need to understand the process that a researcher uses to guide a study. For example, when Rick's committee considered if blood transfusions could be infused safely with smaller-gauge IV needles, they needed to know if this had been tested on patients similar to the ones admitted on their unit and the outcomes or results of the studies. Otherwise the evidence might not be relevant to patients on Rick's unit. The scientific method is a systematic, step-by-step process. When completed correctly, you know that the study supports the **validity**, **reliability**, and **generalizability** of the data. Thus you can safely apply the findings of this study to similar subjects in a different study.

Researchers use the scientific method to understand, explain, predict, or control a nursing phenomenon (Polit and Beck, 2011). Systematic, orderly procedures reduce the possibility for error. Although this possibility always exists, the scientific method minimizes the chance that **bias** or opinion by a researcher will influence the results of research and thus the knowledge gained. Scientific research includes the following characteristics:

- The research identifies the problem area or area of interest to study.
- The steps of planning and conducting a research study are systematic and orderly.
- Researchers try to control external factors that are not being studied but can influence a relationship between the phenomena they are studying. For example, if a nurse is studying the relationship between diet and heart disease, he or she controls other characteristics among subjects such as stress or smoking history because they are risk factors for heart disease. Patients on an experimental diet and those on a regular diet would both need to have similar levels of stress and smoking histories to test the true effect of the diet.
- Researchers gather **empirical data** through the use of observations and assessments and use the data to discover new knowledge.
- The goal is to apply the knowledge gained from a study to a broader group of patients.

Nursing and the Scientific Approach

In the past much of the information used in nursing practice was borrowed from other disciplines such as biology, physiology, and psychology. Often nurses applied this information to their practice without testing it. For example, nurses use several methods to help patients sleep. Interventions such as giving a patient a back rub, making sure that the bed is clean and comfortable, and preparing the environment by dimming the lights are nursing measures that are used frequently and in general are logical, commonsense approaches. However, when these measures are considered in greater depth, questions arise about their applications. For example, are they the best methods to promote sleep? Do different patients in different situations require other interventions to promote sleep?

Research allows you to study nursing questions and problems in greater depth within the context of nursing. Nurses who do not use an evidence-based approach to practice often rely solely on personal experience or the advice of nursing experts. These nurses do not question if there is an intervention that produces better outcomes. When an intervention is not successful, nurses who do not use EBP will usually use an approach practiced by a colleague or try a different sequence of accepted measures. Even if an intervention discovered with this trial-and-error approach is effective for one or more patients, it is not always appropriate for patients in other settings. Nursing interventions must be tested through research to determine the measures that work best with specific patients.

Nursing research addresses issues important to the discipline of nursing. Some of these issues relate to the profession itself, education of nurses, patient and family needs, and issues within the health care delivery system. Once research is completed, it is important to disseminate or communicate the findings. One method of dissemination is through publication of the findings in professional journals. Nursing research uses many methods to study clinical problems (Box 5-2). There are two broad approaches to research: quantitative and qualitative methods.

Quantitative Research. Quantitative nursing research is the study of nursing phenomena that offers precise measurement and quantification. Two examples of quantitative research are (1) a study dealing with a new pain therapy quantitatively measures participants' pain severity, and (2) a study testing different forms of surgical dressings measures the extent of wound healing. Quantitative research is the precise, systematic, objective examination of specific concepts. It focuses on numerical data, statistical analysis, and controls to eliminate bias in findings (Polit and Beck, 2011). Although there are many quantitative methods, the following sections briefly describe experimental, nonexperimental, survey, and evaluation research.

Experimental Research. An RCT is a true experimental study that tightly controls conditions to eliminate bias with the goal of generalizing the results of the study to similar groups of subjects. Researchers test an intervention (e.g., new drug, therapy, or education method) against the usual standard of care (Box 5-3). They randomly assign subjects to either a control or a treatment group. All subjects in an RCT have an equal chance to be in either group. The treatment group receives the experimental intervention, and the control group receives the usual standard of care. The researchers measure both groups for the same outcomes to see if there is a difference. When an RCT is completed, the researcher hopes to know if the intervention leads to better outcomes than the standard of care.

Controlled trials without randomization are studies that test interventions, but researchers have not randomized the subjects into control or treatment groups. Thus there is bias in how the study is conducted.

BOX 5-2 Types of Research

- **Historical research:** Studies designed to establish facts and relationships concerning past events. Example: Study examining the societal factors that led to the acceptance of advanced practice nurses by patients.
- **Exploratory research:** Initial study designed to develop or refine the dimensions of phenomena (facts or events) or to develop or refine a hypothesis about the relationships among phenomena. Example: Pilot study testing the benefits of a new exercise program for older adults with dementia.
- **Evaluation research:** Study that tests how well a program, practice, or policy is working. Example: Study measuring the outcomes of an informational campaign designed to improve parents' ability to follow immunization schedules for their children.
- **Descriptive research:** Study that measures characteristics of people, situations, or groups and the frequency with which certain events or characteristics occur. Example: Study to examine RNs' biases toward caring for obese patients.
- **Experimental research:** Study in which the investigator controls the study variable and randomly assigns subjects to different conditions to test the variable. Example: RCT comparing chlorhexidine with Betadine in reducing the incidence of IV-site phlebitis.
- **Correlational research:** Study that explores the interrelationships among variables of interest without any active intervention by the researcher. Example: Study examining the relationship between RNs' educational levels and their satisfaction in the nursing role.

RNs, Registered nurses; *RCT,* randomized controlled trial; *IV,* intravenous.

BOX 5-3 Example of a Randomized Controlled Trial

- **Research question:** Will an educational program for patients at risk for diabetes compared with a traditional educational pamphlet improve patient's blood glucose level and weight control?
- **Subjects:** 130 adult patients with risk factors for diabetes who visit a local medicine clinic
- **Randomization:** Patients are randomly assigned to one of two groups using a random-numbers table.
- **Treatment group:** 65 patients attend an 8-hour class on diabetes prevention, with group discussion, lecture, and interactive computer program use.
- **Control group:** 65 patients receive a printed pamphlet outlining risks for diabetes and health promotion strategies.
- **Outcome measure:** Both groups have blood glucose levels and weight measured before receiving education and every month for 3 months after receiving education.
- **Analysis:** Statistical tests comparing the blood glucose levels and weight for the two groups will demonstrate if the treatment group shows significant improvements in blood glucose levels and weight as predicted.

Some findings are distorted because of how the study was designed. A researcher wants to be as certain as possible when testing an intervention that the intervention is the reason for the desired outcomes. In a nonrandomized controlled trial the way in which subjects fall into the control or treatment group sometimes influences the results. This suggests that the intervention tested was not the only factor affecting the results of the study. Careful critique allows you to determine if bias

was present in a study and what effect, if any, the bias had on the results of the study.

Although RCTs investigate cause and effect and are excellent for testing drug therapies or medical treatments, this approach is not always the best for testing nursing interventions. The nature of nursing care causes nurse researchers to ask questions that are not always answered best by an RCT. For example, nurses help patients with problems such as knowledge deficits and symptom management. When researchers attempt to plan an RCT, it is often realized that ethical issues will develop if the control group does not receive the new therapeutic intervention. Also, learning to understand how patients experience health problems cannot always be addressed through an RCT. Therefore nonexperimental descriptive studies are often used in nursing research.

Nonexperimental Research. Nonexperimental descriptive studies describe, explain, or predict phenomena. Two examples include a study examining factors that lead to an adolescent's decision to smoke cigarettes and a study determining factors that lead patients with dementia to fall in a hospital setting.

A case control study is one in which researchers study one group of subjects with a certain condition (e.g., asthma) at the same time as another group of subjects who do not have the condition. A case control study determines if there is an association between one or more predictor variables and the condition (Melnyk and Fineout-Overholt, 2014). For example, is there an association between predictor variables such as family history or environmental exposure to dust and the incidence of asthma? Often a case control study is conducted retrospectively, or after the fact. Researchers look back in time and review available data about their two groups of subjects to understand which variables explain the condition. These studies involve a small number of subjects, creating a risk of bias. Sometimes the subjects in the two groups differ on certain other variables (e.g., amount of stress or history of contact allergies) that also influence the incidence of the condition, more so than the variables being studied. Correlational studies describe the relationship between two variables (e.g., the age of the adolescents and if the adolescents smoke). The researcher determines if the two variables are correlated or associated with one another and to what extent.

Many times researchers use findings from descriptive studies to develop studies that test interventions. For example, if the researcher determines that adolescents 15 years old and older tend to smoke, he or she might later test if participation in a program about smoking for older adolescents is effective in helping adolescents stop smoking.

Surveys. Surveys are common in quantitative research. They obtain information regarding the frequency, distribution, and interrelation of variables among subjects in the study (Polit and Beck, 2011). An example is a survey designed to measure nurses' perceptions of physicians' willingness to collaborate in practice. Surveys obtain information about practices, perceptions, education, experience, opinions, and other characteristics of people. The most basic function of a survey is description. Surveys gather a large amount of data to describe the population and the topic of study. It is important in survey research that the population sampled is large enough to keep sampling error at a minimum.

Evaluation Research. **Evaluation research** is a form of quantitative research that determines how well a program, practice, procedure, or policy is working (Polit and Beck, 2011). An example is outcomes research. Evaluation research determines why a program or some components of the program are successful or unsuccessful. When programs are unsuccessful, evaluation research identifies problems with the program and opportunities for change or barriers to program implementation.

Qualitative Research. **Qualitative nursing research** is the study of phenomena that are difficult to quantify or categorize such as patients' perceptions of illness or quality of life. This research method describes information obtained in a nonnumeric form (e.g., data in the form of transcribed written transcripts from a series of interviews). Qualitative researchers aim to understand patients' experiences with health problems and the contexts in which the experiences occur. Patients have the opportunity to tell their stories and share their experiences in these studies. The findings are in depth because patients are usually very descriptive in what they choose to share. Examples of qualitative studies include "patient's perceptions of nurses' caring in a palliative care unit," and "the perceptions of stress by family members of critically ill patients."

Qualitative research involves **inductive reasoning** to develop generalizations or theories from specific observations or interviews (Polit and Beck, 2011). For example, a nurse extensively interviews cancer survivors and then summarizes the common themes from all of the interviews to inductively determine the characteristics of cancer survivors' quality of life. Qualitative research involves the discovery and understanding of important behavioral characteristics or phenomena. An example is a qualitative research study conducted by Nixon and Narayanasamy (2010) that described the spiritual needs of patients with brain tumors and how well nurses support these needs.

There are a number of different qualitative research methods, including ethnography, phenomenology, and grounded theory. Each is based on a different philosophical or methodological view of how to collect, summarize, and analyze qualitative data.

RESEARCH PROCESS

The **research process** is an orderly series of steps that allow a researcher to move from asking the research question to finding the answer. Usually the answer to the initial research question leads to new questions and other areas of study. The research process builds knowledge for use in other similar situations. For example, a nurse researcher wants to seek knowledge about the best way to provide psychosocial support for patients with breast cancer. The research process ultimately provides knowledge that nurses from a variety of settings will use to provide evidence-based nursing care. Table 5-2 summarizes steps of the research process. Initially the researcher identifies an area of inquiry (identifying a problem), which often results from clinical practice. For example, a nurse notices that many surgical patients experience nausea after colon surgery. While speaking with a researcher at a professional nursing conference, the nurse decides to conduct a pilot study on the nursing unit to determine if chewing peppermint gum following colon surgery prevents patients from having nausea and reduces the incidence of postoperative ileus. The nurse reviews the relevant literature to determine what is known about chewing peppermint gum and its effect on bowel mobility and nausea following abdominal surgery. The nurse notes that, although many patients report problems with nausea and return of bowel function, there is limited research on the effects of chewing gum on these two outcomes.

Following identification of the problem and review of the literature, the nurse forms a research team who designs a study with the help of a nurse researcher. The research team includes nurses, gastrointestinal surgeons, and a statistician. The study sample includes all patients who are having elective colon resections. Subjects are excluded if they need to have surgery because of an emergency situation. After obtaining approval from the hospital institutional review board, the research team places each subject into one of the two groups (experimental or control) on the basis of random assignment. The control group receives standard postoperative care. The experimental or treatment group

TABLE 5-2 Comparison of Steps of the Nursing Process with the Research Process

Nursing Process	Research Process
Assessment	Identify area of interest or clinical problem. • Review literature. • Formulate theoretical framework. • Reflect on personal practice and/or discuss clinical issues with experts to better define the problem.
Diagnosis	Develop research question(s)/hypotheses.
Planning	Determine how study will be conducted: • Select research design/methodology. • Identify plan to recruit sample, taking into consideration population, number, and assignment to groups. • Identify study variables: specific interventions (independent variable) and outcomes (dependent variables). • Select data collection methods. • Select approach for measuring outcomes: questionnaires, surveys, physiological measures, interviews, observations. • Formulate plan to analyze data: statistical methods to answer research questions/hypotheses.
Implementation	Conduct the study: • Obtain necessary approvals. • Recruit and enroll subjects. • Implement the study protocol/collect data.
Evaluation	Analyze results of the study: • Continually analyze study methodology. Is study consistently carried out? Are all investigators following study protocol? • Interpret demographics of study population. • Analyze data to answer each research question/hypothesis. • Interpret results, including conclusions, limitations. Use of the findings: • Formulate recommendations for further research. • Determine implications for nursing. • Disseminate the findings: presentations, publications, need for further study, how to apply findings in practice.

research and the implications of participation; (3) have the power of free choice to voluntarily consent or decline participation in the research; and (4) understand how the researcher maintains confidentiality or anonymity. **Confidentiality** guarantees that any information a subject provides will not be reported in any manner that identifies the subject and will not be accessible to people outside the research team.

Once the study begins, the nurses on the unit collect data as indicated in the study protocol. The team analyzes the data from the nausea instrument and the chart review about bowel function from the two groups studied. With the help of the statistician, analysis of the results determines whether patients who chewed peppermint gum experienced less nausea and a quicker return of bowel function than the patients who had standard nursing care. The results from this study may advance postoperative nursing care.

Researchers always need to consider study limitations. Limitations are factors that affect study findings such as a small sample of subjects, a unique setting where the study was conducted, or the failure of the study to include representative cultural groups or age-groups. The research team conducted a pilot study because little data were available about the benefits of chewing gum following abdominal surgery. The sample size only included 20 patients in each group, and it was challenging to collect all the data from the patient charts because of inconsistencies in documentation. Therefore the results of the study have limited generalizability to other patients who are experiencing abdominal surgery. These limitations help the team decide how to refine or adapt the study for further investigation in the future.

A researcher also addresses the implications for nursing practice. This ultimately helps fellow researchers, clinicians, educators, and administrators know how to apply findings from a study in practice. At the end of the chewing gum study, the research team recommends that patients who have elective colon resections be offered the opportunity to chew peppermint gum following surgery. The surgeons on the unit agreed to the change in practice. The team decides to conduct another study to investigate this intervention with patients who have other types of abdominal surgeries to enhance the generalizability of the results. In addition, the team suggests ways to effectively introduce the use of chewing gum into other surgical units following surgery.

THE RELATIONSHIP BETWEEN EBP, RESEARCH, AND QUALITY IMPROVEMENT

EBP, research, and quality improvement (QI) are closely interrelated (Figure 5-3; see Chapter 2). All three processes require you to use the best evidence to provide the highest quality of patient care. As a nurse you are professionally accountable to know the differences and which process to select when facing clinical problems or when you desire to improve patient care. Although you will use all of these in nursing practice, it is important to know the similarities and differences among them (Table 5-3). When implementing an EBP project, it is important to first review evidence from appropriate research and QI data. This information helps you better understand the extent of a problem in practice and within your organization. QI data inform you about how processes work within an organization and thus offer information about how to make EBP changes. EBP and QI sometimes provide opportunities for research.

The following is an example of how the three processes merge to improve nursing practice:

A nursing unit is experiencing a decrease in patient satisfaction with pain management over the last several months. QI data identify factors associated with pain management (e.g., the types

receives standard postoperative care, and they chew gum for 5 minutes 3 times a day. Subjects have a 50-50 chance of being in each group. The research team selects appropriate instruments to measure postoperative nausea and decides to use patient assessment data to determine when nurses first hear bowel sounds and when patients first pass flatus and have their first bowel movement after surgery.

Before conducting any study with human subjects, a researcher obtains approvals from the human subjects committee or institutional review board (IRB) of an agency. An IRB includes scientists and laypeople who review all studies conducted in the institution to ensure that ethical principles, including the rights of human subjects, are followed. **Informed consent** means that research subjects (1) are given full and complete information about the purpose of a study, procedures, data collection, potential harm and benefits, and alternative methods of treatment; (2) are capable of fully understanding the

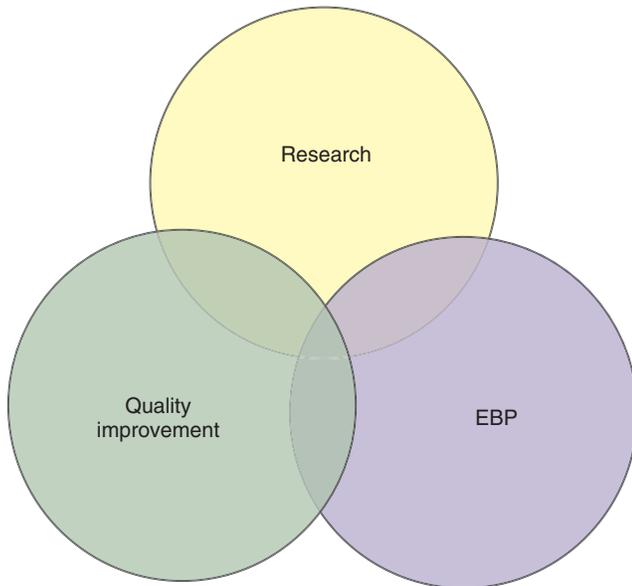
of pain medications typically ordered, patient reports of pain relief following administration of pain medications). A thorough analysis of QI data leads a unit-based quality council team of nurses to conduct a literature review and implement the best evidence available to improve their pain-management protocol for the type of patients on the unit. The staff implement the revised protocol and evaluate its results. Despite the implementation of the revised pain-management protocol, patient satisfaction data continue to be lower than desired. Thus staff decide to conduct a research *study to further investigate this clinical problem and improve patient care.*


FIGURE 5-3 The overlapping relationship among research, evidence-based practice, and quality improvement. *EBP,* Evidence-based practice.

KEY POINTS

- A challenge in EBP is to obtain the very best and most relevant, accurate, and current information at the right time, when you need it for patient care.
- Using your clinical expertise and considering patients' values and preferences ensures that you will apply the evidence in practice both safely and appropriately.
- The steps of EBP provide a systematic approach to rational clinical decision making.
- A focused PICOT question allows you to search for evidence in the scientific literature.
- The hierarchy of available evidence offers a guide to the types of literature or information that offer the best scientific evidence.
- An RCT is the highest level of experimental research.
- Expert clinicians are a rich source of evidence because they use it frequently to build their own practice and solve clinical problems.
- The critique or evaluation of evidence includes determining the value, feasibility, and usefulness of evidence for making a practice change.
- After critiquing all articles for a PICOT question, synthesize or combine the findings to consider the scientific rigor of the evidence and whether it has application in practice.
- When you decide to apply evidence, consider the setting and whether there is support from staff and available resources.
- Research is a systematic process that asks and answers questions that generate knowledge, which provides a scientific basis for nursing practice.
- Outcomes research is designed to assess and document the effectiveness of health care services and interventions.

TABLE 5-3   Similarities and Differences Among Evidence-Based Practice, Research, and Quality Improvement

	Evidence-Based Practice	**Research**	**Quality Improvement**
Purpose	Use of information from research, professional experts, personal experience, and patient preferences to determine safe and effective nursing care with the goal of improving patient care and outcomes	Systematic inquiry answers questions, solves problems, and contributes to the generalizable knowledge base of nursing; it may or may not improve patient care.	Improves local work processes to improve patient outcomes and efficiency of health systems; results usually not generalizable
Focus	Implementation of evidence already known into practice	Evidence is generated to find answers for questions that are not known about nursing practice.	Measures effects of practice and/or practice change on specific patient population
Data sources	Multiple research studies, expert opinion, personal experience, patients	Subjects or participants have predefined characteristics that include or exclude them from the study; researcher collects and analyzes data from subjects.	Data from patient records or patients who are in a specific area such as on a patient care unit or admitted to a particular hospital
Who conducts the activity?	Practicing nurses and possibly other members of the health care team	Researchers who may or may not be employed by the health care agency and usually are not a part of the clinical health care team conduct it.	Employees of a health care agency such as nurses, physicians, pharmacists
Is activity part of regular clinical practice?	Yes	No	Yes
Is IRB approval needed?	Sometimes	Yes	Sometimes
Funding sources	Internal, from health care agency	Funding is usually external such as a grant.	Internal, from health care agency

IRB, Institutional review board.

- Nursing research involves two broad approaches for conducting studies: quantitative and qualitative methods.
- Although EBP, research, and QI are closely related, they are separate processes.
- When posed with a clinical problem, you need to use the appropriate approach.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

The nursing staff on Rick's surgical unit have been reviewing their patients' medical records and have seen a steady increase in the incidence of catheter-acquired urinary tract infections (CAUTIs) in patients over the last 3 months. The staff agrees to look into the current practice guidelines about the prevention of CAUTIs and determine if a change in practice is indicated.

1. What is an appropriate PICOT question for this group to ask? Identify each part of the PICOT question.
2. The nurses on Rick's unit conduct a literature search and gather research articles about the PICOT question. Which step of the evidence-based practice (EBP) process do they need to implement next? Describe what the nurses will do during this step.
3. The staff on the surgical unit implemented a new protocol 4 months ago for patients who have catheters after surgery. The staff need to determine if this practice change has been effective. Identify one outcome the nurses could measure to determine the effectiveness of this change. Describe one method they could use to measure this outcome.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse researcher studies the effectiveness of a new program designed to educate parents to promote the immunization of children. The nurse divides the parents randomly into two groups. One group receives the typical educational program and the other group receives the new program. This is an example of which type of study?
   1. Historical
   2. Qualitative
   3. Correlational
   4. Experimental
2. A nurse who works on a pediatric unit asks, "I wonder if children who interact with therapy dogs have reduced anxiety when they are in the hospital." In this example of a PICOT question, which of the following is the O?
   1. Children
   2. Therapy dogs
   3. The pediatric unit
   4. Anxiety
3. A nurse researcher wants to know which factors are associated with a person's decision to exercise. The nurse distributes a survey to people who recently joined an exercise wellness program and analyzes the data to determine which factors and characteristics are most significantly linked to the decision to start exercising. Which type of a research study is this?
   1. Qualitative
   2. Descriptive

   3. Correlational
   4. Randomized controlled trial
4. A group of nurses have identified that the elderly patients on their unit have a high incidence of pressure ulcers after they have a stroke. During a unit meeting they discuss different interventions that they think may reduce the development of pressure ulcers. What is the nurses' next step to investigate this clinical problem further?
   1. Conduct a literature review
   2. Share the findings with others
   3. Conduct a statistical analysis
   4. Create a well-defined PICOT question
5. Arrange the following steps of evidence-based practice (EBP) in the appropriate order.
   1. Integrate the evidence.
   2. Ask the burning clinical question.
   3. Create a spirit of inquiry.
   4. Evaluate the practice decision or change.
   5. Share the results with others.
   6. Critically evaluate the evidence you gather.
   7. Collect the most relevant and best evidence.
6. When recruiting subjects to participate in a study about the effects of an educational program to help patients at home take their medications as ordered, the researcher tells the subjects that their names will not be used and no one but the research team will have access to their information and responses. This is an example of:
   1. Bias.
   2. Anonymity.
   3. Confidentiality.
   4. Informed consent.
7. Nurses in a community clinic have seen an increase in the numbers of obese children. The nurses who care for children are discussing ways to reduce childhood obesity. One nurse asks a colleague, "I wonder what the most effective ways are to help school-age children maintain a healthy weight?" This question is an example of a/an:
   1. Hypothesis.
   2. PICOT question.
   3. Problem-focused trigger.
   4. Knowledge-focused trigger.
8. The nurses on a medical unit have seen an increase in the number of medication errors on their unit. They decide to evaluate the medication administration process on the basis of data gained from chart reviews and direct observation of nurses administering medications. Which process are the nurses using?
   1. Evidence-based practice
   2. Research
   3. Quality improvement
   4. Problem identification
9. A nursing student is preparing to read the methods section of a research article. Which type of information will the student expect to find in this section? (Select all that apply.)
   1. How the researcher conducted the study
   2. A description about how to use the findings of the study
   3. The number and type of subjects who participated in the study
   4. Summaries of other research articles that support the need for this study
   5. Implications for future research studies
10. A group of nurses on the research council of a local hospital are measuring nursing-sensitive outcomes. Which of the following is a nursing-sensitive outcome that the nurses need to consider measuring? (Select all that apply.)

1. Frequency of low blood sugar episodes in children at a local school
2. Number of patients who develop a urinary tract infection from a Foley catheter
3. Number of patients who fall and experience subsequent injury on the evening shift
4. Number of sexually active adolescent girls who attend the community-based clinic for birth control
5. Patient-reported quality of life following coronary artery bypass graft surgery and cardiac rehabilitation

11. Which of the following statements about evidence-based practice (EBP) made by a nursing student would require the nursing professor to correct the student's understanding?
    1. "In evidence-based practice the patients are the subjects."
    2. "It is important to talk with experts and patients when making an evidence-based decision."
    3. "A nurse wanting to investigate the evidence to solve a problem starts by forming a PICOT question."
    4. "It is important to ask a librarian for help when searching for literature to help you answer your PICOT question."

12. A nurse is reading a research article. The nurse just finished reading a brief summary of the research study that included the purpose of the study and its implications for nursing practice. Which part of the article did the nurse just read?
    1. Abstract
    2. Analysis
    3. Discussion
    4. Literature review

13. A researcher is studying the effectiveness of an individualized evidence-based teaching plan on young women's intention to wear sunscreen to prevent skin cancer. In this study which of the following research terms best describes the individualized evidence-based teaching plan?
    1. Sample
    2. Intervention
    3. Survey
    4. Results

14. A nurse researcher wants to conduct historical research. Which of the following ideas for a study could the nurses conduct? (Select all that apply.)
    1. Determining the effect of unemployment on emergency room usage
    2. Understanding how Clara Barton shaped nursing in America
    3. Evaluating the effect of the Vietnam War on nursing leadership and practice
    4. Analyzing the evolution of nursing and patient care during recent disasters
    5. Investigating barriers to exercise in women who have become mothers in the past year

15. A nurse researcher is collecting data following approval from the institutional review board (IRB). In which part of the research process is this nurse?
    1. Analyzing the data
    2. Designing the study
    3. Conducting the study
    4. Identifying the problem

Answers: 1. 4; **2.** 4; **3.** 4; **4.** 5; **5.** 3, 4; **6.** 1, 4, 5; **7.** 3; **8.** 3; **9.** 1, 3; **10.** 2, 3; **11.** 1; **12.** 1; **13.** 2; **14.** 2, 3, 4; **15.** 3.

Health and Wellness

OBJECTIVES

- List the four general *Healthy People 2020* public health goals for Americans.
- Discuss the definition of health.
- Discuss the health belief, health promotion, basic human needs, and holistic health models to understand the relationship between patients' attitudes toward health and health practices.
- Describe variables influencing health beliefs and practices.
- Describe health promotion, wellness, and illness prevention activities.
- Discuss the three levels of preventive care.
- Describe four types of risk factors affecting health.
- Discuss risk-factor modification and changing health behaviors.
- Describe variables influencing illness behavior.
- Describe the effect of illness on patients and families.
- Discuss a nurse's role in health and illness.

- Case Study with Questions
- Audio Glossary
- Content Updates

In the past most individuals and societies viewed good health, or wellness, as the opposite or absence of disease. This simple attitude ignores the states of health that exist between disease and good health. Health is a multidimensional concept and is viewed from a broader perspective. An assessment of a patient's state of health is an important aspect of nursing.

Models of health offer a perspective to understand the relationships among the concepts of health, wellness, and illness. Nurses are in a unique position to help patients achieve and maintain optimal levels of health. They need to understand the challenges of today's health care system and embrace the opportunities to promote health and wellness and prevent illness. In an era of rising costs and advanced technology, nurses are a vital link to the improved health of individuals and society. Through assessment and knowledge of patients, nurses identify actual and potential risk factors that predispose an individual or a group to illness. In addition, a nurse uses risk factor modification strategies to promote health and wellness and prevent illness.

Different attitudes cause people to react in different ways to illness or the illness of a family member; this reaction is *illness behavior.* Nurses who understand how patients react to illness can minimize its effects and help them and their families maintain or return to the highest level of functioning.

HEALTHY PEOPLE DOCUMENTS

Healthy People provides evidence-based, 10-year national objectives for promoting health and preventing disease. In 1979 an influential document, *Healthy People: the Surgeon General's Report on Health Promotion and Disease Prevention,* was published; it introduced a goal for improving the health of Americans by 1990. The report outlined priority objectives for preventive services, health protection, and health promotion that addressed improvements in health status, risk reduction, public and professional awareness of prevention, health services and protective measures, surveillance, and evaluation. The report served as a framework for the 1990s as the United States increased the focus on health promotion and disease prevention instead of illness care. The strategy required is a cooperative effort by government, voluntary and professional organizations, businesses, and individuals. Widely cited by popular media, in professional journals, and at health conferences, it has inspired health promotion programs throughout the country.

Healthy People 2000: National Health Promotion and Disease Prevention Objectives, published in 1990, identified health improvement goals and objectives to be reached by the year 2000 (U.S. Department of Health and Human Services [USDHHS, Public Health Service], 1990). *Healthy People 2010,* published in 2000, served as a

road map for improving the health of all people in the United States for the first decade of the twenty-first century (USDHHS, 2000). This edition emphasized the link between individual and community health and the premise that the health of communities determines the overall health status of the nation. *Healthy People 2020* was approved in December 2010. Healthy People 2020 promotes a society in which all people live long, healthy lives. There are four overarching goals: (1) attain high-quality, longer lives free of preventable disease, disability, injury, and premature death; (2) achieve health equity, eliminate disparities, and improve the health of all groups; (3) create social and physical environments that promote good health for all; and (4) promote quality of life, healthy development, and healthy behaviors across all life stages (USDHHS, n.d.).

DEFINITION OF HEALTH

Defining health is difficult. The World Health Organization (WHO) defines **health** as a "state of complete physical, mental, and social well-being, not merely the absence of disease or infirmity" (WHO, 1947). Many aspects of health need to be considered. Health is a state of being that people define in relation to their own values, personality, and lifestyle. Each person has a personal concept of health. Pender and colleagues (2015) define health as the actualization of inherent and acquired human potential through goal-directed behavior, competent self-care, and satisfying relationships with others while adjustments are made as needed to maintain structural integrity and harmony with the environment.

Individuals' views of health vary among different cultural orientations (Pender et al., 2015). Pender (1996) explains that "all people free of disease are not equally healthy." Views of health have broadened to include not only physical well-being, but also mental, social, and spiritual well-being and a focus on health at the family and community levels.

To help patients identify and reach health goals, nurses discover and use information about their concepts of health. Pender et al. (2015) suggest that for many people conditions of life rather than pathological states define health. Life conditions can have positive or negative effects on health long before an illness is evident (Pender et al., 2015). Life conditions include socioeconomic variables such as environment, diet, lifestyle practices or choices, and many other physiological and psychological variables.

Health and illness are defined according to individual perception. Health often includes conditions previously considered to be illness. For example, a person with epilepsy who has learned to control seizures with medication and who functions at home and work or a person fully recovered from a stroke with limited paralysis and living independently may no longer consider himself or herself ill. A nurse needs to consider the total person and the environment in which the person lives to individualize nursing care and enhance meaningfulness of the patient's future health status.

MODELS OF HEALTH AND ILLNESS

A model is a theoretical way of understanding a concept or idea. Models represent different ways of approaching complex issues. Because health and illness are complex concepts, models explain the relationships between these concepts and a patient's attitudes toward health and **health behaviors**.

Health beliefs are a person's ideas, convictions, and attitudes about health and illness. They may be based on factual information or misinformation, common sense or myths, or reality or false expectations. Because health beliefs usually influence health behavior, they can positively or negatively affect a patient's level of health. Positive health behaviors are activities related to maintaining, attaining, or regaining good health and preventing illness. Common positive health behaviors include immunizations, proper sleep patterns, adequate exercise, stress management, and nutrition. Negative health behaviors include practices actually or potentially harmful to health such as smoking, drug or alcohol abuse, poor diet, and refusal to take necessary medications.

Nurses developed the following health models to understand patients' attitudes and values about health and illness and to provide effective health care. These nursing models allow you to understand and predict patients' health behavior, including how they use health services and adhere to recommended therapy. Positive health models focus on the individual's strengths, resiliencies, resources, potential, and capabilities rather than on disease or pathology (Pender et al., 2015).

Health Belief Model

Rosenstoch's (1974) and Becker and Maiman's (1975) **health belief model** (Figure 6-1) addresses the relationship between a person's beliefs and behaviors. The health belief model helps you understand factors influencing patients' perceptions, beliefs, and behavior to plan care that will most effectively help patients maintain or restore health and prevent illness.

The first component of this model involves an individual's perception of susceptibility to an illness. For example, a patient needs to recognize the familial link for coronary artery disease. After this link is recognized, particularly when one parent and two siblings have died in their fourth decade from myocardial infarction, the patient may perceive the personal risk of heart disease.

The second component is an individual's perception of the seriousness of the illness. This perception is influenced and modified by demographic and sociopsychological variables, perceived threats of the illness, and cues to action (e.g., mass media campaigns and advice from family, friends, and medical professionals). For example, a patient may not perceive his heart disease to be serious, which may affect the way he takes care of himself.

The third component is the likelihood that a person will take preventive action. This component results from a person's perception of the benefits of and barriers to taking action. Preventive actions include lifestyle changes, increased adherence to medical therapies, or a search for medical advice or treatment. A patient's perception of susceptibility to disease and his or her perception of the seriousness of an illness help to determine the likelihood that the patient will or will not partake in healthy behaviors.

Health Promotion Model

The health promotion model (HPM) proposed by Pender (1982; revised, 1996) was designed to be a "complementary counterpart to models of health protection" (Figure 6-2). It defines health as a positive, dynamic state, not merely the absence of disease (Pender et al., 2015). Health promotion is directed at increasing a patient's level of well-being. The HPM describes the multidimensional nature of people as they interact within their environment to pursue health (Pender, 1996; Pender et al., 2015). The model focuses on the following three areas: (1) individual characteristics and experiences; (2) behavior-specific knowledge and affect; and (3) behavioral outcomes, in which the patient commits to or changes a behavior. The HPM notes that each person has unique personal characteristics and experiences that affect subsequent actions. The set of variables for behavioral-specific knowledge and affect have important motivational significance. These variables can be modified through nursing actions. Health-promoting

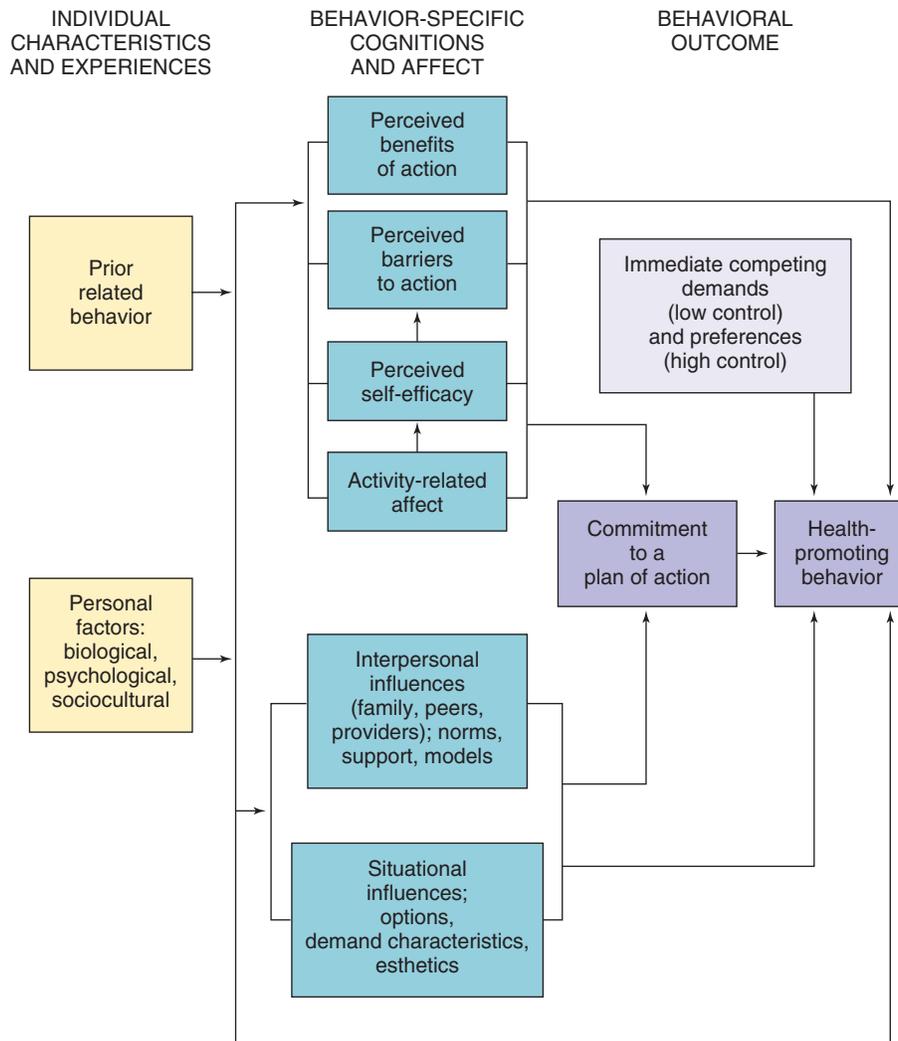
behavior is the desired behavioral outcome and the end point in the HPM. Health-promoting behaviors result in improved health, enhanced functional ability, and better quality of life at all stages of development (Pender et al., 2015) (Box 6-1).

Maslow's Hierarchy of Needs

Basic human needs are elements that are necessary for human survival and health (e.g., food, water, safety, and love). Although each person has unique needs, all people share the basic human needs, and the extent to which people meet their basic needs is a major factor in determining their level of health.


Maslow's hierarchy of needs is a model that nurses use to understand the interrelationships of basic human needs (Figure 6-3). According to this model, certain human needs are more basic than others (i.e., some needs must be met before other needs [e.g., fulfilling the physiological needs before the needs of love and belonging]). Self-actualization is the highest expression of one's individual potential and allows for continual self-discovery. Maslow's model takes into account individual experiences, which are always unique to that individual (Touhy and Jett, 2012).

The hierarchy of needs model provides a basis for nurses to care for patients of all ages in all health settings. However, when applying the model, the focus of care is on a patient's needs rather than on strict adherence to the hierarchy. It is unrealistic to always expect a patient's

---

BOX 6-1 FOCUS ON OLDER ADULTS

Health Promotion

- Promote healthy lifestyles by encouraging regular physical activity tailored to the individual's ability, accepting responsibility for one's own health, using stress-management strategies, focusing on self-care abilities, improving self-efficacy, and practicing relaxation exercises (Pascucci et al., 2012; Pender et al., 2015).
- Consider an older adult's social environment and strengthen social support to promote health and provide access to resources (Touhy and Jett, 2012).
- Injury prevention is a key strategy to promote and improve health (Touhy and Jett, 2012).
- Promote community-based exercise programs to decrease social isolation and increase independence (Wallace et al., 2014).
- Factors that have been reported to affect older adults' willingness to engage in health promotion activities may include socioeconomic factors, beliefs and attitudes of patients and providers, encouragement by a health care professional, specific motivation based on efficacy beliefs, access to resources, age, number of chronic illnesses, mental and physical health, marital status, ability for self-care, gender, education, and support system presence (Byam-Williams and Salyer, 2010; Pascucci et al., 2012).
- Encourage frequent healthy meals that are well balanced and contain fruits, vegetables, and dairy (Pascucci et al., 2012).

basic needs to occur in the fixed hierarchical order. In all cases an emergent physiological need takes precedence over a higher-level need. In other situations a psychological or physical safety need takes priority. For example, in a house fire, fear of injury and death takes priority over self-esteem issues. Although it would seem that a patient who has just had surgery might have the strongest need for pain control in the psychosocial area, if the patient just had a mastectomy, her main need may be in the areas of love, belonging, and self-esteem. It is important not to assume the patient's needs just because other patients reacted in a certain way. Maslow's hierarchy can be very useful when applied to each patient individually. To provide the most effective care, you need to understand the relationships of different needs and the factors that determine the priorities for each patient.

Holistic Health Models

Health care has begun to take a more holistic view of health by considering emotional and spiritual well-being and other dimensions of an individual to be important aspects of physical wellness. The **holistic health model** of nursing attempts to create conditions that promote a patient's optimal level of health. In this model nurses using the nursing process consider patients to be the ultimate experts concerning their own health and respect patients' subjective experience as relevant in

maintaining health or assisting in healing. In the holistic health model patients are involved in their healing process, thereby assuming some responsibility for health maintenance (Edelman and Mandle, 2014).

Nurses using the holistic nursing model recognize the natural healing abilities of the body and incorporate complementary and alternative interventions such as meditation, music therapy, reminiscence, relaxation therapy, therapeutic touch, and guided imagery because they are effective, economical, noninvasive, nonpharmacological complements to traditional medical care (see Chapter 33). These holistic strategies, which can be used in all stages of health and illness, are integral in the expanding role of nursing.

Nurses use holistic therapies either alone or in conjunction with conventional medicine. For example, they use reminiscence in the geriatric population to help relieve anxiety for a patient dealing with memory loss or for a cancer patient dealing with the difficult side effects of chemotherapy. Music therapy in the operating room creates a soothing environment. Relaxation therapy is frequently useful to distract a patient during a painful procedure such as a dressing change. Breathing exercises are commonly taught to help patients deal with the pain associated with labor and delivery.

VARIABLES INFLUENCING HEALTH AND HEALTH BELIEFS AND PRACTICES

Many variables influence a patient's health beliefs and practices. Internal and external variables influence how a person thinks and acts. As previously stated, health beliefs usually influence health behavior or health practices and likewise positively or negatively affect a patient's level of health. Therefore understanding the effects of these variables allows you to plan and deliver individualized care.

Internal Variables

Internal variables include a person's developmental stage, intellectual background, perception of functioning, and emotional and spiritual factors.

Developmental Stage. A person's thought and behavior patterns change throughout life. A nurse considers a patient's level of growth and development when using his or her health beliefs and practices as a basis for planning care (see Chapter 11). The concept of illness for a child, adolescent, or adult depends on the individual's developmental stage. Fear and anxiety are common among ill children, especially if thoughts about illness, hospitalization, or procedures are based on lack of information or lack of clarity of information. Emotional development may also influence personal beliefs about health-related matters. For example, you use different techniques for teaching about contraception to an adolescent than you use for an adult. Knowledge of the stages of growth and development helps predict a patient's response to the present illness or the threat of future illness. Adapt the planning of nursing care to developmental expectations and to the patient's abilities to participate in self-care.

Intellectual Background. A person's beliefs about health are shaped in part by the person's knowledge, lack of knowledge, or incorrect information about body functions and illnesses, educational background, traditions, and past experiences. These variables influence how a patient thinks about health. In addition, cognitive abilities shape the *way* a person thinks, including the ability to understand factors involved in illness and apply knowledge of health and illness to personal health practices. Cognitive abilities also relate to a person's developmental stage. A nurse considers intellectual background so

these variables can be incorporated into communication and instructional approaches (Edelman and Mandle, 2014).

Perception of Functioning. The way people perceive their physical functioning affects health beliefs and practices. When you assess a patient's level of health, gather subjective data about the way the patient perceives physical functioning such as level of fatigue, shortness of breath, or pain. Then obtain objective data about actual functioning such as blood pressure, height measurements, and lung sound assessment. This information allows you to more successfully plan and implement individualized approaches, such as self-care and mobility.

Emotional Factors. The patient's degree of stress, depression, or fear can influence health beliefs and practices. The manner in which a person handles stress throughout each phase of life influences the way he or she reacts to illness. A person who generally is very calm may have little emotional response during illness, whereas another individual may be unable to cope emotionally with the threat of illness and may overreact or deny the presence of symptoms and not take therapeutic action (see Chapter 38).

Spiritual Factors. Spirituality is reflected in how a person lives his or her life, including the values and beliefs exercised, the relationships established with family and friends, and the ability to find hope and meaning in life. Spirituality serves as an integrating theme in people's lives (see Chapter 36). Religious practices are one way that people exercise spirituality. Some religions restrict the use of certain forms of medical treatment. For example, persons of the Jehovah Witness faith do not receive blood transfusions. You need to understand patients' spiritual dimensions to involve patients effectively in nursing care.

External Variables

External variables influencing a person's health beliefs and practices include family practices, psychosocial and socioeconomic factors, and cultural background.

Family Practices. The way that patients' families use health care services generally affects their health practices. Their perceptions of the seriousness of diseases and their history of preventive care behaviors (or lack of them) influence how patients think about health. For example, if a young woman's mother never had annual gynecological examinations or Papanicolaou (Pap) smears, it is unlikely that the daughter will have annual Pap smears.

Psychosocial and Socioeconomic Factors. Socioeconomic and psychosocial factors increase the risk for illness and influence the way that a person defines and reacts to illness. Psychosocial variables include the stability of the person's marital or intimate relationship, lifestyle habits, and occupational environment. A person generally seeks approval and support from social networks (neighbors, peers, and co-workers), and this desire for approval and support affects health beliefs and practices.

Socioeconomic variables partly determine how the health care system provides medical care. The organization of the health care system determines how patients obtain care, the treatment method, cost to patients, and potential reimbursement to the health care agency or patients.

Economic variables often affect a patient's level of health by increasing the risk for disease and influencing how or at what point the patient enters the health care system. A person's compliance with a treatment designed to maintain or improve health is also affected by economic

BOX 6-2 CULTURAL ASPECTS OF CARE

Cultural Health Beliefs

The cultural backgrounds of patients shape their views of health, how to treat and prevent illness, and what constitutes good care (Narayan, 2010; Purnell, 2013). Two common beliefs of health exist: the individual, family, or community is able to influence its own health; or the individual has little control over his or her health because health is a gift from a higher being or power (Purnell, 2013). Health beliefs often vary within a cultural group; therefore it is important to assess the health beliefs of each patient and not stereotype a patient based on cultural background (Kersey-Matusiak, 2012). Cultural health beliefs influence individuals' responses to health and illness such as eye contact, response to pain and pain management, use of touch, perception and treatment of mental illness, and sick role behaviors (Narayan, 2010; Purnell, 2013). Other examples of cultural beliefs that affect health care practices include yin/yang balance, hot-and-cold foods, influence of humors, the importance of hexes, and spirits and soul loss (Giger, 2013). Recognizing a patient's health beliefs helps the nurse provide culturally competent nursing care that considers the physical, psychological, social, emotional, and spiritual needs of each patient. Nurses need to use culturally appropriate resources and be able to provide evidence-based cultural practices (Douglas et al., 2011).

Implications for Patient-Centered Care

- Be aware of the effect of culture on a patient's view and understanding of illness.
- Understand a patient's traditions, values, and beliefs and how these dimensions may affect health, wellness, and illness.
- Do not stereotype patients based on their culture and do not assume that they will adopt all cultural beliefs and practices (Kersey-Matusiak, 2012).
- When teaching patients about their illness and treatment regimens, you need to understand that unique cultural perceptions exist regarding the cause of an illness and its treatment.
- Use a trained interpreter if possible when a patient and family do not speak English to avoid misinterpretation of information (Purnell, 2013).
- Be aware of your own cultural background and recognize prejudices that lead to stereotyping and discrimination (Purnell, 2013).

BOX 6-3 EVIDENCE-BASED PRACTICE

Health Promotion Strategies

PICO Question: For individuals in the community, do psychosocial strategies effectively promote health and assist individuals with lifestyle changes?

Evidence Summary

Nurses use a variety of psychosocial strategies to improve health promotion in individuals. Research shows that some are more effective than others. One growing strategy is faith community nursing (FCN). FCN is a specialized area of nursing in which parish nurses focus on the goals of holistic health promotion (Dandridge, 2014). A wide variety of health promotion programs are presented by the parish nurses in their faith communities. Further research is needed on the outcomes of these FCN programs (Dandridge, 2014).

Face-to-face communication is another psychosocial strategy. Motivational interviewing (MI) is a face-to-face communication strategy that nurses use to assess an individual's readiness for change (Droppa and Lee, 2014). Through engaging individuals in communication, nurses who use MI are better able to understand their patients' motivation, help their patients work through resistance to change, empower the individual, and help support his or her self-efficacy (Droppa and Lee, 2014). MI techniques help move the individual through established targets in their health promotion journey. Han and Yan (2014) also found that face-to-face communication is effective in improving physical activity in individuals.

Application to Nursing Practice

- Use face-to-face dialogues when possible to encourage individuals regarding health promotion and lifestyle changes (Han and Yan, 2014).
- Provide support to individuals as they work on lifestyle changes (Hornsten et al., 2014).
- Determine if the individual has access to FCN—sponsored health promotion programs (Dandridge, 2014).
- Use motivational interview techniques to determine an individual's concerns and motivation for change (Droppa and Lee, 2014).

status. A person who has high utility bills, cares for a large family, and has a low income tends to give a higher priority to food and shelter than to costly drugs or treatment or expensive foods for special diets. Some patients decide to take medications every other day rather than every day as prescribed to save money, which greatly affects the effectiveness of the medications.

Cultural Background. Cultural background influences beliefs, values, and customs. It influences the approach to the health care systems, personal health practices, and the nurse-patient relationship. Cultural background also influences an individual's beliefs about causes of illness and remedies or practices to restore health (Box 6-2). If you are not aware of your own cultural patterns of behavior and language, you will have difficulty recognizing and understanding your patient's behaviors and beliefs. You will also probably have difficulty interacting with patients. As with family and socioeconomic variables, you need to incorporate cultural variables into a patient's care plan (see Chapter 9).

HEALTH PROMOTION, WELLNESS, AND ILLNESS PREVENTION

Currently, health care is more focused on health promotion, wellness, and illness prevention. In addition, changes in health care cost and insurance coverage have motivated people to seek ways to improve health, decrease incidence of disease and disability, and minimize the results of disease or disability.

The concepts of health promotion, wellness, and illness prevention are closely related and in practice overlap to some extent. All are focused on the future; the difference among them involves motivations and goals. **Health promotion** activities such as routine exercise and good nutrition help patients maintain or enhance their present levels of health. They motivate people to act positively to reach more stable levels of health. **Wellness** education teaches people how to care for themselves in a healthy way and includes topics such as physical awareness, stress management, and self-responsibility. Wellness strategies help people achieve new understanding and control of their lives. **Illness prevention** activities such as immunization programs protect patients from actual or potential threats to health. They motivate people to avoid a decline in health or functional levels.

Nurses emphasize health promotion activities, wellness-enhancing strategies, and illness-prevention activities as important forms of health care because they help patients maintain and improve health. The goal of a total health program is to improve a patient's level of well-being in all dimensions, not just physical health. Total health programs are based on the belief that many factors can affect a person's level of health (Box 6-3).

Examples of the health topics and objectives as defined by *Healthy People 2020* include physical activity, adolescent health, tobacco use, substance abuse, sexually transmitted diseases, mental health and

TABLE 6-1 Three Levels of Prevention

PRIMARY PREVENTION		SECONDARY PREVENTION		TERTIARY PREVENTION
Health Promotion	**Specific Protection**	**Early Diagnosis and Prompt Treatment**	**Disability Limitations**	**Restoration and Rehabilitation**
Health education Good standard of nutrition adjusted to developmental phases of life Attention to personality development Provision of adequate housing and recreation and agreeable working conditions Marriage counseling and sex education Genetic screening Periodic selective examinations	Use of specific immunizations Attention to personal hygiene Use of environmental sanitation Protection against occupational hazards Protection from accidents Use of specific nutrients Protection from carcinogens Avoidance of allergens	Case-finding measures: individual and mass screening activities Selective examinations to cure and prevent disease process, prevent spread of communicable disease, prevent complications and sequelae, and shorten period of disability	Adequate treatment to arrest disease process and prevent further complications and sequelae Provision of facilities to limit disability and prevent death	Provision of hospital and community facilities for retraining and education to maximize use of remaining capacities Education of public and industry to use rehabilitated persons to fullest possible extent Selective placement Work therapy in hospitals Use of sheltered colony

Data from Leavell H, Clark AE: *Preventive medicine for the doctors in his community,* ed 3, New York, 1965, McGraw-Hill; and modified from Edelman CL, Mandle CL: *Health promotion throughout the life span,* ed 7, St Louis, 2014, Mosby.

mental disorders, injury and violence prevention, environmental health, immunization and infectious disease, and access to health care (USDHHS, 2015). A complete list of topics and objectives is available on the *Healthy People* website (www.healthypeople.gov). These objectives and topics show the importance of health promotion, wellness, and illness prevention and encourage all to participate in the improvement of health.

Individual practices such as poor eating habits and little or no exercise influence health. Physical stressors such as a poor living environment, work stress, exposure to air pollutants, and an unsafe environment also affect health. Hereditary and psychological stressors such as emotional, intellectual, social, developmental, and spiritual factors influence one's level of health. Total health programs are directed at individuals' changing their lifestyles by developing more health-oriented habits.

Other programs are aimed at specific health care problems. For example, support groups help people with human immunodeficiency virus (HIV) infection. Exercise programs encourage participants to exercise regularly to reduce their risk of cardiac disease. Stress-reduction programs teach participants to cope with stressors and reduce their risks for multiple illnesses such as infections, gastrointestinal disease, and cardiac disease.

Some health promotion, wellness education, and illness prevention programs are operated by health care agencies; others are operated independently. Many businesses have on-site health promotion activities for employees. Likewise, colleges and community centers offer health promotion and illness prevention programs. Some nurses actively participate in these programs, providing direct care, and others act as consultants or refer patients to them. The goal of these activities is to improve a patient's level of health through preventive health services, environmental protection, and health education.

Health care professionals who work in the field of health promotion use proactive attempts to prevent illness or disease. Health promotion activities are passive or active. With **passive strategies of health promotion**, individuals gain from the activities of others without acting themselves. The fluoridation of municipal drinking water and the fortification of homogenized milk with vitamin D are examples of passive health promotion strategies. With **active strategies of health promotion**, individuals adopt specific health programs. Weight-reduction and smoking-cessation programs require patients to be actively

involved in measures to improve their present and future levels of wellness while decreasing the risk of disease.

Health promotion is a process of helping people improve their health to reach an optimal state of physical, mental, and social well-being (WHO, 2009). An individual takes responsibility for health and wellness by making appropriate lifestyle choices. Lifestyle choices are important because they affect a person's quality of life and well-being. Making positive lifestyle choices and avoiding negative lifestyle choices also play a role in preventing illness. In addition to improving quality of life, preventing illness has an economic impact because it decreases health care costs.

Levels of Preventive Care

Nursing care oriented to health promotion, wellness, and illness prevention is described in terms of health activities on primary, secondary, and tertiary levels (Table 6-1).

Primary Prevention. **Primary prevention** is true prevention; it precedes disease or dysfunction and is applied to patients considered physically and emotionally healthy. Primary prevention aimed at health promotion includes health education programs, immunizations, nutritional programs, and physical fitness activities. It includes all health promotion efforts and wellness education activities that focus on maintaining or improving the general health of individuals, families, and communities (Edelman and Mandle, 2014). Primary prevention includes specific protection such as immunization for influenza and hearing protection in occupational settings.

Secondary Prevention. **Secondary prevention** focuses on individuals who are experiencing health problems or illnesses and are at risk for developing complications or worsening conditions. Activities are directed at diagnosis and prompt intervention, thereby reducing severity and enabling the patient to return to a normal level of health as early as possible (Edelman and Mandle, 2014). A large portion of nursing care related to secondary prevention is delivered in homes, hospitals, or skilled nursing facilities. It includes screening techniques and treating early stages of disease to limit disability by averting or delaying the consequences of advanced disease. Screening activities also become a key opportunity for health teaching as a primary prevention intervention (Edelman and Mandle, 2014).

Tertiary Prevention. Tertiary prevention occurs when a defect or disability is permanent and irreversible. It involves minimizing the effects of long-term disease or disability by interventions directed at preventing complications and deterioration (Edelman and Mandle, 2014). Activities are directed at rehabilitation rather than diagnosis and treatment. For example, a patient with a spinal cord injury undergoes rehabilitation to learn how to use a wheelchair and perform ADLs independently. Care at this level helps patients achieve as high a level of functioning as possible, despite the limitations caused by illness or impairment.

RISK FACTORS

A risk factor is any situation, habit, or other variable such as social, environmental, physiological, psychological, developmental, intellectual, or spiritual that increases the vulnerability of an individual or group to an illness or accident. An example would be risk factors for falls, such as impaired gait, reduced vision, and lower extremity weakness. Risk factors and behaviors, risk factor modification, and behavior modification are integral components of health promotion, wellness, and illness prevention. Nurses in all areas of practice have opportunities to reduce patients' risk factors to promote health and decrease risks of illness or injury.

The presence of risk factors does not mean that a disease will develop, but risk factors increase the chances that the individual will experience a particular disease or dysfunction. Nurses and other health care professionals are concerned with risk factors, sometimes called *health hazards,* for several reasons. Risk factors play a major role in how a nurse identifies a patient's health status. They also often influence health beliefs and practices if a person is aware of their presence. Risk factors are often placed in the following interrelated categories: genetic and physiological factors, age, physical environment, and lifestyle.

Genetic and Physiological Factors

Physiological risk factors involve the physical functioning of the body. Certain physical conditions such as being overweight place increased stress on physiological systems (e.g., the circulatory system), increasing susceptibility to illness. Heredity, or genetic predisposition to specific illness, is a major physical risk factor. For example, a person with a family history of diabetes mellitus is at risk for developing the disease later in life. Other documented genetic risk factors include family histories of cancer, heart disease, kidney disease, or mental illness.

Age

Age affects a person's susceptibility to certain illnesses and conditions. For example, premature infants and neonates are more susceptible to infections. As a person ages, the risk of heart disease and many types of cancers increases. Age risk factors are often closely associated with other risk factors such as family history and personal habits. Nurses need to educate their patients about the importance of regularly scheduled checkups for their age-group. Various professional organizations and federal agencies develop and update recommendations for health screenings, immunizations, and counseling. Access to scientific evidence, recommendations for clinical prevention services, and information on how to incorporate recommended preventive services into practice can be found at http://www.ahrq.gov/professionals/prevention-chronic-care/index.html.

Environment

Where we live and the condition of that area (its air, water, and soil) determine how we live, what we eat, the disease agents to which we are exposed, our state of health, and our ability to adapt. The physical environment in which a person works or lives can increase the likelihood that certain illnesses will occur. For example, some kinds of cancer and other diseases are more likely to develop when industrial workers are exposed to certain chemicals or when people live near toxic waste disposal sites. Nursing assessments extend from the individual to the family and the community in which they live focusing on the short term effects of exposure and the potential for long-term effects (Edelman and Mandle, 2014).

Lifestyle

Many activities, habits, and practices involve risk factors. Lifestyle practices and behaviors have positive or negative effects on health. Those with potential negative effects are risk factors. Some habits are risk factors for specific diseases. For example, excessive sunbathing increases the risk of skin cancer; smoking increases the risk of lung diseases, including cancer; and a poor diet and being overweight increase the risk of cardiovascular disease. Because patients often take risks, there is an increased emphasis for nurses to provide preventive care. Lifestyle choices lead to health problems that cause a huge impact on the economics of the health care system. Therefore it is important to understand the effect of lifestyle behaviors on health status. Nurses educate their patients and the public on wellness-promoting lifestyle behaviors.

Stress is a lifestyle risk factor if it is severe or prolonged or if the person is unable to cope with life events adequately. Stress threatens both mental health (emotional stress) and physical well-being (physiological stress). Both play a part in the development of an illness and affect a person's ability to adapt to potential changes associated with the illness and survive a life-threatening illness. Stress also interferes with patients adopting health promotion activities and the ability to implement needed lifestyle modifications. Some emotional stressors result from life events such as divorce, pregnancy, death of a spouse or family member, and financial instabilities. For example, job-related stressors overtax a person's cognitive skills and decision-making ability, leading to "mental overload" or "burnout" (see Chapters 1 and 38). Stress also threatens physical well-being and is associated with illnesses such as heart disease, cancer, and gastrointestinal disorders (Pender et al., 2015). Always review life stressors as part of a patient's comprehensive risk factor analysis.

The goal of risk factor identification is to help patients visualize the areas in their life that they can modify, control, or even eliminate to promote wellness and prevent illness. You can use a variety of available health risk appraisal forms to estimate a person's specific health threats based on the presence of various risk factors (Edelman and Mandle, 2014). Link the health risk appraisal tool with educational programs and other community resources if a patient needs to make lifestyle changes and reduce health risks (Pender et al., 2015).

RISK-FACTOR MODIFICATION AND CHANGING HEALTH BEHAVIORS

Identifying risk factors is the first step in health promotion, wellness education, and illness prevention. Discuss health hazards with a patient following a comprehensive nursing assessment, then help the patient decide if he or she wants to maintain or improve his or her health status by taking risk-reduction actions (Edelman and Mandle, 2014). Risk-factor modification, health promotion, illness prevention activities, or any program that attempts to change unhealthy lifestyle behaviors is a wellness strategy. Emphasize wellness strategies that teach patients to care for themselves in a healthier way because they have the

TABLE 6-2 Stages of Health Behavior Change

Stage	Definition	Nursing Implications
Precontemplation	Not intending to make changes within the next 6 months	Patient is not interested in information about the behavior and may be defensive when confronted with it.
Contemplation	Considering a change within the next 6 months	Ambivalence may be present, but patients will more likely accept information since they are developing more belief in the value of change.
Preparation	Making small changes in preparation for a change in the next month	Patient believes that advantages outweigh disadvantages of behavior change; needs assistance in planning for the change.
Action	Actively engaged in strategies to change behavior; lasts up to 6 months	Previous habits may prevent taking action relating to new behaviors; identify barriers and facilitators of change.
Maintenance stage	Sustained change over time; begins 6 months after action has started and continues indefinitely	Changes need to be integrated into the patient's lifestyle.

Data from Prochaska JO, DiClemente CC: Stages of change in the modification of problem behaviors, *Prog Behav Modif* 28:184, 1992; and Conn VS: A staged-based approach to helping people change health behaviors, *Clin Nurs Spec* 8(4):187, 1994.

ability to increase their quality of life and decrease the potential high costs of unmanaged health problems.

Some attempts to change are aimed at the cessation of a health-damaging behavior (e.g., tobacco use or alcohol misuse) or the adoption of a healthy behavior (e.g., healthy diet or exercise) (Pender et al., 2015). It is difficult to change negative health behavior, especially when the behavior is ingrained in a person's lifestyle patterns. The importance of nurses using a health promotion model to identify risky behaviors and implement the change process cannot be overemphasized because it is the nurse who spends the greatest amount of time in direct contact with patients. In addition, leading causes of death continue to relate to health behaviors that require a change, and nurses are able to motivate and facilitate important health behavior change when working with individuals, families, and communities (Edelman and Mandle, 2014).

Understanding the process of changing behaviors will help you support difficult **health behavior changes** in patients. It is believed that change involves movement through a series of stages. DiClemente and Prochaska (1998) describe the stages of change in the transtheoretical model of change (Table 6-2). These stages range from no intention to change (precontemplation), considering a change within the next 6 months (contemplation), making small changes (preparation), and actively engaging in strategies to change behavior (action) to maintaining a changed behavior (maintenance stage). As individuals attempt a change in behavior, relapse followed by recycling through

BOX 6-4 PATIENT TEACHING

Lifestyle Changes

Objective
- Patient will reduce health risks related to poor lifestyle habits (e.g., high-fat diet, sedentary lifestyle) through behavior change.

Teaching Strategies
- Practice active listening and ask the patient how he or she prefers to learn.
- Begin with determining information that the patient knows regarding health risks related to poor lifestyle.
- Ask which barriers the patient perceives with the planned lifestyle change.
- Help the patient establish goals for change.
- In collaboration with the patient, establish time lines for modification of eating and exercise lifestyle habits.
- Reinforce the process of change.
- Use written resources at an appropriate reading level (Ward-Smith, 2012).
- Ensure education materials are culturally appropriate (Douglas et al., 2011).
- Include family members to support the lifestyle change.

Evaluation
- Ask the patient to repeat back the teaching on reducing risks and lifestyle changes (Ward-Smith, 2012).
- Have the patient maintain an exercise and eating calendar to track adherence and provide positive reinforcement.
- Ask the patient to discuss success with lifestyle changes such as minutes spent in activity or actual number of fruits and vegetables eaten.

the stages frequently occurs. When relapse occurs, a person will return to the contemplation or precontemplation stage before attempting the change again. Relapse is a learning process, and people can apply the lessons learned from relapse to their next attempt to change. It is important to understand what happens at the various stages of the change process to time the implementation of interventions (wellness strategies) adequately and provide appropriate assistance at each stage.

Once an individual identifies a stage of change, the change process facilitates movement through the stages. To be most effective, you choose nursing interventions that match the stage of change (DiClemente and Prochaska, 1998). Most behavior-change programs are designed for (and have a chance of success when) people are ready to take action regarding their health behavior problems. Only a minority of people are actually in this action stage (Prochaska, 1991). Changes are maintained over time only if they are integrated into an individual's overall lifestyle (Box 6-4). Maintaining healthy lifestyles can prevent hospitalizations and potentially lower the cost of health care.

ILLNESS

Illness is a state in which a person's physical, emotional, intellectual, social, developmental, or spiritual functioning is diminished or impaired. Cancer is a disease process, but one patient with leukemia who is responding to treatment may continue to function as usual, whereas another patient with breast cancer who is preparing for surgery may be affected in dimensions other than the physical. Therefore illness is not synonymous with disease. Although nurses need to be familiar with different types of diseases and their treatments, they often are concerned more with illness, which may include disease but also includes the effects on functioning and well-being in all dimensions.

Acute and Chronic Illness

Acute and chronic illnesses are two general classifications of illness used in this chapter and throughout this text. Both acute and chronic illnesses have the potential to be life threatening. An **acute illness** is usually reversible, has a short duration, and is often severe. The symptoms appear abruptly, are intense, and often subside after a relatively short period. An acute illness may affect functioning in any dimension. A **chronic illness** persists, usually longer than 6 months, is irreversible, and affects functioning in one or more systems. Patients often fluctuate between maximal functioning and serious health relapses that may be life threatening. A person with a chronic illness is similar to a person with a disability in that both have varying degrees of functional limitations that result from either a pathological process or an injury (Larsen, 2013a). In addition, the social surroundings and physical environment in which an individual lives frequently affect the abilities, motivation, and psychological maintenance of the person.

Chronic illnesses and disabilities remain a leading health problem in North America for older adults and children. Issues of coping and living with a chronic illness can be complex and overwhelming. The Centers for Disease Control and Prevention report that in 2012 about half of the adults in the United States had at least one chronic disease or health problem (CDC, 2015). Many chronic illnesses are related to four modifiable health behaviors: physical inactivity, poor nutrition, use of tobacco, and excessive alcohol consumption (CDC, 2015). A major role for nursing is to provide patient education aimed at helping patients manage their illness or disability. The goal of managing a chronic illness is to reduce the occurrence or improve the tolerance of symptoms. By enhancing wellness, nurses improve the quality of life for patients living with chronic illnesses or disabilities.

Patients with chronic diseases and their families continually adjust and adapt to their illnesses. How an individual perceives an illness influences the type of coping responses. In response to a chronic illness, an individual develops an illness career. The illness career is flexible and changes in response to changes in health, interactions with health professionals, psychological changes related to grief, and stress related to the illness (Larsen, 2013b).

Illness Behavior

People who are ill generally act in a way that medical sociologists call **illness behavior**. It involves how people monitor their bodies, define and interpret their symptoms, take remedial actions, and use the resources in the health care system (Mechanic, 1995). Personal history, social situations, social norms, and past experiences affect illness behaviors (Larsen, 2013b). How people react to illness varies widely; illness behavior displayed in sickness is often used to manage life adversities (Mechanic, 1995). In other words, if people perceive themselves to be ill, illness behaviors become coping mechanisms. For example, illness behavior results in a patient being released from roles, social expectations, or responsibilities. A homemaker views the "flu" as either an added stressor or a temporary release from child care and household responsibilities.

Variables Influencing Illness and Illness Behavior

Internal and external variables influence both health and health behavior and illness and illness behavior. The influences of these variables and a patient's illness behavior often affect the likelihood of seeking health care, adherence to therapy, and health outcomes. Plan individualized care based on an understanding of these variables and behaviors to help patients cope with their illness at various stages. The goal is to promote optimal functioning in all dimensions throughout an illness.

Internal Variables. Internal variables such as patient perceptions of symptoms and the nature of the illness influence patient behavior. If patients believe that the symptoms of their illnesses disrupt their normal routine, they are more likely to seek health care assistance than if they do not perceive the symptoms to be disruptive. Patients are also more likely to seek assistance if they believe the symptoms are serious or life threatening. Persons awakened by crushing chest pains in the middle of the night generally view this symptom as potentially serious and life threatening, and they will probably be motivated to seek assistance. However, such a perception can also have the opposite effect. Individuals may fear serious illness, react by denying it, and not seek medical assistance.

The nature of the illness, either acute or chronic, also affects a patient's illness behavior. Patients with acute illnesses are likely to seek health care and comply readily with therapy. On the other hand, a patient with a chronic illness in which symptoms are not cured but only partially relieved may not be motivated to adhere to the therapy plan. Some patients who are chronically ill become less actively involved in their care, experience greater frustration, and adhere less readily to care. Because nurses generally spend more time than other health care professionals with chronically ill patients, they are in the unique position of being able to help these patients overcome problems related to illness behavior. A patient's coping skills and his or her locus of control (the degree to which people believe they control what happens to them) are other internal variables that affect the way the patient behaves when ill (see Chapter 38).

External Variables. External variables influencing a patient's illness behavior include the visibility of symptoms, social group, cultural background, economic variables, accessibility of the health care system, and social support. The visibility of the symptoms of an illness affects body image and illness behavior. A patient with a visible symptom is often more likely to seek assistance than a patient with no visible symptoms.

Patients' social groups either assist in recognizing the threat of illness or support the denial of potential illness. Families, friends, and co-workers all potentially influence patients' illness behavior. Patients often react positively to social support while practicing positive health behaviors. A person's cultural background teaches the person how to be healthy, how to recognize illness, and how to be ill. The effects of disease and its interpretation vary according to cultural circumstances. For example, ethnic differences influence decisions about health care and the use of diagnostic and health care services. Dietary practices and cultural beliefs contribute to illness and disease maintenance (Giger, 2013).

Economic variables influence the way a patient reacts to illness. Because of economic constraints, some patients delay treatment and in many cases continue to carry out daily activities. Patients' access to the health care system is closely related to economic factors. The health

care system is a socioeconomic system that patients enter, interact within, and exit. For many patients entry into the system is complex or confusing, and some patients seek nonemergency medical care in an emergency department because they do not know how otherwise to obtain health services or do not have access to care. The physical proximity of patients to a health care agency often influences how soon they enter the system after deciding to seek care.

Impact of Illness on the Patient and Family

Illness is never an isolated life event. The patient and family deal with changes resulting from illness and treatment. Each patient responds uniquely to illness, requiring you to individualize nursing interventions. The patient and family commonly experience behavioral and emotional changes and changes in roles, body image and self-concept, and family dynamics.

Behavioral and Emotional Changes. People react differently to illness or the threat of illness. Individual behavioral and emotional reactions depend on the nature of an illness, a patient's attitude toward it, the reaction of others to it, and the variables of illness behavior.

Short-term, non–life-threatening illnesses evoke few behavioral changes in the functioning of a patient or family. For example, a father who has a cold lacks the energy and patience to spend time in family activities. He becomes irritable and prefers not to interact with his family. This is a behavioral change, but the change is subtle and does not last long. Some may even consider such a change a normal response to illness.

Severe illness, particularly one that is life threatening, leads to more extensive emotional and behavioral changes such as anxiety, shock, denial, anger, and withdrawal. These are common responses to the stress of illness. You can develop interventions to help a patient and family cope with and adapt to this stress when the stressor itself usually cannot be changed.

Impact on Body Image. Body image is the subjective concept of physical appearance (see Chapter 34). Some illnesses result in changes in physical appearance. Patients' and families' reactions differ and usually depend on the type of changes (e.g., loss of a limb or an organ), their adaptive capacity, the rate at which changes take place, and the support services available.

When a change in body image such as that which results from a leg amputation occurs, the patient generally adjusts in the following phases: shock, withdrawal, acknowledgment, acceptance, and rehabilitation. Initially the patient is in shock because of the change or impending change. He or she depersonalizes the change and talks about it as though it were happening to someone else. As the patient and family recognize the reality of the change, they become anxious and often withdraw, refusing to discuss it. Withdrawal is an adaptive coping mechanism that helps the patient adjust. As a patient and family acknowledge the change, they move through a period of grieving (see Chapter 37). At the end of the acknowledgment phase, they accept the loss. During rehabilitation the patient is ready to learn how to adapt to the change in body image through use of prosthesis or changing lifestyles and goals.

Impact on Self-Concept. Self-concept is a mental self-image of strengths and weaknesses in all aspects of personality. Self-concept depends in part on body image and roles but also includes other aspects of psychology and spirituality (see Chapters 34 and 36). The effect of illness on the self-concepts of patients and family members is usually more complex and less readily observed than role changes.

Self-concept is important in relationships with other family members. For example, a patient whose self-concept changes because of illness may no longer meet family expectations, leading to tension or conflict. As a result, family members change their interactions with the patient. In the course of providing care, you observe changes in the patient's self-concept (or in the self-concepts of family members) and develop a care plan to help them adjust to the changes resulting from the illness.

Impact on Family Roles. People have many roles in life such as wage earner, decision maker, professional, child, sibling, or parent. When an illness occurs, parents and children try to adapt to the major changes that result. Role reversal is common (see Chapter 10). If a parent of an adult becomes ill and cannot carry out usual activities, the adult child often assumes many of the parent's responsibilities and in essence becomes a parent to the parent. Such a reversal of the usual situation sometimes leads to stress, conflicting responsibilities for the adult child, or direct conflict over decision making.

Such a change may be subtle and short term or drastic and long term. An individual and family generally adjust more easily to subtle, short-term changes. In most cases they know that the role change is temporary and will not require a prolonged adjustment. However, long-term changes require an adjustment process similar to the grief process (see Chapter 37). The patient and family often require specific counseling and guidance to help them cope with role changes.

Impact on Family Dynamics. As a result of the effects of illness on the patient and family, family dynamics often change. Family dynamics are the processes by which the family functions, makes decisions, gives support to individual members, and copes with everyday changes and challenges. When a parent in a family becomes ill, family activities and decision making often come to a halt as the other family members wait for the illness to pass, or the family members delay action because they are reluctant to assume the ill person's roles or responsibilities. This often creates tension or anxiety in the family. Role reversal is also common. If a parent of an adult becomes ill and is unable to carry out usual activities, the adult child often becomes the family caregiver and assumes many of the parent responsibilities. Such reversal leads to conflict responsibilities for the adult child and often direct conflict over decision making. The nurse views the whole family as a patient under stress, planning care to help the family regain the maximal level of functioning and well-being (see Chapter 10).

CARING FOR YOURSELF

To be able to provide competent, quality and safe care, nurses need to take care of themselves to ensure they remain healthy. Nurses are particularly susceptible to the development of compassion fatigue, which is a combination of secondary traumatic stress (STS) and burnout (BO) (see Chapter 1). Secondary traumatic stress develops as a result of the relationships that nurses develop with their patients and families, whereas BO stems from conflicts or nurse job dissatisfaction within the work setting (Boyle, 2011; Potter et al., 2013a). Compassion fatigue frequently affects a nurse's health, often leading to a decline in health, changes in sleep and eating patterns, emotional exhaustion, irritability, restlessness, impaired ability to focus and engage with patients, feelings of hopelessness, inability to take pleasure from activities, and anxiety (Potter et al., 2013a). In the workplace the effects of compassion fatigue are often manifested by diminished performance, reduced ability to feel empathy, depersonalization of the patient, poor judgment, chronic absenteeism, high turnover rates, and conflict between nurses (Jenkins and Warren, 2012). It is important for nurses

to engage in personal and professional strategies to help combat compassion fatigue and promote resiliency.

Personal strategies focus on health-promoting behaviors and healthy lifestyle choices. In an effort to combat STS and BO, you need to eat a nutritious diet, get adequate sleep regularly, engage in regular exercise and relaxation activities, establish a good work-family balance, and engage in regular nonwork activities (Beck, 2011). Other strategies that can help you prevent or deal with STS and BO include developing coping skills, allowing personal time for grieving the loss of patients, and focusing on one's own spiritual health (Beck, 2011). Another strategy is to find a mentor or experienced nurse who understands the stress of the job and is able to help you identify coping strategies (Lombardo and Eyre, 2011).

An increasing number of health care institutions and organizations are offering educational programs for the nursing staff that are designed to help decrease compassion fatigue and increase resiliency (Flarity et al., 2013; Jenkins and Warren, 2012). These programs educate nurses about compassion fatigue and its negative effects and provide resources and tools for nurses to use to prevent or cope with STS and BO (Potter et al., 2013b). Participating in debriefing sessions or a compassion fatigue support group allows nurses to identify stressors and work as a group to develop healthy coping strategies (Beck, 2011; Boyle, 2011). Health care organizations need to also provide resources for nurses such as a mental health professional to provide assistance in managing STS and BO (Beck, 2011). It is important that organizations provide nurses with the education and resources needed to care for themselves.

KEY POINTS

- Health and wellness are not merely the absence of disease and illness.
- A person's state of health, wellness, or illness depends on individual values, personality, and lifestyle.
- Multiple models of health in which persons are active participants explain relationships among health beliefs, health behaviors, health promotion, and individual well-being.
- Health beliefs, practices, and illness behaviors are influenced by internal and external variables, and you need to consider them when planning care.
- Health promotion activities help maintain or enhance health, whereas wellness education teaches patients how to care for themselves.
- Illness prevention activities protect against health threats and thus maintain an optimal level of health.
- Nursing incorporates health promotion activities, wellness education, and illness prevention activities rather than simply treating illness.
- The three levels of preventive care are primary, secondary, and tertiary.
- Risk factors threaten health, influence health practices, and are important considerations in illness prevention activities.
- Improvement in health usually involves a change in health behaviors.
- The transtheoretical model of change describes a series of changes through which patients progress for successful behavior change rather than simply assuming that all patients are in an action stage.
- Illness has many effects on a patient and family, including changes in behavior and emotions, family roles and dynamics, body image, and self-concept.
- Using personal and professional strategies that focus on caring for self can help to decrease or prevent compassion fatigue.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Ms. Thom, age 46, works as an RN in the intensive care unit at a large busy medical center. Over the last three years she has gained 30 lbs and quit attending the fitness classes at the local recreation center. Her co-workers keep trying to get her to come back to fitness class, but she says that she is too tired after work and just wants to go home. She has smoked for 15 years, but says that she is trying to cut back on the number of cigarettes each day because she watched her mother die from emphysema. She has picked up some literature from Employee Health on smoking cessation. She was recently diagnosed with hypertension.

1. Using the health belief model, identify the modifying factors impacting Ms. Thom's likelihood of taking a preventive health action.
2. Which primary intervention activities are important for Ms. Thom?
3. Using the transtheoretical model of change, in which stage is Ms. Thom most likely related to her smoking? Explain your answer.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse is presenting a program to workers in a factory covering safety topics, including the wearing of hearing protectors when workers are in the factory. Which level of prevention is the nurse practicing?
   1. Primary prevention
   2. Secondary prevention
   3. Tertiary prevention
   4. Quaternary prevention
2. A patient had surgery for a total knee replacement a week ago and is currently participating in daily physical rehabilitation sessions at the surgeon's office. In what level of prevention is the patient participating?
   1. Primary prevention
   2. Secondary prevention
   3. Tertiary prevention
   4. Quaternary prevention
3. Based on the transtheoretical model of change, what is the most appropriate response to a patient who states: "Me, stop smoking? I've been smoking since I was 16!"
   1. "That's fine. Some people who smoke live a long life."
   2. "OK. I want you to decrease the number of cigarettes you smoke by one each day, and I'll see you in 1 month."
   3. "I understand. Can you think of the greatest reason why stopping smoking would be challenging for you?"
   4. "I'd like you to attend a smoking cessation class this week and use nicotine replacement patches as directed."
4. A patient comes to the local health clinic and states: "I've noticed how many people are out walking in my neighborhood. Is walking good for you?" What is the best response to help the patient through the stages of change for exercise?
   1. "Walking is OK. I really think running is better."
   2. "Yes, walking is great exercise. Do you think you could go for a 5-minute walk next week?"
   3. "Yes, I want you to begin walking. Walk for 30 minutes every day and start to eat more fruits and vegetables."

4. "They probably aren't walking fast enough or far enough. You need to spend at least 45 minutes if you are going to do any good."

5. A male patient has been laid off from his construction job and has many unpaid bills. He is going through a divorce from his marriage of 15 years and has been seeing his pastor to help him through this difficult time. He does not have a primary health care provider because he has never really been sick and his parents never took him to a physician when he was a child. Which external variables influence the patient's health practices? (Select all that apply.)
   1. Difficulty paying his bills
   2. Seeing his pastor as a means of support
   3. Age of patient (46 years)
   4. Stress from the divorce and the loss of a job
   5. Family practice of not routinely seeing a health care provider

6. A nurse is conducting a home visit with an older-adult couple. While in the home the nurse weighs each individual and reviews the 3-day food diary with them. She also checks their blood pressure and encourages them to increase their fluids and activity levels to help with their voiced concern about constipation. The nurse is addressing which level of need according to Maslow?
   1. Physiological
   2. Safety and security
   3. Love and belonging
   4. Self-actualization

7. When taking care of patients, a nurse routinely asks if they take any vitamins or herbal medications, encourages family members to bring in music that the patient likes to help the patient relax, and frequently prays with her patients if that is important to them. The nurse is practicing which model?
   1. Holistic
   2. Health belief
   3. Transtheoretical
   4. Health promotion

8. Using the Transtheoretical Model of Change, order the steps that a patient goes through to make a lifestyle change related to physical activity.
   1. The individual recognizes that he is out of shape when his daughter asks him to walk with her after school.
   2. Eight months after beginning walking, the individual participates with his wife in a local 5K race.
   3. The individual becomes angry when the physician tells him that he needs to increase his activity to lose 30 lbs.
   4. The individual walks 2 to 3 miles, 5 nights a week, with his wife.
   5. The individual visits the local running store to purchase walking shoes and obtain advice on a walking plan.

9. Which statement made by a nurse shows that the nurse is engaging in an activity to help cope with secondary traumatic stress and burnout?
   1. "I don't need time for lunch since I am not very hungry."
   2. "I am enjoying my quilting group that meets each week at my church."
   3. "I am going to drop my gym membership because I don't have time to go."
   4. "I don't know any of the other nurses who met today to discuss hospital-wide problems with nurse satisfaction."

10. Which of the following are symptoms of secondary traumatic stress and burnout that commonly affect nurses? (Select all that apply.)
    1. Regular participation in a book club
    2. Lack of interest in exercise
    3. Difficulty falling asleep
    4. Lack of desire to go to work
    5. Anxiety while working

11. After a class on Pender's health promotion model, students make the following statements. Which statement does the faculty member need to clarify?
    1. "The desired outcome of the model is health-promoting behavior."
    2. "Perceived self-efficacy is not related to the model."
    3. "The individual has unique characteristics and experiences that affect his or her actions."
    4. "Patients need to commit to a plan of action before they adopt a health-promoting behavior."

12. A patient registered at the local fitness center and purchased a pair of exercise shoes. The patient is in what stage of behavioral change?
    1. Precontemplation
    2. Contemplation
    3. Preparation
    4. Action

13. As part of a faith community nursing program in her church, a nurse is developing a health promotion program on breast self-examination for the women's group. Which statement made by one of the participants is related to the individual's perception of susceptibility to an illness?
    1. "I have a door hanging tag in my bathroom to remind me to do my breast self-examination monthly."
    2. "Since my mother had breast cancer, I know that I am at increased risk for developing breast cancer."
    3. "Since I am only 25 years of age, the risk of breast cancer for me is very low."
    4. "I participate every year in our local walk/run to raise money for breast cancer research."

14. The nurse assesses the following risk factors for coronary artery disease (CAD) in a female patient. Which factors are classified as genetic and physiological? (Select all that apply.)
    1. Sedentary lifestyle
    2. Mother died from CAD at age 48
    3. History of hypertension
    4. Eats diet high in sodium
    5. Elevated cholesterol level

15. Which activity shows a nurse engaged in primary prevention?
    1. A home health care nurse visits a patient's home to change a wound dressing.
    2. A nurse is assessing risk factors of a patient in the emergency department admitted with chest pain.
    3. A school health nurse provides a program to the first-year students on healthy eating.
    4. A nurse schedules a patient who had a myocardial infarction for cardiac rehabilitation sessions weekly.

Answers: 1. 1; **2.** 3; **3.** 4; **4.** 5; **5.** 1, 5; **6.** 1; **7.** 1; **8.** 3, 1, 5, 4, 2; **9.** 2; **10.** 2, 3, 4, 5; **11.** 2; **12.** 3; **13.** 2; **14.** 2, 3, 5; **15.** 3.

Caring in Nursing Practice

Caring is central to nursing practice, but it is even more important in today's hectic, high-tech health care environment. The demands, pressure, and time constraints in the health care environment leave little room for caring practice, which results in nurses and other health professionals becoming dissatisfied with their jobs and cold and indifferent to patient needs (Watson, 2009; 2010). Increasing use of technological advances for rapid diagnosis and treatment often causes nurses and other health care providers to perceive the patient relationship as less important. However, it is important to preserve a relationship-centered approach to patient care for all aspects of nursing, whether the care focuses on pain management, teaching self-care, or basic hygiene measures (Winsett and Hauck, 2011). Technological advances become dangerous without a context of skillful and compassionate care. Despite these challenges in health care, more professional organizations are stressing the importance of caring in health care and keeping the nurse engaged at the patient's bedside (RWJF, 2014). *Nursing's Agenda for the Future* (ANA, 2002) states that "Nursing is the pivotal health care profession highly valued for its specialized knowledge, skill, and caring in improving the health status of the individual, family, and the community." The American Organization of Nurse Executives (AONE, 2015) describes caring and knowledge as the core of nursing, with caring being a key component of what a nurse brings to a patient experience (Figure 7-1).

It is time to value and embrace caring practices and expert knowledge that are the heart of competent nursing practice (Benner et al., 2010). When you engage patients in a caring and compassionate manner, you learn that the therapeutic gain in caring makes enormous contributions to the health and well-being of your patients.

Have you ever been ill or experienced a problem requiring health care intervention? Think about that experience. Then consider the following two scenarios and select the situation that you believe most successfully demonstrates a sense of caring.

> A nurse enters a patient's room, greets the patient warmly while touching him or her lightly on the shoulder, makes eye contact, sits down for a few minutes and asks about the patient's thoughts and concerns, listens to the patient's story, looks at the intravenous (IV) solution hanging in the room, briefly examines the patient, and then checks the vital sign summary on the bedside computer screen before leaving the room.
>
> A second nurse enters the patient's room, looks at the IV solution hanging in the room, checks the vital sign summary sheet on the bedside computer screen, and acknowledges the patient but never sits down or touches him or her. The nurse makes eye contact from above while the patient is lying in bed. He or she asks a few brief questions about the patient's symptoms and leaves.

There is little doubt that the first scenario presents the nurse in specific acts of caring. The nurse's calm presence, parallel eye contact, attention to the patient's concerns, and physical closeness all express a patient-centered, comforting approach. In contrast, the second scenario is task-oriented and expresses a sense of indifference to patient concerns. Both of these scenarios take approximately the same amount of time but leave very different patient perceptions. It is important to remember that, during times of illness or when a person seeks the professional guidance of a nurse, caring is essential in helping the individual reach positive outcomes.

THEORETICAL VIEWS ON CARING

Caring is a universal phenomenon influencing the ways in which people think, feel, and behave in relation to one another. Since Florence Nightingale, nurses have studied caring from a variety of philosophical and ethical perspectives. A number of nursing scholars have developed theories on caring because of its importance to nursing practice. This chapter does not detail all of the theories of caring, but it is designed to help you understand how caring is at the heart of a nurse's ability to work with all patients in a respectful and therapeutic way.

Caring Is Primary

Benner offers nurses a rich, holistic understanding of nursing practice and caring through the interpretation of expert nurses' stories. After listening to nurses' stories and analyzing their meaning, she described the essence of excellent nursing practice, which is caring. The stories revealed the nurses' behaviors and decisions that expressed caring. Caring means that people, events, projects, and things matter to people (Benner and Wrubel, 1989; Benner et al., 2010). It is a word for being connected.

Caring determines what matters to a person. It underlies a wide range of interactions, from parental love to friendship, from caring for one's work to caring for one's pet, to caring for and about one's patients (Burtson and Stichler, 2010). Benner and Wrubel (1989) note: "Caring creates possibility." Personal concern for another person, an event, or a thing provides motivation and direction for people to care. Through caring, nurses help patients recover in the face of illness, give meaning to their illness, and maintain or reestablish connection. Understanding how to provide humanistic caring and **compassion** begins early in nursing education and continues to mature through experiential practice (Gallagher-Lepak and Kubsch, 2009).

Patients are not all the same. Each person brings a unique background of experiences, values, and cultural perspectives to a health care encounter. Caring is always specific and relational for each nurse-patient encounter. As nurses acquire more experience, they typically learn that caring helps them focus on the patients for whom they care. Caring facilitates a nurse's ability to know a patient, allowing the nurse to recognize a patient's problems and find and implement individualized solutions on the basis of the patient's unique needs, which is one of the primary objectives of using the nursing process.

Illness is a human experience. It impacts an individual's independent function, and the associated treatments disrupt a patient's lifestyle and social and family interactions. Expert nurses understand the differences among health, illness, and disease. Develop a caring relationship with your patients and listen to their stories to fully understand the meaning and impact of their condition. This information and understanding helps you provide individualized patient-centered care.

Leininger's Transcultural Caring

From a **transcultural** perspective, Madeleine Leininger (1991) describes the concept of care as the essence and central, unifying, and dominant domain that distinguishes nursing from other health disciplines (see Chapter 4). Care is an essential human need, necessary for the health and survival of all individuals. Care, unlike cure, helps an individual or group improve a human condition. Acts of caring refer to nurturing and skillful activities, processes, and decisions to assist people in ways that are empathetic, compassionate, and supportive. An act of caring depends on the needs, problems, and values of the patient. Leininger's studies of numerous cultures around the world found that care helps protect, develop, nurture, and provide survival to people. It is needed for people of all cultures to recover from illness and to maintain healthy life practices.

Leininger (1991) stresses how important it is for nurses to understand cultural caring behaviors. Even though human caring is a universal phenomenon, the expressions, processes, and patterns of caring vary among people of different cultures (Box 7-1). Caring is very personal; thus its expression differs for each patient. For caring to be effective, nurses need to learn culturally specific behaviors and words that reflect human caring in different cultures to identify and meet the needs of all patients (see Chapter 9). As nurses we care for patients from certain "subcultures" that have very unique needs (e.g., the chronically ill, physically disabled, developmentally challenged, foster children, the homeless). When caring for your patients, you must remember that a difference in culture does not always mean that a person is from a different country.

Watson's Transpersonal Caring

Caring is a central focus of nursing and it is integral to maintain the ethical and philosophical roots of the profession (Watson 2008; Lusk and Fater, 2013). Patients and their families expect a high quality of human interaction from nurses; however, unfortunately many conversations between patients and their nurses are very brief and disconnected. Many are not really "conversations," but rather simply the nurse reporting information to the patient and family. Watson's theory of caring is a holistic model for nursing that suggests that a conscious intention to care promotes healing and wholeness (Watson, 2008, 2010). It integrates the human caring processes with healing environments, incorporating the life-generating and life-receiving processes of human caring and healing for nurses and their patients (WCSI, 2014). The theory describes a consciousness that allows nurses to raise new questions about what it means to be a nurse, to be ill, and to be caring and healing. The transpersonal caring theory rejects the disease

orientation to health care and *places care before cure* (Watson, 2008). When the nurse focuses on transpersonal caring, he or she looks for deeper sources of inner healing to protect, enhance, and preserve a person's dignity, humanity, wholeness, and inner harmony (see also Chapter 4).

In Watson's view caring becomes almost spiritual. It preserves human dignity in the technological, cure-dominated health care

system (Watson, 2009). Creating caring-healing environments in the current high-tech health care system is crucial to establishing and maintaining the nurse-patient relationship (Jackson, 2012). In Watson's model the emphasis is on the nurse-patient relationship. The focus is on carative behaviors and the nurse-patient caring relationship (Table 7-1). A nurse communicates caring-healing to a patient through the nurse's consciousness. This takes place during a single caring moment between nurse and patient when a connection forms. The model is **transformative** because the relationship influences both the nurse and the patient for better or for worse (Watson, 2008, 2010). Caring-healing consciousness promotes healing. Application of Watson's caring model in practice enhances nurses' caring practices (Box 7-2).

Swanson's Theory of Caring

Kristen Swanson (1991) studied patients and professional caregivers in an effort to develop a theory of caring for nursing practice. This theory of caring was developed from three perinatal studies involving interviews with women who miscarried, parents and health care professionals in a newborn intensive care unit, and socially at-risk mothers who received long-term public health intervention (Swanson, 1999). After analyzing the stories and descriptions of the three groups, Swanson developed a theory of caring, which includes five caring processes (Table 7-2). Swanson (1991) defines caring as a nurturing way of relating to an individual (i.e., when one feels a personal sense of commitment and responsibility). The theory provides direction for how to develop useful and effective caring strategies appropriate for multiple age-group and health care settings (Andershed and Olsson, 2009). It supports the claim that caring is a central nursing phenomenon but not necessarily unique to nursing practice.

Summary of Theoretical Views

Nursing caring theories have common themes. Duffy et al. (2007) identify these commonalities as human interaction or communication, mutuality, appreciating the uniqueness of individuals, and improving

---

🌐 BOX 7-1   CULTURAL ASPECTS OF CARE

Nurse Caring Behaviors

Caring includes knowing a patient's cultural values and beliefs. Although the need for human caring is universal, its application is influenced by cultural norms. As a result, expectations may change across cultures (Kelley et al., 2013; Suliman et al., 2009). For example, providing time for family presence is often more valuable than a nursing presence. Using touch to convey caring sometimes crosses cultural norms. Sometimes a gender-congruent caregiver or the patient's family needs to provide caring touch. When listening to a patient, remember that some cultures view eye contact as disrespectful.

Implications for Patient-Centered Care
- Know the patient's beliefs and attitudes regarding health care and caring practices.
- Know the patient's cultural practices regarding end-of-life care. In some cultures it is considered insensitive to tell the patient that he or she is dying (Maroon, 2012).
- Determine if a member of the patient's family or cultural group is the best resource to guide the use of caring practices such as providing presence or touching (Lusk and Fater, 2013).
- Know the patient's cultural practices regarding the removal of life support (Maroon, 2012).
- Know the patient's cultural practices regarding care of the body after death.

TABLE 7-1   Watson's 10 Carative Factors (Watson, 2008)

Carative Factor	Example in Practice
Forming a human-altruistic value system	Use loving kindness to extend yourself. Use self-disclosure appropriately to promote a therapeutic alliance with your patient (e.g., share a personal experience in common with your patient such as a childrearing experience, an illness, or an experience with a parent who needs assistance).
Instilling faith-hope	Provide a connection with the patient that offers purpose and direction when trying to find the meaning of an illness.
Cultivating a sensitivity to one's self and to others	Learn to accept yourself and others for their full potential. A caring nurse matures into becoming a self-actualized nurse.
Developing a helping, trusting, human caring relationship	Learn to develop and sustain helping, trusting, authentic caring relationships through effective communication with your patients.
Promoting and expressing positive and negative feelings	Support and accept your patients' feelings. In connecting with your patients you show a willingness to take risks in sharing in the relationship.
Using creative problem-solving, caring processes	Apply the nursing process in systematic, scientific problem-solving decision making in providing patient-centered care.
Promoting transpersonal teaching-learning	Learn together while educating the patient to acquire self-care skills. The patient assumes responsibility for learning.
Providing for a supportive, protective, and/or corrective mental, physical, societal, and spiritual environment	Create a healing environment at all levels, physical and nonphysical. This promotes wholeness, beauty, comfort, dignity, and peace.
Meeting human needs	Help patients with basic needs with an intentional care and caring consciousness.
Allowing for existential-phenomenological-spiritual forces	Allow spiritual forces to provide a better understanding of yourself and your patient.

BOX 7-2   EVIDENCE-BASED PRACTICE

Enhancing Caring

PICO Question: Do patient satisfaction scores among hospitalized adult patients improve when carative nursing practices are used?

Evidence Summary

Patient satisfaction is an important indicator for the quality of health care received. Caring practices facilitate healing and improve patient satisfaction with nursing care (Palese et al., 2011; Zolnierek, 2014). Caring behaviors were integrated into a nursing care model in multiple European hospitals; and researchers wanted to determine if (1) there were any correlations between caring and patient satisfaction; (2) there were any differences across countries; and (3) did caring behaviors affect patient satisfaction. Caring behaviors, especially those of connectedness, presence, and respect, highly correlated with patient satisfaction; and there were no differences across countries. Nurses' knowledge and skill level were expectations of care and did not correlate with patient satisfaction scores (Palese et al., 2011). Carative nursing practices improve and solidify the nurse-patient relationship and contribute to patient-centered care and patient satisfaction measures (Dobrina et al., 2014; Lusk and Fater, 2013).

Application to Nursing Practice

- Use caring nursing practices to design a wholistic approach for individualized patient-centered care (Maroon, 2012).
- Use caring practices of listening, presence, and connectedness to partner with the patient and family through their illness. Use these practices with humility, love, kindness, and compassion (Dobrina et al., 2014).
- Knowing the patient enables a nurse to partner with a patient and family to obtain vital health care information, understand the patient's expectation and fears, and identify health care priorities. Knowing the patient is continuous, and the nurse must use every patient interaction to "know" the patient better (Kelley et al., 2013; Zolinierek, 2014).
- Being with and doing for a patient are components of presence, whether it is a dedicated one-on-one interaction during a nursing shift or quietly sitting with a patient (Drenkard, 2008; Yagasaki and Komatsu, 2013). Presence often helps elicit important health care information from a patient and reduces patient fears and anxiety.

TABLE 7-2   Swanson's Theory of Caring (Swanson, 1991)

Caring Process	Definitions	Subdimensions
Knowing	Striving to understand an event as it has meaning in the life of the other	Avoiding assumptions Centering on the one cared for Assessing thoroughly Seeking clues to clarify the event Engaging the self or both
Being with	Being emotionally present to the other	Being there Conveying ability Sharing feelings Not burdening
Doing for	Doing for the other as he or she would do for self if it were at all possible	Comforting Anticipating Performing skillfully Protecting Preserving dignity
Enabling	Facilitating the other's passage through life transitions (e.g., birth, death) and unfamiliar events	Informing/explaining Supporting/allowing Focusing Generating alternatives Validating/giving feedback
Maintaining belief	Sustaining faith in the other's capacity to get through an event or transition and face a future with meaning	Believing in/holding in esteem Maintaining a hope-filled attitude Offering realistic optimism "Going the distance"

the welfare of patients and their families. Caring is highly relational. A nurse and patient enter into a relationship that is much more than one person simply "doing tasks for" another. There is a mutual give-and-take that develops as nurse and patient begin to know and care for one another (Jackson, 2012; Parcells and Locsin, 2011). Caring theories are valuable when assessing patient perceptions of being cared for in a multicultural environment (Suliman et al., 2009). Frank (1998) described a personal situation when he was suffering from cancer: "What I wanted when I was ill was a mutual relationship of *people* who were also clinician and patient." It was important for Frank to be seen as one of two fellow human beings, not the dependent patient being cared for by the expert technical clinician.

Caring seems highly invisible at times when a nurse and patient enter a relationship of respect, concern, and support. A nurse's empathy and compassion become a natural part of every patient encounter. However, when caring is absent, it becomes very obvious. For example, if a nurse shows disinterest or chooses to avoid a patient's request for help, his or her inaction quickly conveys an uncaring attitude. Benner and Wrubel (1989) relate the story of a clinical nurse specialist who learned from a patient what caring is

all about: "I felt that I was teaching him a lot, but actually he taught me. One day he said to me (probably after I had delivered some well-meaning technical information about his disease), 'You're doing an OK job, but I can tell that every time you walk in that door you're walking out.'" In this nurse's story the patient perceived that the nurse was simply going through the motions of teaching and showed little caring toward the patient. Patients quickly know when nurses fail to relate to them.

As you practice caring, your patient will sense your commitment and willingness to enter into a relationship that allows you to understand his or her experience of illness. In a study of patients receiving oral chemotherapy, patients noted that it was essential for nurses to develop a partnership and connect with them, to be attentive, and be proactive in providing committed patient support (Yagasaki and Komatsu, 2013). Thus the nurse becomes a coach and partner rather than a detached provider of care.

One aspect of caring is enabling, when a nurse and patient work together to identify alternatives in approaches to care and resources. Consider a nurse working with a patient recently diagnosed with diabetes mellitus who must learn how to administer daily insulin injections. The nurse enables the patient by providing instruction in a manner that allows the patient to successfully modify lifestyle to incorporate diabetes self-management strategies such as medication administration, exercise, and changes in diet.

Another common theme of caring is to understand the context of a person's life and illness. It is difficult to show caring for another

TABLE 7-3 Comparison of Research Studies Exploring Nurse Caring Behaviors (As Perceived by Patients)

Surgical Patient Satisfaction As an Outcome of Nurses' Caring Behaviors: a Descriptive and Correlational Study in Six European Countries (Palese et al., 2011)	Information Needed to Support Knowing the Patient (Kelley et al., 2013)	The Need for a Nursing Presence in Oral Chemotherapy (Yagasaki and Komatsu, 2013)
Caring behaviors and patient satisfaction are intertwined. Major caring factors associated with patient satisfaction follow. Connecting (connectedness) with patients and their families allows them to tell their health care story. Being present (presence) shows time, interest, and caring. Respecting the patient's values, beliefs, and health care choices further solidifies the nurse patient relationship. Although nurses' knowledge and skill level is an expectation of patient-centered care, it alone does not impact patient satisfaction.	Knowing the patient is an essential element of caring nursing practice. How the nurse obtains the information needed to support knowing the patient is crucial in establishing and maintaining caring practice. Displaying compassion and patience is important. Developing patient-nurse trust and responsiveness to the patient is critical to collecting clinical and personal information so the nurse can better know and understand the patient's health care story and expectations for care, identify and correct for missing information, and design individualized care.	Nursing presence contributes to knowing the patient. Illness and treatments often cause major changes in a patient's lifestyle. Nursing presence for patients receiving oral chemotherapy is as important as identifying those patients at risk for nonadherence. It is the nursing presence that provides emotional and knowledge-based support for patients who are new to or receiving additional oral chemotherapy.

individual without gaining an understanding of who the person is and his or her perception of the illness. Exploring the following questions with your patients helps you understand their perceptions of illness: How was your illness first recognized? How do you feel about the illness? How does your illness affect your daily life practices? Knowing the context of a patient's illness helps you choose and individualize interventions that will actually help the patient. This approach is more successful than simply selecting interventions on the basis of your patient's symptoms or disease process.

PATIENTS' PERCEPTIONS OF CARING

Theories of caring provide an excellent beginning to understanding the behaviors and processes that characterize caring. Researchers have explored nurse caring behaviors as perceived by patients (Table 7-3). Their findings emphasize what patients expect from their caregivers and thus provide useful guidelines for your practice. Patients continue to value nurses' effectiveness in performing tasks; but clearly patients value the affective dimension of nursing care. When we talk about the art and science of nursing, caring is a significant part of the art of nursing.

The study of patients' perceptions is important because health care is placing greater emphasis on patient satisfaction (see Chapter 2). Health care consumers can search online for specific information about health care agencies with regard to their ratings by patients in various areas of performance. The Caring Assessment Tool (CAT) was developed to measure caring from a patient's perspective (Duffy et al., 2007). This tool and other caring assessments help you, as a beginning professional, to appreciate the type of behaviors that hospitalized patients identify as caring. When patients sense that health care providers are sensitive, sympathetic, compassionate, and interested in them as people, they usually become active partners in the plan of care (Gallagher-Lepak and Kubsch, 2009). Suliman et al. (2009) studied the impact of Watson's caring theory as an assessment framework in a multicultural environment. Patients in the study indicated that they did not perceive any cultural bias when they perceived nurses to be caring. As institutions strive to improve patient satisfaction, creating an environment of caring is a necessary and worthwhile goal. Patient

satisfaction with nursing care is an important factor in a patient's decision to return to a specific health care facility.

As you begin clinical practice, consider how patients perceive caring and the best approaches to provide care. Behaviors associated with caring offer an excellent starting point. It is also important to determine an individual patient's perceptions and unique expectations. Frequently patients and nurses differ in their perceptions of caring. For that reason focus on building a relationship that allows you to learn what is important to your patients (Gallagher-Lepak and Kubsch, 2009). For example, your patient is fearful of having an intravenous catheter inserted, and you are still a novice at catheter insertion. Instead of giving a lengthy description of the procedure to relieve anxiety, you decide that the patient will benefit more if you obtain assistance from a skilled staff member. Knowing your patients helps you select caring approaches that are most appropriate to their needs.

ETHIC OF CARE

Caring is a moral imperative, not a commodity to be bought and sold. Caring for other human beings protects, enhances, and preserves human dignity. It is a professional, ethical covenant that nursing has with its public (Watson, 2010). Caring science provides a disciplinary foundation from which you deliver patient-centered care. Chapter 22 explores the importance of ethics in professional nursing. The term *ethic* refers to the ideals of right and wrong behavior. In any patient encounter a nurse needs to know what behavior is ethically appropriate. An ethic of care is unique so professional nurses do not make professional decisions based solely on intellectual or analytical principles. Instead, an ethic of care places caring at the center of decision making. For example, which resources should be used to care for an indigent patient? Is it caring to place a terminally ill patient on a ventilator or a disabled relative in a long-term care facility?

An **ethic of care** is concerned with relationships between people and with a nurse's character and attitude toward others. Nurses who function from an ethic of care are sensitive to unequal relationships that lead to an abuse of one person's power over another—intentional or otherwise. In health care settings patients and families are often on unequal footing with professionals because of a patient's illness, lack

of information, regression caused by pain and suffering, and unfamiliar circumstances. An ethic of care places the nurse as the patient's advocate, solving ethical dilemmas by attending to relationships and giving priority to each patient's unique personhood.

CARING IN NURSING PRACTICE

It is impossible to prescribe ways that guarantee whether or when a nurse becomes a caring professional. Experts disagree as to whether caring is teachable or more fundamentally a way of being in the world. For those who find caring a normal part of their lives, it is a product of their culture, values, experiences, and relationships with others. People who do not experience care in their lives often find it difficult to act in caring ways. As you deal with health and illness in your practice, you grow in your ability to care and develop caring behaviors. We learn from our patients. Our patients tell us that a simple touch, a simple phrase (e.g., "I'm here") or a promise to remain at the bedside represent caring and compassion (Engle, 2010).

Caring is one of those human behaviors that we can give and receive. As a nurse it is important to assess both your caring needs and your caring behaviors. Recognize the importance of nurses' self-care (see Chapters 1 and 6). You cannot give fully engaged, compassionate care when you feel depleted or uncared for. Take time to recognize stressors and reach out to colleagues and family and friends for help in coping with these stressors. Use caring behaviors to reach out to your colleagues and care for them as well (Jackson, 2012). Whether you are giving or receiving care, the value of caring in your nursing practice benefits your patients, your colleagues, and your health care agency.

Providing Presence

In today's high-tech health care environment in which patients are discharged quickly from hospitals, nursing practice and patient satisfaction improves when "nursing presence" is part of the health care culture (Yagasaki and Komatsu, 2013). Providing **presence** is a person-to-person encounter conveying a closeness and sense of caring. Presence involves "being there" and "being with." "Being there" is not only a physical presence; it also includes communication and understanding. Nursing presence is the connectedness between the nurse and the patient (Kostovich, 2012).

Presence is an interpersonal process that is characterized by sensitivity, wholism, intimacy, vulnerability, and adaptation to unique circumstances. It results in improved mental well-being for nurses and patients and improved physical well-being in patients (Finfgeld-Connett, 2008). The interpersonal relationship of "being there" depends on the fact that a nurse is attentive to the patient. Presence translates into an actual caring art that affects the healing and well-being of both the nurse and patient. Nurses use presence in conjunction with other nursing interventions such as establishing the nurse-patient relationship, providing comfort measures, providing patient education, and listening (Kostovich, 2012). The outcomes of nursing presence include alleviating suffering, decreasing a sense of isolation and vulnerability, and personal growth (Lai and Lee, 2012). This type of presence is something you offer to each patient in achieving patient care goals.

"Being with" is also interpersonal. A nurse gives of himself or herself, which means being available and at a patient's disposal. If a patient accepts a nurse, the patient will invite the nurse to see, share, and touch his or her vulnerability and suffering. One's human presence never leaves one unaffected (Watson, 2010). The nurse then enters the patient's world. In this presence the patient is able to put words to feelings and understand himself or herself in a way that leads to identifying solutions, seeing new directions, and making choices.

When a nurse establishes presence, eye contact, body language, voice tone, listening, and a positive and encouraging attitude act together to create openness and understanding. Establishing presence enhances a nurse's ability to learn from patients, including their hopes, dreams, need for support, and expectations of care. Learning from a patient strengthens a nurse's ability to provide adequate and appropriate nursing care (Dobrina et al., 2014).

It is especially important to establish presence and caring when patients are experiencing stressful events or situations. Awaiting a physician's report of test results, preparing for an unfamiliar procedure, and planning for a return home after serious illness are just a few examples of events in the course of a person's illness that can create unpredictability and dependency on care providers. A nurse's presence and caring help to calm anxiety and fear related to stressful situations. Giving reassurance and thorough explanations about a procedure, remaining at the patient's side, and coaching the patient through the experience all convey a presence that is invaluable to a patient's well-being.

Touch

Patients face situations that are embarrassing, frightening, and painful. Whatever the feeling or symptom, they look to nurses to provide comfort. The use of touch is one **comforting** approach that reaches out to patients to communicate concern and support (Busch et al., 2012).

Touch is relational and leads to a connection between nurse and patient. It involves contact and noncontact touch. Contact touch involves obvious skin-to-skin contact, whereas noncontact touch refers to eye contact. It is difficult to separate the two. Both in turn are providing a connectedness between a patient and nurse (Palese et al., 2011; Jackson, 2012). Before implementing touch be aware of your patient's cultural practices and past experiences. For some people a simple touch on the arm may be perceived as invasive, and for victims of abuse a simple touch may be perceived as a threat.

Nurses use task-oriented touch when performing a task or procedure. The skillful and gentle performance of a nursing procedure conveys security and a sense of competence. An expert nurse learns that any procedure is more effective when it is explained and administered carefully and in consideration of any patient concern. For example, if a patient is anxious about having a procedure such as the insertion of a nasogastric tube, offer comfort through a full explanation of the procedure and what the patient will feel. Then perform the procedure safely, skillfully, and successfully. This is done as you prepare the supplies, position the patient, and gently manipulate and insert the nasogastric tube. Throughout a procedure talk quietly with the patient to provide reassurance and support.

Caring touch is a form of nonverbal communication, which successfully influences a patient's comfort and security, enhances self-esteem, increases confidence of the caregivers, and improves mental well-being (Gillespie et al., 2012). You express this in the way you hold a patient's hand, give a back massage, gently position a patient, or participate in a conversation. When using a caring touch, you connect with the patient physically and emotionally.

Protective touch is a form of touch that protects a nurse and/or patient (Fredriksson, 1999). The patient views it either positively or negatively. The most obvious form of protective touch is preventing an accident (e.g., holding and bracing the patient to avoid a fall). Protective touch can also protect a nurse emotionally. A nurse withdraws or distances herself or himself from a patient when he or she is unable to tolerate suffering or needs to escape from a situation that is causing tension. When used in this way, protective touch elicits negative feelings in a patient (Fredriksson, 1999).

Because touch conveys many messages, use it with discretion. Touch itself is a concern when crossing cultural boundaries of either the patient or the nurse (Benner et al., 2010). Patients generally permit task-orientated touch because most individuals give nurses and physicians a license to enter their personal space to provide care (see Box 7-1). Know and understand if patients accept touch and how they interpret your intentions.

Listening

Caring involves an interpersonal interaction that is much more than two people simply talking back and forth (Bunkers, 2010). Listening is a critical component of nursing care and is necessary for meaningful interactions with patients. It is a planned and deliberate act in which the listener is present and engages the patient in a nonjudgmental and accepting manner. It includes "taking in" what a patient says, interpreting and understanding what the patient is saying, and then giving back that understanding to the patient. Listening to the meaning of what a patient says helps create a mutual relationship. True listening leads to knowing and responding to what really matters to the patient and family.

When an individual becomes ill, he or she usually has a story to tell about the meaning of the illness. Any critical or chronic illness affects all of a patient's life choices and decisions, and sometimes the individual's identity. Being able to tell that story helps the patient break the distress of illness. Thus a story needs a listener. Frank (1998) described his own feelings during his experience with cancer: "I needed a [health care professional's] gift of listening in order to make my suffering a relationship between *us,* instead of an iron cage around *me.*" He needed to be able to express what he needed when he was ill. The personal concerns that are part of a patient's illness story determine what is at stake for the patient. Caring through listening enables you to become a participant in the patient's life.

To listen effectively you need to silence yourself and listen with openness (Fredriksson, 1999). Fredriksson describes silencing one's mouth and also the mind. It is important to remain intentionally silent and concentrate on what the patient has to say. Give patients your full, focused attention as they tell their stories.

When an ill person chooses to tell his or her story, it involves reaching out to another human being. Telling the story implies a relationship that develops only if the clinician exchanges his or her stories as well. Frank (1998) argues that professionals do not routinely take seriously their own need to be known as part of a clinical relationship. Yet, unless the professional acknowledges this need, there is no reciprocal relationship, only an interaction. There is pressure on a clinician to know as much as possible about a patient, but it isolates the clinician from the patient. By contrast, in knowing and being known, each supports the other.

Through active listening you begin to truly know your patients and what is important to them (Bunkers, 2010). Learning to listen to a patient is sometimes difficult. It is easy to become distracted by tasks at hand, colleagues shouting instructions, or other patients waiting to have their needs met. However, the time you take to listen effectively is worthwhile, in both the information gained and the strengthening of the nurse-patient relationship. Listening involves paying attention to the individual's words and tone of voice and entering his or her frame of reference (see Chapter 24). By observing the expressions and body language of the patient, you find cues to help the patient explore ways to achieve greater peace.

Knowing the Patient

Knowing the patient is a complex process with a temporal nature that occurs within the context of the nurse-patient relationship (Zolnierek,

2014). It is an essential element of nursing practice and is linked to patient satisfaction and successful outcomes of care (Kelley et al., 2013). One of the five caring processes described by Swanson (1991) is knowing the patient. Knowing the patient comprises both a nurse's understanding of a specific patient and his or her subsequent selection of interventions. It is essential when providing patient-centered care. Knowing emerges from a caring relationship between a nurse and a patient, in which the nurse engages in a continuous assessment, striving to understand and interpret the patient's needs across all dimensions (Kelley et al., 2013).

Two elements that facilitate knowing are continuity of care and clinical expertise. When patient care is fragmented, knowing the patient declines, and patient-centered care is compromised (Zolinierek, 2014). Knowing develops over time as a nurse learns the clinical conditions within a specialty and the behaviors and physiological responses of patients. Intimate knowing helps the nurse respond to what really matters to the patient. To know a patient means that a nurse avoids assumptions, focuses on the patient, and engages in a caring relationship with the patient that reveals information and cues that facilitate critical thinking and clinical judgments (see Chapter 15). Knowing the patient is at the core of the clinical decision-making process.

Factors that contribute to knowing the patient include time, continuity of care, teamwork of the nursing staff, trust, and experience. Barriers to knowing the patient are often related to the organizational structure of the organization and economic constraints. Organizational changes often result in decreasing the amount of time that registered nurses are able to spend with their patients, which in turn affects the nurse-patient relationships. Decreased length of stay also reduces the interactions' between nurses and their patients (Zolnierek, 2014).

Consequences of not knowing the patient are many. For example, in the acute care setting, not knowing the patient contributes to risk for falls and actual falls. Patients and their families don't understand the complexities of treatment and their participation in care (Kelley et al., 2013). Finally, patients do not adequately understand their discharge guidelines and may administer their home medications or treatments incorrectly. A caring nurse-patient relationship helps you to better know the patient as a unique individual and choose the most appropriate and efficacious nursing therapies (WCSI, 2014).

A caring relationship coupled with your growing knowledge and experience provides a rich source of meaning when changes in a patient's clinical status occur. Expert nurses develop the ability to detect changes in patients' conditions almost effortlessly (Benner et al., 2010). Clinical decision making, perhaps the most important responsibility of a professional nurse, involves various aspects of knowing the patient: responses to therapies, routines and habits, coping resources, physical capacities and endurance, and body typology and characteristics. Experienced nurses know additional facts about their patients such as their experiences, behaviors, feelings, and perceptions (Benner et al., 2010). You will achieve improved patient satisfaction and patient health outcomes when you make clinical decisions accurately in the context of knowing a patient well (Zolnierek, 2014). When you base care on knowing a patient, the patient perceives care as personalized, comforting, supportive, and healing.

The most important thing for a beginning nurse to recognize is that knowing a patient is more than simply gathering data about the patient's clinical signs and condition. Success in knowing the patient lies in the relationship you establish. To know a patient is to enter into a caring, social process that also includes interaction with members of the health care team, which results in a deep nurse-patient relationship whereby the patient comes to feel known by the nurse (Kelley et al., 2013).

FIGURE 7-2 Nurse discusses patient's health care needs with the family.

Relieving Symptoms and Suffering

Relieving symptoms such as pain and nausea and suffering is more than giving pain medications, repositioning the patient, cleaning a wound, or providing end-of-life care. The relief of symptoms and suffering encompasses caring nursing actions that give a patient comfort, dignity, respect, and peace and provide necessary comfort and support measures to the family or significant others (Maroon, 2012). Ensuring that the patient care environment is clean and pleasant and includes personal items makes the physical environment a place that soothes and heals the mind, body, and spirit (Gallagher-Lepak and Kubsch, 2009). This is a responsibility of a professional nurse and not a task automatically delegated to nursing assistive personnel. Always be aware of your patient's environment, assess symptoms thoroughly, and take the necessary steps to make the environment comfortable.

Through skillful and accurate assessment of a patient's level and type of pain or other symptoms, you are able to design patient-centered care to improve the patient's level of comfort. There are multiple interventions for pain relief (see Chapter 44) and approaches for relieving nausea or fatigue. However, knowing about the patient and the meaning of his or her symptoms guides your care. Often conveying a quiet caring presence, touching a patient, or listening helps you to assess and understand the meaning of your patient's discomfort. The caring presence helps you and your patient design goals for symptom relief.

Human suffering is multifaceted, affecting a patient physically, emotionally, socially, and spiritually. It also affects a patient's family and friends. You may find yourself working with a young family whose newborn baby has multiple developmental challenges. Their emotional suffering encompasses anger, guilt, fear, or grief. You cannot fix it, but you can provide comfort through a listening, nonjudgmental caring presence. Patients and their families are comforted by a caring listener.

Family Care

People live in their worlds in an involved way. Each person experiences life through relationships with others. Thus caring for an individual cannot occur in isolation from that person's family. As a nurse it is important to know the family almost as thoroughly as you know a patient (Maroon, 2012). The family is an important resource (Figure 7-2). Success with nursing interventions often depends on their willingness to share information about the patient, their acceptance and understanding of therapies, whether the interventions fit with their daily practices, and whether they support and deliver the therapies recommended.

Spiritual Caring

An individual achieves spiritual health after finding a balance between his or her own life values, goals, and belief systems and those of others (see Chapter 36). An individual's beliefs and expectations affect his or her own physical well-being.

Research shows that nurses who develop spiritual caring practices early in their career development are able to identify methods to incorporate these practices into routine care and do not perceive variables such as a lack of sufficient time or patient census as barriers (Ronaldson et al., 2012). Establishing a caring relationship with a patient involves interconnectedness between the nurse and the patient. This interconnectedness is why Watson (2008, 2010) describes the caring relationship in a spiritual sense. Spirituality offers a sense of connectedness: intrapersonally (connected with oneself), interpersonally (connected with others and the environment), and transpersonally (connected with the unseen, God, or a higher power). In a caring relationship the patient and the nurse come to know one another so both move toward a healing relationship by (Watson, 2010; WCSI, 2014):

- Mobilizing hope for the patient and the nurse.
- Finding an interpretation or understanding of illness, symptoms, or emotions that is acceptable to the patient.
- Assisting the patient in using social, emotional, or spiritual resources.
- Recognizing that caring relationships connect us human to human, spirit to spirit.

BOX 7-3   Nurse Caring Behaviors as Perceived by Families

- Providing honest, clear, and accurate information
- Listening to patient and family concerns, complaints, fears
- Advocating for patient's care preferences and end-of-life decisions
- Asking permission before doing something to a patient
- Providing comfort (e.g., offering warm blanket, rubbing a patient's back)
- Reading patient passages from religious texts, favorite book, cards, or mail
- Providing for and maintaining patient privacy
- Informing the patient about the types of nursing services and the people who may enter the personal care area
- Assuring the patient that nursing services will be available
- Helping patients do as much for themselves as possible
- Teaching the family how to keep the relative physically comfortable

Data from Maroon, AM: Ethical palliative family nursing care: a new concept of caring for patients and families, *JONA's Healthc Law Ethics Regul* 14(4):115, 2012; Lusk JM, Fater K: A concept analysis of patient-centered care, *Nurs Forum* 48(2):89, 2013.

Families of patients with cancer perceived many nurse caring behaviors to be most helpful (Box 7-3). It is critical that a nurse ensures the patient's well-being and safety and helps the family members to be active participants (AONE, 2015). Although specific to families of patients with cancer, these behaviors offer useful guidelines for developing a caring relationship with all families. Begin a relationship by learning who makes up the patient's family and their roles in the patient's life. Showing a family that you care for and are concerned about the patient creates an openness that then enables a relationship to form with a family. Caring for the family takes into consideration the context of the patient's illness and the stress it imposes on all members (see Chapter 10).

THE CHALLENGE OF CARING

Assisting individuals during a time of need is the reason many enter nursing. When you are able to affirm yourself as a caring individual, your life achieves a meaning and purpose (Benner et al., 2010). Caring is a motivating force for people to become nurses, and it becomes a source of satisfaction when nurses know that they have made a difference in their patients' lives.

Today's health care system presents many challenges for the nurse to provide a caring patient-centered plan of care (Lusk and Fater, 2013). Nurses are often torn between the human caring model and the task-oriented biomedical model and institutional demands that consume their practice (Winsett and Hauck, 2011). They have increasingly less time to spend with patients, making it much harder to know who they are. A reliance on technology and cost-effective health care strategies and efforts to standardize and refine work processes all undermine the nature of caring. Too often patients become just a number, with their real needs either overlooked or ignored.

The American Nurses Association (ANA), National League for Nursing (NLN), American Organization of Nurse Executives (AONE), and American Association of Colleges of Nursing (AACN) recommend strategies to reverse the current nursing shortage. A number of these strategies have potential for creating work environments that enable nurses to demonstrate more caring behaviors. In addition, the Robert Wood Johnson Foundation's "Future of Nursing: Campaign for Action" is identifying methods to improve both patient care and satisfaction and nurse job satisfaction. This campaign is focusing on increasing the amount of time nurses actually spend with their patients and families. Environmental factors promote a more artful nursing and caring presence that further enhances patient-centered care. Strategies include greater emphasis on improving the work environment to facilitate more nurse-patient interaction, improving nurse staffing, providing nurses with autonomy over their practice, and promoting increased educational requirements and opportunities (RWJF, 2014).

If health care is to make a positive difference in their lives, patients cannot be treated like machines or robots. Instead health care must become more wholistic and humanistic. Nurses play an important role in making caring an integral part of health care delivery. This begins by making it a part of the philosophy and environment in the workplace. Incorporating caring concepts into standards of nursing practice establishes the guidelines for professional conduct. Finally, during day-to-day practice with patients and families, nurses need to be committed to caring and willing to establish the relationships necessary for personal, competent, compassionate, and meaningful nursing care. "Consistent with the wisdom and vision of Nightingale, nursing is a lifetime journey of caring and healing, seeking to understand and preserve the wholeness of human existence and to offer compassionate, informed knowledgeable human caring …" (Watson, 2009).

KEY POINTS

- Caring is the heart of a nurse's ability to work with people in a respectful and therapeutic way.
- Caring is specific and relational for each nurse-patient encounter.
- For caring to achieve cure, nurses need to learn the culturally specific behaviors and words that reflect human caring in different cultures.
- Because illness is the human experience of loss or dysfunction, any treatment or intervention given without consideration of its meaning to the individual is likely to be worthless.
- Caring involves a mutual give-and-take that develops as nurse and patient begin to know and care for one another.
- Presence involves a person-to-person encounter that conveys closeness and a sense of caring that involves "being there" and "being with" patients.
- Research shows that touch, both contact and noncontact, includes task-orientated touch, caring touch, and protective touch.
- The skillful and gentle performance of a nursing procedure conveys security and a sense of competence in the nurse.
- Listening is not only "taking in" what a patient says; it also includes interpreting and understanding what the patient is saying and giving back that understanding.
- Knowing the patient is at the core of the process that nurses use to make clinical decisions.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Mrs. Lowe is a 52-year-old patient being treated for lymphoma (cancer of the lymph nodes) that occurred 6 years after a lung transplant. Mrs. Lowe is discouraged about her current health status and has a lot of what she describes as muscle pain. The unit where Mrs. Lowe is receiving care has a number of very sick patients and is short staffed.
   a. You enter her room to do a morning assessment and find Mrs. Lowe crying. How are you going to use caring practices to help her, knowing that your day has just begun and you have many nursing interventions to complete?

b. When you listen to Mrs. Lowe, she explains that her muscle pain is very bothersome and it was worse when she was alone. Both you and Mrs. Lowe determine that an injection for her pain would be beneficial. In what way can you show caring in the way you administer the injection to Mrs. Lowe?

c. Mrs. Lowe's day is getting better. She seems more comfortable and is crying less. You find that your day is more controlled. What else can you do for Mrs. Lowe?

2. During your next clinical practicum, select a patient to talk with for at least 15 to 20 minutes. Ask the patient to tell you about his or her illness. Review the skills of listening in this chapter and in Chapter 24. Immediately after your discussion, reflect on the discussion with the patient and determine if you have enough information about him or her to answer the following questions:

a. What do you believe the patient was trying to tell you about his or her illness?

b. Why was it important for the patient to share his or her story?

c. What did you do that made it easy or difficult for the patient to talk with you? What did you do well? What could you have done better?

d. Would you rate yourself a good listener? How can you listen better?

▮ REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse hears a colleague tell a nursing student that she never touches a patient unless she is performing a procedure or doing an assessment. The nurse tells the student that from a caring perspective:
   1. She does not touch the patients either.
   2. Touch is a type of verbal communication.
   3. Touch is only used when a patient is in pain.
   4. Touch forms a connection between nurse and patient.

2. Of the five caring processes described by Swanson, which describes "knowing the patient?"
   1. Anticipating the patient's cultural preferences
   2. Determining the patient's physician preference
   3. Establishing an understanding of a specific patient
   4. Gathering task-oriented information during assessment

3. A Muslim woman enters the clinic to have a woman's health examination for the first time. Which nursing behavior applies Swanson's caring process of "knowing the patient?"
   1. Sharing feelings about the importance of having regular woman's health examinations
   2. Gaining an understanding of what a woman's health examination means to the patient
   3. Recognizing that the patient is modest; and obtaining gender-congruent caregiver
   4. Explaining the risk factors for cervical cancer

4. **Fill-in-the-Blank.** Swanson's caring process of _____ is demonstrated by a nurse helping a new mother through the birthing experience.

5. A patient is fearful of upcoming surgery and a possible cancer diagnosis. He discusses his love for the Bible with his nurse, who recommends a favorite Bible verse. Another nurse tells the patient's nurse that there is no place in nursing for spiritual caring. The patient's nurse replies:

1. "You're correct; spiritual care should be left to a pastoral care professional."
2. "You're correct; religion is a personal decision."
3. "Nurses should explain their own religious beliefs to patients."
4. "Spiritual, mind, and body connections can affect health."

6. Which of the following is a strategy for creating work environments that enable nurses to demonstrate more caring behaviors? (Select all that apply.)
   1. Decreasing the number of consecutive shifts of the nursing staff
   2. Increasing salary and vacation benefits of the nursing staff
   3. Increasing the number of nurses who work each shift to decrease the nurse-patient ratio
   4. Encouraging increased input concerning nursing functions from health care providers
   5. Providing nursing staff an opportunity to discuss practice changes they can implement to enhance opportunities for patient caring

7. When a nurse helps a patient find the meaning of cancer by supporting beliefs about life, this is an example of:
   1. Instilling hope and faith.
   2. Forming a human-altruistic value system.
   3. Cultural caring.
   4. Being with.

8. An example of a nurse caring behavior that families of acutely ill patients perceive as important to patients' well-being is:
   1. Making health care decisions for patients.
   2. Having family members provide a patient's total personal hygiene.
   3. Injecting the nurse's perceptions about the level of care provided.
   4. Asking permission before performing a procedure on a patient.

9. A nurse demonstrated caring by helping family members to: (Select all that apply.)
   1. Become active participants in care.
   2. Remove themselves from personal care.
   3. Make health care decisions for the patient.
   4. Have uninterrupted time for family and patient to be together.
   5. Have opportunities for the family to discuss their concerns.

10. Listening is not only "taking in" what a patient says, but it also includes:
    1. Incorporating the views of the physician.
    2. Correcting any errors in the patient's understanding.
    3. Injecting the nurse's personal views and statements.
    4. Interpreting and understanding what the patient means.

11. A nurse is caring for an older adult who needs to enter an assisted-living facility following discharge from the hospital. Which of the following is an example of listening that displays caring?
    1. The nurse encourages the patient to talk about his concerns while reviewing the computer screen in the room.
    2. The nurse sits at the patient's bedside, listens as he relays his fear of never seeing his home again, and then asks if he wants anything to eat.
    3. The nurse listens to the patient's story while sitting on the side of the bed and then summarizes the story.
    4. The nurse listens to the patient talk about his fears of not returning home and then tells him to think positively.

12. Presence involves a person-to-person encounter that:
    1. Enables patients to care for self.
    2. Provides personal care to a patient.
    3. Conveys a closeness and a sense of caring.
    4. Describes being in close contact with a patient.

13. A nurse enters a patient's room, arranges the supplies for a Foley catheter insertion, and explains the procedure to the patient. She tells the patient what to expect; just before inserting the catheter, she tells the patient to relax and that, once the catheter is in place, she will not feel the bladder pressure. The nurse then proceeds to skillfully insert the Foley catheter. This is an example of what type of touch?
    1. Caring touch
    2. Protective touch
    3. Task-oriented touch
    4. Interpersonal touch

14. A hospice nurse sits at the bedside of a male patient in the final stages of cancer. He and his parents made the decision that he would move home and they would help him in the final stages of his disease. The family participates in his care, but lately the nurse has increased the amount of time she spends with the family. Whenever she enters the room or approaches the patient to give care, she touches his shoulder and tells him that she is present. This is an example of what type of touch?
    1. Caring touch
    2. Protective touch
    3. Task-oriented touch
    4. Interpersonal touch

15. Match the following caring behaviors with their definitions.
    1. Knowing
    2. Being with
    3. Doing for
    4. Maintaining belief
    a. Sustaining faith in one's capacity to get through a situation
    b. Striving to understand an event as meaning for another person
    c. Being emotionally there for another person
    d. Providing for another as he or she would do for themselves

Answers: 1. 4; **2.** 3; **3.** 2; **4.** Enabling; **5.** 4; **6.** 3; **5.** 7; **8.** 1; **9.** 1, 4, 5; **10.** 4; **11.** 3; **12.** 3; **13.** 3; **14.** 1; **15.** 1b, 2c, 3d, 4a.

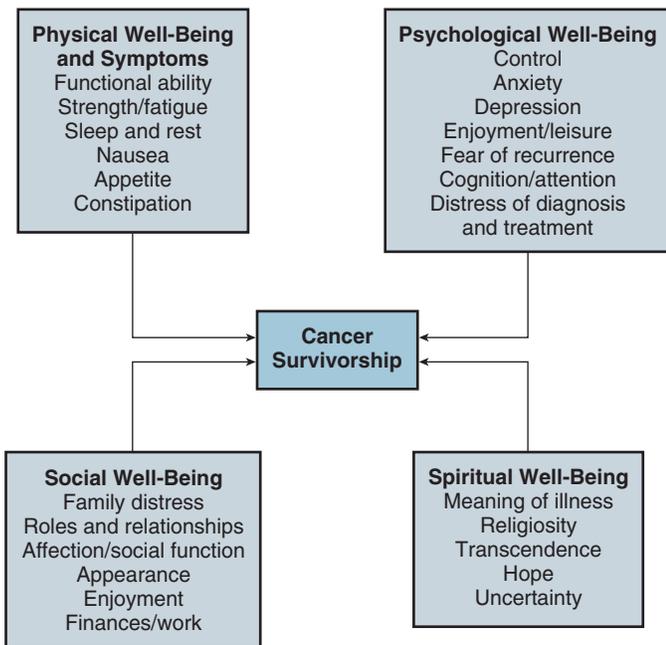
Caring for the Cancer Survivor

Currently there are 14.5 million adult and childhood cancer survivors in the United States; the number of survivors will continue to grow since more than 1.7 million new cases of cancer are diagnosed each year (American Cancer Society [ACS], 2014a; National Cancer Institute [NCI], 2015). Most cancer survivors (64%) were diagnosed initially 5 or more years ago; 50% of cancer survivors are 70 years of age or older (ACS, 2014a; NCI, 2015).

It is estimated that by January 2024 there will be 19 million cancer survivors in the United States (ACS, 2014a). Increased detection at the early stage of disease and improvements in all modes of treatment through research increase a prolonged life such that cancer diagnosis equates to cure for some and for others cancer is a managed chronic illness. The major forms of cancer therapy—surgery, immunotherapy, **chemotherapy**, **hormone therapy**, **biological response modifiers (biotherapy)**, and **radiation therapy**—often create unwanted long-term effects on tissues and organ systems that impair a person's health and quality of life (QOL) in many ways (Institute of Medicine [IOM], 2006).

There are many stages of the cancer continuum (Figure 8-1). Children and adolescents who receive aggressive chemotherapy and radiation are at greatest risk for developing secondary malignancies, sometimes related to the initial treatment received for the primary cancer. Adult cancer survivors may also experience new malignancies related to prior treatment but also may be genetically predisposed to recurrent tumors. With continued focus on cancer treatment going beyond acute treatment, health care providers are improving care needed for all long-term cancer survivors. Thus cancer survivorship has enormous implications for the way these individuals monitor and manage their health throughout their lives. As a nurse you will care for these patients when they seek care for their cancer and other medical conditions.

Cancer survivorship begins at the time of cancer diagnosis, includes treatment, and extends to the rest of the person's life (National Coalition for Cancer Survivorship [NCCS], 2015). Family members and friends are also survivors because they experience the effects that cancer has on their loved ones. Cancer is a life-changing event. Although progress is being made, evidence shows that many cancer survivors do not receive adequate follow-up care during the period following first diagnosis and initial treatment and before the development of a recurrence of the initial cancer or death (IOM, 2006). Following treatment, contact with a cancer care provider often stops, and survivors' needs go unnoticed or untreated. Improvements have occurred in follow-up treatment for some cancer survivors, but many long-term survivors suffer unnecessarily and die from delayed second cancer diagnoses or treatment-related chronic disease.


Nurses have the responsibility to better understand the needs of cancer survivors and provide the most current evidence-based approaches for managing late and long-term effects of cancer and cancer treatment. Although progress in early detection is improving in the underserved, more work is needed. Being able to provide comprehensive care to a cancer survivor begins with recognizing the effects of cancer and its treatment and learning about the survivor's own meaning of health.

THE EFFECTS OF CANCER ON QUALITY OF LIFE

As people live longer after diagnosis and treatment for cancer, it becomes important to understand the types of distress that many

Prevention and risk reduction	Screening	Diagnosis	Treatment	Survivorship	End-of-life care
• Tobacco control • Diet • Physical activity • Sun and environmental exposures • Alcohol use • Chemoprevention • Immunization	• Age and gender specific screening • Genetic testing	• Biopsy • Pathology reporting • Histological assessment • Staging • Biomarker assessment • Molecular profiling	• Systemic therapy • Surgery • Radiation	• Surveillance for recurrences • Screening for related cancers • Hereditary cancer predisposition/ genetics	• Implementation of advance care planning • Hospice care • Bereavement care

• Care planning
• Palliative care
• Psychosocial support

survivors experience and how it affects their QOL (Figure 8-2). QOL in cancer survivorship means having a balance between the experience of increased dependence while seeking both independence and interdependence. Of course there are always exceptions in regard to the level of distress that survivors face. For some, cancer becomes an experience of self-reflection and an enhanced sense of what life is about. Regardless of each survivor's journey with cancer, having cancer affects each person's physical, psychological, social, and spiritual well-being.

Physical Well-Being and Symptoms

Cancer survivors are at increased risk for cancer (either a recurrence of the cancer for which they were treated or a second cancer) and for a wide range of treatment-related problems (IOM, 2006). The increased risk for developing a second cancer is the result of cancer treatment, genetic factors, other susceptibility, or an interaction between treatment and susceptibility (ACS, 2014a). The risk for treatment-related problems is associated with the complexity of the cancer itself (e.g., type of tumor and stage of disease); the type, variety, and intensity of treatments used (e.g., chemotherapy and radiation combined); and the age and underlying health status of the patient.

A number of tissues and body systems are impaired as a result of cancer and its treatment (Table 8-1). Late effects of chemotherapy and/ or radiation include osteoporosis, heart failure, diabetes, amenorrhea in women, sterility in men and women, impaired gastrointestinal motility, abnormal liver function, impaired immune function, **paresthesias**, hearing loss, and problems with thinking and memory (IOM, 2006).

Chemotherapy-induced peripheral neurotoxicity (CIPN) refers to peripheral nerve damage resulting from the effects of certain chemotherapeutic agents (Park et al., 2013). Damage to large sensory nerves causes feelings of numbness and tingling in the hands and feet. Motor function may also be affected, but usually to a lesser degree than sensory function. Permanent chronic **neuropathy** occurs in 58% of patients with CIPN, resulting in increased falls and other motor and sensory dysfunction (Gewandter et al., 2013).

Certain conditions resolve over time, but tissue damage causes some symptoms to persist indefinitely, especially when patients receive high-dose chemotherapy. Health care professionals do not always recognize these conditions as delayed problems. Often conditions such as osteoporosis, hearing loss, or change in memory are instead considered to be age related. It is common for patients with cancer to have multiple symptoms, and more attention is being given to the existence

TABLE 8-1   Examples of Late Effects of Surgery Among Adult Cancer Survivors

Procedure	Late Effect
Any surgical procedure	Pain, psychosocial distress, impaired wound healing
Surgery involving brain or spinal cord	Impaired cognitive function, motor sensory alterations, altered vision, swallowing, language, bowel and bladder control
Head and neck surgery	Difficulties with communication, swallowing, breathing, physical appearance/body image
Abdominal surgery	Risk of intestinal obstruction, hernia, altered bowel function
Lung resection	Difficulty breathing, fatigue, generalized weakness
Prostatectomy	Urinary incontinence, sexual dysfunction, poor body image

BOX 8-1   EVIDENCE-BASED PRACTICE

Fear of Cancer Recurrence Among Cancer Survivors

PICO Question: How does fear of cancer recurrence affect adult cancer survivors?

Evidence Summary

Several researchers explored how fear of cancer recurrence impacts survivors' health care use or interventions to address their fears. Breast cancer survivors with high fear of recurrence had higher levels of depression and lower quality of life (Koch et al., 2014). Cancer survivors with high fear of recurrence had a significantly higher number of outpatient and emergency department visits in the prior 6 months (Lebel et al., 2013). Following a 6-week cognitive-existential group intervention, breast and ovarian cancer survivors reported lower fear of recurrence, which was maintained for a 3-month period (Lebel et al., 2014).

Application to Nursing Practice

- Nurses need to be aware of the potential fear of recurrence of disease in cancer survivors regardless of the type and location of cancer.
- When patients fear recurrence of cancer, they are prone to using more health care services. Fear needs to be recognized and treated in those struggling with fear of recurrence.
- Cognitive-based therapies (exploration of relationships among a person's thoughts, feelings, and behaviors) show promise in helping cancer survivors deal with fear of recurrent disease and maintain an improved perspective.
- Further research needs to be done to clearly identify additional interventions and screening tools to identify fear of recurrence.

of symptom clusters. A symptom cluster is a group of several related and coexisting symptoms such as pain-insomnia-fatigue or pain-depression-fatigue (Nguyen et al., 2011; Oh et al., 2012). Researchers are trying to better understand symptom clusters, their effects on patients, and whether clusters require a different treatment approach than current symptom management.

Cancer-related fatigue (CRF) and associated sleep disturbances are among the most frequent and distressing complaints of people with cancer. The symptoms often last many months after chemotherapy and radiation. The fatigue affects patients physically, psychologically, and socially and limits their ability to function and socialize in enjoyable activities (Borneman et al., 2012). The National Comprehensive Cancer Network (NCCN) *Clinical Practice Guidelines* (2014) for CRF treatment includes interventions for controlling fatigue through routine physical exercise, rest (such as taking an entire day off), development of good sleep habits, eating a balanced diet, and counseling for depression that often accompanies CRF.

Chemotherapy-related cognitive impairment (CRCI) is consistently associated with people who receive systemic chemotherapy. In addition to chemotherapy, radiation, hormone therapy, and the use of tranquilizers may also contribute to cognitive impairment in survivors (Rey et al., 2012) Breast cancer survivors report having difficulty with short-term memory, focusing, working, reading with comprehension, and driving (Myers, 2012).

A 44-year-old woman reported the following when asked if chemotherapy was responsible for memory deterioration … . "Yes absolutely. I mean I was forgetful before but not to the degree I am now. I would have had some vague memory of someone saying something, but now I really just don't remember. It doesn't ring any bells. It's just a complete blank." (Mitchell and Turton, 2011).

Suggested positive coping strategies include writing things down, focusing on one task at a time, allowing others to help with activities requiring focus, reading simpler texts, using audiobooks, and giving oneself permission to make mistakes (Potrata et al., 2010). There is no way to predict if a person will have CRCI or the degree of cognitive change. Some people who experience this symptom have difficulty working and processing information, which affects daily functioning and the quality of their work and social life.

Often health care providers wrongly attribute the symptoms of cancer or the symptoms from the side effects of treatment to aging. This often leads to late diagnosis or a failure to provide aggressive and effective treatment of symptoms. Cancer is a chronic disease because of the serious consequences and persistent nature of some of its late effects (IOM, 2006). The range of effects that patients suffer varies greatly. For example, a 46-year-old woman with early-stage melanoma on the right arm underwent successful surgery and only had an inconspicuous scar. In contrast, a 52-year-old woman diagnosed with Hodgkin's disease underwent intensive chemotherapy followed by an extended course of radiation. She faced serious and substantial long-term health problems from her treatment. Patients living with cancer present significant variations in the type of conditions they develop and the length of time the conditions persist.

Psychological Well-Being

The physical effects of cancer and its treatment sometimes cause serious psychological distress (see Chapter 38). Fear of cancer recurrence is the most common concern among cancer survivors (Koch et al., 2014, Ness et al., 2013; Simard et al., 2013). Cancer diagnosis and time since diagnosis impact prevalence and severity of fears (Ness et al., 2013). Being younger and considering oneself as a tumor patient increase the likelihood of moderate-to-high fear of recurrence in long-term breast cancer survivors (Koch et al, 2014) (Box 8-1).

Another common psychological problem for survivors is **posttraumatic stress disorder (PTSD)**. PTSD is a psychiatric disorder characterized by an acute emotional response to a traumatic event or situation. When incidence of PTSD-like symptoms is measured, rates range from 20% in patients with early-stage cancer to 80% in those with recurrent cancer (NCI, 2014b). Grief, intrusive thoughts about the disease, nightmares, relational difficulties, or fear may present in these people. Being unmarried or less educated or having a lower income and less social

and emotional support increases the risk for PTSD in adult survivors (Stuber et al., 2010). In young adults with cancer, higher rates of PTSD appear in those who are unemployed or not in school, had surgical treatment for cancer, currently receive treatment, and have a diagnosis of a cancer type with a 90% to 100% survival rate (Kwak et al., 2013). In these young adults PTSD symptoms observed as early as 6 months following the diagnosis remained stable for 12 months.

The following description is an example of a cancer survivor's response to the stressors of cancer treatment:

> The first question I asked my radiation oncologist after completing treatment for non-metastatic breast and ovarian cancer was: "When can I go back to my job?" He said, "Considering the work you do, I would think that 8 weeks of rest and recovery is the minimum." I left the clinic excited that my treatments were over and I could get on with my life. Eight weeks later I woke up tired after sleepless nights. I was bald and had peripheral neuropathy in my hands and feet that was crippling, and the drug I was taking made me feel like I had arthritis all over my body. Where was my energy and soft blond hair? Why couldn't I think straight? There is no way I could do my job like this. I felt like I was drowning (Bush, 2009, p. 395).

The disabling effects of chronic cancer symptoms disrupt family and personal relationships, impair individuals' work performance, and often isolate survivors from normal social activities. Such changes in lifestyle create serious implications for a survivor's psychological well-being. When cancer changes a patient's body image or alters sexual function, the survivor frequently experiences significant anxiety and depression in interpersonal relationships. In the case of breast cancer survivors, studies show that poorer self-ratings of QOL are associated with poor body image, coping strategies, and a lack of social support (IOM, 2006).

The NCCN guidelines (NCCN, 2014) suggest a variety of nonpharmacological interventions to treat anxiety and depression in cancer survivors. Therapies include education, routine exercise, adequate sleep, supportive therapy or cognitive behavioral intervention, and reassurance that anxiety and depression are commonly seen in cancer survivors. Pharmacological intervention may also be warranted based on individual survivor response. Patients who use problem-oriented, active, and emotionally expressive coping processes also manage stress well (see Chapter 38). Survivors who have social and emotional support systems and maintain open communication with their treatment providers will also likely have less psychological distress.

Social Well-Being

Cancer affects any age-group (Figure 8-3). The developmental effects of cancer are perhaps best seen in the social impact that occurs across the life span. For adolescents and young adults, cancer seriously alters social skills, sexual development, body image, and the ability to think about and plan for the future (see Chapter 12). Adults (ages 30 to 59) who have cancer experience significant changes in their families. Once a member of the family is diagnosed with cancer, every family member's role, plans, and abilities change. The healthy spouse often takes on added job responsibilities to provide additional income for the family. A spouse, sibling, grandparent, or child often assumes caregiving responsibilities for the patient.

Adult patients who experience changes in sexuality, intimacy, and fertility see their marriages affected, often resulting in divorce. Impaired fertility is a concern since chemotherapy and radiation may be gonadotoxic (Kort et al., 2014). Infertility or subfertility may be present following cancer treatment. Male cancer survivors may also face erectile dysfunction; female survivors may face premature menopause or

FIGURE 8-3 A family representing young and old. Each member could be a cancer survivor.

changes in vaginal tissue, impacting sexual intercourse. All of these reproductive challenges may impact sexual health between cancer survivor and spouse. The potential fertility issues secondary to chemotherapy and radiation impact family planning. To cope with these issues, pretreatment discussions regarding potential effect of treatment on sexual relations and fertility are essential (Harden et al., 2013; Kort et al., 2014; NCCN, 2014; Rossen et al., 2012). Guidelines from NCCN (2014) suggest cryopreservation of ova or sperm pretreatment to address fertility concerns.

A history of cancer significantly affects employment opportunities and has affected the ability of survivors to obtain and retain health and life insurance in the past. However, changes in the availability and affordability of health insurance resulting from the Patient Protection and Affordable Care Act of 2010 has made insurance more attainable for cancer survivors (NCCS, 2012a). There are now many options for health insurance. Cancer survivors should obtain comprehensive health coverage that will pay for all of their basic health care needs such as hospital and doctor care, lab tests, medical equipment, and prescription drugs. Beginning in 2014, most people are required to have comprehensive health coverage that includes a defined set of essential health benefits that provide minimum essential coverage (NCCS, 2012b).

Often a survivor experiences health-related work limitations that require a reduced work schedule or a complete change in employment. Between 64% and 84% of cancer survivors who worked before their diagnosis return to work (Steiner et al., 2010). The most common problems reported by survivors who return to work are physical effort, heavy lifting, stooping, concentration, and keeping up with the work pace. Factors that affect a return to work include cancer site, prognosis, type of treatment, socioeconomic status, and characteristics of the work to be done. The economic burden of cancer is enormous. If a survivor's illness affects his or her ability to work, less income goes to the individual and family. The problems are even greater for low-income survivors if they are underinsured. The ACS (2014b) offers excellent tips on returning to work after cancer treatment: http://www.cancer.org/treatment/survivorshipduringandaftertreatment/stayingactive/workingduringandaftertreatment/returning-to-work-after-cancer-treatment.

Older adults face many social concerns as a result of cancer. The disease causes some survivors to retire prematurely or decrease work hours, thus decreasing income. The older adult faces a fixed income and the limitations of Medicare reimbursement. Many older adults have moved to retirement residences in other states and find

themselves isolated from the social support of their families. Older adults also face a high level of disability as a result of cancer and cancer treatment and report a higher incidence of limitations in activities of daily living than older adults without cancer (IOM, 2006). As a result, many older cancer survivors require ongoing caregiving support either from family members or professional caregivers.

Spiritual Well-Being

Cancer challenges a person's spiritual well-being (see Chapter 36). Key features of spiritual well-being include a harmonious interconnectedness, creative energy, and a faith in a higher power or life force. Cancer and its treatment create physical and psychological changes that cause survivors to question, "Why me?" and wonder if perhaps their disease is a form of punishment. Cancer survivors who participate in religious activities and report belief in God experience increased emotional function and coping (Holt et al., 2011; Schreiber, 2011). Relationships with a God, a higher power, nature, family, or community are critical for survivors. Cancer threatens relationships because it makes it difficult for survivors to maintain a connection and a sense of belonging. It isolates survivors from meaningful interaction and support, which then threatens their ability to maintain hope. Long-term treatment, cancer recurrence, and the lingering side effects of treatment create a level of uncertainty for survivors.

CANCER AND FAMILIES

A survivor's family takes different forms: the traditional nuclear family, extended family, single-parent family, close friends, and blended families (see Chapter 10). Once cancer affects a member of the family, it affects all other members as well. Although the research is from 2006, a summary of issues affecting families of patients with cancer still holds true (Lewis, 2006):

- Family members are substantially distressed when a member has cancer.
- Family members do not know, understand, or respond supportively to the expressed thoughts, feelings, and behavior of other family members about the cancer.
- Families try to cope with both the impact of the cancer and tension in the family caused or worsened by the cancer.
- Family members struggle to maintain their core functions when one of them is a long-term survivor.

Usually a member of the family becomes the patient's caregiver. Family caregiving is a stressful experience, depending on the relationship between patient and caregiver and the nature and extent of the patient's disease. Members of the "sandwich generation" (i.e., caregivers who are 30 to 50 years old) are often caught in the middle of caring for their own immediate family and a parent with cancer. The demands are many, from providing ongoing encouragement and support and assisting with household chores to providing hands-on physical care (e.g., bathing, assisting with toileting, or changing a dressing) when cancer is advanced. Caregiving also involves the psychological demands of communicating, problem solving, and decision making; social demands of remaining active in the community and work; and economic demands of meeting financial obligations.

Families struggle to maintain core functions when one of their members is a cancer survivor. Core family functions include maintaining an emotionally and physically safe environment, interpreting and reducing the threat of stressful events (including the cancer) for family members, and nurturing and supporting the development of individual family members (Lewis, 2006). In childrearing families, this means providing an attentive parenting environment for children and information and support to children when their sense of well-being

becomes threatened. Spouses often do not know what to do to support the survivor, and they struggle with how to help. In the end family functions become fragmented, and family members develop an uncertainty about their roles.

IMPLICATIONS FOR NURSING

Cancer survivorship creates many implications for nurses who help survivors plan for optimal lifelong health. Nurses are in a strong position to take the lead in improving public health efforts to manage the long-term consequences of cancer. Improvement is also necessary in the education of nurses and survivors about the phenomenon of survivorship. This section addresses approaches to incorporate cancer survivorship into your nursing practice.

Survivor Assessment

Knowing that there are many cancer survivors in the health care system, consider how to assess patients who report a history of cancer. It is important to assess a cancer survivor's needs as a standard part of your practice. When you are collecting a nursing history (see Chapters 16 and 31), have patients tell you their stories through a narrative. A narrative makes it possible to know people through their stories (i.e., the narratives they tell) and provides contextual detail and person-revealing characteristics that make them individuals (Hall and Powell, 2011). As you explore the patient's history of cancer and the treatment received in the past, ask questions such as, "How did that come about?" vs. why or yes/no questions. Let the patient take you on a journey explaining his or her condition. You might ask, "Tell me how your disease most affects you right now," or "What are the biggest problems that you're having from cancer?" or "What can I do to help you at this point?" A narrative approach elicits stories that will illustrate the social context of events and implicitly provide answers to questions of feeling and meaning (Hall and Powell, 2011). Show a caring approach so patients know that their stories are accepted.

Be aware that some patients do not always report that they have had cancer. Thus, when a patient tells you that he or she has had surgery, ask if it was cancer related. When a patient reveals a history of chemotherapy, radiation, biotherapy, or hormone therapy, refer to resources to help you understand how these therapies typically affect patients in both the short and long term. Then extend your assessment to determine if these treatment effects exist for your patient. Consider not only the effects of the cancer and its treatment (such as potential symptoms) but how it will affect any other medical condition. For example, if a patient also has heart disease, how will cancer-related fatigue affect this individual?

As of 2015 all accredited cancer centers must meet new standards of the American College of Surgeons Commission on Cancer (2012). Standard 2.3 includes risk assessment and genetic counseling for people at risk for familial or hereditary cancers. Genetic testing provides early detection and improved outcomes in appropriate patients and their family members. This should also be included in patient assessments.

Symptom management is an ongoing problem for many cancer survivors. If cancer is their primary diagnosis, it will be natural for you to explore any presenting symptoms. Be sure to learn specifically how symptoms are affecting the patient. For example, is pain also causing fatigue, or is a neuropathy causing the patient to walk with an abnormal gait? If cancer is secondary, you do not want important symptoms to go unrecognized. Ask the patient, "Since your diagnosis of and treatment for cancer, which physical changes or symptoms have you had?" "Tell me how these changes affect you now?" You explore each symptom that a patient identifies to gain a complete picture of his or her health

TABLE 8-2   Examples of Assessment Questions for Cancer Survivors

Category	Examples of Questions
Symptoms	• Tell me about the symptoms you're having from your cancer treatment. • Describe any pain or discomfort in the area where you had surgery or radiation; discomfort, pain, or unusual sensations in your hands or feet; weakness in your legs or arms; or problems moving around. • Describe for me the fatigue, sleeplessness, or shortness of breath you're feeling. • Sometimes people believe that they are starting to have problems after chemotherapy such as paying attention, remembering things, or finding words. Have you noticed any changes like these?
Psychosocial problems	• How distressed are you feeling at this point on a scale of 0 to 10, with 10 being the worst distress that you could imagine? • Tell me how you think your family is handling your cancer? • What do you see in your family members' responses to your cancer that concerns you?
Sexuality problems	• If you have had sexual changes, which strategies have you tried to make things better? Have these strategies worked? • Would you be open to a health care provider who knows how to help you? • Since your cancer, do you see yourself differently as a person?

status (Table 8-2). Some patients are reluctant to report or discuss their symptoms. Be patient and, once you identify a symptom, explore the extent to which the symptom is currently affecting the patient.

Because you know that cancer affects a patient's QOL in many ways, be sure to explore the patient's psychological, social, and spiritual needs and resources. Sometimes you will not be able to conduct a thorough assessment when you perform an initial nursing history. If this is the case, incorporate your assessment into your ongoing patient care. Observe your patient's interactions with family members and friends. When you are administering care to patients, talk about their daily lives and determine the extent to which cancer has changed their lifestyle.

One area that is often difficult for nurses to assess well is a patient's sexuality. Sexuality is more than simply the physical ability to perform a sex act or conceive a child. It also includes a person's self-concept and body image (see Chapter 34), sexual response (e.g., interest and satisfaction), and sexual roles and relationships (see Chapter 35). Surgery for many cancers is disfiguring, and chemotherapy and radiation often alter a patient's sexual response (e.g., prostate, breast, and gynecological cancers). Cancer therapies have the potential to cause fatigue, apathy, nausea, vomiting, malaise, and sleep disturbances, all of which interfere with a patient's sexual function. It is important to simply realize that cancer often influences the patient's sexuality. It helps to develop a comfort level in acknowledging with patients that sexual changes are common at any age level. Ask a patient, "Since your diagnosis of and treatment for cancer, has your ability or interest in sexual activity changed? If so, how?" Patients will appreciate your sensitivity and interest in their well-being. When they begin to discuss their sexuality, be familiar with the expert resources in your institution (e.g., psychologist or social worker) available for patient referral.

Patient Education

When you care for a cancer patient, it is important to understand whether the patient administers most of his or her own self-care or if support is required from a family caregiver. This is essential to provide the most appropriate patient education, both in the form of content and in your teaching approach. Schumacher et al. (2006) developed a conceptual model, the transactional model of cancer family caregiving skill, which describes the relationship among cancer patients and family caregivers in the performance of family caregiving skills (Figure 8-4). The model offers a perspective on caregivers and cancer survivors both as individuals and as a team. Family caregiving skill is the ability to respond effectively and smoothly to the demands of an illness and pattern of care using multiple caregiving processes. Illness demands of cancer include dealing with symptoms, responding to illness behaviors (e.g., role changes, avoiding interaction), modifying activities for an illness situation, nutritional support, interpersonal care, use of community resources, managing acute illness episodes, and implementing treatments. The patient and caregiver follow a continuum of three patterns of care: the self-caregiving pattern (patients are mostly independent with caregivers in a standby role), the collaborative care pattern (patients and caregivers share care activities and respond together to illness demands), and the family caregiving pattern (patients are unable to perform independently and require extensive caregiver involvement) (Schumacher et al., 2006).

A patient's and caregiver's response to a caregiving demand involves performing caregiving processes (e.g., monitoring [observing for problems], interpreting [identifying the problem], making decisions and adjustments, accessing resources, and providing hands-on care). In terms of providing hands-on care, family caregivers often provide complex nursing procedures in the home such as managing intravenous infusions or irrigating wounds. Knowledge about caregiving or self-care, previous experience, and emotions influence the way caregivers and survivors respond and acquire caregiving processes. Schumacher's model is a helpful resource for you to apply when initially assessing the patient and caregiver condition, identifying their learning needs, and recognizing the type of information to teach. Learn where the patient and caregiver are along the caregiving continuum and determine the information needed to support them in meeting caregiving demands and performing caregiving processes. Frequently this means that any education will involve both the patient and family caregiver together, unless the relationship is strained and the patient chooses not to involve the caregiver.

It is a nurse's responsibility to educate cancer survivors and their families about the effects of cancer and cancer treatment. This means that, when you care for a cancer survivor, you need to understand the nature of the patient's particular disease and know the short- and long-term effects of each therapy. When designing education that promotes self-management in caregiving, plan activities on the basis of the family caregiver's and cancer survivor's perceived disease-related problems and help them problem solve and gain the self-efficacy or confidence to deal with these problems. The online publication, *Facing Forward: Life After Cancer Treatment* (NCI, 2014a) provides information about follow-up medical care and managing physical, social, work, and intimacy concerns. Available in both English and Spanish, it is a valuable resource for cancer survivors to guide a forward perspective in managing life challenges. Patient education helps survivors assume healthier lifestyle behaviors that will give them control of aspects of their health and improve outcomes from cancer and chronic illness.

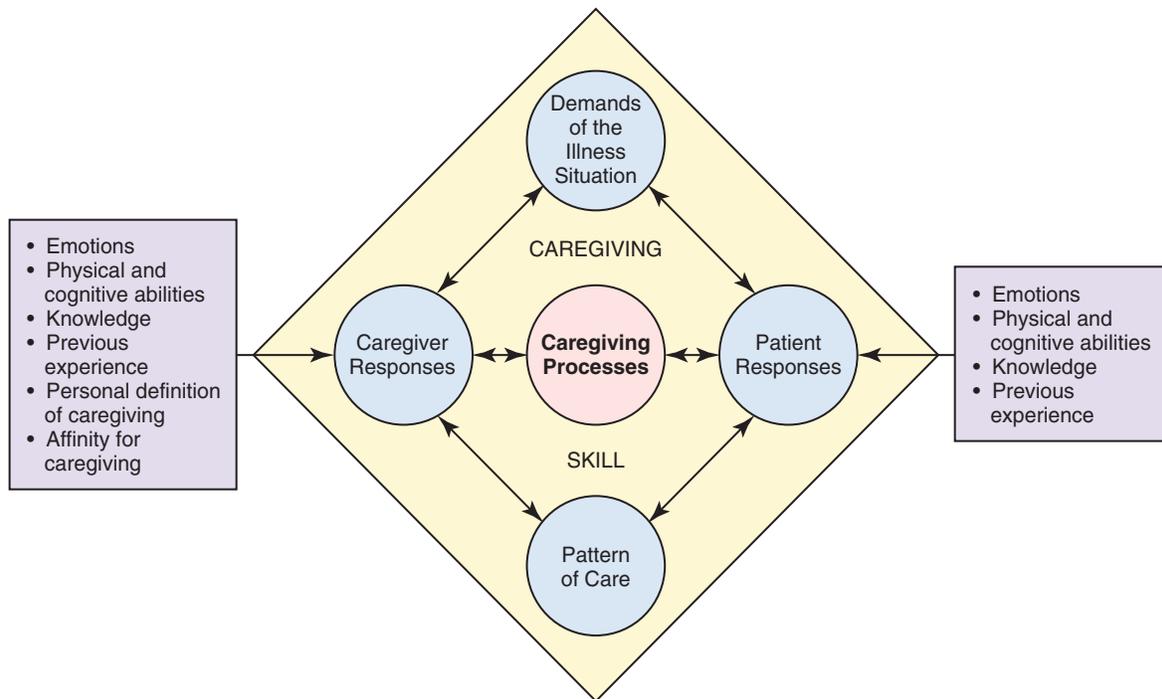
When caring for patients with an initial diagnosis of cancer, reinforce their health care provider's explanations of the risks related to their cancer and treatment, what they need to self-monitor (e.g.,


FIGURE 8-4 Transactional model of cancer family caregiving skill. (From Schumacher KL et al: A transactional model of family caregiving skill, *Adv Nurs Sci* 29(3):271, 2006.)

appetite, weight, and effects of fatigue), and what to discuss with health care providers in the future. If you teach patients and their family caregivers about the potential for treatment effects such as pain, neuropathy, or cognitive change, they are more likely to report their symptoms. It allows them to know which signs or changes to anticipate and monitor. Survivors need to learn how to manage problems related to persistent symptoms. For example, survivors with neuropathy need to learn how to protect the hands and feet, prevent falls, and avoid accidental burns.

Because survivors have an increased risk for developing a second cancer and/or chronic illness, it is important to educate them about lifestyle behaviors and the importance of participating in ongoing cancer screening and early detection practices. Lifelong cancer screening provides the opportunity to identify new cancers in early stages. Female cancer survivors who have a history of nonmetastatic cancer are more likely to participate in mammography and pelvic/Papanicolaou screening than women with no cancer history (Schumacher et al., 2012). This may be related to fear of cancer recurrence and a health care provider's recommendation for follow-up screening in cancer survivors. Many survivors become interested in learning more about dietary supplements and nutritional complementary therapies to manage disease symptoms (IOM, 2006). Scientific evidence shows that several health promotion areas are of interest to cancer survivors (i.e., smoking cessation, physical activity, diet and nutrition) (see Chapter 45), and the use of complementary and alternative medicine (see Chapter 33). Teach patients useful strategies to promote their health.

Providing Resources

Numerous organizations provide resources to cancer survivors. However, many survivors do not receive timely and appropriate referrals to them. As a nurse you will find that many people (e.g., friends, neighbors, and family members) come to you for advice about health care before they actually become a patient. It is important to know that cancer-related hospital and ambulatory care are not standardized. For

example, when a patient with cancer is hospitalized, the availability of ancillary services for long-term care varies by care setting. Hospital-based oncologists are usually in larger hospitals and not in smaller ones. An NCI-designated cancer center offers the most comprehensive and up-to-date clinical care. NCI-designated centers also conduct important clinical trials to investigate the most current cancer therapies. Your role is to tell patients about the different resources available so they are able to make informed choices about their care. Refer patients to the NCI website (http://www.cancer.gov/). It contains a current list of NCI-designated comprehensive cancer centers.

A wealth of cancer-related community support services is available to survivors through voluntary organizations such as the ACS (www.cancer.org) and the NCCS (http://www.canceradvocacy.org). Most offer their services at no cost. Many supportive services offer call centers and Internet-based information and discussion boards in addition to direct-service delivery (IOM, 2006). Health care professionals are not consistent in referring patients to these valuable services. In addition, although community-based services help most survivors, there are gaps in service provision for assistance with transportation, home care, child care, and financial assistance. Become knowledgeable about the services within your community.

COMPONENTS OF SURVIVORSHIP CARE

Once primary cancer treatment ends, health care professionals need to develop an organized plan for survivorship care. This does not always occur because of inadequacies in the health care system, including a health care provider not assuming responsibility for coordinating care, fragmentation of care between specialists and general practitioners, and a lack of guidance about how survivors can improve their health outcomes (IOM, 2006). Patients with cancer often do not receive non-cancer care (e.g., care for diabetes or heart conditions) when their cancer diagnosis shifts attention away from care that is routine but necessary. The IOM (2006) recommends four essential components of

BOX 8-2   A Survivorship Care Plan

On discharge from cancer treatment, every patient and his or her primary health care provider should receive a record of all care received from the oncologist. The patient and health care provider should also receive a follow-up plan incorporating available evidence-based standards of care.

Care Summary
- Diagnostic tests performed and results
- Tumor characteristics (e.g., site, stage, and grade)
- Dates when treatment started and stopped
- Surgery, chemotherapy, radiotherapy, transplant, hormone therapy, or gene therapy provided, including the specific agents used
- Psychosocial, nutritional, and other supportive services provided
- Full contact information for treating institutions and key providers
- Identification of a key point of contact and coordinator of care

Follow-Up Plan
- Need for ongoing treatment and clinic follow-up plan
- Description of recommended cancer screening and other periodic testing/examinations
- Information about possible late and long-term effects of treatment and symptoms of such effects
- Information about possible signs of recurrence and second tumors and follow-up tests
- Recommendations for healthy behaviors (e.g., nutrition, sun screen use, exercise, no smoking)
- Information about genetic counseling and testing as appropriate
- Referrals to specific follow-up care providers
- A listing of cancer-related resources and information

Data from American Society of Clinical Oncology: *New ASCO survivorship care plan template is simpler, faster for healthcare providers,* October 14, 2014, http://www.asco.org/advocacy/new-asco-survivorship-care-plan-template-simpler-faster-healthcare-providers.

survivorship care: (1) prevention and detection of new cancers and recurrent cancer; (2) surveillance for cancer spread, recurrence, or second cancers; (3) intervention for consequences of cancer and its treatment (e.g., medical problems, symptoms, and psychological distress); and (4) coordination between specialists and primary care providers.

Survivorship Care Plan

To meet the health care needs of cancer survivors, it is essential for a "survivorship care plan" to be written by the principal provider who coordinates the patient's **oncology** treatment (Box 8-2) (IOM, 2006). The care plan contains important information about the patient's treatment, the need for future check-ups and cancer tests, the potential long-term late effects of the treatment, and ideas for improving the patient's health (ASCO, 2015). When a survivor is released from an oncologist, the internist and other health care providers provide and coordinate care on the basis of knowledge of prior cancer history and treatment. On the basis of Standard 3.3 of the American College of Surgeons Commission on Cancer (2012), by 2015 fully accredited cancer centers must develop and disseminate a comprehensive patient specific follow-up survivorship care plan for all patients when they complete treatment. Some patients receive care at cancer centers without this type of resource and may not have a survivorship care plan.

The IOM (2006) also recommends that health insurance plans cover care outlined in a survivorship care plan. Survivor plans are not always developed, and health insurance companies do not routinely cover this type of care. Ideally you review a survivorship care plan with a patient when he or she is formally discharged from a treatment program. The plan then becomes a guide for any future cancer or cancer-related care. Health care providers use the plan as a guide for patient education and screening for secondary cancers. Survivors use it to raise questions with health care providers to prompt appropriate care during follow-up visits.

> **QSEN**   **QSEN: BUILDING COMPETENCY IN PATIENT-CENTERED CARE** Mrs. Henry is a 45-year-old patient who received treatment for breast cancer at an outpatient clinic. Her cancer treatments ended 1 year ago. This is the first time she is coming to the primary health provider for a physical examination. As the nurse, you ask her to bring a copy of her survivorship care plan with her to the appointment. Mrs. Henry says that she does not have one. She said her oncologist has told her to follow up with her care with her primary health provider. What is the best response to Mrs. Henry? Which nursing assessments need to be done before her first appointment at the physical examination?

Barriers to develop and implement survivorship care plans (SCPs) focus on financial and human resource costs (Stricker and O'Brien, 2014). Average reimbursement of patient visits for assessment and discussion of an SCP is 55% of the billed amount. Some private insurance companies reimbursed an average of 38% for the visit while Medicare/Medicaid averages 59% of the bill (Rosales et al., 2014). No reimbursement exists for the development costs of an SCP.

Cancer organizations such as the Lance Armstrong Foundation (http://www.livestrong.org/), the Association of Cancer Online Resources (ACOR) (http://www.acor.org) and the NCCS (http://www.canceradvocacy.org/toolbox/) provide Internet guides for the development of survivorship care plans. Many NCI-designated cancer centers and pediatric cancer centers provide survivorship care planning (NCI, 2014a). Many survivors do not receive care at NCI-designated cancer centers and are discharged with no survivor plan. Thus nurses and other health care providers need to become more vigilant in recognizing cancer survivors and attempting to link them with the support and resources they require. Nurses make a difference when they consider the long-term issues that cancer survivors face after their time of diagnosis and in contributing to solutions to manage or relieve cancer-associated health problems. A strong interprofessional approach that includes nurses, oncology specialists, dietitians, social workers, pastoral care, and rehabilitation professionals is necessary. Together an interprofessional team provides a plan of care that addresses treatment-related problems and future health risks and offers a wellness focus to give patients a sense of hope as he or she enters the survivor experience.

■ KEY POINTS

- Nurses care for cancer survivors when they seek care for their cancer and other medical conditions.
- Cancer survivors may have serious health problems related to their treatments.
- How well a survivor adapts to the cancer experience psychologically depends on predisposing factors, the person's current psychological status, the extent of his or her disease, and the presence of disruptive signs and symptoms.
- The disabling effects of chronic cancer symptoms disrupt family and personal relationships, impair individuals' work performance, and often isolate survivors from normal social activities.

- Adults who have cancer experience significant changes within their families, including a change in each member's role.
- Relationships among cancer survivors and family members become difficult to maintain because family members often do not know, understand, or have the skills or confidence to support the survivor's reactions to cancer.
- Because survivors are at an increased risk for developing a second cancer and/or chronic illness, it is important to educate them about lifestyle behaviors that will improve the quality of their lives.
- Fear of recurrence is a common concern of cancer survivors and should be addressed to determine if it exists and if intervention is needed.
- Once a patient's primary cancer treatment ends, health care professionals should develop an organized plan for survivorship care.
- Ideally you review a survivorship care plan with a patient when he or she is formally discharged from a treatment program, and it becomes a guide for any future cancer or cancer-related care.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Do you have a friend or family member who has cancer and is willing to talk about it? If so, ask the individual to tell you what the experience has been like and what he or she would recommend to help you provide better care for survivors.
2. Ms. Ritter is a 32-year-old woman who visits the medical outpatient clinic to discuss her treatment options for breast cancer. She is married and has one child, a daughter, who is 6 years old. She and her husband hoped to have another child in the near future but now wonder if that will be possible. She shares with the nursing staff her concerns about the future and how cancer will affect her and her family. Identify two follow-up care plan components that would be important when considering Ms. Ritter's role as a wife and parent.
3. Ms. Ritter tells her nurse, "This chemotherapy has made me feel so tired, and there are many nights when I can't sleep very well. I'm looking forward to this ending." What is an appropriate response the nurse might give Ms. Ritter?

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. Cancer survivors are at risk for treatment-related problems. Which of the patients listed here has the greatest risk for developing such problems?
   1. An 80-year-old woman undergoing surgery for removal of a basal cell carcinoma on the face
   2. A 71-year-old man getting high-dose chemotherapy/radiation for advanced-stage lymphoma
   3. A 26-year-old man receiving chemotherapy for testicular cancer that is localized to the testicle
   4. A 48-year-old woman receiving radiation for Hodgkin's disease that involves lymph nodes extending above and below the diaphragm
2. A 34-year-old patient who is a 5-year survivor of Hodgkin's disease continues to have symptoms related to chemotherapy treatment. The patient is a computer expert and enjoys Internet

discussion groups. Which of the following is the best resource a nurse can recommend to help the patient access a survivorship care plan?
   1. Association of Cancer Online Resources (ACOR)
   2. National Coalition for Cancer Survivorship
   3. American Cancer Society (ACS)
   4. National Cancer Institute (NCI)
3. A nurse reviews the medical record of a 40-year-old patient newly admitted to the medical nursing unit for evaluation of diabetes. While reviewing the medical history, the nurse notices that the patient had bladder surgery 3 years ago. Which of the following assessment questions is most appropriate for the nurse to ask to determine if the patient is a cancer survivor?
   1. Determining if the patient had additional surgeries recently
   2. Assessing the patient's medication history
   3. Determining if the surgery was cancer related
   4. Assessing if the patient's parents had cancer
4. A nurse working in a gynecological oncology clinic knows that it is important to recognize that cancer survivors may have impaired sexual function. Which of the following statements is most appropriate to determine if sexual impairment is a problem?
   1. "I'm embarrassed to ask you this, but is your sex life OK?"
   2. "Treatment for cervical cancer may change sexual relations. Describe concerns you have about this.
   3. "You're probably too tired to have intercourse with your husband, right?"
   4. "Did the doctor tell you that you can still have sex while you are being treated?"
5. A 20-year-old man who has been diagnosed with testicular cancer is about to begin treatment, including intense chemotherapy, radiation, and surgery. He says to the nurse, "I'm scared that I'll never be able to be a father." The most appropriate response by the nurse is:
   1. "You're young. You'll beat this cancer and have a long and happy life."
   2. "Tell me what you mean about your fear of never being a father."
   3. "Cancer treatment has really improved, and more people are surviving it."
   4. "Your doctor is really good and has a high cure rate. He'll take care of you. "
6. Symptoms of chemotherapy-related cognitive impairment (CRCI) may include difficulty: (Select all that apply.)
   1. Driving a car.
   2. Sleeping 6 to 8 hours at night.
   3. Reading with comprehension.
   4. Walking with a steady gait.
   5. Focusing on balancing a checkbook.
   6. Eating a balanced diet.
7. A support group of cancer survivors is discussing cancer-related fatigue (CRF). The survivor most likely to gain relief from CRF is the survivor who does which of the following? (Select all that apply.)
   1. Takes naps during the day and evening
   2. Drinks energy drinks daily
   3. Exercises at least every other day
   4. Eats a balanced diet
   5. Joins a cancer support group
8. A patient has received multiple chemotherapy regimens and a course of radiation for colon cancer. He performs his own hygiene but needs assistance from his wife to move about safely in the

home because of ongoing fatigue and weakness. His wife helps him dress when he becomes excessively tired. This caregiving skill pattern is best described as which of the following?
1. The self-caregiving pattern
2. The collaborative care pattern
3. The family caregiving pattern
4. The team caregiving pattern

9. A 50-year-old patient who has completed systemic chemotherapy and radiation for breast cancer tells you that she is having difficulty remembering things and paying attention to a television show for over 5 minutes. Interventions that may help the patient include: (Select all that apply.)
1. Stop reading any nonessential materials.
2. Identify a trusted support person to help with banking and bill payment.
3. Rest as much as possible and do not exercise.
4. Try listening to a book on tape and see if that helps understanding.
5. Eat as much protein and as many vitamin K—enriched foods as possible.
6. Write appointments on your calendar and keep a list to organize what you are to do.

10. A nurse in an oncology outpatient clinic has been seeing a woman and her husband since the woman was diagnosed with breast cancer. Sometimes the husband appears supportive, asking questions about his wife's care. At other times the husband seems easily distracted and uninterested. The nurse decides to reassess the psychosocial condition of the patient and her husband. Which of the following questions best elicits needed psychosocial information?
1. "In what way does the pain you have affect you on a daily basis?"
2. "Describe what you eat in a typical day."
3. "Tell me how you think you and your husband are dealing with your cancer."
4. "Are the two of you having any relational difficulties because of your cancer?"

11. A child in remission for leukemia and her mother come to the pediatrician's office for a routine physical examination. The nurse asks the child whether she is having continued symptoms. Her mom says, "I don't know why you want all of this information about her cancer treatment. The leukemia is gone." The best response from the nurse in support of the child and mother would be:
1. "The doctor likes to keep the records complete on all of her patients."
2. "Just because she is in remission does not mean that it will stay that way."

3. "Children sometimes have delayed effects from treatment; we need this information to plan her care properly."
4. "I understand your concern. If you don't want to provide the information, sign this release form."

12. A 60-year-old breast cancer survivor was told by her physician that she is experiencing late effects of chemotherapy and chest radiation. Which of the following are known late effects of cancer treatment? (Select all that apply.)
1. Impaired immune function
2. Heart failure
3. Osteoporosis
4. Loss of sense of smell
5. Abnormal liver function

13. A 45-year-old patient who has recurrent cancer is having nightmares and obsessive thoughts about the disease, is unable to focus on anything else, and has a breakdown in relationships with her family. These symptoms are associated with:
1. Chemotherapy-related cognitive impairment (CRCI).
2. Cancer-related fatigue (CRF).
3. Family dysfunction caused by cancer.
4. Posttraumatic stress disorder (PTSD).

14. Survivorship care plans should include information to provide future caregivers with important information about the treatment a patient with cancer has received. The most important entries in a well-written survivorship care plan include: (Select all that apply.)
1. Type of tumor and dates of diagnosis.
2. Screening tests that are appropriate for future use.
3. Type of chemotherapy or radiation treatment used and length of dose.
4. Typical side effects the patient experienced immediately after a dose of chemotherapy was given.
5. Lifestyle recommendations for diet and exercise.

15. Caring for a patient with cancer is unique because of the effects of the disease and associated treatment. An understanding of a patient's symptom experience is critical and best revealed by a nurse asking which of the following questions? (Select all that apply.)
1. "What symptoms do you think you're having as a result of your cancer?"
2. "Describe how the symptoms affect you in your daily life."
3. "Let's discuss your pain. Tell me how it affects you."
4. "Describe how your family provides care for your symptoms."

Cultural Awareness

In the United States many individuals face greater obstacles to good health on the basis of one or more of the following factors: racial or ethnic group; religion; socioeconomic status; gender; age; mental health; cognitive, sensory, or physical disability; sexual orientation or gender identity; geographic location; or other characteristics historically linked to discrimination or exclusion (U.S. Department of Health and Human Services [USDHHS], 2015). The concept of culture comprises all of these factors. Research findings reveal differences in rates of cancer, diabetes, infant mortality, organ transplantation, and many other health conditions because of cultural factors. For example, African-Americans have the highest mortality rate of any racial and ethnic group for all cancers combined, contributing in part to a lower life expectancy for both African-American men and women (Office of Minority Health [OMH], 2013a). Asian Americans generally have lower cancer rates than the non-Hispanic white population, but they also have the highest incidence rates of liver cancer for both sexes compared with Hispanic, non-Hispanic Whites, or non-Hispanic Blacks (OMH, 2013b). Hispanic youths ages 2 to 19 are more likely to be overweight or obese than the non-Hispanic White or Black youths of the same age, which places them at a greater risk of developing a number of chronic diseases such as type 2 diabetes, high blood pressure, and asthma (Leadership for Healthy Communities, 2014).

Discrimination based on the cultural factors of sexual orientation and gender identity contributes to health and health care inequities. Gay, lesbian, and bisexual young people have a significantly increased risk for depression, anxiety, and substance use disorders and are four times as likely as their straight peers to make suicide attempts that

require medical attention (Hollenbach et al., 2014). Transgender individuals are more likely to postpone medical care because of lack of insurance and encounters with discrimination than people who do not identify as transgender (Hollenbach et al., 2014).

The cultural differences in infant mortality are also alarming. In American Indian and Alaska Native populations, the infant mortality rate is 60% higher than in non-Hispanic Whites (OMH, 2014). In 2008 the infant mortality rate for African-American infants was more than twice the rate for non-Hispanic white infants. Disparities in infant mortality remain even when comparing groups of similar socioeconomic status. For example, the infant mortality rate among children born to college-educated African-American women is significantly higher than among babies born to white women who are similarly educated (Kaiser Family Foundation, 2008).

HEALTH DISPARITIES

Healthy People 2020 defines a **health disparity** as "a particular type of health difference that is closely linked with social, economic, and/or environmental disadvantage" (USDHHS, 2015). The word *parity* means "equality." Health *dis*parity is literally an inequality or difference (i.e., a gap) between the health status of a disadvantaged group such as people with low incomes and wealth and an advantaged group such as people with high incomes and wealth. Members of the disadvantaged group bear a burden of disease, injury, and violence that is out of proportion to the size of the group (CDC, 2013). Although Americans' health overall has improved during the past few decades,

the health of members of marginalized groups has actually declined (CDC, 2013).

So what causes health disparities? People in **marginalized groups** are more likely to have poor health outcomes and die at an earlier age because of a complex interaction between individual genetics and behaviors; public and health policy; community and environmental factors; and quality of health care (United Health Foundation, 2014). Many organizations have developed different models incorporating **social determinants of health** to explain the complexity of these interactions (McGovern et al., 2014). According to the World Health Organization (2013), social determinants of health are "the conditions in which people are born, grow, live, work and age…shaped by the distribution of money, power and resources at global, national, and local levels." Income and wealth, family and household structure, social support, education, occupation, discrimination, neighborhood conditions, and social institutions are some examples of social determinants of health (McGovern et al., 2014).

Health Disparities and Health Care

Health disparities are the differences among populations in the incidence, prevalence, and outcomes of health conditions, diseases, and related complications. On the other hand, **health care disparities** are differences among populations in the availability, accessibility, and quality of health care services (e.g., screening, diagnostic, treatment, management and rehabilitation) aimed at prevention, treatment, and management of diseases and their complications.

Poor access to health care is one social determinant of health that contributes to health disparities. Access to primary care is an important indicator of broader access to health care services. A patient who regularly visits a primary care provider is more likely to receive adequate preventive care than a patient who lacks such access. The 2013 National Healthcare Disparities Report (AHRQ, 2013a) revealed that African-Americans, Asians, and Hispanics are less likely than non-Hispanic Whites to see a primary care provider regularly.

A similar disparity in access to care exists in other disadvantaged groups. Less care is available or accessible to people in low- and middle-income groups compared with people in high-income groups. Uninsured people ages 0 to 64 are less likely to have a regular primary care provider than those with private or public insurance (AHRQ, 2013a). Research suggests that some subgroups of the LGBT community have more chronic health conditions and a higher prevalence and earlier onset of disabilities than heterosexuals (Ranji et al., 2015).

In addition to the poor access to health care, a large body of research shows that health care systems and health care providers can contribute significantly to the problem of health disparities. More than a decade ago, reports by the Institute of Medicine (IOM, 2001, 2010) defined quality health care as care that is safe, effective, patient centered, timely, efficient, and equitable or without variation in outcomes as determined by stratified outcomes data. Although the U.S. health care system has improved in most of these areas since the IOM reports were published, the focus on equity has lagged behind (Mutha et al., 2012). Inadequate resources, poor patient-provider communication, a lack of culturally competent care, fragmented delivery of care, and inadequate access to language services all compromise patient outcomes (NQF, 2012). As a result, many disparities in health care and health outcomes remain.

Disparities in access to care, quality of care, preventive health, health education, and available resources to enable self-management when patients are outside of the health care setting contribute to poor population health. Health disparities are also very costly. Recent analysis estimates that 30% of direct medical costs for Blacks, Hispanics, and Asian Americans are excess because of health inequities and

that overall the economy loses an estimated $309 billion per year because of the direct and indirect costs of disparities (Kaiser Family Foundation, 2012).

Addressing Health Care Disparities

The United States is a complex multicultural society. By the year 2050 the percentage of racial and ethnic minority groups in the United States is expected to climb to 50%. According to the Administration on Aging (2014), the population age 65 years and over increased from 35.9 million in 2003 to 44.7 million in 2013 (a 24.7% increase) and is projected to more than double to 98 million in 2060. The American Community Survey reports that the number of people in poverty increased to about 48.8 million or 15.9%, with African-Americans, Hispanics, and Native Americans having the highest national poverty rates (U.S. Census Bureau, 2013). According to the 2003 *National Adult Assessment of Literacy* (NAAL), only 12% of U.S. adults are proficient in obtaining, processing, and understanding basic health information and services needed to make appropriate health decisions (NCES, 2006). In addition, more than ever before, individuals are openly expressing their religious views, sexual orientation, and gender identities. All of these factors contribute to the complexities of delivering health care in the United States. Thus nurses, other health care providers, and health care organizations need to consider which skills, knowledge, attitudes, and policies can help them deliver the best care to all patients.

The Joint Commission (TJC), the National Quality Forum (NQF), and the National Commission on Quality Assurance (NCQA) are a few of the influential organizations that have responded to these complexities by implementing new standards focused on cultural competency, health literacy, and patient- and family-centered care. These standards recognize that valuing each patient's unique needs improves the overall safety and quality of care and helps to eliminate health disparities.

CULTURE

Culture is associated with norms, values, and traditions passed down through generations. It also has been perceived to be the same as ethnicity, race, nationality, and language (Kleinman and Benson, 2006). A more contemporary view of culture acknowledges its many other facets such as gender, sexual orientation, location, class, and immigration status. This more dynamic perspective recognizes that we all belong simultaneously to multiple social groups within changing social and political contexts, a framework often referred to as **intersectionality** (Box 9-1). According to this framework our memberships in social groups are not neutral. **Oppression** is a formal and informal system of advantages and disadvantages tied to our membership in social groups, such as those at work, at school, and in families (Adams et al., 2007). It impacts an individual's access to resources such as health care, housing, education, employment, and legal services. Whether we live in a disadvantaged community or a community with access to social power and resources, we are all affected by the system of oppression. Understanding the dynamics of oppression that operate on various levels while simultaneously affecting you and your patients helps you engage in the process of becoming more culturally competent.

The many categories that comprise culture are not isolated from each other—they stand alone, interact and are interdependent and mutually reinforcing. Although both groups and individuals within cultural groups may share commonalties in their experiences of oppression(s), there are also differences in these experiences. Including oppression in our definition of culture helps us recognize the profound effect it has on the individual and group experiences of all of us.

BOX 9-1	Key Concepts of Intersectionality

Intersectionality refers to the notion that intersecting categories such as race, ethnicity, gender, socioeconomic status, sexual orientation, and other axes of identity contribute to systemic injustice and social inequality (Cho et al., 2013).

- Social inequality: Groups have unequal access to resources, services, and positions.
- Overinclusion and underinclusion: Many groups have been overlooked in research and the design of interventions. For example, much of what is currently known about racial and ethnic disparities is drawn from national information sources and combines both sexes, despite the large body of evidence of sex and gender differences in the prevalence of health conditions and the use of health services (James et al., 2009).
- Marginalization: Groups are left out (e.g., limited access or exclusion from facets of the society such as political system, labor market, positions of power).
- Social location: One's place in society is based on membership in a social group (e.g., gender, race, class, sexual orientation) that determines access to resources. Social location is not based on biology but on the meaning that society constructs and gives to one's social group.
- Matrix of domination: Instead of thinking about race, gender, immigration status, class, and other axes of identity as descriptive categories only, it is important to understand them within the context of the larger system of power and privilege that permeates society.

Adapted from Murphy Y et al: Incorporating intersectionality in social work practice, research, policy, and education, Washington, DC, 2009, NASW Press.

To better understand this more dynamic and complex way of thinking about culture, consider this example. As a nurse think about how a 27-year-old homeless woman with diabetes, an 85-year-old African-American retired nurse from rural Alabama, a 32-year-old Latina lesbian executive in San Francisco who is Catholic, and an undocumented immigrant woman from Eastern Europe who has a 3-year-old child with a developmental disability experience their womanhood. How may their experiences compare to the experiences of others as they live in America? How do their experiences compare with regard to using a health care system, managing their diabetes, or perceiving the presence or absence of opportunities to live a happy, safe, and productive life? How could age affect their perspective? How would these answers change if one looked at their lives 15 or 35 years ago? How would the experiences change if these individuals were men or transgender? These scenarios are likely to draw a wide range of responses.

Understanding culture requires you to adopt an intersectional perspective like the one in the example. This allows you to consider the multitude of different experiences of your patients so that you can provide effective, evidence-based, culturally competent care.

Culturally Congruent Care

Leininger (2002) defines **transcultural nursing** as a comparative study of cultures to understand their similarities (culture that is universal) and the differences among them (culture that is specific to particular groups). The goal of transcultural nursing is to provide **culturally congruent care**, or care that fits a person's life patterns, values, and system of meaning. Patterns and meaning are generated by people themselves rather than from predetermined criteria. For example, rather than instructing all patients to always take their medications at the same set times during a day, you learn their lifestyle patterns, eating habits, sleep habits, and beliefs about medications and then try to plan a dosage schedule that fits each patient's needs. Culturally congruent care is sometimes different from the values and meanings of the professional health care system. Discovering patients' cultural values, beliefs, and practices as they relate to nursing and health care requires you to assume the role of learner and to partner with your patients and their families to determine what is needed to provide meaningful and beneficial nursing care (Leininger and McFarland, 2002). Effective nursing care integrates the cultural values and beliefs of individuals, families, and communities with the perspectives of a multidisciplinary team of health care providers.

When you provide culturally congruent care, you bridge cultural gaps to provide meaningful and supportive care for all patients. For example, during nursing school you are assigned to care for a female patient who observes Muslim beliefs. You notice the woman's discomfort with several of the male health care providers. You wonder if this discomfort is related to your patient's religious beliefs. While preparing for clinical, you learn that Muslims differ in their adherence to tradition but that modesty is the "overarching Islamic ethic" pertaining to interaction between the sexes (Rabin, 2010). Thus you say to the patient, "I know that for many of our Muslim patients, modesty is very important. Is there some way I can make you more comfortable?" You do not assume that the information will automatically apply to this patient. Instead you combine your knowledge about a cultural group with an attitude of helpfulness and flexibility to provide quality, patient-centered, culturally congruent care.

Meaning of Disease and Illness

Culture affects social determinants of health and how an individual defines the meaning of illness. It also provides the context in which a person interacts with family members, peers, community members, and institutions (e.g., educational, religious, media, health care, legal). Culture and life experiences shape a person's world view about health, illness, and health care.

To provide culturally congruent care, you need to understand the difference between disease and illness. Illness is the way that individuals and families react to disease, whereas disease is a malfunctioning of biological or psychological processes. People tend to react differently to diseases on the basis of their unique cultural perspective. Most health care providers in the United States are primarily educated to treat disease, whereas most individuals seek health care because of their experience with illness. In addition, there is a lack of cultural diversity among health care providers (OMH, 2013c). This often frustrates patients and providers, fostering a lack of trust, lack of adherence, and poor health outcomes. Providing safe, quality care to all patients means taking into consideration both disease and illness.

CULTURAL COMPETENCY

Cultural competency is defined by the National Institutes of Health (2015) as the enabling of health care providers to deliver services that are respectful of and responsive to the health beliefs, practices, and cultural and linguistic needs of diverse patients. Developing cultural competency allows systems, agencies, and groups of professionals to function effectively to understand the needs of groups accessing health information and health care and thus help eliminate health care disparities and ultimately health disparities (NIH, 2015). It is a developmental process that evolves over time. Both individuals and organizations are at various levels of awareness, knowledge, and skills that affect their ability to effectively function in a multicultural context (National Center for Cultural Competence [NCCC], n.d.). According to the NCCC framework, culturally competent organizations:

- Value diversity
- Conduct a cultural self-assessment
- Manage the dynamics of difference
- Institutionalize cultural knowledge
- Adapt to diversity

A culturally competent organization integrates these principles and capabilities into all aspects of the organization (e.g., policy making, administration, service delivery) and systematically involves consumers, key stakeholders, and communities.

In 2000 the Office of Minority Health (OMH) developed the Culturally and Linguistically Appropriate Standards (CLAS). In 2013, after 10 years of successful implementation, the OMH updated the standards to reflect the tremendous growth in the field and the increasing diversity of the nation (Box 9-2). The enhanced national CLAS are intended to advance health equity, improve quality, and help eliminate health care disparities by establishing a blueprint to help individuals and health care organizations implement culturally and linguistically appropriate services (OMH, 2013c).

In its early stages, the field of cultural competency primarily focused on the cultural barriers between health care providers educated in Western health care practices and immigrants arriving from non-Western parts of the world. The early pioneers in cross-cultural medicine outlined a set of universal skills that are still applicable for helping health care providers work effectively with patients from any culture (Berlin and Fowkes, 1982; Kleinman, 1980; Leininger, 2002). These skills include:

1. Respecting a patient's health beliefs as valid and understanding the effect of his or her beliefs on health care delivery

2. Shifting a model of understanding a patient's experience from a disease happening in his or her organ systems to that of an illness occurring in the context of culture (biopsychosocial context)
3. Ability to elicit a patient's explanation of an illness and its causes (patient's explanatory model)
4. Ability to explain to a patient in understandable terms the health care provider's perspective on the illness and its perceived causes
5. Being able to negotiate a mutually agreeable, safe, and effective treatment plan

Expanding the original focus on interpersonal skills, many of the current approaches to cultural competency now also focus on: (1) all marginalized groups and not just immigrants; (2) prejudice, stereotyping, and social determinants of health; and (3) the health system, communities, and institutions (Saha et al., 2008).

You broaden your understanding of the world by learning about other people's world views, which determines how people perceive others, how they interact and relate to reality, and how they process information (Walker et al., 2010). Cultural competency is dynamic and developmental, thus taking time to evolve as a new nurse. A variety of models for acquiring cultural competency exist. One model suggests that nurses see themselves as *becoming* rather than being culturally competent (Campinha-Bacote, 2007) because cultural competency is developmental. Campinha-Bacote's model of cultural competency (2002) has five interrelated components:

- **Cultural awareness:** An in-depth self-examination of one's own background, recognizing biases, prejudices, and assumptions about other people

---

BOX 9-2   National Standards for Culturally and Linguistically Appropriate Services (CLAS) in Health and Health Care

The National CLAS Standards are intended to advance health equity, improve quality, and help eliminate health care disparities by establishing a blueprint for health and health care organizations to:

Principal Standard
1. Provide effective, equitable, understandable, and respectful quality care and services that are responsive to diverse cultural health beliefs and practices, preferred languages, health literacy, and other communication needs.

Governance, Leadership, and Workforce
2. Advance and sustain organizational governance and leadership that promotes CLAS and health equity through policy, practices, and allocated resources.
3. Recruit, promote, and support a culturally and linguistically diverse governance, leadership, and workforce that are responsive to the population in the service area.
4. Educate and train governance, leadership, and workforce in culturally and linguistically appropriate policies and practices on an ongoing basis.

Communication and Language Assistance
5. Offer language assistance to individuals who have limited English proficiency and/or other communication needs, at no cost to them, to facilitate timely access to all health care and services.
6. Inform all individuals of the availability of language assistance services clearly and in their preferred language, verbally and in writing.

7. Ensure the competence of individuals providing language assistance, recognizing that the use of untrained individuals and/or minors as interpreters should be avoided.
8. Provide easy-to-understand print and multimedia materials and signage in the languages commonly used by the populations in the service area.

Engagement, Continuous Improvement, and Accountability
9. Establish culturally and linguistically appropriate goals, policies, and management accountability, and infuse them throughout the organization's planning and operations.
10. Conduct ongoing assessments of the organization's CLAS-related activities and integrate CLAS-related measures into assessment measurement and continuous quality improvement activities.
11. Collect and maintain accurate and reliable demographic data to monitor and evaluate the impact of CLAS on health equity and outcomes and to inform service delivery.
12. Conduct regular assessments of community health assets and needs and use the results to plan and implement services that respond to the cultural and linguistic diversity of populations in the service area.
13. Partner with the community to design, implement, and evaluate policies, practices, and services to ensure cultural and linguistic appropriateness.
14. Create conflict- and grievance-resolution processes that are culturally and linguistically appropriate to identify, prevent, and resolve conflicts or complaints.
15. Communicate the organization's progress in implementing and sustaining CLAS to all stakeholders, constituents, and the general public.

From the United States Department of Health and Human Services (USDHHS): *National standards for culturally and linguistically appropriate services (CLAS) in health and health care,* Washington, D.C., 2013. USDHHS Office of Minority Health.

- **Cultural knowledge:** Sufficient comparative knowledge of diverse groups, including the values, health beliefs, care practices, world view, and bicultural ecology commonly found within each group
- **Cultural skills:** Ability to assess social, cultural, and biophysical factors that influence patient treatment and care
- **Cultural encounters:** Cross-cultural interactions that provide opportunities to learn about other cultures and develop effective intercultural communication
- **Cultural desire:** The motivation and commitment to caring that moves an individual to learn from others, accept the role as a learner, be open to and accepting of cultural differences, and build on cultural similarities.

Blanchet and Pepin (2015) have recently described the processes involved in the development of cultural competence among registered nurses and undergraduate student nurses. Clinical experience and interactions with patients and fellow clinicians help to build cultural competency. The researchers describe three dimensions of cultural competence:

- Building a relationship with the other
- Working outside the usual practice framework
- Reinventing practice in action

When you compare features of the models and the universal skills associated with cultural competence, a central theme is being able to know patients through their eyes and learning their stories. Failing to understand a person's world view may result in your being very impersonal and detached from the individual, and unique, lively individuals become static objects of your assessment. You do not form the important relationship that is needed to provide patient-centered care. You may be tempted to categorize people according to simplistic differences if you approach understanding all patients in the same way (Kumagai and Lypson, 2009). By describing people only in terms of how they differ from the majority, you unintentionally reinforce the dominant culture and lose the details of each individual's character and behavior. As a nurse you are responsible for assessing patients' health issues within their world view. For example, are their issues simply the effects of their illness, or are they associated with underlying societal conditions (Grace and Willis, 2012) such as poverty, lack of transportation, or an unsafe neighborhood?

Patient-Centered Care

Two landmark reports from the Institute of Medicine (IOM)—*Crossing the Quality Chasm* (IOM, 2001) and *Unequal Treatment* (Smedley et al., 2003)—highlight the importance of patient-centered care and cultural competence. *Crossing the Quality Chasm* identifies patient-centered care as one of six "aims" for high quality health care, and *Unequal Treatment* stresses the importance of developing cultural competence among health care providers to eliminate racial/ethnic health care disparities (Box 9-3). The differences between cultural competence and patient-centered care are not always clear. However, Beach and colleagues (2006) succinctly summarize the differences and similarities between these two concepts:

Both patient-centeredness and cultural competence aim to improve health care quality, but each emphasizes different aspects of quality. The primary goal of the patient-centeredness movement has been to provide individualized care and restore an emphasis on personal relationships. It aims to elevate quality for all patients. Alternatively, the primary aim of the cultural competence movement has been to increase health equity and reduce disparities by concentrating on people of color and other disadvantaged populations (p. vii).

BOX 9-3   Patient-Centered Care for LGBT Patients

- Create a welcoming environment that is inclusive of LGBT patients. A health care organization should have a prominently posted nondiscrimination policy or patient bill of rights that explicitly mentions sexual orientation and gender identity. Any displayed art and health materials should include images and topics relevant to LGBT patients.
- Health care organizations should create or designate unisex or single-stall restrooms because patients whose appearance may not conform to traditional gender expressions may feel less comfortable using traditional male- and female-designated restrooms.
- Ensure that visitation policies are fair and implemented in a nondiscriminatory manner. Any denial of access should have a clear medical explanation.
- Avoid assumptions about sexual orientation and gender identity, remembering that any patient can be LGBT, regardless of his or her age, appearance, and other axis of identification.
- Include LGBT-inclusive language on forms and assessments to facilitate disclosure, knowing that disclosure is a choice impacted by many factors. For example, provide options such as "partnered" under relationship status. For parents, use parent/guardian, instead of mother/father.
- Use neutral and inclusive language when talking with patients (e.g., partner or significant other), listening and reflecting patient's choice. Remember that some LGBT patients are also legally married.

Data from Gay and Lesbian Medical Association (GLMA): *Guidelines for care of lesbian, gay, bisexual, and transgender patients*, 2006, http://www.clark.wa.gov/public-health/hiv/documents/GLMA%20Welcoming.pdf. Accessed August 2015.

Campinha-Bacote (2011) views cultural competency as an expansion of patient-centered care. More specifically, cultural competence can be seen as a necessary set of skills for nurses to attain in order to render effective patient-centered care. It is important for nurses to see themselves as becoming culturally competent. Your ability to exercise cultural competence by applying the components of Campinha-Bacote's (2002) model of cultural competency will allow you to deliver patient centered care.

Cultural Awareness. Curiosity about other ways of being in the world is an important attitude for cultural competence; however, it is also important for you to understand the forces that influence your own world view. Everyone holds biases about human behavior. A bias is a predisposition to see people or things in a certain light, either positive or negative. Becoming more self-aware of your biases and attitudes about human behavior is the first step in providing patient-centered care. You should spend time reflecting on what you learned, formally and informally, throughout your life about health, illness (physical and mental), health care system, gender roles, sexual orientation, race, ability, age, family, and many other issues as a part of your commitment to becoming a culturally competent nurse. It is helpful to think about cultural competence as a lifelong process of learning about others and also about yourself.

Cultural Knowledge—World Views. Historical and social realities shape an individual's or group's **world view**, which determines how people perceive others, how they interact and relate to reality, and how they process information (Walker et al., 2010). World view refers to "the way people tend to look out upon the world or their universe to form a picture or value stance about life or the world around them" (Leininger, 2006). The cycle of socialization is the lifetime process of

interacting with family, peers, communities, organizations, media, and institutions through which we develop our world view (Figure 9-1). As a nurse it is important that you advocate for patients by gaining knowledge about their world view. When you assess a patient's cultural background and needs, you take into account each patient's world view, then you plan and provide nursing care in partnership with each patient to ensure that it is safe, effective, and culturally sensitive (McFarland and Eipperle, 2008).

In any intercultural encounter there is an insider perspective (emic world view) and an outsider perspective (etic world view). For example, a Korean woman requests seaweed soup for her first meal after giving birth. This request puzzles her nurse. The nurse has an insider's view of professional postpartum care but is an outsider to the Korean culture. As such, the nurse is not aware of the significance of the meal to the patient. Conversely the Korean patient has an outsider's view of American professional postpartum care and assumes that seaweed soup is available in the hospital because, according to her cultural beliefs, the soup cleanses the blood and promotes healing and lactation (Edelstein, 2011).

It is easy for nurses to stereotype various cultural groups after reading general information about ethnic practices and beliefs (Kleinman, 2013). Avoid stereotypes or unwarranted generalizations about any particular group that prevents an accurate assessment of an individual's unique characteristics and world view. Instead approach each person individually and ask questions to gain a better understanding of his or her perspective and needs.

Health care has its own culture of hierarchies, power dynamics, values, beliefs, and practices. Research supports the idea that group membership such as membership in a professional group shapes one's world view (Sue, 2006). Most health care providers educated in Western traditions are immersed in the culture of science and biomedicine through their course work and professional experience. Consequently they often have a world view that differs from that of their patients (Kleinman, 2013). As a nurse it is best to see every patient encounter as being cross-cultural.

Even when a patient and health care provider are similar in age or have the same gender or ethnicity, two different perspectives are present each time they interact. When patients access the health care system, they want to: (1) see their health care provider, and (2) feel better. In return the health care providers expect patients to: (1) make and keep appointments; (2) give a medication history; (3) give informed consent; (4) follow (discharge) instructions; (5) read, understand, and use health education materials; (6) correctly complete insurance forms; (7) pay their bills; and (8) go home and manage their care by taking their medication the right way, eating the right foods, and stopping/starting/changing a variety of behaviors (AMA, 2007). This list shows how complex each patient interaction is even before the interaction begins. The complexity increases as you consider the interactive effect between a health care provider's and patient's multiple social group identities and unique life experiences.

Nurses, patients, and all other health care providers bring each of their world views into the care process. The Iceberg Analogy (Figure 9-2) is a tool that helps you to visualize the visible and invisible aspects of your world view and recognize that the same applies to your patients. Just as most of an iceberg lies beneath the surface of the water, most aspects of a person's world view lie outside of his or her awareness and are invisible to those around the person. For example, a young female patient who has willingly agreed to be admitted to the hospital for a serious medical condition requiring surgery may refuse the surgery for religious reasons. In the patient's view she came to the hospital for help to eliminate the pain and infection from her illness. At the same time she believes that she needs to seek God's will for a decision that entails removing a body part. The patient's health care provider assumes that the patient is in the hospital to receive care for a serious illness and is willing to accept any and all treatments to cure the illness. The patient's deeply held religious beliefs about removing a body part are not obvious by assessing for a religious preference. Thus you would need to conduct a comprehensive **cultural assessment** (Box 9-4) to understand the patient's world view, including how her religious values affected her willingness to receive care. These deeply held values reside underneath the iceberg. The observed behavior (in this case, coming to the hospital) is a visible sign of a person's world view, but the beliefs, attitudes, knowledge, and experiences that guide the behavior are not visible to others; they lie under the surface. Conflict arises when health care providers interpret the behaviors of patients through their own world view lens instead of trying to uncover the world view that guides this behavior.

Because of differences in age, gender, political preferences, class, religion, or other variables, cultural values frequently differ within a

How We Develop Our World View

CULTURE: Shared experiences and commonalities that have developed and continue to evolve in relation to changing social and political contexts based on multiple social group memberships (Warrier, 2005).

SOCIALIZATION through family, friends, community, peers, schooling, media, work, religious institutions, government, legal system, health care system, etc.

| BOX 9-4 | **Nursing Assessment Questions** |

Open-Ended
- What do you think caused your illness?
- How do you want us to help you with your problem?
- Tell me how your beliefs affect your views on medical treatment choices and your willingness to receive care.

Focused
- Did you have this problem before?
- Is there someone with whom you want us to talk about your care?

Contrast
- How different is this problem from the one you had previously?
- What is the difference between what we are doing and what you think we should be doing for you?

Ethnohistory
- What is your ethnic background or ancestry?
- For patients who are first- or second-generation immigrants:
  - How long have you/your parents resided in this country?
  - Tell me why you/your family left your homeland.
  - How different is your life here from back home?

Sexual Orientation and Gender Identity
- What is your legal name?
- How do you prefer to be addressed?
- What is your preferred pronoun? (he, she, they, or something else)
- What is your gender?
- Are your current sexual partners men, women, or both?
- In the past have your sexual partners been men, women, or both?
- What is your current relationship status?

Social Organization
- Who lives with you?
- Whom do you consider members of your family?

- Where do other members of your family live?
- Who makes the decisions for you or your family?
- To whom do you go outside of your family for support?
- What expectations do you have of your family members and support people? Are there different expectations for family members and support people of different ages and genders?

Socioeconomic Status
- What is your main source of income?
- If employed: What do you do for a living?

Bicultural Ecology and Health Risks
- What caused your problem?
- How does this problem affect or how has it affected your life and your family?
- How do you treat this problem at home?
- What other problems do you have?

Language and Communication
- What language(s) do you speak at home?
- What language(s) do you use to read and write?
- How should we address you or what should we call you?
- Which kinds of communication upset or offend you?

Caring Beliefs and Practices
- What do you do to keep yourself well?
- What do you do to show someone you care?
- How do you take care of sick family members?
- Which caregivers do you seek when you are sick?
- How different is what we do from what your family does for you when you are sick?

single social group such as a family or a group of nurses. For patients, family members, and members of the health care team alike, culture is a process through which ordinary activities such as greeting another person or selecting a doctor take on an emotional tone and moral meaning beyond that which appears on the surface (Kleinman, 2013). Think about the complexity of culture and world views. Realize the need to develop your assessment skills and cultural interventions that will allow you to successfully negotiate the various world views present in encounters with patients and families (and frequently other team members). Most important, remember that the core of this negotiation is compassionate care. Perhaps it may be helpful to think about these encounters as gift exchanges between individuals whose relationship to one another really matters (Kleinman, 2013). During these encounters participants not only exchange information but also acknowledgment, presence, and affirmation (Kleinman, 2013).

Skills and Interventions. You need to develop assessment skills and be able to provide culturally congruent interventions to become culturally competent. To provide patient-centered culturally competent care, you must know how to collect relevant cultural data about a patient's presenting health problem(s) and how to then use it (Campinha-Bacote, 2011). Critical to success is your ability to conduct a systematic cultural assessment, communicate effectively), and have the skills to successfully manage world view differences with others.

Cultural Assessment. The goal of a cultural assessment is to obtain accurate information from a patient that allows you to formulate a mutually acceptable and culturally relevant plan of care for each health problem of a patient (Campinha-Bacote, 2011). Nurses need skills to perform a systematic cultural assessment of individuals, groups, and communities as to their cultural beliefs, values, and practices. Numerous models and assessment tools exist to facilitate cultural assessment, including Leininger's Sunrise Model (2002), Giger and Davidhizar's Transcultural Assessment Model (2002), and the Purnell Model for Cultural Competence (Purnell, 2002). Regardless of which one you select, using a cultural assessment model will help you focus on the information that is most relevant to your patient's problems. It will also help you better understand the complex factors that influence your patient's cultural world view. You need to assess and interpret a patient's perspective during your assessment. Use open-ended, focused, and contrasted questions. Encourage your patients to describe the values, beliefs, and practices that are significant to their care. Culturally oriented questions are by nature broad and require learning more about the patient's personal narratives (see Box 9-4).

One effective approach to assessment is to ask questions that will help you understand a patient's **explanatory model**—his or her views about health and illness and its treatment. There are five questions in most explanatory models: etiology, time and mode of onset of symptoms, pathophysiology, course of illness (including severity and type

of sick role), and treatment for an illness episode. Understanding a patient's perceptions of these concepts and the relationship among them helps you provide patient-centered care that combines a patient's values and beliefs with your perspectives. Using a cultural model during your assessment (such as the one in Figure 9-3 that integrates Kleinman's explanatory model with the previously discussed Iceberg Analogy) will help you develop open-ended questions that effectively reveal your patient's views on illness (Kleinman and Benson, 2006). Table 9-1 summarizes and contrasts a patient's explanatory model of illness with the biomedical explanatory model of illness (Lynch and Medin, 2006).

In contrast to standard approaches for health assessment, cultural assessment is intrusive and may take more time to conduct because it requires building a trusting relationship between participants. Miscommunication commonly occurs in intercultural transactions. This occurs because of differences in verbal communication between participants and differences in interpreting one another's behaviors.

You can use transcultural communication skills to better understand a patient's behavior and to behave in a culturally congruent way. Effective communication is a critical skill in providing quality and safe care.

A number of authors have developed mnemonic cultural assessment and planning tools. Mnemonics, or memory aids, offer you a different option that makes it easier to perform assessments and communicate effectively with patients about their plan of care (Box 9-5). They help you remember the steps of each communication technique. For example, if you use the LEARN mnemonic, your first step is to *l*isten to the patient's explanation or story of the presenting problem. Then you *e*xplain your perception of the patient's problem, whether it is physiological, psychological, or cultural. Then you *a*cknowledge the similarities and differences between the two perceptions. It is important to recognize differences but build on the similarities (Campinha-Bacote, 2011). The fourth step involves *r*ecommendations that require you to involve the patient and family when appropriate. The last step is to then *n*egotiate a mutually agreeable, culturally oriented, patient-centered plan. Remember, cultural assessment and care planning requires a level of negotiation. Leininger (2006) describes cultural care negotiation as assistive, accommodating, facilitative, or enabling creative provider care actions or decisions that help people with different backgrounds adapt to or negotiate with others for culturally congruent care.

Linguistic Competence. **Linguistic competence** is the ability of an organization and its staff to communicate effectively and convey information in a manner that is easily understood by diverse audiences. These audiences include people of limited English proficiency, those who have low literacy skills or are not literate, individuals with disabilities, and those who are deaf or hard of hearing. Linguistic competency requires organizational resources (e.g., instructional resources designed at a 6th-grade reading level or lower, interpreters) and providers who are able to respond effectively to the health and mental health literacy needs of the populations served. One important service that health care organizations must provide is an interpretive service.

Most health care providers and virtually all health care organizations nationwide are subject to federal civil rights laws. These laws outline requirements for the provision of language access services.

TABLE 9-1 **Explanatory Model Comparison**	
Patient's Explanatory Model	**Biomedical Explanatory Model**
What do you call your problem? What name does it have?	Etiology
What do you think has caused your problem? Why do you think it started when it did?	Time and mode of onset
What do you think your sickness does to you? How does this illness work inside your body?	Pathophysiology
What will happen to you? What do you fear most about your sickness? What are the chief problems your sickness has caused for you?	Course of illness (including symptom severity and trajectory: acute, chronic, impaired)
How should your sickness be treated?	Recommended treatment

Adapted from Lynch E, Medin D: Explanatory models of illness: study of within-culture variation, *Cogn Psychol* 53(4):285, 2006.

RN's behavior / Explanatory Model

1. What do you call the problem? What name does it have?
2. What do you think has caused the problem?
3. Why do you think it started when it did?
4. What does your sickness do to you? How does it work?
5. How severe is it? Will it last a long or short time?
6. What do you fear most about this sickness?
7. What are the chief problems your sickness has caused for you?
8. What type of treatment do you think you should receive? What are the most important results you hope to receive from the treatment?

Patient's behavior / Explanatory Model

BOX 9-5   Communication Techniques Using Mnemonics

Communication Technique	Process
LEARN Berlin EA, Fowkes WC Jr: A teaching framework for cross-cultural health care, *West J Med* 139(6):934, 1982.	*L*isten with empathy and understanding to patient's perception of problem. *E*xplain your perceptions of the problem (physiological, psychological, spiritual, and/or cultural). *A*cknowledge and discuss cultural differences and similarities between you and your patient. *R*ecommend treatment (involving patient). *N*egotiate agreement (incorporate selected aspects of patient's culture into patient-centered plan).
RESPECT Bigby JA, editor: *Cross-cultural medicine,* Philadelphia, 2003, American College of Physicians, p. 20.	*R*apport • Connect on a social level. • Seek the patient's point of view. • Consciously attempt to suspend judgment. • Recognize and avoid making assumptions. *E*mpathy • Remember that the patient has come to you for help. • Seek out and understand the patient's rationale for his or her behaviors or illness. • Verbally acknowledge and legitimize the patient's feelings. *S*upport • Ask about and try to understand barriers to care and adherence. • Help the patient overcome barriers by providing resources. • Involve family members if appropriate. • Reassure the patient that you are and will be available to help. *P*artnership • Be flexible with regard to issues of control. • Negotiate roles when necessary. • Stress that you will be working together to address medical problems. *E*xplanations • Check often for understanding. • Use verbal clarification techniques. *C*ultural Competence • Respect the patient and his or her culture and beliefs. • Understand that the patient's view of you may be influenced by stereotypes. • Be aware of your own biases and preconceptions. • Know your limitations in addressing medical issues across cultures. • Understand your personal style and recognize when it may not be working with a given patient. *T*rust • Self-disclosure may be difficult for some patients. • Do not assume trust; instead take necessary time and consciously work to earn trust.
ETHNIC Levin S, Like, R, Gottlieb J: *ETHNIC: a framework for culturally competent clinical practice.* New Brunswick, NJ, 2000, Department of Family Medicine, UMDNJ-Robert Wood Johnson Medical School.	*E*xplanation—Patient explains his or her perception of problem, or you ask what most concerns the patient. *T*reatment—Which types of treatments have the patient tried for the problem? *H*ealers—Has the patient sought advice from alternative health practitioners? *N*egotiate—Try to find an option that is mutually acceptable. *I*ntervention—Agree on an appropriate intervention, which may incorporate alternate treatments. *C*ollaboration—Include patient, family members, and other health care professionals, healers, and community resources.
C-LARA *C-LARA* was developed by the organization Love Makes a Family; *C* (check your pulse) addition has been contributed by the organization Nonviolent Peaceforce.	*C*alm yourself down. Take a deep breath. Check your pulse. *L*isten to the patient's and family's perspective. *A*ffirm: Express connection with something that was shared: a feeling, perspective, principle. *R*espond: To what was said. Answer the question. *A*dd: Share additional information for the patient and family to consider. In this step you can educate.

They also help ensure meaningful access to health care for people with limited English proficiency (LEP) and offer effective communication services for those who are deaf or hard-of-hearing (TJC, 2013). As a nurse, it is critical for you to know that these laws require health care organizations to do the following:

• Provide language assistance services free of charge at all points of contact to all patients who speak limited English or are deaf
• Notify patients, both verbally and in writing, of their right to receive language-assistance services

- Take steps to provide auxiliary aids and services, including qualified interpreters, note takers, computer-aided transcription services, and written materials
- Ensure that interpreters are competent in medical terminology and understand issues of confidentiality and impartiality

Do not use a patient's family members to interpret for you or other health care providers. Cultural dynamics, lack of interpreting skills, low health literacy, and bias could lead to inaccurate interpretation. Box 9-6 provides guidelines for effectively working with an interpreter.

Health Literacy. The concept of linguistic competence encompasses both health literacy and limited English proficiency. Choosing a healthy lifestyle, knowing how to seek medical care, and taking advantage of preventive health care measures requires people to understand and use health information. Health literacy is the ability to obtain, process, and understand health information needed to make informed health decisions (Office of Disease Prevention and Health Promotion, n.d.). Studies show that health literacy has direct effects on health outcomes, linking poor health outcomes to limited health literacy (Berkman et al., 2011; Cho et al., 2008; DeWalt et al., 2004). More specifically, lower health literacy has been associated with higher risk of mortality for seniors, poorer ability to demonstrate taking medications appropriately, poorer ability to interpret labels and health messages, and poorer overall health status among seniors (Berkman et al., 2011). Approximately nine out of ten people in the United States experience challenges in using health care information (NCES, 2006). Patients who are especially vulnerable are the elderly (age 65+), immigrants, people with low incomes, people who do not have a high-school diploma or GED, and people with chronic mental and/or physical health conditions (AMA, 2007).

Commonly used measures of health literacy include literacy measures such as the Rapid Estimate of Adult Literacy in Medicine (REALM), which is a word recognition test; and the Test of Functional Health Literacy in Adults (TOFHLA), which measures reading skills and numeracy. No gold-standard instrument is currently available to assess adequately the more global concept of health literacy, including the interactions of reading ability, numeracy, and oral literacy (Berkman et al., 2011). However, researchers are beginning to develop instruments more specifically for health literacy (e.g., Newest Vital Sign, Diabetes Numeracy Test) that are framed in specific health contexts and assess condition-related skills (Berkman et al., 2011). Interestingly, in a study involving patients in the Veterans Administration (VA) system, the single question, "How confident are you filling out medical forms for yourself", showed a high correlation with being able to detect inadequate health literacy (Chew et al., 2008).

Teach Back. Evidence suggests that health care providers who attend to both health literacy and cultural differences help reduce medical errors and improve adherence, patient-provider-family communication, and outcomes of care at both individual and population levels (Lie et al., 2012). Clear communication is essential for effective delivery of quality and safe health care, but most patients experience significant challenges when communicating with their health care providers. The Teach Back method is an intervention that helps you to confirm that you have explained what a patient needs to know in a manner that the patient understands. The Teach Back technique is an ongoing process of asking patients for feedback through explanation or demonstration and presenting information in a new way until you feel confident that you communicated clearly and that your patient has a full understanding of the information presented (Figure 9-4) (see Chapter 25). You also use Teach Back to help you identify explanations and communication strategies that your patients most commonly understand (AHRQ, 2013b).

When using the Teach Back technique, do not ask a patient, "Do you understand?" or "Do you have any questions?" Instead ask open-ended questions to verify his or her understanding. You can ask the question in the following ways.

- "I've given you a lot of information to remember. Please explain it back to me so I can be sure that I gave you the information you need to take good care of yourself."

BOX 9-6   Working with Interpreters

If a patient needs an interpreter, do not ask the patient's family members and friends or other health care providers not trained as medical interpreters to help with communication. Instead request a medically trained interpreter. The interpreter could be available in person or via technology such as speakerphone or video. During each encounter:

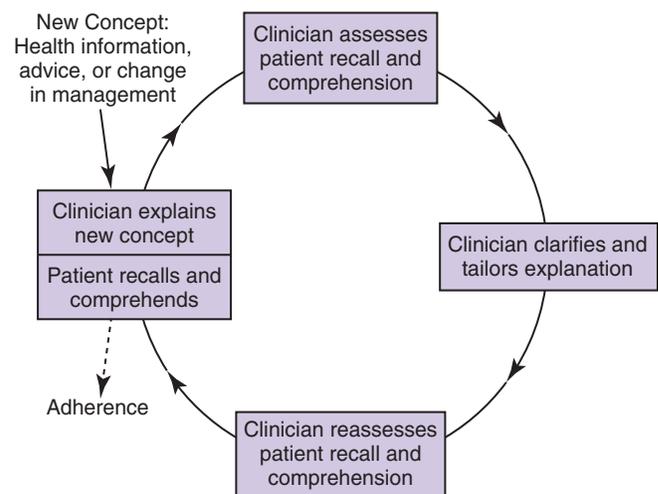
- Introduce yourself to the interpreter and briefly describe the purpose of the meeting.
- Determine the interpreter's qualifications.
- Make sure that the interpreter can speak the patient's dialect or has an appropriate level of certification in case of American Sign Language (ASL).
- Consider the possible impact of differences in educational and socioeconomic status between the patient and the interpreter.
- Make sure that both the patient and interpreter are compatible and that both understand the expectations of the interpreter role.
- Introduce the interpreter to the patient.
- Do not expect the interpreter to interpret your statements word for word. Although the interpreter must ensure that everything that was said is interpreted, he or she may need to use more or fewer words to convey the meaning of your conversation with a patient.
- If you sense that the interpretation is not going well, stop and address the situation directly with the interpreter.
- Pace your speech by using short sentences but do not break your sentences. Allow time for the patient's response to be interpreted.
- Direct your questions to the patient. Look at the patient instead of at the interpreter.
- Ask the patient for feedback and clarification at regular intervals.
- Observe the patient's nonverbal and verbal behaviors.
- Thank both patient and interpreter.


FIGURE 9-4 Using Teach Back technique to close the loop. (From the U.S. Health Resources and Services Administration.)

- "What will you tell your wife (or husband/partner/child) about the changes we made to your medications today?"
- "We've gone over a lot of information today about how you might change your diet, and I want to make sure that I explained everything clearly. In your own words, please review what we talked about. How will you make it work at home?"

It is important to understand that Teach Back is not intended to test a patient but rather to confirm the clarity of your communication (AHRQ, 2013b). Many patients are embarrassed by their inability to sort out health information or instructions. By regarding Teach Back as a test of your communication skills, you take responsibility for the success or failure of the interaction and create a shame-free environment for your patients.

Helpful hints to consider when trying the Teach Back method follow.

- *Plan your approach.* Think about how you will ask your patient to teach back in a shame-free way. Keep in mind that some situations are not appropriate for Teach Back (AHRQ, 2013b).
- *Use handouts, pictures,* and *models* to reinforce your teaching (AHRQ, 2013b).
- *Clarify*. If a patient cannot remember or accurately repeat your instructions, clarify your information and allow him or her to teach it back again. Do this until the patient is able to teach back in his or her own words without parroting back what you said (AHRQ, 2013b). Understand Teach Back as a process of "closing the loop" (see Figure 9-4).
- *Practice***.** Although it takes time to get used to Teach Back, studies show that it doesn't take longer to perform once it becomes a part of your routine (AHRQ, 2013b).

Cultural Encounters. A cultural encounter is an intervention that involves a nurse directly interacting with patients from culturally diverse backgrounds (Campinha-Bacote, 2011). The use of a caring, therapeutic, and culturally congruent relationship will lessen the likelihood of conflict when you engage in such encounters. A cultural encounter enables new forms of community and collective identity between you and your patients. Campinha-Bacote (2011) describes two goals of a cultural encounter: (1) to generate a wide variety of responses and to send and receive both verbal and nonverbal communication accurately and appropriately, and (2) to continuously interact with patients from culturally diverse backgrounds in order to validate, refine, or modify existing values, beliefs, and practices and to develop cultural desire, awareness, skill, and knowledge. The challenge is being able to show compassion, especially if cross-cultural conflict develops. However, conflict gives you an excellent opportunity for developing compassion and sharing one's suffering to achieve better health outcomes for your patients. A patient-centered and culturally competent encounter must be viewed as a "win-and-lose" situation for a patient and a "win-and-lose" situation for a nurse. Such an encounter effectively resolves cultural conflict by avoiding a "win-or-lose" situation for either the patient or nurse and instead results in a "win-lose/win-lose" situation in which the values of both the patient and nurse are respected (Campinha-Bacote, 2011).

Cultural Desire. It is easy to avoid cultural encounters with patients. Time, our personal discomfort in communicating with others who are "different," and a focus on physical care priorities are just some of the factors that may limit encounters with patients. Cultural desire is the motivation of a health care professional to "want to"—not "have to"—engage in the process of becoming culturally competent (Campinha-Bacote, 2011). It involves a natural inclination to engage in the cultural competence process that is characterized by passion,

commitment, and caring. An ethically responsible professional nurse must embrace the importance of cultural competency and apply principles in daily patient encounters.

Within health care organizations today, more changes are occurring to integrate cultural competence principles into everyday organizational processes and practices. Health care regulatory agencies, national think tanks, and government agencies expect health care organizations to incorporate cultural competence into policies and practices to ensure effective communication, patient safety and quality, and patient-centered care. Examples of such organizational policies and practices include:

- Instituting a requirement for all staff to be trained in cultural competence.
- Embedding a broad description of family in written policies.
- Expanding visitation policies and practices to include a patient's preferences.
- Requiring nursing staff to conduct and document a cultural assessment on all patients within the clinical documentation system.
- Ensuring that people who are deaf or speak limited English have access to an interpreter.
- Embedding health literacy principles in written and verbal communication.
- Collecting race, ethnicity, and language information from patients on admission and stratifying outcomes data by these and other demographic indicators to identify disparities in care.
- Using stratified outcomes data to improve the health of populations.

CORE MEASURES

The Joint Commission (TJC) and the Centers for Medicare and Medicaid Services (CMS) are two of the many regulatory bodies that hold health care providers accountable for considering patients' unique cultural perspectives to provide safe and quality care. To improve health outcomes, TJC and the CMS developed a set of evidence-based, scientifically researched standards of care called *core measures* (TJC, 2013). The **core measures** are key quality indicators that help health care institutions improve performance, increase accountability, and reduce costs. All of the core measures such as screening for depression and controlling high blood pressure are consistent with national health priorities. They represent clinical conditions such as heart failure, acute myocardial infarction, pneumonia, and surgical-site infections. Following these standards of care on a nationwide scale is expected to reduce mortality, complications, and inpatient readmissions (Chassin et al., 2010; VanSuch et al., 2006).

In addition, core measures are intended to reduce health disparities. According to the 2013 National Health Care Disparities Report, Blacks and Hispanics received worse care than Whites for about 40% of quality measures; American Indians and Alaska Natives received worse care than Whites for about 30% of core measures; Asians received worse care than Whites for about 25% of core measures; poor people received worse care than high-income people for about 60% of core measures (AHRQ, 2013a).

Although most disparities in quality are significantly worse for some populations compared to White patients, there are some improvements in these outcomes as more and more effort is focused on addressing these disparities. Box 9-7 provides an example of a successful equity-focused QI effort and an evidence-based process for conducting equity-focused QI. The 2013 National Health Care Disparities Report identified that the number of disparities that are getting smaller

BOX 9-7 EVIDENCE-BASED PRACTICE

Equity-Focused Quality Improvement

PICO Question: What is the most effective quality improvement (QI) process that nurses can use to eliminate disparities in patient outcomes on their unit?

Evidence Summary

Health care disparities persist and indicate a clear inequity in care quality on the basis of race, ethnicity, sexual orientation, socioeconomic status, and other accesses of social identity. However, evidence for QI interventions that successfully decreased disparities is limited because of many challenges in developing, implementing, and studying QI with vulnerable populations or in under-resourced settings (Lion and Raphael, 2015). In addition, general QI interventions designed to improve overall quality (as opposed to targeting the specific needs of the population experiencing disparities) may not improve disparities and in some cases may increase them if there is greater uptake or effectiveness of the intervention among the population with better outcomes at baseline (Lion and Raphael, 2015). Designing equity-centered QI efforts is key to eliminating health care disparities.

In a recent study the investigators used an information technology (IT) surveillance for identifying and tracking patients overdue for colorectal cancer (CRC) screening to reduce socioeconomic disparities in their screening (Berkowitz et al., 2015). CRC is the third leading cause of cancer mortality for men and women and can be effectively prevented through different screening strategies (Berkowitz et al., 2015). The investigators implemented this effort in 18 primary care practice sites, including four community health centers within a practice-based research network in and around Boston. After the investigators discovered that CRC screening completion was lower for patients who had not finished high school than for patients who did, they contacted identified patients via letter or a telephone call. In addition, high-risk patients received patient navigation. The intervention resulted in a 3% increase in CRC screening overall and modestly reduced screening disparity among those with a lower level of educational attainment. Although the investigators achieved only a modest reduction in disparities, the intervention demonstrated overall screening improvement from a population health standpoint (Paluri, 2015). This study serves as an example that equity-centered QI efforts can address quality and equity.

Finding Answers, a national program office of the Robert Wood Johnson Foundation (RWJF), has been researching strategies and interventions to eliminate disparities in health outcomes. After conducting 12 systematic literature reviews and funding 33 innovative research projects, Finding Answers recommended a road map for organizations looking to implement equity-focused QI efforts and eliminate disparities in health outcomes (Clarke et al., n.d.).

Application to Nursing Practice

Emerging evidence-based strategies can help health care organizations working to reduce disparities in health outcomes. The road map offers a comprehensive approach to achieving equity. Use the following six steps described in *A Roadmap and Best Practices for Organizations to Reduce Racial and Ethnic Disparities in Health Care* (Chin et al., 2012) to implement equity-focused QI in your practice:

1. *Recognize disparities and commit to reducing them.* The Affordable Care Act makes the collection of a health care organization's performance data stratified by race, ethnicity, and language (REL) a priority. Cultural competency will improve your ability to assess for patient disparities.
2. *Implement a basic quality improvement structure and process.* An ongoing process is needed for a health care organization to build interventions. Nursing staff play a role in identifying opportunities to improve practice approaches for vulnerable patient groups.
3. *Make equity an integral component of quality improvement efforts.* It is necessary for health care organizations to think about the needs of vulnerable patients served as they design interventions to improve patient care.
4. *Design the intervention(s).* Interventions should be designed using evidence-based strategies; however, they must be tailored to fit the patient population and the context. They should target one or more of the appropriate levels of influence (i.e., the patient, provider, microsystem, organization, community, or policy).
5. *Implement, evaluate, and adjust the intervention(s).* Organizations should start by implementing a change on a small scale (pilot testing), learning from each test, and refining the intervention through performance improvement cycles (e.g., plan, do, study, and act) (PDSA) (see Chapter 5). This process will help organizations prepare for implementation on a larger scale
6. *Sustain the intervention(s).* Any change in practices must be continuously evaluated to ensure that recommended interventions are maintained.

---

exceeded the number that are getting larger for Blacks, Hispanics, Asians, and individuals with lower socioeconomic status (AHRQ, 2013a).

Nurses and other health care providers need to be familiar with how policies and institutional forces enable or inhibit their ability to provide culturally competent, patient-centered, high-quality, safe care to all patients. When policies impede the delivery of effective care, you and your colleagues must advocate for policy change.

QSEN: BUILDING COMPETENCY IN QUALITY IMPROVEMENT You are a nurse on a cardiology floor. Some of your patients have been readmitted to the hospital within 30 days of discharge with the same prestischarge diagnosis. You don't know why some patients are readmitted at a rate that seems higher than other patients. How might you identify patients with the highest readmission rate? What are some steps you could take to determine the patient's ability to self-manage post-discharge?

Ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

KEY POINTS

- Disparities in the access to quality of health care, preventive health, and health education contribute to poor population health.
- Health care systems and providers contribute to the problem of health disparities as a result of inadequate resources, poor patient-provider communication, lack of culturally competent care, fragmented delivery of care, and inadequate access to language services.
- Culturally competent health care providers and organizations can contribute to elimination of health disparities.
- Current evidence shows that addressing limited health literacy and cultural differences often reduces medical errors and improves adherence, patient-provider-family communication, and outcomes of care.
- Cultural desire involves a natural inclination to engage in the cultural competence process that is characterized by passion, commitment, and caring.
- A person's culture and life experiences shape his or her world view about health, illness, and health care.

- An effective approach to patient assessment is to use a patient's explanatory model instead of a traditional biomedical model to reveal your patient's views on illness
- Becoming culturally competent is an ongoing long-term process for a health care provider.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Ms. Jackson is a 44-year-old overweight woman who was diagnosed with diabetes 2 years ago and is now insulin dependent. In 2012 the company she worked for downsized, and Ms. Jackson lost her job. As a result she was unable to pay her mortgage and became homeless. Since then she has been staying with various family members and friends because she has not been able to afford her own apartment. She has been working as an office temp from time to time but has not been able to find full-time work. She arrived at the emergency department (ED) with a blood sugar of 322 (normal range is 80 to 120) and a hemoglobin A1C of 11% (normal is approximately 5%).

Sam is a 23-year-old nursing student assigned to care for Ms. Jackson. After Sam reads Ms. Jackson's chart, she notices that she has come to the ED on several occasions over the past 6 months with the same issue. She also notices that health care providers who took care of Ms. Jackson during the previous visits documented that she verbalized an understanding of how to manage her diabetes but has been nonadherent with her treatment plan.

After Sam conducts a cultural assessment using an explanatory model with questions, she learns that Ms. Jackson fears that she will eventually die because her mother died of diabetes. She also learns that Ms. Jackson cannot get her medications filled because she doesn't have health insurance. After obtaining this information, Sam consults with a social worker, who tells Sam about a community health center within eight blocks of the place where Ms. Jackson is currently living. This health center has a diabetes management program and can offer ongoing support to Ms. Jackson. Sam spends time with Ms. Jackson explaining that people do not die from diabetes if they manage it effectively. Sam also discusses with Ms. Jackson some realistic ways to manage her diabetes given her challenging circumstances. In addition, she escorts Ms. Jackson to the social worker's office so they can discuss possible housing and unemployment resources. Sam realizes that there is an opportunity for her to learn more about the social determinants of health that affect Ms. Jackson's ability to manage her care. She also realizes that by gaining skills in cultural competence she will be more confident in providing culturally competent care to her patients.

1. List some of the social determinants of health that Sam most likely discovered while conducting a cultural assessment with Ms. Jackson.
2. On the basis of a cultural assessment, Sam discovers that Ms. Jackson believes that she may die. Select the C-LARA communication mnemonic listed in this chapter and plot a discussion that might help Ms. Jackson understand that diabetes is a manageable chronic illness that does not have to result in death.
3. Ms. Jackson is discharged and returns to the ED several months later because she is having difficulty managing her diabetes again. You are assigned to care for her. How will her weight, history of nonadherence, and past visits to the ED possibly affect your treatment? How could these factors trigger biases and assumptions that will get in the way of providing quality care? How could self-awareness help you reduce the effect of bias on the quality of care you provide?

Ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse enters the examination room of the emergency clinic and meets a 29-year-old patient who missed her last two follow-up appointments. The nurse notes from the medical record that the patient has high blood pressure that the doctor has been trying to help her manage. The patient just spoke with her doctor who left the room frustrated because the patient has not been taking her medication as prescribed. The patient confronts the nurse, saying, "I'm tired of being treated this way; no one cares. I need to find another doctor!" Using the C-LARA mnemonic, match the nurse's response to the correct letter of the mnemonic.

   1. C _____
   2. L _____
   3. A _____
   4. R _____
   5. A _____

   a. The nurse acknowledges that it is absolutely reasonable for patients to expect that their health care providers care about their situations and that it is disappointing when they have experiences that make them feel like they do not.
   b. The nurse uses a relaxation technique before responding to the patient's concerns. Calm yourself. Take a deep breath. Check your pulse.
   c. The nurse says, "I want to help you. I can do that better if you tell me what's making it difficult for you to come to your appointments and take your medicine each day."
   d. The nurse maintains eye contact and allows the patient to discuss her perspective while remaining attentively quiet.
   e. The nurse explains, "One thing I want you to understand is that your blood pressure medicine will only work if you take the same amount each day. Your follow-up appointments are important so we can get this blood pressure under control. Let me get a social worker who can help you figure out these transportation issues or see if he can find a doctor closer to your house."

2. Which of the following are considered social determinants of health? (Select all that apply.)
   1. Lack of primary health care providers in a zip code
   2. Poor-quality public school education that prevents a person from developing adequate reading skills
   3. Lack of affordable health insurance
   4. Employment opportunities that do not provide paid vacation or sick leave
   5. The number of times a person exercises during a week
   6. Neighborhood safety that prevents a person from walking around the block or socializing with neighbors outside of his or her home

3. Which of the following changes can help create a more inclusive environment for lesbian, gay, bisexual, and transgender (LGBT) patients? (Select all that apply.)
   1. Explicitly including sexual orientation and gender identity into nondiscrimination policies
   2. Displaying art that reflects LGBT community
   3. Modifying health care forms to provide opportunities for gender identity and sexual orientation disclosure
   4. Not asking patients about their gender identity and sexual orientation to avoid making them uncomfortable
   5. Ensuring access to unisex or single-stall bathrooms

4. Which of the following are examples of problems with the health care system that contribute to health disparities? (Select all that apply.)
   1. A health care provider assumes that the patient missed two appointments because the patient does not care about his or her health and does not inquire about the reasons for missed visits.
   2. The discharge nurse at a hospital uses Teach Back with a patient to ensure that she has communicated the discharge instructions clearly.
   3. A community hospital lacks an adequate staff of social workers who are able to ensure patients' access to resources they need to take care of their health.
   4. A hospital discharges a patient without ensuring that the patient has a primary care provider and has made a follow-up appointment.
   5. A nurse uses a family member as an interpreter to explain the patient's medications.
   6. The hospital conducts quality improvement without stratifying data by race, ethnicity, language, socioeconomic status, sexual orientation, and other axes of social group identities.

5. Match each letter of the RESPECT mnemonic with a statement that describes the concept the letter represents.
   1. R. _____
   2. E. _____
   3. S. _____
   4. P. _____
   5. E. _____
   6. C. _____
   7. T. _____

   a. Ask about and try to understand barriers to care and adherence, and then offer resources to help the patient overcome them, involving family members if appropriate, and reassuring the patient that you are and will be available to help.
   b. Patients may have different reasons for not disclosing important information. Earn a patient's confidence through actions and attitude that demonstrate respect, compassion, and your interest in partnership.
   c. Work closely together with the patient by being flexible with regard to issues of control, negotiating roles when necessary, and stressing that you will be working together to mutually address medical problems.
   d. Provide explanations for the process and your action, checking often for understanding and using verbal clarification techniques such as Teach Back.
   e. Approach each encounter thinking about cultural competence and how you can demonstrate respect for the patient and his or her culture and beliefs.
   f. Approach the encounter with empathy, remembering that the patient has come to you for help. Seek out and understand the patient's rationale for his or her behaviors or illness, verbally acknowledging and legitimizing his or her feelings.
   g. Connect on a social level, seeking the patient's point of view; consciously attempt to suspend judgment; and avoid making assumptions.

6. A patient is admitted through the emergency department (ED) after a serious car accident. The nurse assesses the patient and quickly learns that he speaks little English. Spanish is his primary language. The nurse speaks some Spanish. Which interventions would be appropriate at this time? (Select all that apply.)
   1. The nurse requests a professional interpreter.
   2. Since this is an emergent situation, the nurse will interpret and identify the patient's priority needs.
   3. The nurse determines the interpreter's qualifications and makes sure that the interpreter can speak the patient's dialect.
   4. The nurse uses short sentences to explain the treatments provided in the ED.
   5. The nurse directs questions to the patient by looking at the patient instead of at the interpreter.

7. A new nurse is caring for a hospitalized obese patient who is homeless. This is the first time the patient has been admitted to the hospital, and the patient is scheduled for surgery. Which of the following is a universal skill that will help the nurse work effectively with this patient?
   1. The nurse shifts her focus to understanding the patient by asking her, "Describe for me the course of your illness."
   2. The nurse tells the patient, "Your choices of foods and unwillingness to exercise are adding to your health problems."
   3. The nurse asks the patient, "Tell me about the main problems you have had with your health from not having a home."
   4. The nurse explains, "Because you have obesity, it is important to know the effects it has on wound healing because of reduced tissue perfusion."

8. Which statement made by a new graduate nurse about the teach-back technique requires intervention and further instruction by the nurse's preceptor?
   1. "After teaching a patient how to use an inhaler, I need to use the Teach Back technique to test my patient's understanding."
   2. "The Teach Back technique is an ongoing process of asking patients for feedback."
   3. "Using Teach Back will help me identify explanations and communication strategies that my patients will most commonly understand."
   4. "Using pictures, drawings, and models can enhance the effectiveness of the Teach Back technique."

9. In the United States, there has never been a president of Asian or Hispanic culture. This is an example of:
   1. Social inequality
   2. Marginalization
   3. Under inclusion
   4. Social location

10. A nurse has worked in a home health agency for a number of years. She goes to visit a patient who has diabetes and who lives in a public housing facility. This is the first time the nurse has cared for the patient. The patient has four other family members who live with her in the one-bedroom apartment. Which of the following, based on Campinha-Bacote's (2002) model of cultural competency, is an example of cultural awareness?
    1. The nurse begins a discussion with the patient by asking, "Tell me about your family members who live with you?"
    2. The nurse asks, "What do you believe is needed to make you feel better?"
    3. The nurse silently reflects about how her biases regarding poverty can influence how she assesses the patient.
    4. The nurse uses a therapeutic and caring approach to how she interacts with the patient.

11. Match the following definitions with the key terms related to intersectionality.
    1. Under inclusion
    2. Social inequality
    3. Social location

    a. Groups have unequal access to resources, services, and positions.
    b. A group has been overlooked in research and the design of interventions.
    c. One's place in society is based on membership in a social group that determines access to resources.

12. A nurse is preparing to perform a cultural assessment of a patient. Which of the following questions is an example of a contrast question?
    1. Tell me about your ethnic background.
    2. Have you had this problem in the past?
    3. Where do other members of your family live?
    4. How different is this problem from the one you had previously?
13. How can a nurse work on developing cultural awareness? (Select all that apply.)
    1. Reflect on his or her past learning about health, illness, race, gender, and sexual orientation
    2. Develop greater self-knowledge about personal biases
    3. Recognize consciously the multiple factors that influence his or her own world view
    4. Engage in an in-depth self-examination of his or her own background
    5. Learn as many facts as possible about an ethnic group
14. During an encounter with an elderly patient, the nurse recognizes that a thorough cultural assessment is necessary because the patient has recently come to the United States from Russia and has never been hospitalized before. The nurse wants to discuss cultural similarities between herself and the patient. Which step of the LEARN mnemonic is this?

1. Listen
2. Explain
3. Acknowledge
4. Recommend treatment
5. Negotiate agreement

15. When you care for a patient who does not speak English, it is necessary to call on a professional interpreter. Which of the following are proper principles for working with interpreters? (Select all that apply.)
    1. Expect the interpreter to interpret your statements word-for-word so there is no misunderstanding by the patient.
    2. If you feel an interpretation is not correct, stop and address the situation directly with the interpreter.
    3. Pace a conversation so there is time for the patient's response to be interpreted.
    4. Direct your questions to the interpreter.
    5. Ask the patient for feedback and clarification at regular intervals.

Answers: 1. 1b, 2d, 3a, 4c, 5e; **2.** 1, 2, 3, 4, 6; **3.** 1, 2, 3, 5; **4.** 1, 3, 4, 5, 6; **5.** 1g, 2f, 3a, 4c, 5d, 6e, 7b; **6.** 1, 3, 4, 5; **7.** 3; **8.** 1; **9.** 2; **10.** 3; **11.** 1b, 2a, 3c; **12.** 4; **13.** 1, 2, 3, 4; **14.** 3; **15.** 2, 3, 5.

Caring for Families

THE FAMILY

The family is a central institution in society; however, the concept, structure, and functioning of the family unit continue to change over time. Families face many challenges, including the effects of health and illness, childbearing and childrearing, changes in family structure and dynamics, and caring for older parents. Family characteristics or attributes such as durability, resiliency, and diversity help families adapt to these challenges.

Family durability is a system of support and structure within a family that extends beyond the walls of the household. For example, the parents may remarry, or the children may leave home as adults, but in the end the "family" transcends long periods and inevitable lifestyle changes.

Family resiliency is the ability of a family to cope with expected and unexpected stressors. The family's ability to adapt to role and structural changes, developmental milestones, and crises shows resilience. For example, a family is resilient when the wage earner loses a job and another member of the family takes on that role. The family survives and thrives as a result of the challenges they encounter from stressors.

Family diversity is the uniqueness of each family unit. For example, some families experience marriage for the first time and then have children in later life. Another family includes parents with young children and grandparents living in the home. Every person within a family unit has specific needs, strengths, and important developmental considerations.

As you care for patients and their families, you are responsible for understanding family dynamics, which include the family makeup (configuration), structure, function, problem-solving, and coping

capacity. Use this knowledge to build on a patient's and family's strengths and resources (Duhamel, 2010). The rapidly changing health care delivery system promotes early discharge of patients back to the community. Living as a family in the midst of an illness is challenging; family functions, communications, and roles are altered (Arestedt et al., 2013). The goal of family-centered nursing care is to address the comprehensive health care needs of the family as a unit; and to advocate, promote, support, and provide for the well-being and health of the patient and individual family members (Martin et al., 2013; Brazil et al., 2012; Popejoy, 2011).

Concept of Family

The term family brings to mind a visual image of adults and children living together in a satisfying, harmonious manner (Figure 10-1). For some this term has the opposite image. Families represent more than a set of individuals, and a family is more than a sum of its individual members (Kaakinen et al., 2014). Families are as diverse as the individuals who compose them. Patients have deeply ingrained values about their families that deserve respect.

The specific relationships among patient, families, and health care providers are at the center of patient and family care. Unfortunately these relationships are often defined and shaped by the beliefs of health care providers (Bell, 2013), and not the needs of the patient and family caregiver. As a nurse, you need to assess for and understand how your patients define their families and how they perceive the general state of member relationships. Think of a **family** as a set of relationships that a patient identifies as family or as a network of individuals who influence one another's lives, whether or not there are actual biological or legal ties.

FIGURE 10-1 Family celebrations and traditions strengthen the role of the family.

Definition: What Is a Family?

Defining family initially appears to be a simple undertaking. However, different definitions result in heated debates among social scientists and legislators. The definition of family is significant and affects who is included on health insurance policies, who has access to children's school records, who files joint tax returns, and who is eligible for sick-leave benefits or public assistance programs. The family is defined biologically, legally, or as a social network with personally constructed ties and ideologies. For some patients, family includes only people related by marriage, birth, or adoption. To others, aunts, uncles, close friends, cohabiting people, and even pets are family. Understand that families take many forms and have diverse cultural and ethnic orientations. No two families are alike; each has its own strengths, weaknesses, resources, and challenges. You must care for both the family and the patient. Effective nursing administrators have a clear vision that caring for families is crucial to the mission of the health care facility and the health of the nation (Bell, 2014).

FAMILY FORMS AND CURRENT TRENDS

Family forms are patterns of people considered by family members to be included in a family (Box 10-1). Although all families have some things in common, each family form has unique problems and strengths. Remain open about who makes up a family so you do not overlook potential resources and concerns.

Although the institution of the family remains strong, the family itself is changing. In some situations people are marrying later, women are delaying childbirth, and couples are choosing to have fewer children or none at all. The number of people living alone is expanding rapidly and represents approximately 25% of all households (U.S. Bureau of the Census, 2011). Between 2006 and 2010, the Centers for Disease Control and Prevention reported the probability of a first marriage lasting at least 10 years as 68% for women and 70% for men and the probability of a first marriage surviving 20 years as 52% for women and 56% for men (Copen et al., 2012). A number of divorced adults remarry. Remarriage often results in a blended family with a complex set of relationships among all members

Marital roles are also more complex as families increasingly comprise two wage earners. The majority of women work outside the home, and about 60% of mothers are in the workforce (U.S. Bureau of the Census, 2011). Balancing employment and family life creates a

---

BOX 10-1   Family Forms

Nuclear Family
The nuclear family consists of husband and wife (and perhaps one or more children).

Extended Family
The extended family includes relatives (aunts, uncles, grandparents, and cousins) in addition to the nuclear family.

Single-Parent Family
The single-parent family is formed when one parent leaves the nuclear family because of death, divorce, or desertion or when a single person decides to have or adopt a child.

Blended Family
The blended family is formed when parents bring unrelated children from prior adoptive or foster parenting relationships into a new, joint living situation.

Alternative Family
Relationships include multi-adult households, "skip-generation" families (grandparents caring for grandchildren), communal groups with children, "nonfamilies" (adults living alone), cohabiting partners, and homosexual couples.

---

variety of challenges in terms of child care and household work for both parents.

The number of single-parent families appears to be stabilizing. Forty-one percent of children are living with mothers who have never married; many of these children are a result of an adolescent pregnancy. Although mothers head most single-parent families, father-only families are on the rise (U.S. Bureau of the Census, 2011).

Adolescent pregnancy is an ever-increasing concern. The majority of adolescent mothers continue to live with their families. A teenage pregnancy has long-term consequences for the mother. For example, adolescent mothers frequently quit high school and have inadequate job skills and limited health care resources. The overwhelming task of being a parent while still being a teenager often severely stresses family relationships and resources. In addition, there is an increased risk for subsequent adolescent pregnancy, inability to obtain quality job skills, and poor lifestyles (Harper et al., 2010). Stressors are also placed on teenage fathers when their partner becomes pregnant. Teenage fathers usually have poorer support systems and fewer resources to teach them how to parent. In addition, adolescent fathers report early adverse family relationships such as exposure to domestic violence and parental separation or divorce and lack positive fathering role models (Biello et al., 2010). As a result, both adolescent parents often struggle with the normal tasks of development and identity but must accept a parenting role that they are not ready for physically, emotionally, socially, and/or financially.

Many homosexual couples define their relationship in family terms. Approximately half of all gay male couples live together compared to three fourths of lesbian couples. Same-sex couples are more open about their sexual preferences and more vocal about their legal rights. Some homosexual families include children, through adoption or artificial insemination or from prior relationships (Reczek and Umberson, 2012).

The fastest-growing age-group in America is 65 years of age and over. For the first time in history the average American has more living parents than children, and children are more likely to have living

grandparents and even great-grandparents. This "graying" of America continues to affect the family life cycle, particularly the "sandwich generation"—composed of the children of older adults (see section on restorative care). These individuals, who are usually in the middle years, have to meet their own needs along with those of their children and their aging parents. This balance of needs often occurs at the expense of their own well-being and resources.

Family caregivers also require support from professional health professionals (Touhy and Jett, 2014). These caregivers frequently provide more than 20 hours of care per week, and this care is integrated into current family and work obligations (Touhy and Jett, 2014). Caring for a frail or chronically ill relative is an ongoing process in which families must continue to redefine their relationships and roles (Arestedt et al., 2013). It is not uncommon for spouses in their 60s and 70s to be the major caregivers for one another, and these caregivers have unique concerns (Box 10-2).

More grandparents are raising their grandchildren (U.S. Bureau of the Census, 2011). This new parenting responsibility is the result of a number of societal factors: military deployment, unemployment, adolescent pregnancy and substance abuse; and divorce rate resulting in single parenthood. Most grandparents resume a parenting role for their grandchildren as a consequence of legal intervention when parents are unfit or renounce their parental obligations (Touhy and Jett, 2014).

Families face many challenges, including changing structures and roles in the changing economic status of society. In addition, social scientists identify five further trends as threats or concerns facing families: (1) changing economic status (e.g., declining family income and lack of access to health care), (2) homelessness, (3) domestic violence, (4) the presence of acute or chronic illnesses or trauma, and (5) end-of-life care (Kim et al., 2011; Martin et al, 2013).

Changing Economic Status

For some families, making ends meet is a daily concern because of their declining economic status. Economics affects families at the lower end of the economic scale, and single-parent families are especially vulnerable. As a result, many families have inadequate health insurance coverage. Because of recent economic trends, adult children are often faced with moving back home after college because they cannot find employment or in some cases lose their jobs.

The number of American children living below the poverty level continues to rise. There are 16.4 million children living below the poverty level; and approximately 8 million children are uninsured (Children's Defense Fund [CDF], 2014). Although the Affordable Care Act (ACA) aims to improve access to affordable health insurance, the challenge to access appropriate health care continues (USDHHS, 2014). When caring for these families, be sensitive to their need for independence and help them obtain appropriate financial and health care resources. For example, help a family by providing information about resources within the community to obtain assistance with energy bills, dental and health care, and school supplies.

Homelessness

Homelessness is a major public health issue. According to public health organizations, absolute homelessness describes people without physical shelter who sleep outdoors, in vehicles, in abandoned buildings, or in other places not intended for human habitation. Relative homelessness describes those who have a physical shelter but one that does not meet the standards of health and safety (National Coalition for the Homeless, 2014).

The fastest growing section of the homeless population is families with children. This includes complete nuclear families and single-parent families. It is expected that 3.5 million people are homeless and 1.35 million are families with children. Poverty, mental and physical illness, and lack of affordable housing are primary causes of homelessness (National Coalition for the Homeless, 2014). Homelessness severely affects the functioning, health, and well-being of the family and its members (CDF, 2014). Children of homeless families are often in fair or poor health and have higher rates of asthma, ear infections, stomach problems, and mental illness (see Chapter 3). As a result, usually the only access to health care for these children is through an emergency department.

Children who are homeless face difficulties such as meeting residency requirements for public schools, inability to obtain previous enrollment records, and enrolling in and attending school. As a result, they are more likely to drop out of school and become unemployable (National Coalition for the Homeless, 2014). Homeless families and their children are at serious risk for developing long-term health, psychological, and socioeconomic problems. For example, children are frequently under immunized and at risk for childhood illnesses; they may fall behind in school and are at risk of dropping out; or they can develop risky behaviors (CDF, 2014).

Domestic Violence

Domestic violence includes not only intimate-partner relationships of spousal, live-in partners, and dating relationships, but also familial, elder, and child abuse. Abuse includes emotional, physical, and sexual abuse, which occurs across all social classes (Futures without Violence, 2014).

Factors associated with family violence are complex and include stress, poverty, social isolation, psychopathology, and learned family behavior. Other factors such as alcohol and drug abuse, pregnancy, sexual orientation, and mental illness increase the incidence of abuse within a family (Futures without Violence, 2014). Although abuse sometimes ends when one leaves a specific family environment, negative long-term physical and emotional consequences often linger. One of the consequences includes moving from one abusive situation to another. For example, an adolescent girl sees marriage as a way to leave

her parents' abusive home and in turn marries a person who continues the abuse in her marriage.

IMPACT OF ILLNESS AND INJURY

Any acute or chronic illness influences an entire family economically, emotionally, socially, and functionally and affects a family's decision-making and coping resources. Hospitalization of a family member is stressful for the whole family. Hospital environments are foreign, physicians and nurses are strangers, the medical language is difficult to understand or interpret, and family members are separated from one another.

Acute/Chronic Illness

During an acute illness such as a trauma, myocardial infarction, or surgery, family members are often left in waiting rooms to receive information about their loved one. Communication among family members may be misdirected from fear and worry. Sometimes previous family conflicts rise to the surface, whereas others are suppressed. When implementing a patient-centered care model, patients' family members and surrogate decision makers must become active partners in decision making and care. Involving family during bedside handover from one care provider to another, for example, provides an opportunity to involve the patient and family in discussing the present and long-term plan of care (Tobiano et al., 2012). When possible, patients and family caregivers want to participate in shared decision making about treatment and ongoing disease/symptom management (Brazil et al., 2012). Incorporating a patient's and family's cultural beliefs, values, and communication patterns is essential to provide individualized patient/family-centered care (Campinha-Bacote, 2011).

Chronic illnesses are a global health problem and present continuous challenges for families. Frequently family patterns and interactions, social activities, work and household schedules, economic resources, and other family needs and functions must be reorganized around the chronic illness or disability. Despite the stressors, families want to accept and manage the illness and strive to gain a balance in family life (Arestedt et al., 2013). Astute nursing care involves the patient and family in preventing and/or managing medical crises, controlling symptoms, learning how to provide specific therapies, adjusting to changes over the course of the illness, avoiding isolation, obtaining community resources, and helping the family with conflict resolution (Arestedt et al., 2013; O'Shea et al., 2014).

Trauma

Trauma is sudden, unplanned, and sometimes life-threatening. Family members often struggle to cope with the challenges of a severe life-threatening event, which can include the stressors associated with a family member hospitalized in an intensive care environment, anxiety, depression, economic burden, and the impact of the trauma on family functioning and decision making (McDaniel and Allen, 2012). The powerlessness that family members experience makes them very vulnerable and less able to make important decisions about the health of the family. In caring for family members, advocate for the patient and family and answer their questions honestly (Grant and Ferrell, 2012). When you do not know the answer, find someone who does. Provide realistic assurance; giving false hope breaks the nurse-patient trust and also affects how the family can adjust to "bad news." When a patient who has experienced trauma is hospitalized, take time to make sure that the family is comfortable. You can bring them something to eat or drink, give them a blanket, or encourage them to get a meal. Sometimes telling a family that you will stay with their loved one while they are gone is all they need to feel comfortable in leaving.

End-of-Life Care

You will encounter many families with a terminally ill member. Although people equate terminal illness with cancer, many diseases have terminal aspects (e.g., heart failure, pulmonary and renal diseases, and neuromuscular diseases). Although some family members may be prepared for their loved one's death, their need for information, support, assurance, and presence is great (see Chapter 37). Use presence to refine a therapeutic relationship with a patient and family (see Chapter 7). Also use presence and therapeutic communication to enhance family members' relationships with one another and to promote shared decision making (Dobrina et al., 2014). The more you know about your patient's family, how they interact with one another, their strengths, and their weaknesses, the better. Each family approaches and copes with end-of-life decisions differently. Encourage the patient and family to make decisions about care (e.g., pain control or preferred nonpharmacologic comfort measures) and specific therapies. Help the family set up home care if they desire and obtain hospice and other appropriate resources, including grief support (Brazil et al., 2012). Provide information about the dying process and make sure family members know what to do at the time of death. If you are present at the time of death, be sensitive to the family's needs (e.g., provide for privacy and allow sufficient time for saying good-byes).

APPROACHES TO FAMILY NURSING: AN OVERVIEW

Understanding family developmental stages and attributes enables you to provide nursing care to a patient, the family as a whole, and individuals within the family structure. These theoretical perspectives and their concepts provide the foundation for family assessment and interventions.

Developmental Stages

Families, like individuals, change and grow over time. Although they are far from identical to one another, they tend to go through common stages. Each developmental stage has its own challenges, needs, and resources and includes tasks that need to be completed before the family is able to successfully move on to the next stage. Societal changes and an aging population have caused changes in the stages and transitions in the family life cycle. For example, adult children are not leaving the nest as predictably or as early as in the past, and many are returning home. In addition, more people are living into their 80s and 90s. Sixty-five is now considered the "backside of middle age," and the length of the midlife stage in the family life cycle has increased, as has the later stage in family life.

McGoldrick and Carter based their 1985 classic model of family life stages on expansion, contraction, and realignment of family relationships that support the entry, exit, and development of the members (Kaakinen et al., 2014). This model describes the emotional aspects of lifestyle transition and the changes and tasks necessary for the family to proceed developmentally (Table 10-1). Use this model to promote family behaviors to achieve essential tasks and help families prepare for later transitions (e.g., preparing for a new baby or adjusting to dealing with chronic illness) (see Chapter 13).

Attributes of Families

It is important to assess for and understand how family attributes affect the care of a family. Families have a structure and a way of functioning. Structure and function are closely related and continually interact with one another and impact family health.

TABLE 10-1 **Stages of the Family Life Cycle**		
Family Life-Cycle Stage	**Emotional Process of Transition: Key Principles**	**Changes in Family Status Required to Proceed Developmentally**
Unattached young adult	Accepting parent-offspring separation	Differentiating self in relation to family of origin Developing intimate peer relationships Establishing self in work
Joining of families through marriage: newly married couple	Committing to new system	Forming marital system Realigning relationships with extended families and friends to include spouse
Family with young children	Accepting new generation of members into system	Adjusting marital system to make space for children Taking on parental roles Realigning relationships with extended family to include parenting and grandparenting roles
Family with adolescents	Increasing flexibility of family boundaries to include children's independence	Shifting parent-child relationships to permit adolescents to move into and out of system Refocusing on midlife material and career issues Beginning shift toward concerns for older generation
Family with young adults	Launching children and moving on Accepting multitude of exits from and entries into family system	Adjusting to reduction in family size Developing adult-to-adult relationships between grown children and their parents Realigning relationships to include in-laws and grandchildren Dealing with disabilities and death of parents (grandparents)
Family without children	Maintaining flexibility	Refocusing on career issues and new career opportunities Refocusing on partner and marriage issues Redefining recreational activities
Family in later life	Accepting shifting of generational roles	Maintaining own or couple functioning and interests in the face of physiological decline; exploring new familial and social role options Making room in system for wisdom and experience of older adults; supporting older generations without overfunctioning for them Dealing with retirement Dealing with loss of spouse, siblings, and other peers and preparation for own death; a life review, in which one reviews life experiences and decisions

Structure. Structure is based on the ongoing membership of the family and the pattern of relationships, which are often numerous and complex. Each family has a unique structure and way of functioning. For example, a family member may have a relationship with a spouse, child, employer, and work colleagues. Each of these relationships has different demands, roles, and expectations. The multiple relationships and their expectations are often sources for personal and family stress (see Chapter 38).

Although the definitions of structure vary, you can assess family structure by asking the following questions: "Who is included in your family?" "Who performs which tasks (e.g., cooking, managing finances, caring for parent)?" and "Who makes which decisions?" Structure either enhances or detracts from a family's ability to respond to the expected and unexpected stressors of daily life. Structures that are too rigid or flexible sometimes threaten family functioning. Rigid structures specifically dictate who accomplishes different tasks and also limit the number of people outside the immediate family allowed to assume these tasks. For example, in a rigid family structure, the mother is the only acceptable person to provide emotional support for the children and/or to perform all of the household chores. The husband is the only acceptable person to provide financial support, maintain the vehicles, do the yard work, and/or make all of the home repairs. A change in the health status of the person responsible for a task places a burden on a rigid family because no other person is available, willing, or considered acceptable to assume that task. An extremely flexible structure also presents problems for the family. There is sometimes an absence of stability that would otherwise lead to automatic action during a crisis or rapid change.

Function. Family functioning is what a family does. Specific functional aspects include the way a family reproduces, interacts to socialize its young, cooperates to meet economic needs, and relates to the larger society. Family functioning also focuses on the processes used by the family to achieve its goals. Some processes include communication among family members, goal setting, conflict resolution, caregiving, nurturing, and use of internal and external resources. Traditional reproductive, sexual, economic, and educational goals that were once universal family goals no longer apply to all families. For example, a married couple who decides not to have children still consider themselves a family. Another example includes a blended family whose spouses bring school-age children into the new marriage. However, the spouses decide not to comingle their finances and have separate educational goals for their minor children. As a result, this family does not have the traditional economic patterns of a nuclear family.

Families achieve goals more successfully when communication is clear and direct. Clear communication enhances problem solving and conflict resolution, and it facilitates coping with life-changing or life-threatening stressors. Another process to facilitate goal achievement includes the ability to nurture and promote growth. For example, some

families have a specific celebration for a good report card, a job well done, or specific milestones. They also nurture by helping children know right and wrong. In this situation a family might have a specific form of discipline such as "time out" or taking away privileges, and the children know why the discipline is given. Thus when a situation occurs, the child is disciplined and learns not to behave like that again.

Families need to have multiple resources available. For example, a social network is an excellent resource. Social relationships such as friends or churches within the community are important for family celebrations but also act as buffers, particularly during times of stress, and reduce a family's vulnerability.

Family and Health. When assessing a family, it is important to use a guide such as the family health system (FHS) approach to identify all of their needs. The FHS is a holistic model that guides the assessment and care for families (Anderson, 2000; Anderson and Friedemann, 2010). It includes five realms/processes of family life: interactive, developmental, coping, integrity, and health. The FHS approach is one method for family assessment to determine areas of concern and strengths, which helps you develop a plan of care with outcomes and specific family nursing interventions. As with all systems, the FHS has both unspoken and spoken goals, which vary according to the stage in the family life cycle, family values, and individual concerns of the family members. When working with families, the goal of care is to improve family health or well-being, assist in family management of illness conditions or transitions, and achieve health outcomes related to the family areas of concern.

Many factors influence the health of a family (e.g., its relative position in society, economic resources, and geographical boundaries). Although American families exist within the same culture, they live in very different ways as a result of race, values, social class, and ethnicity. In some minority groups multiple generations of single-parent families live together in one home. Class and ethnicity produce differences in the access of families to the resources and rewards of society. This access creates differences in family life, most significantly in different life chances for its members.

Distribution of wealth greatly affects the capacity to maintain health. Low educational preparation, poverty, and decreased social support compound one another, magnifying their effect on sickness in the family and the amount of sickness in the family. Economic stability increases a family's access to adequate health care, creates more opportunity for education, increases good nutrition, and decreases stress (CDF, 2014; National Coalition for the Homeless, 2014).

The family is the primary social context in which health promotion and disease prevention take place. A family's beliefs, values, and practices strongly influence health-promoting behaviors of its members. In turn the health status of each individual influences how a family unit functions and its ability to achieve goals. When a family satisfactorily functions to meet its goals, its members tend to feel positive about themselves and their family. Conversely, when they do not meet goals, families view themselves as ineffective (Epley et al., 2010).

Some families do not place a high value on good health. In fact, some families accept harmful practices. In some cases a family member gives mixed messages about health. For example, a parent chooses to smoke while telling children that smoking is bad for them. Family environment is crucial because health behavior reinforced in early life has a strong influence on later health practices. In addition, the family environment is a crucial factor in an individual's adjustment to a crisis. Although relationships are strained when confronted with illness, research indicates that, when family members receive support from health care professionals, they have the potential to adapt to the stressors and develop coping mechanisms (Arestedt et al., 2013).

Attributes of Healthy Families. The family is a dynamic unit; it is exposed to threats, strengths, changes, and challenges. Some families are crisis proof, whereas others are crisis prone. The crisis-proof, or effective, family is able to combine the need for stability with the need for growth and change. This type of family has a flexible structure that allows adaptable performance of tasks and acceptance of help from outside the family system. The structure is flexible enough to allow adaptability but not so flexible that the family lacks cohesiveness and a sense of stability. The effective family has control over the environment and influences the immediate environment of home, neighborhood, and school. The ineffective, or crisis-prone family lacks or believes it lacks control over its environments.

Hardiness and **resiliency** are factors that moderate a family's stress. Family hardiness is the internal strengths and durability of the family unit. A sense of control over the outcome of life, a view of change as beneficial and growth producing, and an active rather than passive orientation in adapting to stressful events characterize family hardiness (McCubbin et al., 1996). Resiliency helps to evaluate healthy responses when individuals and families experience stressful events. Resources and techniques that a family or individuals within the family use to maintain a balance or level of health aid in understanding a family's level of resiliency.

Genetic Factors. Genetic factors reflect a family's heredity or genetic susceptibility to diseases that may or may not result in actual development of a disease. The scope of genomics in nursing care is broad and encompasses risk assessment, risk management, counseling and treatment options, and treatment decisions (Calzone et al., 2012). Clinical applications of genetic and genomic knowledge for nurses have implications for care of people, families, communities, and populations across the life span (Calzone et al., 2013).

In certain families identification of genetic factors and genetic counseling help family members decide whether or not to test for the presence of a disease and/or to have children (Calzone et al., 2013; Kirk, 2013). Some families choose not to have children, whereas others choose not to know genetic risks and have children; other families choose to know the risk and then determine whether or not to have children. Some of these diseases (e.g., heart or kidney disease) are manageable. With genetic risks for certain cancers such as certain breast cancers, a woman may choose prophylactic bilateral mastectomies to reduce the risk for developing the disease. Families with genetic neurological diseases such as Huntington's disease may choose not to have children. When families know of these risks, they have the opportunity to make informed decisions about their lifestyle and health behaviors, are more vigilant about recognizing changes in their health, and in some cases seek medical intervention earlier (Kirk, 2013).

FAMILY NURSING

To provide compassion and caring for your patients and their families, you need a scientific knowledge base in family theory and knowledge in family nursing. A focus on the family is necessary to safely discharge patients back to the family or community settings. The members of the family may need to assume the role of primary caregiver. Family caregivers have unique nursing and caregiving needs. They often need to understand the disease process and outcomes and learn how to provide nursing skills, but too often they feel abandoned by the health care system (Plank et al., 2012). When a life-changing illness occurs, the family has to make major adjustments to care for a family member. Often the psychological, social, and health care needs of the caregiver go unmet (Tamayo et al., 2010).

FIGURE 10-2 Family recreational activities strengthen family functioning. (Courtesy Bill Branson, National Cancer Institute.)

Family nursing is based on the assumption that all people, regardless of age, are members of some type of family form such as the traditional nuclear family or an alternate family (Figure 10-2). The goal of family nursing is to help a family and its individual members reach and maintain maximum health throughout and beyond the illness experience. Family nursing is the focus of the future across all practice settings and is important in all health care environments.

There are different approaches for family nursing practice. For the purposes of this chapter, family nursing practice has three levels of approaches: (1) **family as context**; (2) **family as patient**; and (3) the newest model, called **family as system**. Family as system includes both relational and transactional concepts. All approaches recognize that patient-centered care for one member influences all members and affects family functioning. Families are continually changing. As a result, the need for family support changes over time, and it is important for you to understand that the family is more complex than simply a combination of individual members.

Family As Context

When you view a family as context, the primary focus is on the health and development of an individual member existing within a specific environment (i.e., the patient's family). Although the focus is on an individual's health status, assess how much the family provides the individual's basic needs. These needs vary, depending on the individual's developmental level and situation. Because families provide more than just material essentials, you also need to consider their ability to help patients meet psychological needs.

Family As Patient

When you view a family as patient, the family processes and relationships (e.g., parenting or family caregiving) are the primary focuses of nursing care. Focus your nursing assessment on family patterns vs. characteristics of individual members. Concentrate on patterns and processes that are consistent with reaching and maintaining family and individual health. For example, in the case of family caregiving, assess who are the family caregivers for a patient, their different roles, and how they interact to meet the patient's needs. Plan care to meet not only the patient's needs but also the changing needs of the family. Dealing with very complex family problems often requires an interdisciplinary approach. Always be aware of the limits of nursing practice and make referrals when appropriate.

Family As System

It is important to understand that, although you are able to make theoretical and practical distinctions between the family as context and the family as patient, they are not necessarily mutually exclusive. When you care for a family as a system, you are caring for each family member (family as context) and the family unit (family as patient), using all available environmental, social, psychological, and community resources.

The following clinical scenario illustrates three levels of approaches to family care.

> You are assisting with end-of-life care for David Daniels, who is 35 years old and at one time was a computer analyst. David and his wife, Lisa, have three school-age children. David expressed a wish to die at home and not in a hospital or an extended care facility. Lisa is on family leave from her job to help David through this period. Both Lisa and David are only children. David's parents are no longer living, but Lisa's mother is committed to staying with the family to help Lisa and David.

When you view this family as context, you focus first on the patient (David) as an individual. You assess and meet David's needs at end-of-life, such as comfort, hygiene, and nutrition, as well as his social and emotional needs. You determine how David is coping with knowing his life is coming to an end and how he perceives it will affect his family. When viewing the family as patient, you assess and meet the needs of David's wife and children. Determine to what extent the family's basic needs for normal activity, comfort, and nutrition are being met and whether they have resources for emotional and social support. You determine the family's need for rest (especially the wife) and their stage of coping (the older child shows much anger and fear). It is important to determine the demands placed on David and the family, such as economic survival and well-being of the children. In addition, you need to continually assess the family's available resources such as time, coping skills, and energy level to support David through the end of life.

When viewing a family as system, you use elements from both of the previous perspectives, but you also assess the resources available to the family. Using the knowledge of the family as context, patient, and system, individualize care decisions based on the family assessment and your clinical judgment. For example, on the basis of your assessment, you determine that the family is not eating adequately. You also determine that Lisa is experiencing more stress, not sleeping well, and trying to "do it all" regarding her children's school and after-school activities. In addition, Lisa does not want to leave David's bedside when members of their church come to help. You recognize that this family is under enormous stress and that their basic needs such as meals, rest, and school activities are not adequately met. As a result, you determine that (1) the family needs help with meals, (2) Lisa needs time to rest, and (3) the family's church is eager to help with David's day-to-day care. On the basis of these decisions, you work with Lisa, David, and the family to set up a schedule among Lisa, her mother, and two close church members to provide Lisa with some time away from David's bedside. However, David and Lisa determine when this time will be. Because of the church involvement, members of the church begin to take responsibility for groceries and all meal preparation for the family. In addition, other members of the church help with the children's school and after-school activities.

NURSING PROCESS FOR THE FAMILY

Nurses interact with families in a variety of community-based and clinical settings. The nursing process is the same whether the focus is context, patient, or system. It is also the same as that used with individuals and incorporates the needs of the family and the patient. You use the nursing process to care for an individual within a family (e.g., the family as context) or the entire family (e.g., the family as patient).

BOX 10-3   Five Realms of Family Life: Family Health System—Family Assessment Plan

Interactive Processes
- Family relationships—Is the family a nuclear or blended family? Is it a single-parent family?
- Family communication—How do family members share ideas, concerns, problems?
- Family nurturing—How are family values set and communicated? How are house rules established?
- Intimacy expression—Does the family hug, touch, laugh, or cry together?
- Social support—Who in the community, school, or workplace is close to the family?
- Conflict resolution—How does conflict resolution occur? Who initiates it? What is the common conflict?
- Roles (instrumental and expressive)—What are the formal roles such as wage earner, disciplinarian, problem solver? What are the informal roles (e.g., peacekeeper)?
- Family leisure life—Vacations: what does the family do to relax? Do the parents have "date night?"

Developmental Processes
- Current family transitions—Recent death, divorces, children leaving/returning home, new births
- Family stage task completion or progression—Childbearing years, empty nesters, grandparenting
- Individual developmental issues that affect family development—Individuals in the family with social issues such as difficulty in school or legal issues who cannot participate in family development
- Development of health issue and family impact—Acute or chronic illnesses, high-risk pregnancies, delayed physical development

Coping Processes
- Problem solving—How did the family solve previous problems? Is there a single problem solver or a family resolution?
- Use of resources—Does the family use family or individual therapists, Alcoholics Anonymous, conflict-resolution resources, anger-management resources?
- Family life stressors and daily hassles—What are the family's financial concerns? Are the children overscheduled with activities? Who is the caregiver for older adults?
- Family coping strategies and effectiveness—How do the family and individual members cope (e.g., exercise, avoidance, overeating, arguing)?

- Past experiences with handling crises—How have past crises been managed (e.g., dealing with financial stress, illness, and legal problems).
- Family resistance resources—Does the family take measures to avoid stress (e.g., adhering to a budget, obtaining tutoring resources for their children)?

Integrity Processes
- Family values—What do the family consider as their important values (e.g., health, togetherness)?
- Family beliefs—What are the family beliefs about health/illness, end-of-life care, and advance directives?
- Family meaning—Ask the patient or a significant family member to describe what the family means to him or her.
- Family rituals—How does the family celebrate holidays, birthdays, weddings; how does the family cope with death (e.g., wakes, funerals)?
- Family spirituality—Ask what spirituality means. How does the family define their spirituality?
- Family culture and practices—Identify cultural customs and practices that impact health care.

Health Processes
- Family health beliefs and beliefs about health concerns or problems—Does the family practice health and illness prevention or wait until a problem occurs?
- Health behaviors of the family—How does the ill family member react? How does the family react to illness? Do the family members react the same way to an ill family member, or do they react differently when a homemaker vs. the wage earner is ill?
- Health patterns and health management activities—How do the family members manage their health? How do they manage care of a sick family member?
- Family caretaking responsibilities—When someone is ill, who is the caregiver? Is it always the same person?
- Disease conditions, treatments, and consequences for the family—Obtain current disease and treatment history for the family.
- Family illness stressors—What are these stressors (e.g., worsening of a chronic illness or when "Mom" is sick and cannot run the household)?
- Relationship with health care providers and health system access—Which type of health care provider does the family have (e.g., primary care, pediatrician)? How often does the family see the providers? Any hospitalizations?

When initiating the care of families, use these approaches to organize a family approach to the nursing process:
1. Assess all individuals within their family context.
2. Assess the family as patient.
3. Assess the family as a system.

Assessing the Needs of a Family

Family assessment is a priority to provide adequate family care and support. You have an essential role in helping families adjust to acute, chronic, and terminal illness; but first you need to understand the family unit and what a patient's illness means to the family members and family functioning (Anderson and Friedemann, 2010). You also need to understand how the illness affects the family structure and the support the family requires (Kaakinen et al., 2014). Although the family as a whole differs from individual members, the measure of family health is more than a summary of the health of all members.

The form, structure, function, and health of the family are areas unique to family assessment. Box 10-3 lists the five areas of family life to include in an assessment.

During an assessment, incorporate knowledge of the patient's illness and assess the patient and the family. When focusing on the family, begin the family assessment by determining the patient's definition of and attitude toward the family. The concept of family is highly individualized. The patient's definition will influence how much you are able to incorporate the family into nursing care. To determine family form and membership, ask who the patient considers family or with whom the patient shares strong emotional feelings. If the patient is unable to express a concept of family, ask with whom he or she lives, spends time, and shares confidences and then ask whether he or she considers them to be family or like family. To further assess the family structure, ask questions that determine the power structure and patterning of roles and tasks (e.g., "Who decides where to go on vacation?"

FIGURE 10-3 Nurse providing family education. (From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 10, St Louis, 2015, Mosby.)

"How are tasks divided in your family?" "Who mows the lawn?" "Who usually prepares the meals?").

Assess family functions such as the ability to provide emotional support for members, the ability to cope with current health problems or situations, and the appropriateness of its goal setting and progress toward achievement of developmental tasks (Figure 10-3). Also determine whether the family is able to provide and distribute sufficient economic resources and whether its social network is extensive enough to provide support.

Cultural Aspects. Always recognize and respect a family's cultural background during your assessment (see Chapter 9). Culture is an important variable when assessing a family because race and ethnicity affect structure, function, health beliefs, values, and the way a family perceives events (Box 10-4). A comprehensive, culturally sensitive family assessment is critical to forming an understanding of family life, current changes in family life, overall goals and expectations, and planning family-centered care.

Forming conclusions about families' needs based on cultural backgrounds requires critical thinking. It is imperative to remember that categorical generalizations are often misleading. Overgeneralizations in terms of racial and ethnic group characteristics do not lead to greater understanding of a culturally diverse family. Culturally different families vary in meaningful and significant ways; however, neglecting to examine similarities leads to inaccurate assumptions and stereotyping (Giger, 2013).

Knowing about a family's culture and the meaning of that culture to a family's structure and functioning, health practices, and family celebrations helps to design family-centered care (see Chapter 9). To determine the influence of culture on a family, you ask the patient about his or her cultural background. Then ask questions concerning cultural practices. For example, "What type of foods do you eat?" "Who cares for sick family members?" "Have you or anyone in your family been hospitalized?" "Did family members remain at the hospital?" "Do you use any health practices of your culture such as acupuncture or meditation?" "What role do grandparents play in raising your children?"

⊕ BOX 10-4   CULTURAL ASPECTS OF CARE

Family Nursing

Families have unique perspectives and characteristics; and they have differences in values, beliefs, and philosophies. The cultural heritage of a family or member of the family affects religious, childrearing, and health care practices; recreational activities; and nutritional preferences. Be culturally sensitive and respectful when caring for multicultural patients. Incorporate individualized cultural preferences into your plan of care so it is culturally congruent. Design your care to integrate the personal values, life patterns, and beliefs of the patient and family into prescribed therapies.

Implications for Patient-Centered Care

- Focus on the needs of the family and understand the family's beliefs, values, customs, and roles when designing care (Brazil et al., 2012). Perception of certain events varies across cultural groups and has particular impact on families. For example, the care of the grandmother has a great significance to the extended family.
- Family caregiving values, practices, and roles vary across cultures (Plank et al., 2012).
- The family structure sometimes includes multiple generations living together. Intergenerational support and patterns of living arrangements are related to cultural background. For example, first-generation families are more likely to live in extended family households (Giger, 2013).
- In some cultures it is a sign of elder disrespect to place older adults in nursing homes, even when an older adult family member has severe dementia (Giger, 2013).
- Modesty is a strong value among many cultures. Some women bring female family members to health care visits, and a female health care provider must examine the woman.
- In the presence of a critical or terminal illness, some cultures come in groups to pray together with the family at the patient's bedside (Giger, 2013).
- Health beliefs differ among various cultures, which affect the decision of a family and its members about when and where to seek help.

A comprehensive, culturally sensitive family assessment is critical for you to understand family life, the current changes within it, and a family's overall goals and expectations (Campinha-Bacote, 2011). These data provide the foundation for family-centered nursing care (Anderson and Friedemann, 2010).

Discharge Planning. If a patient has been hospitalized or is in a rehabilitation setting, discharge planning begins with the initiation of care and includes the family. You are responsible for an accurate assessment of what will be needed for care in the home at the time of discharge, along with any shortcomings in the home setting. For example, if a postoperative patient is discharged to home and the older-adult husband does not feel comfortable with the dressing changes required, you need to find out if anyone else in the family or neighborhood is willing and able to do this. If not, you will need to arrange for a home care service referral. If the patient also needs exercise and strength training, you consult with the primary health care provider to recommend referral for physical therapy.

Family-Focused Care. Use a family-focused approach when assessing a patient and family to enhance your nursing care. When you establish a relationship with a patient and his or her family, it is important to identify potential and external resources. A complete assessment provides this information.

Collaboration with family members is essential, whether the family is the patient or the context of care. Collaborate closely with all appropriate family members when determining what they hope to achieve with regard to the family's health. You base a positive collaborative relationship on mutual respect and trust. The family needs to feel "in control" as much as possible.

Nursing Diagnosis

After assessing a patient's and family's needs and situation, you identify actual and at-risk nursing diagnoses. A number of diagnoses within the domain of role relationships are identified by the North American Nursing Diagnosis Association International (Herdman and Kamitsuru, 2014): caregiving roles and family relationships. Role relationships are defined by NANDA (Herdman and Kamitsuru, 2014, p. 277) as the "positive and negative connection or associations between people or groups of people and the means by which those connections are demonstrated." Examples of nursing diagnoses applicable to family care are:

- *Caregiver Role Strain*
- *Impaired Parenting*
- *Risk for Caregiver Role Strain*
- *Interrupted Family Processes*

Be sure to cluster appropriate risk factors or defining characteristics when making a nursing diagnosis. Diagnoses need to be relevant so that your plan of care is suitable to patient and family needs.

Planning Care

Once you identify pertinent nursing diagnoses, work together with patients and their families to develop plans of care that all members clearly understand and mutually agree to follow. The goals and outcomes you establish need to be concrete and realistic, compatible with a family's developmental stage, and acceptable to family members and their lifestyle.

By offering alternatives for care activities and asking family members for their own ideas and suggestions, you help to reduce their feelings of powerlessness. For example, offering options for how to prepare a low-fat diet or how to rearrange the furnishings of a room to accommodate a family member's disability gives a family an opportunity to express their preferences, make choices, and ultimately feel as though they have contributed. Collaborating with other disciplines increases the likelihood of a comprehensive approach to a family's health care needs, and it ensures better continuity of care. Using other disciplines is particularly important when discharge planning from a health care facility to home or an extended care facility is necessary (O'Shea et al., 2014; Tyrrell et al., 2012).

When you view a family as the patient, you need to support communication among all family members. This ensures that the family remains informed about the goals and interventions for health care. Often you participate in conflict resolution between family members so each member is able to confront and resolve problems in a healthy way. Help the family identify and use external and internal resources as necessary (Arestedt et al., 2013). For example, who in the family can run errands to get groceries while the patient is unable to drive? Are there members from the church who can come and provide respite care? Ultimately your aim is to help the family reach a point of optimal function, given the family's resources, capacities, and desire to become healthier.

Cultural sensitivity (see Chapter 9) in family nursing requires recognizing not only the diverse ethnic, cultural, and religious backgrounds of patients but also the differences and similarities within the same family. When planning family-centered care, recognize and integrate cultural practices, religious ceremonies, and rituals. Using effective and respectful communication techniques enables you to collaborate with the family to determine how best to integrate their beliefs and practices within the prescribed health care plan. For example, families holding traditions from Asian and Mexican American cultures frequently want to remain at the bedside around the clock and provide personal care for their loved ones. Integrating a family's values and needs into the care plan involves teaching family members how to provide simple, direct care measures, thus providing culturally sensitive and competent care. Together the nurse and the family blend the cultural and health care needs of the patient.

IMPLEMENTING FAMILY-CENTERED CARE

Whether caring for a patient with the family as context, directing care to the family as patient, or providing care to the family as system, nursing interventions aim to increase family members' abilities in certain areas, remove barriers to health care, and do things that the family is not able to do for itself. Assist the family in problem solving, provide practical services, and express a sense of acceptance and caring by listening carefully to family members' concerns and suggestions.

One of the roles you need to adopt is that of educator. Health education is a process by which a nurse and patient share information in a two-way fashion (see Chapter 25). Sometimes you recognize family/patient needs for information through direct questioning, but the methods for recognizing these needs are generally far more subtle (Plank et al., 2012). For example, you recognize that a new father is fearful of cleaning his newborn's umbilical cord or that an older-adult woman is not using her cane or walker safely. Respectful communication is necessary. Often you find the subtle needs for information by saying, "I notice you are trying to not touch the umbilical cord. I see that a lot." Or "You use the cane the way I did before I was shown a way to keep from falling or tripping over it; do you mind if I show you?" When you are confident and skillful instead of coming across as an authority on the subject, your patient's defenses are down, making him or her more willing to listen without feeling embarrassed. You will also recognize patient and family learning needs on the basis of a patient's health condition and physical and mental limitations. Your focus as an educator may be on the family caregiver, to prepare that person to manage the skills and processes needed to manage a patient's needs within the home.

Family Caregiving

Family support is a key driver in remaining in one's home and in the community, but it comes at substantial costs to the caregivers themselves, their families, and society. If family caregivers were no longer available, the economic cost to the U.S. health care and long-term service and support (LTSS) systems would increase astronomically (AARP, 2011). The economic value of family caregiving was estimated at $450 billion, which is more than total Medicaid spending ($361 billion) and approached the total expenditures in Medicare ($509 billion). These costs exceed the total sales of large companies (e.g., Wal-Mart [$408 billion]) (AARP, 2011).

There are approximately 42.1 million caregivers age 19 or older who are providing an average of 20 hours of care per week (AARP, 2011). Often they take on this responsibility without acknowledging the effect that it has on their lives and without realizing that relief is available (McDaniel and Allen, 2012).

The role of the family caregiver is multifaceted (Box 10-5). Family caregivers need preparation to meet these demands, including the physical care and psychological, social, and spiritual support (Grant and Ferrell, 2012). Family caregivers suffer emotionally. As a result, they may be at risk for a variety of physical conditions, ranging from

BOX 10-5 EVIDENCE-BASED PRACTICE

Caregiving Education for the Family Caregiver

PICO Question: Does a caregiving education program designed for family caregivers reduce caregiver stress and burnout?

Evidence Summary

When a family member has an illness or trauma that changes his or her physical or cognitive function, it is often a major life-changing event for the family and family caregiver. As a patient moves through hospitalization and rehabilitation and returns home, the family faces major changes in family dynamics, social interactions, financial commitments, and emotional support systems (Tyrrell et al., 2012; Tamayo et al., 2010). When the patient returns home, existing disabilities affect the primary caregiver and other members of the family. The family's and caregiver's social roles and activities, health-related activities and practices, and family dynamics all change (Bell, 2014). As a result, family members report stress and burnout related to the continual demands of the caregiving role (McDaniel and Allen, 2012). Caregiver preparation education programs help family caregivers identify methods to cope with the demands of caregiving and expand caregiving resources. Identifying interventions and resources helps the caregiver maintain a sense of hope, maintain his or her own health status, engage in more social activities, and have some respite from the day-to-day caregiving tasks (McDaniel and Allen, 2012).

Application to Nursing Practice

- Teach family caregivers how to identify potential stressors such as social isolation, physically demanding caregiving activities, behaviors of patient, and availability of resources (Sansoni et al., 2013).
- Identify the family's strengths (e.g., if some family members are good at helping their loved one exercise, involve them in physical rehabilitation activities) and use these strengths to reduce the potential for caregiver burnout (Sansoni et al., 2013; Tyrrell et al., 2012).
- Assess family caregiver's experience (e.g., has the caregiver observed any technical nursing care? Does the caregiver have a health care background? Has he or she provided care to another person?).
- Design an individualized caregiver education plan to reinforce experience and meet any knowledge gaps.
- Encourage family caregiver to set a routine family meeting to share joys and concerns with the family and identify caregiver needs for assistance (Bell, 2014).
- Encourage the caregiver to set a routine time for respite. The caregiver then knows when he or she can have some relaxation time or spouses can have a "date night."
- Teach family members how to be part of the support system. Show them how to participate in the care of a family member (Bell, 2014; Tamayo et al., 2010).

</td><td>

BOX 10-6 PATIENT TEACHING

Family Caregiving: Caregiver Role Strain

Objective
- Patient/family will adopt two interventions to reduce caregiver role strain.

Teaching Strategies
- Explain to all members of the family involved in caregiving that role strain may be present when the following occur:
  - There is a change in caregiver's appetite/weight, sleeping, or leisure activities. In addition, social withdrawal, irritability, anger, or changes in the caregiver's overall level of health can occur.
  - The caregiver is fearful when learning new therapies or administering new medications to the disabled/ill family member.
  - The caregiver loses interest in his or her personal appearance.
  - Signs of caregiver role strain may intensify if the loved one's health status changes or when institutional care is considered.
- Interventions for caregiver role strain
  - Help family members set up alternating schedules to give the primary caregiver some rest.
  - Design a schedule or other methods to provide groceries, meals, and housekeeping for the caregiver and patient.
  - Identify community resources for transportation, respite care, and support groups.
- Offer an opportunity to ask questions and, when possible, provide a phone number for questions and assistance.
- Provide family members with the contact information of the patient's health care provider and instruct them to call if the caregiver has health problems, the caregiver seems overly exhausted, or they observe changes in the caregiver's interactions and attention to normal activities.

Evaluation
- Ask the family to identify two or three indicators for caregiver role strain.
- Review with the family their plan to provide groceries, meals, and occasional respite care for the caregiver and patient.
- Ask the family where they keep the contact information of the patient's health care provider and when they would call the health care provider.

</table>

depression, cardiac illness, and eating disorders. In addition, the caregiver often puts his or her health needs on the back burner and misses routine primary care visits, routine screenings, and routine dental care (Dobrina et al., 2014; Kim et al., 2011).

Multiple national outreach programs such as the National Family Caregivers Association (www.thefamilycaregiver.org) and the National Alliance for Caregiving (www.caregiving.org) connect family caregivers to information and services that can help improve their lives and the level of care they can offer their loved ones.

Family caregiving is a family process that occurs in response to an illness and encompasses multiple cognitive, behavioral, and interpersonal processes. It typically involves the routine provision of services and personal care activities for a family member by spouses, siblings, friends, or parents. Caregiving activities include finding resources,

providing personal care (bathing, feeding, or grooming), monitoring for complications or side effects of an illness or treatment, providing instrumental activities of daily living (shopping or housekeeping), and the ongoing emotional support and decision making that is necessary. Family caregiving can create caregiver burden and strain. The physical and emotional demands are high, and the patient's disease itself creates changes in the family structure and roles (McDaniel and Allen, 2012). Family caregivers often feel ill prepared to take on the demands of care for their loved ones. Although the caregiver wants to care for the loved one, he or she often feels extreme pressure to do everything and do it correctly, including managing complex symptoms and medications and making accurate judgments about when to contact health professionals (Grant and Ferrell, 2012). Providing education to the family caregiver helps relieve some of the stress of caregiving (Box 10-6).

When an individual becomes dependent on another family member for care and assistance, significant stress affects both the caregiver and the care recipient. In addition, the caregiver needs to continue to meet the demands of his or her usual lifestyle (e.g., raising children, working full time, or dealing with personal problems or illness). In many instances adult children, the sandwich generation, are trying to take care of their parents while meeting the needs of their own family (see Box 10-6). Without adequate preparation and support from health

care providers, caregiving puts the family at risk for serious problems, including a decline in the health of the caregiver and that of the care receiver and dysfunctional and even abusive relationships (McDaniel and Allen, 2012; Tamayo et al., 2010).

Providing care and support for family caregivers enhances patient safety and involves using available family and community resources. Establishing a caregiving schedule that enables all family members to participate, helping patients to identify extended family members who can share any financial burdens posed by caregiving, and having distant relatives send cards and letters communicating their support are very helpful. However, it is imperative to understand the relationship between potential caregivers and care recipients. If the relationship is not a supportive one, community services are often a better resource for the patient and family.

Use of community resources includes locating a service required by the family or providing respite care so the family caregiver has time away from the care recipient. Examples of services that are beneficial to families include caregiver support groups, housing and transportation services, food and nutrition services, housecleaning, legal and financial services, home care, hospice, and mental health resources. Before referring a family to a community resource, it is critical that the nurse understands the family's dynamics and knows whether the family wants support. Often a family caregiver resists help, feeling obligated to be the sole source of support to the care recipient. Be sensitive to family relationships and help caregivers understand the normalcy of caregiving demands. Given the appropriate resources, family caregivers are able to acquire the skills and knowledge necessary to effectively care for their loved ones within the context of the home while maintaining rich and rewarding personal relationships.

Despite its demands, family caregiving can be positive and rewarding. It is more than simply a series of tasks. Caregiving is an interactional process, whether it is a wife caring for a husband or a daughter caring for a mother. The interpersonal dynamics among family members influence the ultimate quality of caregiving. Thus you have a key role in helping them develop better communication and problem-solving skills to build the relationships needed for caregiving to be successful (Tamayo et al., 2010). Caregiving occurs in all aspects of care. As health care costs continue to increase, families are important caregivers. You can help them in their role as caregiver by showing them how to perform specific aspects of physical care (e.g., dressing changes) and helping them find home care equipment (e.g., oxygen therapy) and identify community resources. Preparing members of the family for care activities and responsibilities helps caregiving become a meaningful experience for both the caregiver and the patient.

Health Promotion

Although the family is the basic social context in which members learn health behaviors, the primary focus on health promotion has traditionally been on individuals. When implementing family nursing, health promotion interventions are designed to improve or maintain the physical, social, emotional, and spiritual well-being of the family unit and its members (Duhamel, 2010). Health promotion behaviors need to be tied to the developmental stage of a family (e.g., adequate prenatal care for the childbearing family or adherence to immunization schedules for the childrearing family). Your interventions need to enable individual members and the total family to reach their optimal levels of wellness.

One approach for meeting goals and promoting health is the use of family strengths. Families do often not look at their own system as one that has inherent, positive components. Family strengths include clear communication, adaptability, healthy childrearing practices, support and nurturing among family members, the use of crisis for growth, a commitment to one another and the family unit, a sense of well-being and cohesiveness, and spirituality (Kim et al., 2011). Help the family focus on their strengths instead of on problems and weaknesses. For example, point out that a couple's 30-year marriage has endured many crises and transitions. Therefore they are likely to be able to adapt to this latest challenge. Refer families to health promotion programs aimed at enhancing these attributes as needed. For example, some communities have low-cost fitness activities for school-age children that are designed to reduce the risk for obesity.

Acute Care

The family must be a central focus of nursing care, and it is crucial to emphasize family needs within the context of today's acute health care delivery system. For example, be aware of the implication of early discharge from a hospital for patients and their families. In many families all members of a household often are employed outside the home, and young adults who live at home are also involved with school and part-time jobs. In addition, some households may be multigenerational. These factors are both resources and challenges in preparing family members to help with health care or locate appropriate community resources. Do not assume because there are multiple people in the family that family caregiving is easier to attain. Often when family members assume the role of caregiver, they lose support from significant others and are at risk for caregiver role strain (Laitinen, et al., 2011). Always be sure that families are willing to assume care responsibilities once a patient returns home. Knowledge about a patient's and family's needs is essential to drive nursing interventions and maximize nursing outcomes.

QSEN QSEN: BUILDING COMPETENCY IN TEAMWORK AND COLLABORATION You are caring for the Carlson family. The father, Gary, is 47 years old with amyotrophic lateral sclerosis (Lou Gehrig's disease). He is a chemical engineer and recently took disability from his job. His disease has progressed to the point at which he needs a wheelchair because he tires easily. He is able to help with some of his physical care such as dressing but needs help with hygiene and toileting. His ability to swallow is diminished, and he needs help to eat to avoid the risk of aspiration. His wife, Kathy, is 48 years old and is an information technology specialist at a local company. They have two children. Karen is a college junior at a local university and lives in the residence hall. Kristen is a high school senior. The family is committed to helping Gary remain at home as long as possible. Kathy is working from home and will take a leave of absence if needed. Both girls have changed their schedules so one is home with their mother each evening. Using the family as patient, which assessment questions do you use to identify their strengths and their perceived challenges?

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

In an acute care setting clear communication is essential. Help the family identify methods to maintain open lines of communication with you and the health care team to anticipate your patient's and family members' needs. For example, when a family member is ill, how will you use caring practices to help family members inform the nuclear and extended family about any progress or setbacks? Identify who makes decisions for the family and consistently go to the decision maker. In some situations the decision maker also needs assistance in developing a method to clearly communicate any decisions. In this electronic age, some families are using blogs on the Internet as a way of providing consistent information. Help the family determine if this is the best approach for their family needs and structure.

Likewise it is important that the health care team use communication techniques that are supportive and clear to understand and advocate for a family's expectations (Laitinen et al., 2011). In addition, clear communication from the health care team helps to untangle medical terminology and enables the family to understand the health care issues, types of decisions, and health care outcomes.

Restorative and Continuing Care

In restorative and continuing care settings, the challenge in family nursing is to try to maintain patients' functional abilities within the context of the family. This includes having home care nurses help patients remain in their homes following acute injuries or illnesses, surgery, or exacerbation of a chronic illness. It also requires finding ways to better the lives of chronically ill and disabled individuals and their families.

KEY POINTS

- Family structure and functions influence the lives of its individual members.
- Family members influence one another's health beliefs, practices, and status.
- The concept of family is highly individual; care focuses on a patient's attitude toward the family rather than on an inflexible definition of family.
- The family's structure, functioning, and relative position in society significantly influence its health and ability to respond to health problems.
- A nurse can view the family in three ways: as context, as patient, or as system.
- Measures of family health involve more than a summary of individual members' health.
- Family members as caregivers are often spouses who are either older adults themselves or adult children trying to work full-time and care for aging parents.
- Cultural sensitivity is vital to family nursing. Some members have differing beliefs, traditions, and restrictions, even within the same generation.
- Family caregiving is an interactive process that occurs within the context of the relationships among its members.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

A home health nurse is working with the Kline family. This is a family of four: Carol, a 45-year-old single mother; her two adolescent sons, Matt and Kent; and Sara, her 76-year-old mother, who is in the last stages of Alzheimer's disease. The mother has lived with Carol and her children for 10 years. Sara was a great support to Carol when her husband died 11 years ago. She helped Carol raise Matt and Kent. The family has decided to care for Sara in the home until she dies. Carol is the principal caregiver for Sara in the home.

1. Which type of assessments are important to determine family functioning and structure?
2. What should Carol assess to determine how the family can achieve their goal of caring for Sara?
3. How does Carol help the family determine their strengths, weaknesses, and resources?

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The Collins family includes a mother; stepfather, two teenage biological daughters of the mother; and a 25-year-old biological daughter of the father. The father's daughter just moved home following the loss of her job in another city. The family is converting a study into Stacey's bedroom and is in the process of distributing household chores. When you talk to members of the family, they all think that their family can adjust to lifestyle changes. This is an example of family:
   1. Diversity.
   2. Durability.
   3. Resiliency.
   4. Configuration.
2. What is the most common reason for calling on grandparents to raise their grandchildren?
   1. Single parenthood
   2. Legal interventions
   3. Dual-income families
   4. Increased divorce rate
3. Which of the following most greatly affects a family's access to adequate health care, opportunity for education, and sound nutrition?
   1. Development
   2. Family function
   3. Family structure
   4. Economic stability
4. You are caring for a family that consists of a father and 3-year-old boy who has well-managed asthma but misses care infrequently. They live in state-supported housing. The father is in school studying to be an information technology professional. His income and time are limited, and he admits to going to fast-food restaurants frequently for dinner. However, he and his son spend a lot of time together. The family receives state-supported health care for his son, but he does not have health insurance or a personal physician. He has his son enrolled in a government-assisted day care program. Which of the following are risks to this family's level of health? (Select all that apply.)
   1. Economic status
   2. Chronic illness
   3. Underinsured
   4. Government-assisted day care
   5. Frequency of fast-food dinners
   6. State-supported housing
5. Which of the following family assessments are most important for successful family caregiving? (Select all that apply.)
   1. Educational level of family members
   2. Cultural food preferences
   3. Collaboration between family members
   4. Social support
   5. Conflict resolution practices
6. Which of the following are possible outcomes with clear family communication? (Select all that apply.)
   1. Family goals
   2. Increased socialization
   3. Decision making
   4. Methods of discipline
   5. Improved education
   6. Impaired coping
7. A family has decided to care for a grandparent with terminal cancer in the daughter's home. Family caregiving is new to the

family. When helping this family as they begin to plan for their caregiving roles, what are the two top priority assessments to best learn about family functioning? (Select all that apply.)
   1. Communication
   2. Decision making
   3. Development
   4. Economic status
   5. Family structure
8. A family is facing job loss of the father, who is the major wage earner, and relocation to a new city where there is a new job. The children will have to switch schools, and his wife will have to resign from the job she likes. Which of the following contribute to this family's hardiness? (Select all that apply.)
   1. Family meetings
   2. Established family roles
   3. New neighborhood
   4. Willingness to change in time of stress
   5. Passive orientation to life
9. A family is undergoing a major change. Just as twins graduate from college and leave home to begin their careers, the husband loses his executive well-paying job. Because the family had two children in college at the same time, they did not save for retirement. They planned to save aggressively after the children left college. In this situation, which of the following demonstrate family resiliency? (Select all that apply.)
   1. Resuming full-time work when spouse loses job
   2. Increasing problems among siblings
   3. Developing hobbies when children leave home
   4. Placing blame on family members
   5. Expecting children to help financially
   6. Consulting a financial planner
10. In viewing the family as context, what is the primary focus?
   1. Family members within a system
   2. Family process and relationships
   3. Family relational and transactional concepts
   4. Health needs of an individual member
11. A hospice nurse is caring for a family that is providing end-of-life care for their grandmother, who has terminal breast cancer. When the nurse visits, the focus is on symptom management for the grandmother and helping the family with coping skills. This approach is an example of which of the following?
   1. Family as context
   2. Family as patient
   3. Family as system
   4. Family as structure

12. A new immigrant family consisting of a grandparent, two adults, and three school-age children has decided to receive their health promotion care at the Community Wellness Center. This is their first visit, and a family assessment, a health history, and a physical of each family member are needed. Which of the following are included in a family function assessment? (Select all that apply.)
   1. Cultural practices
   2. Decision making
   3. Neighborhood services
   4. Rituals and celebrations
   5. Neighborhood crime data
   6. Availability of parks
13. Two single mothers are active professionals and have teenage daughters. They also have busy social lives and date occasionally. Three years ago they decided to share a house and housing costs, living expenses, and child care responsibilities. The children consider one another as their family. What type of family form does this represent?
   1. Diverse family relationship
   2. Blended family relationships
   3. Extended family relationship
   4. Alternative family relationship
14. During a visit to a family clinic, a nurse teaches a mother about immunizations, car-seat use, and home safety for an infant and toddler. Which type of nursing interventions are these?
   1. Health promotion activities
   2. Acute care activities
   3. Restorative care activities
   4. Growth and development care activities
15. A family has decided to care for their father who is in the last stages of a debilitating neurological illness. Although he is alert, he cannot speak clearly or carry out self-care activities; he indicates that he wants to remain involved in family life as long as possible and loves spending time with his wife and two teenage children. Which best defines family caregiving? (Select all that apply.)
   1. Designing a nurturing family to raise children
   2. Providing physical and emotional care for a family member
   3. Establishing a safe physical environment for a family
   4. Monitoring for side effects of illness and treatments
   5. Reducing the use of community resources

Developmental Theories

Understanding normal growth and development helps nurses predict, prevent, and detect deviations from patients' expected patterns. Growth encompasses the physical changes that occur from the prenatal period through older adulthood and also demonstrates both advancement and deterioration. Development refers to the biological, cognitive, and socioemotional changes that begin at conception and continue throughout a lifetime. Development is dynamic and includes progression. However, in some disease processes development is delayed or regresses.

Individuals have unique patterns of growth and development. The ability to progress through each developmental phase influences the overall health of the individual. The success or failure experienced within a phase affects the ability to complete subsequent phases. If individuals have repeated developmental failures, inadequacies sometimes result. However, when an individual experiences repeated successes, health is promoted. For example, a child who does not walk by 20 months demonstrates delayed gross motor ability that slows exploration and manipulation of the environment. In contrast, a child who walks by 10 months is able to explore and find stimulation in the environment.

When caring for patients, adopt a life span perspective of human development that takes into account all developmental stages. Traditionally development focused on childhood, but a comprehensive view of development also includes the changes that occur during the adult years. An understanding of growth and development throughout the life span helps in planning questions for health screening and health history, health promotion and maintenance, and health education for patients of all ages.

DEVELOPMENTAL THEORIES

Developmental theories provide a framework for examining, describing, and appreciating human development. For example, knowledge of Erikson's psychosocial theory of development helps caregivers understand the importance of supporting the development of basic trust in the infancy stage. Trust establishes the foundation for all future relationships. Developmental theories are also important in helping nurses assess and treat a person's response to an illness. Understanding the specific task or need of each developmental stage guides caregivers in planning appropriate individualized care for patients. Specific developmental theories that describe the aging process for adults are discussed in Chapters 13 and 14.

Human development is a dynamic and complex process that cannot be explained by only one theory. This chapter presents biophysical, psychoanalytical/psychosocial, cognitive, and moral developmental theories. Chapters 25 and 36 cover the areas of learning theory for patient teaching and spiritual development.

Biophysical Developmental Theories

Biophysical development is how our physical bodies grow and change. Health care providers are able to quantify and compare the changes that occur as a newborn infant grows against established norms. How does the physical body age? What are the triggers that move the body from the physical characteristics of childhood, through adolescence, to the physical changes of adulthood?

Gesell's Theory of Development. Fundamental to Gesell's theory of development is that each child's pattern of growth is unique

TABLE 11-1	Comparison of Major Developmental Theories			
Developmental Stage/Age	Freud (Psychosexual Development)	Erikson (Psychosocial Development)	Piaget (Cognitive/ Moral Development)	Kohlberg (Development of Moral Reasoning)
Infancy (birth to 18 months)	Oral stage	Trust vs. mistrust Ability to trust others	Sensorimotor period Progress from reflex activity to simple repetitive actions	
Early childhood/toddler (18 months to 3 years)	Anal stage	Autonomy vs. shame and doubt Self-control and independence	Preoperational period— thinking using symbols Egocentric	Preconventional level Punishment-obedience orientation
Preschool (3-5 years)	Phallic stage	Initiative vs. guilt Highly imaginative	Use of symbols Egocentric	Preconventional level Premoral Instrumental orientation
Middle childhood (6-12 years)	Latent stage	Industry vs. inferiority Engaged in tasks and activities	Concrete operations period Logical thinking	Conventional level Good boy–nice girl orientation
Adolescence (12-19 years)	Genital stage	Identity vs. role confusion Sexual maturity, "Who am I?"	Formal operations period Abstract thinking	Postconventional level Social contract orientation
Young Adult		Intimacy vs. isolation Affiliation vs. love		
Adult		Generativity vs. self-absorption and stagnation		
Old Age		Integrity vs. despair		

and this pattern is directed by gene activity (Gesell, 1948). Gesell found that the pattern of maturation follows a fixed developmental sequence in humans. Sequential development is evident in fetuses, in which there is a specified order of organ system development. Today we know that growth in humans is both cephalocaudal and proximodistal. The cephalocaudal pattern describes the sequence in which growth is fastest at the top (e.g., head/brain develop faster than arm and leg coordination). The proximodistal growth pattern starts at the center of the body and moves toward the extremities (e.g., organ systems in the trunk of the body develop before arms and legs). Genes direct the sequence of development; but environmental factors also influence development, resulting in developmental changes. For example, genes direct the growth rate in height for an individual, but that growth is only maximized if environmental conditions are adequate. Poor nutrition or chronic disease often affects the growth rate and results in smaller stature, regardless of the genetic blueprint. However, adequate nutrition and the absence of disease cannot result in height beyond that determined by heredity.

Psychoanalytical/Psychosocial Theory

Theories of psychoanalytical/psychosocial development describe human development from the perspectives of personality, thinking, and behavior (Table 11-1). Psychoanalytical theory explains development as primarily unconscious and influenced by emotion. Psychoanalytical theorists maintain that these unconscious conflicts influence development through universal stages experienced by all individuals (Berger, 2011).

Sigmund Freud. **Freud's psychoanalytical model of personality development** development states that individuals go through five stages of psychosexual development and that each stage is characterized by sexual pleasure in parts of the body: the mouth, the anus, and the genitals. Freud believed that adult personality is the result of how an individual resolves conflicts between these sources of pleasure and the mandates of reality (Santrock, 2012b).

Stage 1: Oral (Birth to 12 to 18 Months). Initially sucking and oral satisfaction are not only vital to life but also extremely pleasurable in their own rights. Late in this stage the infant begins to realize that the mother/parent is something separate from self. Disruption in the physical or emotional availability of the parent (e.g., inadequate bonding or chronic illness) could affect an infant's development.

Stage 2: Anal (12 to 18 Months to 3 Years). The focus of pleasure changes to the anal zone. Children become increasingly aware of the pleasurable sensations of this body region with interest in the products of their effort. Through the toilet-training process the child delays gratification to meet parental and societal expectations.

Stage 3: Phallic or Oedipal (3 to 6 Years). The genital organs are the focus of pleasure during this stage. The boy becomes interested in the penis; the girl becomes aware of the absence of the penis, known as *penis envy*. This is a time of exploration and imagination as a child fantasizes about the parent of the opposite sex as his or her first love interest, known as the *Oedipus* or *Electra complex*. By the end of this stage the child attempts to reduce this conflict by identifying with the parent of the same sex as a way to win recognition and acceptance.

Stage 4: Latency (6 to 12 Years). In this stage Freud believed that children repress and channel sexual urges from the earlier Oedipal stage are repressed and channeled into productive activities that are socially acceptable. Within the educational and social worlds of the child, there is much to learn and accomplish.

Stage 5: Genital (Puberty Through Adulthood). In this final stage sexual urges reawaken and are directed to an individual outside the family circle. Unresolved prior conflicts surface during adolescence. Once the individual resolves conflicts, he or she is then capable of having a mature adult sexual relationship.

Freud believed that the components of the human personality develop in stages and regulate behavior. These components are the id, the ego, and the superego. The id (i.e., basic instinctual impulses driven to achieve pleasure) is the most primitive part of the personality and originates in the infant. The infant cannot tolerate delay and must have needs met immediately. The ego represents the reality component,

mediating conflicts between the environment and the forces of the id. It helps people judge reality accurately, regulate impulses, and make good decisions. Ego is often referred to as one's sense of self. The third component, the superego, performs regulating, restraining, and prohibiting actions. Often referred to as the conscience, the superego is influenced by the standards of outside social forces (e.g., parent or teacher).

Some of Freud's critics contend that he based his analysis of personality development on biological determinants and ignored the influence of culture and experience. Others think that Freud's basic assumptions such as the Oedipus complex are not applicable across different cultures. Psychoanalysts today believe that the role of conscious thought is much greater than Freud imagined (Santrock, 2012a).

Erik Erikson. Freud had a strong influence on his psychoanalytical followers, including Erik Erikson (1902-1994), who constructed a theory of development that differed from Freud's in one main aspect: Erikson's stages emphasize a person's relationship to family and culture rather than sexual urges (Berger, 2011).

According to **Erikson's theory of psychosocial development**, individuals need to accomplish a particular task before successfully mastering the stage and progressing to the next one. Each task is framed with opposing conflicts, and tasks once mastered are challenged and tested again during new situations or at times of conflict (Hockenberry and Wilson, 2015). Erikson's eight stages of life are described here.

Trust vs. Mistrust (Birth to 1 Year). Establishing a basic sense of trust is essential for the development of a healthy personality. An infant's successful resolution of this stage requires a consistent caregiver who is available to meet his needs. From this basic trust in parents, an infant is able to trust in himself, in others, and in the world (Hockenberry and Wilson, 2015). The formation of trust results in faith and optimism. A nurse's use of anticipatory guidance helps parents cope with the hospitalization of an infant and the infant's behaviors when discharged to home.

Autonomy vs. Sense of Shame and Doubt (1 to 3 Years). By this stage a growing child is more accomplished in some basic self-care activities, including walking, feeding, and toileting. This newfound independence is the result of maturation and imitation. A toddler develops his or her autonomy by making choices. Choices typical for the toddler age-group include activities related to relationships, desires, and playthings. There is also opportunity to learn that parents and society have expectations about these choices. Limiting choices and/or enacting harsh punishment leads to feelings of shame and doubt. A toddler who successfully masters this stage achieves self-control and willpower. The nurse models empathetic guidance that offers support for and understanding of the challenges of this stage. Available choices for the child must be simple in nature and safe.

Initiative vs. Guilt (3 to 6 Years). Children like to pretend and try out new roles. Fantasy and imagination allow them to further explore their environment. Also at this time they are developing their superego, or conscience. Conflicts often occur between a child's desire to explore and the limits placed on his or her behavior. These conflicts sometimes lead to feelings of frustration and guilt. Guilt also occurs if a caregiver's responses are too harsh. Preschoolers learn to maintain a sense of initiative without imposing on the freedoms of others. Successful resolution of this stage results in direction and purpose. Teaching a child impulse control and cooperative behaviors helps a family avoid the risks of altered growth and development. Preschoolers frequently engage in animism, a developmental characteristic that makes them treat dolls or stuffed animals as if they have thoughts and feelings. Play therapy is also instrumental in helping a child

successfully deal with the inherent threats related to hospitalization or chronic illness.

Industry vs. Inferiority (6 to 11 Years). School-age children are eager to apply themselves to learning socially productive skills and tools. They learn to work and play with their peers. They thrive on their accomplishments and praise. Without proper support for learning new skills or if skills are too difficult, they develop a sense of inadequacy and inferiority. Children at this age need to be able to experience real achievement to develop a sense of competency. Erikson believed that an adult's attitudes toward work are traced to successful achievement of this task (Erikson, 1963). During hospitalization it is important for a school-age child to understand the routines and participate as actively as possible in his or her treatment. For example, some children enjoy keeping a record of their intake and output.

Identity vs. Role Confusion (Puberty). Dramatic physiological changes associated with sexual maturation mark this stage. There is a marked preoccupation with appearance and body image. This stage, in which identity development begins with the goal of achieving some perspective or direction, answers the question, "Who am I?" Acquiring a sense of identity is essential for making adult decisions such as choice of a vocation or marriage partner. Each adolescent moves in his or her unique way into society as an interdependent member. There are also new social demands, opportunities, and conflicts that relate to the emergent identity and separation from family. Erikson held that successful mastery of this stage resulted in devotion and fidelity to others and to their own ideals (Hockenberry and Wilson, 2015). Elkind (1967) identified a notion of perceived invulnerability in adolescents that contributes to risk-taking behaviors. Nurses provide education and anticipatory guidance for parents about the changes and challenges to adolescents. Nurses also help hospitalized adolescents deal with their illness by giving them enough information to allow them to make decisions about their treatment plan.

Intimacy vs. Isolation (Young Adult). Young adults, having developed a sense of identity, deepen their capacity to love others and care for them. They search for meaningful friendships and an intimate relationship with another person. Erikson portrayed intimacy as finding the self and then losing it in another (Santrock, 2012a). If the young adult is not able to establish companionship and intimacy, isolation results because he or she fears rejection and disappointment (Berger, 2011). Nurses must understand that during hospitalization a young adults' need for intimacy remains present; thus young adults benefit from the support of their partner or significant other during this time.

Generativity vs. Self-Absorption and Stagnation (Middle Age). Following the development of an intimate relationship, an adult focuses on supporting future generations. The ability to expand one's personal and social involvement is critical to this stage of development. Middle-age adults achieve success in this stage by contributing to future generations through parenthood, teaching, mentoring, and community involvement. Achieving generativity results in caring for others as a basic strength. Inability to play a role in the development of the next generation results in stagnation (Santrock, 2012a). Nurses help physically ill adults choose creative ways to foster social development. Middle-age people often find a sense of fulfillment by volunteering in a local school, hospital, or church.

Integrity vs. Despair (Old Age). Many older adults review their lives with a sense of satisfaction, even with their inevitable mistakes. Others see themselves as failures, with their lives marked by despair and regret. Older adults often engage in a retrospective appraisal of their lives. They interpret their lives as a meaningful whole or experience regret because of goals not achieved (Berger, 2011). Because the aging process creates physical and social losses, some adults also suffer loss of status

FIGURE 11-1 Quilting keeps this older adult active.

and function (e.g., through retirement or illness). These external struggles are met with internal struggles such as the search for meaning in life. Meeting these challenges creates the potential for growth and the basic strength of wisdom (Figure 11-1).

Nurses are in positions of influence within their communities to help people feel valued, appreciated, and needed. Erikson stated, "Healthy children will not fear life, if their parents have integrity enough not to fear death" (Erikson, 1963). Although Erikson believed that problems in adult life resulted from unsuccessful resolution of earlier stages, his emphasis on family relationships and culture offered a broad, life span view of development. As a nurse you will use this knowledge of development as you deliver care in any health care setting.

Theories Related to Temperament. Temperament is a behavioral style that affects an individual's emotional interactions with others (Santrock, 2012a). Personality and temperament are often closely linked, and research shows that individuals possess some enduring characteristics into adulthood. The individual differences that children display in responding to their environment significantly influence the way others respond to them and their needs. Knowledge of temperament helps parents better understand their child (Hockenberry and Wilson, 2015).

Psychiatrists Stella Chess (1914-2007) and Alexander Thomas (1914-2003) conducted a 20-year longitudinal study that identified three basic classes of temperament:

- *The easy child*—Easygoing and even-tempered. This child is regular and predictable in his or her habits. An easy child is open and adaptable to change and displays a mild to moderately intense mood that is typically positive.
- *The difficult child*—Highly active, irritable, and irregular in habits. Negative withdrawal toward others is typical, and the child requires a more structured environment. A difficult child adapts slowly to new routines, people, or situations. Mood expressions are usually intense and primarily negative.
- *The slow-to–warm up child*—Typically reacts negatively and with mild intensity to new stimuli. The child adapts slowly with repeated contact unless pressured and responds with mild but passive resistance to novelty or changes in routine.

Research on temperament and its stability has continued, with an emphasis on the individual's ability to make thoughtful decisions

about behavior in demanding situations. Knowledge of temperament and how it impacts the parent-child relationship is critical when providing anticipatory guidance for parents. With the birth of a second child, most parents find that the strategies that worked well with the first child no longer work at all. The nurse individualizes counseling to greatly improve the quality of interactions between parents and children (Hockenberry and Wilson, 2015).

Perspectives on Adult Development

Early study of development focused only on childhood because scholars throughout history regarded the aging process as one of inevitable and irreversible decline. However, we now know that, although the changes come more slowly, people continue to develop new abilities and adapt to shifting environments. The life span perspective suggests that understanding adult development requires multiple viewpoints. Two of the ways researchers studied adult development were through the stage-crisis view and the life span approach. The most well-known stage theory is the one developed by Erik Erikson, which was discussed earlier. Another stage theory that contributed to understanding development throughout the life span was provided through the work of Robert Havinghurst.

Stage-Crisis Theory. Physicist, educator, and aging expert Robert Havinghurst (1900-1991) conducted extensive research and developed a theory of human development based on developmental tasks. Havinghurst's theory incorporates three primary sources for developmental tasks: tasks that surface because of physical maturation, tasks that evolve from personal values, and tasks that are a result of pressures from society. As with Erikson, Havinghurst believed that successful resolution of the developmental task was essential to successful progression throughout life. He identified six stages and six-to-ten developmental tasks for each stage: infancy and early childhood (birth to age 6), middle childhood (6 to 12 years), adolescence (13 to 18 years), early adulthood (19 to 30 years), middle adulthood (30 to 60 years), and late adulthood (60 and over). Havinghurst believed that the number of tasks differs in each age level for individuals because of the interrelationship among biology, society, and personal values. In later years he turned his focus to the study of aging. In response to the view that older adults should gradually withdraw from society, Havinghurst proposed an *activity theory,* which states that continuing an active, involved lifestyle results in greater satisfaction and well-being in aging (see Chapter 14).

Life Span Approach. The contemporary life-events approach takes into consideration the variations that occur for each individual. This view considers an individual's personal circumstances (health and family support), how a person views and adjusts to changes, and the current social and historical context in which an individual is living. The increase in life expectancy has made popular the life span approach to development (Santrock, 2012b). Paul Baltes (1939-2006), a life span development expert, viewed life span development as lifelong, multidimensional, multidirectional, plastic, multidisciplinary, and contextual. In Baltes' view development is constructed through an interaction of biological, sociocultural, and individual factors (Baltes et al., 2005). Current research on successful aging is much more consistent with a life span approach that emphasizes age-related goals that are relationship and socially oriented to support continued well-being (Reichstadt et al., 2010).

Cognitive Developmental Theory

Psychoanalytical/psychosocial theories focus on an individual's unconscious thought and emotions; cognitive theories stress how people

BOX 11-1 EVIDENCE-BASED PRACTICE

Applying Developmental Theory to Care of Infants

PICO Question: In infant patients does parental emotional involvement at bedtime result in improved quality and length of infant sleep?

Evidence Summary

Twenty to thirty percent of infants have difficulty falling asleep and staying asleep (Ball, 2014; Shapiro-Mendoza et al., 2015). Mother's emotional availability at bedtime has been linked to improved quality of sleep in infants, thought to be associated with infant feelings of safety and security. On the other hand, excessive parental involvement and physical soothing at bedtime is linked to frequent interruptions in sleep throughout the night. Mothers who have doubts of their parenting ability or who feel angry or helpless at their infant's demands may tend to be overintrusive at bedtime and report poor infant sleep quality (Cook et al., 2012). When mothers did not breastfeed at bedtime, Tikotzky et al. (2015) noted that increased participation by fathers during the bedtime ritual improved infant sleeping. It is important that nurses apply developmental theory and recognize the importance of parental engagement in the quality of infant sleep.

Application to Nursing Practice
- Educate parents how to realign their expectation regarding infant sleeping patterns (Ball, 2014).
- Be aware of the value of involving parents in infant care and feeding, particularly around bedtimes (Ball, 2014).
- Help breastfeeding parents set up a bedtime ritual that involves the father (Tikotzky et al., 2015).
- Understand an infant's need for parental involvement in developing a sense of safety and security to enhance quality of sleep.

FIGURE 11-2 Play is important to a child's development.

learn to think and make sense of their world. As with personality development, cognitive theorists have explored both childhood and adulthood. Some of the theories highlight qualitative changes in thinking; others expand to include social, cultural, and behavioral dimensions.

Jean Piaget. Jean Piaget (1896-1980) was most interested in the development of children's intellectual organization: how they think, reason, and perceive the world. **Piaget's theory of cognitive development** includes four periods that are related to age and demonstrate specific categories of knowing and understanding (see also Chapter 12). He built his theory on years of observing children as they explored, manipulated, and tried to make sense out of the world in which they lived. Piaget believed that individuals move from one stage to the other seeking cognitive equilibrium or a state of mental balance and that they build mental structures to help adapt to the world (Santrock, 2012a). Within each of these primary periods of cognitive development are specific stages (see Table 11-1).

Period I: Sensorimotor (Birth to 2 Years). Infants develop a schema or action pattern for dealing with the environment (Box 11-1). These schemas include hitting, looking, grasping, or kicking. Schemas become self-initiated activities (e.g., the infant learning that sucking achieves a pleasing result generalizes the action to suck fingers, blanket, or clothing). Successful achievement leads to greater exploration. During this stage a child learns about himself and his environment through motor and reflex actions. He or she learns that he or she is separate from the environment and that aspects of the environment (e.g., parents or favorite toy) continue to exist even though they cannot always be seen. Piaget termed this understanding that objects continue to exist even when they cannot be seen, heard, or touched *object permanence* and considered it one of the child's most important accomplishments.

Period II: Preoperational (2 to 7 Years). During this time children learn to think with the use of symbols and mental images. They exhibit "egocentrism" in that they see objects and people from only one point of view, their own. They believe that everyone experiences the world exactly as they do. Early in this stage children demonstrate "animism" in which they personify objects. They believe that inanimate objects have lifelike thought, wishes, and feelings. Their thinking is influenced greatly by fantasy and magical thinking. Children at this stage have difficulty conceptualizing time. Play becomes a primary means by which they foster their cognitive development and learn about the world (Figure 11-2). Nursing interventions during this period recognize the use of play as the way the child understands the events taking place. Play therapy is a nursing intervention that helps the child work through invasive and intrusive procedures that may occur during hospitalization. In addition, play therapy helps the ill child progress developmentally.

Period III: Concrete Operations (7 to 11 Years). Children now are able to perform mental operations. For example, the child thinks about an action that before was performed physically. Children are now able to describe a process without actually doing it. At this time they are able to coordinate two concrete perspectives in social and scientific thinking so they are able to appreciate the difference between their perspective and that of a friend. Reversibility is one of the primary characteristics of concrete operational thought. Children can now mentally picture a series of steps and reverse the steps to get back to the starting point. The ability to mentally classify objects according to their quantitative dimensions, known as *seriation,* is achieved. They are able to correctly order or sort objects by length, weight, or other characteristics. Another major accomplishment of this stage is conservation, or the ability to see objects or quantities as remaining the same despite a change in their physical appearance (Santrock, 2012b).

Period IV: Formal Operations (11 Years to Adulthood). The transition from concrete to formal operational thinking occurs in stages during which there is a prevalence of egocentric thought. This egocentricity leads adolescents to demonstrate feelings and behaviors characterized by self-consciousness: a belief that their actions and appearance are constantly being scrutinized (an "imaginary audience"), that their thoughts and feelings are unique (the "personal fable"), and that they are invulnerable (Santrock, 2012b). These feelings of invulnerability frequently lead to risk-taking behaviors, especially in early adolescence.

As adolescents share experiences with peers, they learn that many of their thoughts and feelings are shared by almost everyone, helping them to know that they are not so different. As they mature, their thinking moves to abstract and theoretical subjects. They have the capacity to reason with respect to possibilities. For Piaget this stage marked the end of cognitive development.

Piaget's work has been challenged over the years as researchers have continued to study cognitive development. For example, some aspects of objective performance emerge earlier than Piaget believed, and other cognitive abilities can surface later than he predicted. We now know that many adults may not become formal operational thinkers and remain at the concrete stage and others have cognitive development that goes beyond the stages that Piaget proposed (Santrock, 2012b). Assessment of cognitive ability becomes critical as you provide health care teaching to patients and families.

Research in Adult Cognitive Development. Research into cognitive development in adulthood began in the 1970s and continues today. It supports that adults do not always arrive at one answer to a problem but frequently accept several possible solutions. Adults also incorporate emotions, logic, practicality, and flexibility when making decisions. On the basis of these observations, developmentalists proposed a fifth stage of cognitive development termed *postformal thought.* Within this stage adults demonstrate the ability to recognize that answers vary from situation to situation and that solutions need to be sensible.

One of the earliest to develop a theory of adult cognition was William Perry (1913-1998), who studied college students and found that continued cognitive development involved increasing cognitive flexibility. As adolescents were able to move from a position of accepting only one answer to realizing that alternative explanations could be right, depending on one's perspective, there was a significant cognitive change. Adults change how they use knowledge, and the emphasis shifts from attaining knowledge or skills to using knowledge for goal achievement.

Moral Developmental Theory

Moral development refers to the changes in a person's thoughts, emotions, and behaviors that influence beliefs about what is right or wrong. It encompasses both *interpersona*l and *intrapersonal* dimensions as it governs how we interact with others (Santrock, 2012b). Although various psychosocial and cognitive theorists address moral development within their respective theories, the theories of Piaget and Kohlberg are more widely known (see Table 11-1).

Lawrence Kohlberg's Theory of Moral Development. **Kohlberg's theory of moral development** expands on Piaget's cognitive theory. Kohlberg interviewed children, adolescents, and eventually adults and found that moral reasoning develops in stages. From an examination of responses to a series of moral dilemmas, he identified six stages of moral development under three levels (Kohlberg, 1981).

Level I: Preconventional Reasoning. This is the premoral level, in which there is limited cognitive thinking and an individual's thinking is primarily egocentric. At this stage thinking is mostly based on likes and pleasures. This stage progresses toward having punishment guide behavior. A person's moral reason for acting, the "why," eventually relates to the consequences that the person believes will occur. These consequences come in the form of punishment or reward. It is at this level that children view illness as a punishment for fighting with their siblings or disobeying their parents. Nurses need to be aware of this egocentric thinking and reinforce that the child does not become ill because of wrongdoing.

Stage 1: Punishment and Obedience Orientation. In this first stage a child's response to a moral dilemma is in terms of absolute obedience to authority and rules. A child in this stage reasons, "I must follow the rules; otherwise I will be punished." Avoiding punishment or the unquestioning deference to authority is characteristic motivation to behave. Physical consequences guide right and wrong choices. If the child is caught, it must be wrong; if he or she escapes, it must be right.

Stage 2: Instrumental Relativist Orientation. In this stage the child recognizes that there is more than one right view; a teacher has one view that is different from that of the child's parent. The decision to do something morally right is based on satisfying one's own needs and occasionally the needs of others. The child perceives punishment not as proof of being wrong (as in stage 1) but as something that one wants to avoid. Children at this stage follow their parent's rule about being home in time for supper because they do not want to be confined to their room for the rest of the evening if they are late.

Level II: Conventional Reasoning. At level II, **conventional reasoning,** the person sees moral reasoning based on his or her own personal internalization of societal and others' expectations. A person wants to fulfill the expectations of the family, group, or nation and also develop a loyalty to and actively maintain, support, and justify the order. Moral decision making at this level moves from, "What's in it for me?" to "How will it affect my relationships with others?" Emphasis now is on social rules and a community-centered approach (Berger, 2011). Nurses observe this when family members make end-of-life decisions for their loved ones. Individual members often struggle with this type of moral dilemma. Grief support involves an understanding of the level of moral decision making of each family member (see Chapter 37).

Stage 3: Good Boy–Nice Girl Orientation. The individual wants to win approval and maintain the expectations of one's immediate group. "Being good" is important and defined as having positive motives, showing concern for others, and keeping mutual relationships through trust, loyalty, respect, and gratitude. One earns approval by "being nice." For example, a person in this stage stays after school and does odd jobs to win the teacher's approval.

Stage 4: Society-Maintaining Orientation. Individuals expand their focus from a relationship with others to societal concerns during stage 4. Moral decisions take into account societal perspectives. Right behavior is doing one's duty, showing respect for authority, and maintaining the social order. Adolescents choose not to attend a party where they know beer will be served, not because they are afraid of getting caught, but because they know that it is not right.

Level III: Postconventional Reasoning. The person finds a balance between basic human rights and obligations and societal rules and regulations in the level of **postconventional reasoning.** Individuals move away from moral decisions based on authority or conformity to groups to define their own moral values and principles. Individuals at this stage start to look at what an ideal society would be like. Moral principles and ideals come into prominence at this level (Berger, 2011).

Stage 5: Social Contract Orientation. Having reached stage 5, an individual follows the societal law but recognizes the possibility of changing the law to improve society. The individual also recognizes that different social groups have different values but believes that all rational people would agree on basic rights such as liberty and life. Individuals at this stage make more of an independent effort to determine what society *should* value rather than what the society as a group *would* value, as would occur in stage 4. The United States Constitution is based on this morality.

Stage 6: Universal Ethical Principle Orientation. Stage 6 defines "right" by the decision of conscience in accord with self-chosen ethical principles. These principles are abstract, like the Golden Rule, and appeal to logical comprehensiveness, universality, and consistency

(Kohlberg, 1981). For example, the principle of justice requires the individual to treat everyone in an impartial manner, respecting the basic dignity of all people, and guides the individual to base decisions on an equal respect for all. Civil disobedience is one way to distinguish stage 5 from stage 6. Stage 5 emphasizes the basic rights, the democratic process, and following laws without question; whereas stage 6 defines the principles by which agreements will be most just. For example, a person in stage 5 follows a law, even if it is not fair to a certain racial group. An individual in stage 6 may not follow a law if it does not seem just to the racial group. For example, Martin Luther King believed that, although we need laws and democratic processes, people who are committed to justice have an obligation to disobey unjust laws and accept the penalties for disobeying these laws (Crain, 1985).

Kohlberg's Critics. Kohlberg constructed a systemized way of looking at moral development and is recognized as a leader in moral developmental theory. However, critics of his work raise questions about his choice of research subjects. For example, most of Kohlberg's subjects were males raised in Western philosophical traditions. Research attempting to support Kohlberg's theory with individuals raised in the Eastern philosophies found that individuals raised in Eastern philosophies never rose above stages 3 or 4 of Kohlberg's model. To some, these findings suggest that people from Eastern philosophies have not reached higher levels of moral development, which is untrue. Others believe that Kohlberg's research design did not allow a way to measure those raised within a different culture.

Kohlberg has also been criticized for age and gender bias. Carol Gilligan criticizes Kohlberg for his gender biases. She believes that he developed his theory on the basis of a justice perspective that focused on the rights of individuals. In contrast, Gilligan's research looked at moral development from a care perspective that viewed people in their interpersonal communications, relationships, and concern for others (Gilligan, 1982; Santrock, 2012b). Other researchers have examined Gilligan's theory in studies with children and have not found evidence to support gender differences (Santrock, 2012b).

Moral Reasoning and Nursing Practice. Nurses need to know their own moral reasoning level. Recognizing your own moral developmental level is essential in separating your beliefs from others when helping patients with their moral decision-making process. It is also important to recognize the level of moral and ethical reasoning used by other members of the health care team and its influence on a patient's care plan. Ideally all members of the health care team are on the same level, creating a unified outcome. This is exemplified in the following scenario: The nurse is caring for a homeless person and believes that all patients deserve the same level of care. The case manager, who is responsible for resource allocation, complains about the patient's length of stay and the amount of resources being expended on this one patient. The nurse and the case manager are in conflict because of their different levels of moral decision making within their practices. They decide to hold a health care team conference to discuss their differences and the ethical dilemma of ensuring that the patient receives an appropriate level of care. Such ethical decisions should be examined through the ethical principles of autonomy; beneficence, nonmaleficence, and justice (see Chapter 22).

Developmental theories help nurses use critical thinking skills when asking how and why people respond as they do. From the diverse set of theories included in this chapter, the complexity of human development is evident. No one theory successfully describes all the intricacies of human growth and development. Today's nurse needs be knowledgeable about several theoretical perspectives when working with patients.

Your assessment of a patient requires a thorough analysis and interpretation of data to form accurate conclusions about his or her developmental needs. Accurate identification of nursing diagnoses relies on your ability to consider developmental theory in data analysis. You compare normal developmental behaviors with those projected by developmental theory. Examples of nursing diagnoses applicable to patients with developmental problems include *risk for delayed development, delayed growth and development,* and *risk for disproportionate growth.*

> **QSEN QSEN: BUILDING COMPETENCY IN SAFETY** Sam is an 84-year-old patient hospitalized for acute abdominal pain. He does not have any local family and lives in an assisted–housing community. He is confused and disoriented. How would your knowledge of developmental theories guide your nursing care for Sam in ensuring his safety?
>

Growth and development, as supported by a life span perspective, is multidimensional. The theories included are the basis for a meaningful observation of an individual's pattern of growth and development. They are important guidelines for understanding important human processes that allow nurses to begin to predict human responses and recognize deviations from the norm.

KEY POINTS

- Nurses administer care for individuals at various developmental stages. Developmental theory provides a basis for nurses to assess and understand the responses seen in their patients.
- Development is not limited to childhood and adolescence; people grow and develop throughout their life span.
- Developmental theories are a way to explain and try to predict human behavior.
- Growth refers to the quantitative changes that nurses measure and compare to norms.
- Development implies a progressive and continuous process of change, leading to a state of organized and specialized functional capacity. These changes are quantitatively measurable but are more distinctly measured in qualitative changes.
- Biophysical development theory explores theories of why individuals age from a biological standpoint, why development follows a predictable sequence, and how environmental factors can influence development.
- Cognitive development focuses on the rational thinking processes that include the changes in how children, adolescents, and adults perform intellectual operations.
- Developmental tasks are age-related achievements, the success of which leads to happiness; whereas failure often leads to unhappiness, disapproval, and difficulty in achieving later tasks.
- Developmental crisis occurs when a person is having great difficulty meeting tasks of the current developmental period.
- Psychosocial theories describe human development from the perspectives of personality, thinking, and behavior, with varying degrees of influence from internal biological forces and external societal/cultural forces.
- Temperament is a behavioral pattern that affects the individual's interactions with others.
- Moral development theory attempts to define how moral reasoning matures for an individual.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Mrs. Banks is an 84-year-old woman who was recently diagnosed with breast cancer. She also has severe cardiovascular disease that limits her choices of treatment. She completed a series of radiation treatments that have left her exhausted and unable to participate in her usual activities. Her oncologist now recommends a cycle of chemotherapy treatments that her cardiologist believes would be fatal. Her family is urging her to do all that is recommended. The patient, who is in good spirits despite her diagnosis, decides against further medical treatment.
   a. How does Mrs. Banks' cognitive developmental stage impact her decision making related to her health care?
   b. Which of the psychosocial developmental theories helps explain her decision?
   c. Using your knowledge of her developmental stage, how can you help the family adjust to her choice?

2. Amanda Peters, 9 years old, was admitted to the unit yesterday with a new diagnosis of type I diabetes. Her mother spent the night with her and is arranging the food on Amanda's breakfast tray when you enter the room to check her blood sugar and administer her insulin. Although the diabetes educator will be meeting with Amanda and her family, as part of her care today you want to begin her discharge teaching.
   a. According to Piaget's theory, how will Amanda's cognitive development direct your teaching?
   b. Using Erikson's theory as a basis, which psychosocial factors will you consider when discussing home care with Amanda and her family?
   c. Based on her developmental stage, how can Amanda's family support her active participation in care?

3. You have been assigned to care for Daniel Jackson, a 17-year-old male who was in an automobile accident several days ago and sustained a fractured pelvis. He had a surgical repair and remains on bed rest. School is starting next month, and he was scheduled to begin football practice next week. During bedside report he refuses to make eye contact with the nursing staff or respond to any questions to help direct his care.
   a. How will you incorporate your knowledge of adolescent development as you establish priorities for his care?
   b. Thinking about Erikson's theory, which psychosocial concerns do you anticipate that Daniel might experience during his hospitalization and recovery period?
   c. How will Daniel's cognitive development contribute to his future planning?

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse is aware that preschoolers often display a developmental characteristic that makes them treat dolls or stuffed animals as if they have thoughts and feelings. This is an example of:
   1. Logical reasoning.
   2. Egocentrism.
   3. Concrete thinking.
   4. Animism.

2. An 18-month-old child is noted by the parents to be "angry" about any change in routine. This child's temperament is most likely to be described as:
   1. Slow to warm up.
   2. Difficult.
   3. Hyperactive.
   4. Easy.

3. Nine-year-old Brian has a difficult time making friends at school and being chosen to play on the team. He also has trouble completing his homework and, as a result, receives little positive feedback from his parents or teacher. According to Erikson's theory, failure at this stage of development results in:
   1. A sense of guilt.
   2. A poor sense of self.
   3. Feelings of inferiority.
   4. Mistrust.

4. The nurse teaches parents how to have their children learn impulse control and cooperative behaviors. This would be during which of Erikson's stages of development?
   1. Trust versus mistrust
   2. Initiative versus guilt
   3. Industry versus inferiority
   4. Autonomy versus sense of shame and doubt

5. When Ryan was 3 months old, he had a toy train; when his view of the train was blocked, he did not search for it. Now that he is 9 months old, he looks for it, reflecting the presence of:
   1. Object permanence.
   2. Sensorimotor play.
   3. Schemata.
   4. Magical thinking.

6. When preparing a 4-year-old child for a procedure, which method is developmentally most appropriate for the nurse to use?
   1. Allowing the child to watch another child undergoing the same procedure
   2. Showing the child pictures of what he or she will experience
   3. Talking to the child in simple terms about what will happen
   4. Preparing the child through play with a doll and toy medical equipment

7. Which of the following are examples of the conventional reasoning form of cognitive development? (Select all that apply.)
   1. A 35-year-old woman is speaking with you about her recent diagnosis of a chronic illness. She is concerned about her treatment options in relation to her ability to continue to care for her family. As she considers the options and alternatives, she incorporates information, her values, and emotions to decide which plan will be the best fit for her.
   2. A young father is considering whether or not to return to school for a graduate degree. He considers the impact the time commitment may have on the needs of his wife and infant son.
   3. A teenage girl is encouraged by her peers to engage in shoplifting. She decides not to join her peers in this activity because she is afraid of getting caught in the act.
   4. A single mother of two children is unhappy with her employer. She has been unable to secure alternate employment but decides to quit her current job.

8. You are caring for a recently retired man who appears withdrawn and says he is "bored with life." Applying the work of Havinghurst, you would help this individual find meaning in life by:
   1. Encouraging him to explore new roles.
   2. Encouraging relocation to a new city.
   3. Explaining the need to simplify life.
   4. Encouraging him to adopt a new pet.

9. Place the following stages of Freud's psychosexual development in the proper order by age progression.
    1. Oedipal
    2. Latency
    3. Oral
    4. Genital
    5. Anal
10. According to Piaget's cognitive theory, a 12-year-old child is most likely to engage in which of the following activities?
    1. Using building blocks to determine how houses are constructed
    2. Writing a story about a clown who wants to leave the circus
    3. Drawing pictures of a family using stick figures
    4. Writing an essay about patriotism
11. Allison, age 15 years, calls her best friend Laura and is crying. She has a date with John, someone she has been hoping to date for months, but now she has a pimple on her forehead. Laura firmly believes that John and everyone else will notice the blemish right away. This is an example of the:
    1. Imaginary audience.
    2. False-belief syndrome.
    3. Personal fable.
    4. Personal absorption syndrome.
12. Elizabeth, who is having unprotected sex with her boyfriend, comments to her friends, "Did you hear about Kathy? You know, she fools around so much; I heard she was pregnant. That would never happen to me!" This is an example of adolescent:
    1. Imaginary audience.
    2. False-belief syndrome.
    3. Personal fable.
    4. Sense of invulnerability.

13. Which of the following activities are examples of the use of activity theory in older adults? (Select all that apply.)
    1. Teaching an older adult how to use e-mail to communicate with a grandchild who lives in another state
    2. Introducing golf as a new hobby
    3. Leading a group walk of older adults each morning
    4. Engaging an older adult in a community project with a short-term goal
    5. Directing a community play at the local theater
14. Dave reports being happy and satisfied with his life. What do we know about him?
    1. He is in one of the later developmental periods, concerned with reviewing his life.
    2. He is atypical, since most people in any of the developmental stages report significant dissatisfaction with their lives.
    3. He is in one of the earlier developmental periods, concerned with establishing a career and satisfying long-term relationships.
    4. It is difficult to determine Dave's developmental stage since most people report overall satisfaction with their lives in all stages.
15. You are working in a clinic that provides services for homeless people. The current local regulations prohibit providing a service that you believe is needed by your patients. You adhere to the regulations but at the same time are involved in influencing authorities to change the regulation. This action represents _____ stage of moral development.

Answers: 1. 4; **2.** 3; **3.** 4; **4.** 2; **5.** 1; **6.** 4; **7.** 1, 2; **8.** 1; **9.** 3, 5, 2, 1, 4; **10.** 2; **11.** 1; **12.** 4; **13.** 1, 2, 4; **14.** 4; **15.** Social contract orientation.

Conception Through Adolescence

STAGES OF GROWTH AND DEVELOPMENT

Human growth and development are continuous and complex processes that are typically divided into stages organized by age-groups such as from conception to adolescence. Although this chronological division is arbitrary, it is based on the timing and sequence of developmental tasks that the child must accomplish to progress to another stage. This chapter focuses on the various physical, psychosocial, and cognitive changes and health risks and health promotion concerns during the different stages of growth and development.

SELECTING A DEVELOPMENTAL FRAMEWORK FOR NURSING

Providing developmentally appropriate nursing care is easier when you base planning on a theoretical framework (see Chapter 11). An organized, systematic approach ensures that you assess the child appropriately and plan care that meets the child's and family's needs. If you deliver nursing care only as a series of isolated actions, you will overlook some of the child's developmental needs. A developmental approach encourages organized care directed at the child's current level of functioning to motivate self-direction and health promotion. For example, nurses encourage toddlers to feed themselves to advance their developing independence and thus promote their sense of autonomy. Another example involves a nurse understanding an adolescent's need to be independent and thus establishing a contract about the care plan and its implementation.

INTRAUTERINE LIFE

From the moment of conception until birth, human development proceeds at a predictive and rapid rate. During gestation or the prenatal period, the embryo grows from a single cell to a complex, physiological being. All major organ systems develop in utero, with some functioning before birth. Development proceeds in a cephalocaudal (head-to-toe) and proximal-distal (central-to-peripheral) pattern (Murray and McKinney, 2010).

Pregnancy that reaches full term is calculated to last an average of 38 to 40 weeks and is divided into three stages or trimesters. Beginning on the day of fertilization, the first 14 days are referred to as the **preembryonic stage**, followed by the **embryonic stage** that lasts from day 15 until the eighth week. These two stages are then followed by the **fetal stage** that lasts from the end of the eighth week until birth (Perry et al., 2014). Gestation is commonly divided into equal phases of 3 months called *trimesters*.

The placenta begins development at the third week of the embryonic stage and produces essential hormones that help maintain the pregnancy. The placenta functions as the fetal lungs, kidneys, gastrointestinal tract, and an endocrine organ. Because the placenta is extremely porous, noxious materials such as viruses, chemicals, and drugs also pass from mother to child. These agents are called *teratogens* and can cause abnormal development of structures in the embryo. The effect of teratogens on the **fetus** or unborn child depends on the developmental stage in which exposure takes place, individual genetic susceptibility, and the quantity of the exposure. The embryonic stage is the most vulnerable since all body organs are formed by the eighth week.

Some maternal infections can cross the placental barrier and negatively influence the health of the mother, fetus, or both. It is important to educate women about avoidable sources of teratogens and help them make healthy lifestyle choices before and during pregnancy.

Health Promotion During Pregnancy

The diet of a woman both before and during pregnancy has a significant effect on fetal development. Women who do not consume adequate nutrients and calories during pregnancy may not be able to meet the fetus' nutritional requirements. An increase in weight does not always indicate an increase in nutrients. In addition, the pattern of weight gain is important for tissue growth in a mother and fetus. For women who are at normal weight for height, the recommended weight gain is 25 to 35 lbs (11 to 15 kg) over three trimesters (Murray and McKinney, 2010). As a nurse you are in a key position to provide women with the education they need about nutrition before conception and throughout an expectant mother's pregnancy.

Pregnancy presents a developmental challenge that includes physiological, cognitive, and emotional states that are accompanied by stress and anxiety. The expectant woman will soon adopt a parenting role; and relationships within the family will change, whether or not there is a partner involved. Pregnancy can be a period of conflict or support; family dynamics impact fetal development. Parental reactions to pregnancy change throughout the gestational period, with most couples looking forward to the birth and addition of a new family member (Perry et al., 2014). Listen carefully to concerns expressed by a mother and her partner and offer support through each trimester.

The age of the pregnant woman sometimes plays a role in the health of the fetus and the overall pregnancy. Fetuses of older mothers are at risk for chromosomal defects, and older women may have more difficulty becoming pregnant. Studies indicate that pregnant adolescents often seek out less prenatal care than women in their 20s and 30s and are at higher risk for complications of pregnancy and labor. Infants of teen mothers are at increased risk for prematurity; low birth weight; and exposure to alcohol, drugs, and tobacco in utero and early childhood (USDHHS, 2014b). Adolescents who have been able to participate in prenatal classes may have improved nutrition and healthier babies.

Fetal growth and hormonal changes during pregnancy often result in discomfort for the expectant mother. Common concerns expressed include problems such as nausea and vomiting, breast tenderness, urinary frequency, heartburn, constipation, ankle edema, and backache. Always anticipate these discomforts and provide self-care education throughout the pregnancy. Discussing the physiological causes of these discomforts and offering suggestions for safe treatment can be very helpful for expectant mothers and contribute to overall health during pregnancy (Perry et al., 2014; USDHHS, 2014b).

Some complementary and alternative therapies such as herbal supplements can be harmful during pregnancy. Your assessment should include questions about use of these substances when providing education (Murray and McKinney, 2010). You can promote maternal and fetal health by providing accurate and complete information about health behaviors that support positive outcomes for pregnancy and childbirth.

TRANSITION FROM INTRAUTERINE TO EXTRAUTERINE LIFE

The transition from intrauterine to extrauterine life requires profound physiological changes in the newborn and occurs during the first 24 hours of life. Assessment of the newborn during this period is essential to ensure that the transition is proceeding as expected. Gestational age and development, exposure to depressant drugs before or during labor, and the newborn's own behavioral style also influence the adjustment to the external environment.

Physical Changes

An immediate assessment of the newborn's condition to determine the physiological functioning of the major organ systems occurs at birth. The most widely used assessment tool is the **Apgar score**. Heart rate, respiratory effort, muscle tone, reflex irritability, and color are rated to determine overall status of the newborn. The Apgar assessment generally is conducted at 1 and 5 minutes after birth and is sometimes repeated until the newborn's condition stabilizes. The most extreme physiological change occurs when the newborn leaves the utero circulation and develops independent circulatory and respiratory functioning.

Nursing interventions at birth include maintaining an open airway, stabilizing and maintaining body temperature, and protecting the newborn from infection. The removal of nasopharyngeal and oropharyngeal secretions with suction or a bulb syringe ensures airway patency. Newborns are susceptible to heat loss and cold stress. Because hypothermia increases oxygen needs, it is essential to stabilize and maintain a newborn's body temperature. A healthy newborn may be placed directly on the mother's abdomen and covered in warm blankets or provided warmth via a radiant warmer. Preventing infection is a major concern in the care of a newborn, whose immune system is immature. Good handwashing technique is the most important factor in protecting a newborn from infection. You can help prevent infection by instructing parents and visitors to wash their hands before touching the infant.

Psychosocial Changes

After immediate physical evaluation and application of identification bracelets, the nurse promotes the parents' and newborn's need for close physical contact. Early parent-child interaction encourages parent-child **attachment**. Merely placing the family together does not promote closeness. Most healthy newborns are awake and alert for the first half-hour after birth. This is a good time for parent-child interaction to begin. Close body contact, often including breastfeeding, is a satisfying way for most families to start bonding. If immediate contact is not possible, incorporate it into the care plan as early as possible, which means bringing the newborn to an ill parent or bringing the parents to an ill or premature child. Attachment is a process that evolves over the infant's first 24 months of life, and many psychologists believe that a secure attachment is an important foundation for psychological development in later life (Perry et al., 2014).

NEWBORN

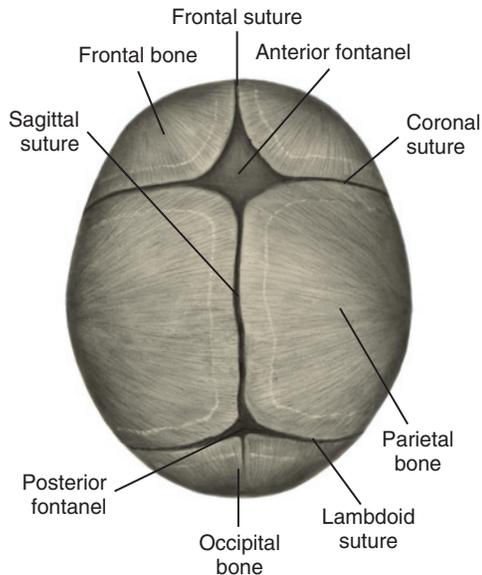
The **neonatal period** is the first 28 days of life. During this stage the newborn's physical functioning is mostly reflexive, and stabilization of major organ systems is the primary task of the body. Behavior greatly influences interaction among the newborn, the environment, and caregivers. For example, the average 2-week-old smiles spontaneously and is able to look at the mother's face. The impact of these reflexive behaviors is generally a surge of maternal feelings of love that prompt the mother to cuddle the baby. You apply knowledge of this stage of growth and development to promote newborn and parental health. For example, the newborn's cry is generally a reflexive response to an unmet need (e.g., hunger, fatigue, or discomfort). Thus you help parents identify ways to meet these needs by counseling them to feed their baby on demand rather than on a rigid schedule.


FIGURE 12-1 Fontanels and suture lines. (From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 10, St Louis, 2015, Mosby.)

Physical Changes

The nurse performs a comprehensive nursing assessment as soon as the newborn's physiological functioning is stable, generally within a few hours after birth. At this time he or she measures height, weight, head and chest circumference, temperature, pulse, and respirations and observes general appearance, body functions, sensory capabilities, reflexes, and responsiveness. Following a comprehensive physical assessment, assess gestational age and interactions between infant and parent that indicate successful attachment (Hockenberry and Wilson, 2015).

The average newborn is 6 to 9 lbs (2700 to 4000 g), 19 to 21 inches (48 to 53 cm) in length, and has a head circumference of 13 to 14 inches (33 to 35 cm). Neonates lose up to 10% of birth weight in the first few days of life, primarily through fluid losses by respiration, urination, defecation, and low fluid intake. They usually regain birth weight by the second week of life; and a gradual pattern of increase in weight, height, and head circumference is evident. Accurate measurement as soon as possible after birth provides a baseline for future comparison (Hockenberry and Wilson, 2015).

Normal physical characteristics include the continued presence of lanugo on the skin of the back; cyanosis of the hands and feet for the first 24 hours; and a soft, protuberant abdomen. Skin color varies according to racial and genetic heritage and gradually changes during infancy. **Molding,** or overlapping of the soft skull bones, allows the fetal head to adjust to various diameters of the maternal pelvis and is a common occurrence with vaginal births. The bones readjust within a few days, producing a rounded appearance to the head. The sutures and fontanels are usually palpable at birth. Figure 12-1 shows the diamond shape of the anterior fontanel and the triangular shape of the posterior fontanel between the unfused bones of the skull. The anterior fontanel usually closes at 12 to 18 months, whereas the posterior fontanel closes by the end of the second or third month.

Assess neurological function by observing the newborn's level of activity, alertness, irritability, and responsiveness to stimuli and the presence and strength of reflexes. Normal reflexes include blinking in response to bright lights, startling in response to sudden loud noises or movement, sucking, rooting, grasping, yawning, coughing, sneezing, palmar grasp, swallowing, plantar grasp, Babinski, and hiccoughing.

FIGURE 12-2 Tonic neck reflex. Newborns assume this position while supine. (From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 10, St Louis, 2015, Mosby.)

Assessment of these reflexes is vital because the newborn depends largely on reflexes for survival and in response to its environment. Figure 12-2 shows the tonic neck reflex in the newborn.

Normal behavioral characteristics of the newborn include periods of sucking, crying, sleeping, and activity. Movements are generally sporadic, but they are symmetrical and involve all four extremities. The relatively flexed fetal position of intrauterine life continues as the newborn attempts to maintain an enclosed, secure feeling. Newborns normally watch the caregiver's face; have a nonpurposeful reflexive smile; and respond to sensory stimuli, particularly the primary caregiver's face, voice, and touch.

In accordance with the recommendations of the American Academy of Pediatrics (AAP, 2014b), position infants for sleep on their backs to decrease the risk of sudden infant death syndrome (SIDS) (Hockenberry and Wilson, 2015; Murray and McKinney, 2010). Newborns establish their individual sleep-activity cycle, and parents develop sensitivity to their baby's cues. Nurses play an important role in demonstrating to parents the correct positioning on the back to reduce the incidence of SIDS (Perry et al., 2014). Co-sleeping or bed sharing has also been reported to possibly be associated with an increased risk for SIDS (Hockenberry and Wilson, 2015). Safeguards include proper positioning; removing stuffed animals, soft bedding, and pillows; and avoiding overheating the infant. Individuals should avoid smoking during pregnancy and around the infant because it places the infant at greater risk for SIDS (Hockenberry and Wilson, 2015).

Cognitive Changes

Early cognitive development begins with innate behavior, reflexes, and sensory functions. Newborns initiate reflex activities, learn behaviors, and learn their desires. At birth infants are able to focus on objects about 8 to 10 inches (20 to 25 cm) from their faces and perceive forms. A preference for the human face is apparent. Teach parents about the importance of providing sensory stimulation such as talking to their babies and holding them to see their faces. This allows infants to seek or take in stimuli, thereby enhancing learning and promoting cognitive development.

For newborns crying is a means of communication to provide cues to parents. Some babies cry because their diapers are wet or they are hungry or want to be held. Others cry just to make noise or because they need a change in position or activity. The crying frustrates the parents if they cannot see an apparent cause. With the nurse's help parents learn to recognize infants' cry patterns and take appropriate action when necessary.

Psychosocial Changes

During the first month of life most parents and newborns normally develop a strong bond that grows into a deep attachment. Interactions during routine care enhance or detract from the attachment process. Feeding, hygiene, and comfort measures consume much of infants' waking time. These interactive experiences provide a foundation for the formation of deep attachments. Early on older siblings need to have opportunity to be involved in the newborn's care. Family involvement helps support growth and development and promotes nurturing (Figure 12-3).

If parents or children experience health complications after birth, this *may* compromise the attachment process. Infants' behavioral cues are sometimes weak or absent, and caregiving is possibly less mutually satisfying. Some tired or ill parents have difficulty interpreting and responding to their infants. Preterm infants and those born with congenital anomalies are often too weak to be responsive to parental cues and require special supportive nursing care. For example, infants born with heart defects tire easily during feedings. Nurses can support parental attachment by pointing out positive qualities and responses of the newborn and acknowledging how difficult the separation can be for parents and infant.

Health Promotion

Screening. Newborn screening tests are administered before babies leave the hospital to identify serious or life-threatening conditions before symptoms begin. Results of the screening tests are sent directly to an infant's pediatrician. If a screening test suggests a problem, the baby's physician usually follows up with further testing and may refer the infant to a specialist for treatment if needed. Blood tests help determine **inborn errors of metabolism (IEMs)**. These are

FIGURE 12-3 Siblings should be involved in newborn care. (Courtesy Elaine Polan, RNC, BSN, MS.)

genetic disorders caused by the absence or deficiency of a substance, usually an enzyme, essential to cellular metabolism that results in abnormal protein, carbohydrate, or fat metabolism. Although IEMs are rare, they account for a significant proportion of health problems in children. Neonatal screening is done to detect phenylketonuria (PKU), hypothyroidism, galactosemia, and other diseases to allow appropriate treatment that prevents permanent mental retardation and other health problems.

The AAP recommends universal screening of newborn hearing before discharge since studies have indicated that the incidence of hearing loss is as high as 1 to 3 per 1000 normal newborns (Perry et al., 2014). If health care providers detect the loss before 3 months of age and intervention is initiated by 6 months, children are able to achieve normal language development that matches their cognitive development through the age of 5 (Hockenberry and Wilson, 2015).

Car Seats. An essential component of discharge teaching is the use of a federally approved car seat for transporting the infant from the hospital or birthing center to home. Automobile injuries are a leading cause of death in children in the United States. Many of these deaths occur when the child is not properly restrained (Hockenberry and Wilson, 2015). Parents need to learn how to fit the restraint to the infant properly and properly install the car seat. All infants and toddlers should ride in a rear-facing car safety seat until they are 2 years of age or until they reach the highest weight or height allowed by the manufacturer or their car safety seat (AAP, 2015a). Placing an infant in a rear-facing restraint in the front seat of a vehicle is extremely dangerous in any vehicle with a passenger-side air bag. Nurses are responsible for providing education on the use of a car seat before discharge from the hospital.

Cribs and Sleep. Federal safety standards were changed in 2011 to prohibit the manufacture or sale of drop-side rail cribs (AAP, 2014b). New cribs sold in the United States must meet these governmental standards for safety. Unsafe cribs that do not meet the safety standards should be disassembled and thrown away (AAP, 2014b). Parents also need to inspect an older crib to make sure the slats are no more than 6 cm (2.4 inches) apart. The crib mattress should fit snugly, and crib toys or mobiles should be attached firmly with no hanging strings or straps. Instruct parents to remove mobiles as soon as the infant is able to reach them (Hockenberry and Wilson, 2015). Also consider using a portable play yard, as long as it is not a model that has been recalled.

TABLE 12-1	Gross- and Fine-Motor Development in Infancy	
Age	**Gross-Motor Skill**	**Fine-Motor Skill**
Birth to 1 month	Complete head lag persists No ability to sit upright Inborn reflexes predominant	Reflexive grasp
2 to 4 months	When prone, lifts head and chest and bears weight on forearms With support able to sit erect with good head control Can turn from side to back	Holds rattle for short periods Looks at and plays with fingers Able to bring objects from hand to mouth
4 to 6 months	Turns from abdomen to back at 5 months and then back to abdomen at 6 months Can support much of own weight when pulled to stand No head lag when pulled to sit	Grasps objects at will and can drop them to pick up another object Pulls feet to mouth to explore Can hold a baby bottle
6 to 8 months	Sits alone without support Bears full weight on feet and can hold on to furniture Can move from a sitting to kneeling position	Bangs objects together Pulls a string to obtain an object Transfers objects from hand to hand
8 to 10 months	Crawls or pulls entire body along floor using arms Pulls self to standing or sitting Creeps on hands and knees	Picks up small objects Uses pincer grasp well Shows hand preference
10 to 12 months	Stands alone Walks holding onto furniture Sits down from a standing position	Can place objects into containers Able to hold a crayon or pencil and make a mark on paper

Adapted from Hockenberry M, Wilson D: *Wong's nursing care of infants and children,* ed 10, St Louis, 2015, Mosby; Perry S et al: *Maternal child nursing care*, ed 5, St Louis, 2014, Mosby.

INFANT

During **infancy**, the period from 1 month to 1 year of age, rapid physical growth and change occur. This is the only period distinguished by such dramatic physical changes and marked development. Psychosocial developmental advances are aided by the progression from reflexive to more purposeful behavior. Interaction between infants and the environment is greater and more meaningful for the infant. During this first year of life the nurse easily observes the adaptive potential of infants because changes in growth and development occur so rapidly.

Physical Changes

Steady and proportional growth of an infant is more important than absolute growth values. Charts of normal age- and gender-related growth measurements enable a nurse to compare growth with norms for a child's age. Measurements recorded over time are the best way to monitor growth and identify problems. Size increases rapidly during the first year of life; birth weight doubles in approximately 5 months and triples by 12 months. Height increases an average of 2.5 cm (1 inch) during each of the first 6 months and about 1.2 cm ($\frac{1}{2}$ inch) each month until 12 months (Hockenberry and Wilson, 2015).

Throughout the first year an infant's vision and hearing continue to develop. Some infants as young as $3\frac{1}{2}$ months are able to link visual and auditory stimuli (Hockenberry and Wilson, 2015). Patterns of body function also stabilize, as evidenced by predictable sleep, elimination, and feeding routines. Some reflexes that are present in the newborn such as blinking, yawning, and coughing remain throughout life; whereas others such as grasping, rooting, sucking, and the Moro or startle reflex disappear after several months.

Gross-motor skills involve large muscle activities and are usually closely monitored by parents who easily report recently achieved milestones. Newborns can only momentarily hold their heads up, but by 4 months most infants have no head lag. The same rapid development is evident as infants learn to sit, stand, and then walk. Fine-motor skills involve small body movements and are more difficult to achieve than gross-motor skills. Maturation of eye-and-hand coordination occurs over the first 2 years of life as infants move from being able to grasp a rattle briefly at 2 months to drawing an arc with a pencil by 24 months. Development proceeds at a variable pace for each individual but usually follows the same pattern and occurs within the same time frame (Table 12-1).

Cognitive Changes

The complex brain development during the first year is demonstrated by an infant's changing behaviors. As he or she receives stimulation through the developing senses of vision, hearing, and touch, the developing brain interprets the stimuli. Thus an infant learns by experiencing and manipulating the environment. Developing motor skills and increasing mobility expand an infant's environment and, with developing visual and auditory skills, enhance cognitive development. For these reasons Piaget (1952) named his first stage of cognitive development, which extends until around the third birthday, the sensorimotor period (see Chapter 11). In this stage of cognitive development, infants explore their world through senses. They learn by experimentation and trial and error. They shake and throw things and put things in their mouths. By the age of 7 to 9 months, they begin to realize that things still exist that that can no longer be seen. This is known as object permanence and is an important developmental milestone because it demonstrates that their memory is beginning to develop.

Infants need opportunities to develop and use their senses. Nurses need to evaluate the appropriateness and adequacy of these opportunities. For example, ill or hospitalized infants sometimes lack the energy to interact with their environment, thereby slowing their cognitive development. Infants need to be stimulated according to their temperament, energy, and age. The nurse uses stimulation strategies that maximize the development of infants while conserving their energy and orientation. An example of this is a nurse talking to and encouraging an infant to suck on a pacifier while administering the infant's tube feeding.

FIGURE 12-4 Smiling at and talking to an infant encourage bonding. (From Murray SS, McKinney ES: *Foundations of maternal-newborn and women's health nursing,* ed 6, St Louis, 2014, Saunders.)

BOX 12-1   Warning Signs of Abuse

- Physical evidence of abuse or neglect, including previous injuries
- Conflicting stories about the accident/trauma
- Injury blamed on sibling or another party
- Injury inconsistent with the history such as a concussion and a broken arm from falling off the bed
- History inconsistent with the child's developmental age (e.g., a 6-month-old burned by turning on the hot water)
- An initial complaint not associated with the signs and symptoms present (e.g., bringing the child to the clinic for a cold when there is evidence of physical trauma)
- Inappropriate response of the child, especially an older child (e.g., not wanting to be touched, looking at caregiver before answering any questions)
- Previous reports of abuse in the family
- Frequent emergency department or clinic visits

Adapted from Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 10, St Louis, 2015, Mosby.

Language. Speech is an important aspect of cognition that develops during the first year. Infants proceed from crying, cooing, and laughing to imitating sounds, comprehending the meaning of simple commands, and repeating words with knowledge of their meaning. According to Piaget this demonstrates that an infant is demonstrating some symbolic abilities. By 1 year infants not only recognize their own names but are able to say three to five words and understand almost 100 words (Hockenberry and Wilson, 2015). As a nurse, you promote language development by encouraging parents to name objects on which their infant's attention is focused. You also assess the infant's language development to identify developmental delays or potential abnormalities.

Psychosocial Changes

Separation and Individuation. During their first year infants begin to differentiate themselves from others as separate beings capable of acting on their own. Initially infants are unaware of the boundaries of self; but, through repeated experiences with the environment, they learn where the self ends and the external world begins. As they determine their physical boundaries, they begin to respond to others (Figure 12-4).

Two- and 3-month-old infants begin to smile responsively rather than reflexively. Similarly they recognize differences in people when their sensory and cognitive capabilities improve. By 8 months most infants are able to differentiate a stranger from a familiar person and respond differently to the two. Close attachment to their primary caregivers, most often parents, usually occurs by this age. Infants seek out these people for support and comfort during times of stress. The ability to distinguish self from others allows infants to interact and socialize more within their environments. For example, by 9 months infants play simple social games such as patty-cake and peek-a-boo. More complex interactive games such as hide-and-seek involving objects are possible by age 1.

Erikson (1963) describes the psychosocial developmental crisis for an infant as trust vs. mistrust. He explains that the quality of parent-infant interactions determines development of trust or mistrust. The infant learns to trust self, others, and the world through the relationship between the parent and child and the care the child receives (Hockenberry and Wilson, 2015). During infancy a child's temperament or behavioral style becomes apparent and influences the interactions between parent and child. You can help parents understand their child's temperament and determine appropriate childrearing practices (see Chapter 11).

Assess the availability and appropriateness of experiences contributing to psychosocial development. Hospitalized infants often have difficulty establishing physical boundaries because of repeated bodily intrusions and painful sensations. Limiting these negative experiences and providing pleasurable sensations are interventions that support early psychosocial development. Extended separations from parents complicate the attachment process and increase the number of caregivers with whom the infant must interact. Ideally the parents provide the majority of care during hospitalization. When parents are not present, either at home or in the hospital, make an attempt to limit the number of different caregivers who have contact with the infant and to follow the parents' directions for care. These interventions foster the infant's continuing development of trust.

Play. Play provides opportunities for development of cognitive, social, and motor skills. Much of infant play is exploratory as infants use their senses to observe and examine their own bodies and objects of interest in their surroundings. Adults facilitate infant learning by planning activities that promote the development of milestones and providing toys that are safe for infants to explore with their mouth and manipulate with their hands such as rattles, wooden blocks, plastic stacking rings, squeezable stuffed animals, and busy boxes.

Health Risks

Injury Prevention. Injury from motor vehicle accidents, aspiration, suffocation, falls, or poisoning is a major cause of death in children 6 to 12 months old. An understanding of the major developmental accomplishments during this time period allows for injury-prevention planning. As the child achieves gains in motor development and becomes increasingly curious about the environment, constant watchfulness and supervision are critical for injury prevention.

Child Maltreatment. Child maltreatment includes intentional physical abuse or neglect, emotional abuse or neglect, and sexual abuse (Hockenberry and Wilson, 2015). More children suffer from neglect than any other type of maltreatment. Children of any age can suffer from maltreatment, but the youngest are the most vulnerable. In addition, many children suffer from more than one type of maltreatment. No one profile fits a victim of maltreatment, and the signs and symptoms vary (Box 12-1).

A combination of signs and symptoms or a pattern of injury should arouse suspicion. It is important for the health care provider to be aware of certain disease processes and cultural practices. Lack of awareness of normal variants such as Mongolian spots causes the health care provider to assume that there is abuse. Children who are hospitalized for maltreatment have the same developmental needs as other children their age, and the nurse needs to support the child's relationship with the parents (Hockenberry and Wilson, 2015).

Health Promotion

Nutrition.   The quality and quantity of nutrition profoundly influence an infant's growth and development. Many women have already selected a feeding method well before an infant's birth; others will have questions for the nurse later in the pregnancy. Nurses are in a unique position to help parents select and provide a nutritionally adequate diet for their infant. Understand that factors such as support, culture, role demands, and previous experiences influence feeding methods (Hockenberry and Wilson, 2015).

Breastfeeding is recommended for infant nutrition because breast milk contains the essential nutrients of protein, fats, carbohydrates, and immunoglobulins that bolster the ability to resist infection. Both the AAP and the U.S. Department of Health and Human Services (USDHHS) recommend human milk for the first year of life (Hockenberry and Wilson, 2015). However, if breastfeeding is not possible or if the parent does not desire it, an acceptable alternative is iron-fortified commercially prepared formula. Recent advances in the preparation of infant formula include the addition of nucleotides and long-chain fatty acids, which augment immune function and increase brain development. The use of whole cow's milk, 2% cow's milk, or alternate milk products before the age of 12 months is not recommended. The composition of whole cow's milk can cause intestinal bleeding, anemia, and increased incidence of allergies (Hockenberry and Wilson, 2015).

The average 1-month-old infant takes approximately 18 to 21 ounces of breast milk or formula per day. This amount increases slightly during the first 6 months and decreases after introducing solid foods. The amount of formula per feeding and the number of feedings vary among infants. The addition of solid foods is not recommended before the age of 6 months because the gastrointestinal tract is not sufficiently mature to handle these complex nutrients and infants are exposed to food antigens that produce food protein allergies. Developmentally infants are not ready for solid food before 6 months. The extrusion (protrusion) reflex causes food to be pushed out of the mouth. The introduction of cereals, fruits, vegetables, and meats during the second 6 months of life provides iron and additional sources of vitamins. This becomes especially important when children change from breast milk or formula to whole cow's milk after the first birthday. Solid foods should be offered one new food at a time. This allows for identification if a food causes an allergic reaction. The use of fruit juices and nonnutritive drinks such as fruit-flavored drinks or soda should be avoided since these do not provide sufficient and appropriate calories during this period (Hockenberry and Wilson, 2015). Infants also tolerate well-cooked table foods by 1 year. The amount and frequency of feedings vary among infants; thus be sure to discuss differing feeding patterns with parents.

Supplementation.   The need for dietary vitamin and mineral supplements depends on an infant's diet. Full-term infants are born with some iron stores. The breastfed infant absorbs adequate iron from breast milk during the first 4 to 6 months of life. After 6 months iron-fortified cereal is generally an adequate supplemental source. Because iron in formula is less readily absorbed than that in breast milk, formula-fed infants need to receive iron-fortified formula throughout the first year.

Adequate concentrations of fluoride to protect against dental caries are not available in human milk; therefore fluoridated water or supplemental fluoride is generally recommended. A recent concern is the use of complementary and alternative medical therapies in children that may or may not be safe. Inquire about the use of such products to help the parent determine whether or not the product is truly safe for the child (Hockenberry and Wilson, 2015).

Immunizations.   The widespread use of immunizations has resulted in the dramatic decline of infectious diseases over the past 50 years and therefore is a most important factor in health promotion during childhood. Although most immunizations can be given to people of any age, it is recommended that the administration of the primary series begin soon after birth and be completed during early childhood. Vaccines are among the safest and most reliable drugs used. Minor side effects sometimes occur; however, serious reactions are rare. Parents need instructions regarding the importance of immunizations and common side effects such as low-grade fever and local tenderness. The recommended schedule for immunizations changes as new vaccines are developed and advances are made in the field of immunology. Stay informed of the current policies and direct parents to the primary caregiver for their child's schedule. The AAP maintains the most current schedule on their Internet website, http://www.aap.org. Research over the past three decades has clearly indicated that infants experience pain with invasive procedures (e.g., injections) and that nurses need to be aware of measures to reduce or eliminate pain with any health care procedure (see Chapter 32).

Sleep.   Sleep patterns vary among infants, with many having their days and nights reversed until 3 to 4 months of age. Thus it is common for infants to sleep during the day. By 6 months most infants are nocturnal and sleep between 9 and 11 hours at night. Total daily sleep averages 15 hours. Most infants take one or two naps a day by the end of the first year. Many parents have concerns regarding their infant's sleep patterns, especially if there is difficulty such as sleep refusal or frequent waking during the night. Carefully assess the individual problem before suggesting interventions to address their concern.

TODDLER

Toddlerhood ranges from the time children begin to walk independently until they walk and run with ease, which is from 12 to 36 months. The toddler has increasing independence bolstered by greater physical mobility and cognitive abilities. Toddlers are increasingly aware of their abilities to control and are pleased with successful efforts with this new skill. This success leads them to repeated attempts to control their environments. Unsuccessful attempts at control result in negative behavior and temper tantrums. These behaviors are most common when parents stop the initial independent action. Parents cite these as the most problematic behaviors during the toddler years and at times express frustration with trying to set consistent and firm limits while simultaneously encouraging independence. Nurses and parents

can deal with the negativism by limiting the opportunities for a "no" answer. For example, do not ask the toddler, "Do you want to take your medicine now?" Instead, tell the child that it is time to take medicine and offer a choice of water or juice to drink with it.

Physical Changes

The average toddler grows 7.5 cm (3 inches) in height and gains approximately 4 to 6 lbs (1.8 to 2.7 kg) each year (Hockenberry and Wilson, 2015). The rapid development of motor skills allows the child to participate in self-care activities such as feeding, dressing, and toileting. In the beginning the toddler walks in an upright position with a broad stance and gait, protuberant abdomen, and arms out to the sides for balance. Soon the child begins to navigate stairs, using a rail or the wall to maintain balance while progressing upward, placing both feet on the same step before continuing. Success provides courage to attempt the upright mode for descending the stairs in the same manner. Locomotion skills soon include running, jumping, standing on one foot for several seconds, and kicking a ball. Most toddlers ride tricycles, climb ladders, and run well by their third birthday.

Fine-motor capabilities move from scribbling spontaneously to drawing circles and crosses accurately. By 3 years the child draws simple stick people and is usually able to stack a tower of small blocks. Children now hold crayons with their fingers rather than with their fists and can imitate vertical and horizontal strokes. They are able to manage feeding themselves with a spoon without rotating it and can drink well from a cup without spilling. Toddlers can turn pages of a book one at a time and can easily turn doorknobs (Hockenberry and Wilson, 2015).

Cognitive Changes

Toddlers increase their ability to remember events and begin to put thoughts into words at about 2 years of age. They recognize that they are separate beings from their mothers, but they are unable to assume the view of another. A toddler's reasoning is based on their own experience of an event. They use symbols to represent objects, places, and people. Children demonstrate this function as they imitate the behavior of another that they viewed earlier (e.g., pretend to shave like daddy), pretend that one object is another (e.g., use a finger as a gun), and use language to stand for absent objects (e.g., request bottle).

Language. The 18-month-old child uses approximately 10 words. The 24-month-old child has a vocabulary of up to 300 words and is generally able to speak in two-word sentences, although the ability to understand speech is much greater than the number of words acquired (Hockenberry and Wilson, 2015). According to Piaget, the preoperational stage of development begins in toddlerhood. Children begin thinking about things more symbolically as their vocabulary develops (Piaget, 1952). "Who's that?" and "What's that?" are typical questions children ask during this period. Verbal expressions such as "me do it" and "that's mine" demonstrate the 2-year-old child's use of pronouns and desire for independence and control. By 36 months the child can use simple sentences, follow some grammatical rules, and learn to use five or six new words each day. Parents can facilitate language development best by talking to their children. Reading to children helps expand their vocabulary, knowledge, and imagination. Television should not be used to replace parent-child interaction, as it has been shown to delay language development (Hockenberry and Wilson, 2015).

Psychosocial Changes

According to Erikson (1963) a sense of autonomy emerges during toddlerhood. Children strive for independence by using their developing

FIGURE 12-5 Safety precautions should be provided for toddlers. (Courtesy Elaine Polan, RNC, BSN, MS.)

muscles to do everything for themselves and become the master of their bodily functions. Their strong wills are frequently exhibited in negative behavior when caregivers attempt to direct their actions. Temper tantrums result when parental restrictions frustrate toddlers. Parents need to provide toddlers with graded independence, allowing them to do things that do not result in harm to themselves or others. For example, young toddlers who want to learn to hold their own cups often benefit from two-handled cups with spouts and plastic bibs with pockets to collect the milk that spills during the learning process.

Play. During the preoperational stage of development the child's imagination develops, and children begin to discern the difference between past and future, although they still do not grasp more complex concepts such as cause and effect (Piaget, 1952). Socially toddlers remain strongly attached to their parents and fear separation from them. In their presence they feel safe, and their curiosity is evident in their exploration of the environment. The child continues to engage in solitary play during toddlerhood but also begins to participate in parallel play, which is playing *beside* rather than *with* another child. Play expands the child's cognitive and psychosocial development. It is always important to consider if toys support development of the child, along with the safety of the toy.

Health Risks

The newly developed locomotion abilities and insatiable curiosity of toddlers make them at risk for injury. Toddlers need close supervision at all times and particularly when in environments that are not child-proofed (Figure 12-5).

Poisonings occur frequently because children near 2 years of age are interested in placing any object or substance in their mouths to learn about it. The prudent parent removes or locks up all possible poisons, including plants, cleaning materials, and medications. These parental actions create a safer environment for exploratory behavior. Lead poisoning continues to be a serious health hazard in the United States, and children under the age of 6 years are most vulnerable (Hockenberry and Wilson, 2015).

Toddlers' lack of awareness regarding the danger of water and their newly developed walking skills make drowning a major cause of accidental death in this age-group. Limit setting is extremely important for toddlers' safety. Motor vehicle accidents account for half of all accidental deaths in children between the ages of 1 and 4 years. Some of these deaths are the result of unrestrained children, and some are attributed to injuries within the car resulting from not using car seat safety guidelines (Hockenberry and Wilson, 2015). Injury prevention is best accomplished by associating various injuries with the attainment of developmental milestones.

Toddlers who become ill and require hospitalization are most stressed by the separation from their parents. Nurses encourage parents to stay with their child as much as possible and actively participate in providing care. Creating an environment that supports parents helps greatly in gaining the cooperation of the toddler. Establishing a trusting relationship with the parents often results in toddler acceptance of treatment.

Health Promotion

Nutrition. Childhood obesity and the associated chronic diseases that result are sources of concern for all health care providers. Children establish lifetime eating habits in early childhood, and there is increased emphasis on food choices. They increasingly meet nutritional needs by eating solid foods. The healthy toddler requires a balanced daily intake of bread and grains, vegetables, fruit, dairy products, and proteins. Because the consumption of more than a quart of milk per day usually decreases a child's appetite for these essential solid foods and results in inadequate iron intake, advise parents to limit milk intake to 2 to 3 cups per day (Hockenberry and Wilson, 2015). Children should not be offered low-fat or skim milk until age 2 because they need the fat for satisfactory physical and intellectual growth.

Mealtime has psychosocial and physical significance. If the parents struggle to control toddlers' dietary intake, problem behavior and conflicts can result. Toddlers often develop "food jags," or the desire to eat one food repeatedly. Rather than becoming disturbed by this behavior, encourage parents to offer a variety of nutritious foods at meals and to provide only nutritious snacks between meals. Serving finger foods to toddlers allows them to eat by themselves and to satisfy their need for independence and control. Small, reasonable servings allow toddlers to eat all of their meals.

Toilet Training. Increased locomotion skills, the ability to undress, and development of sphincter control allow toilet training if a toddler has developed the necessary language and cognitive abilities. Parents often consult nurses for an assessment of readiness for toilet training. Recognizing the urge to urinate and or defecate is crucial in determining a child's mental readiness. The toddler must also be motivated to hold on to please the parent rather than letting go to please the self to successfully accomplish toilet training (Hockenberry and Wilson, 2015). As a nurse, remind parents that patience, consistency, and a nonjudgmental attitude, in addition to the child's readiness, are essential to successful toilet training.

PRESCHOOLERS

The **preschool period** refers to the years between ages 3 and 5. Children refine the mastery of their bodies and eagerly await the beginning of formal education. Many people consider these the most intriguing years of parenting because children are less negative, more accurately share their thoughts, and more effectively interact and communicate. Physical development occurs at a slower pace than cognitive and psychosocial development.

Physical Changes

Several aspects of physical development continue to stabilize in the preschool years. Children gain about 5 lbs (2.3 kg) per year; the average weight at 3 years is 32 lbs (14.5 kg); at 4 years, 37 lbs (16.8 kg); and at 5 years about 41 lbs (18.6 kg). Preschoolers grow 6.2 to 7.5 cm ($2\frac{1}{2}$ to 3 inches) per year, double their birth length around 4 years, and stand an average of 107 cm (43 inches) tall by their fifth birthday. The elongation of the legs results in more slender-appearing children. Little difference exists between the sexes, although boys are slightly larger with more muscle and less fatty tissue. Most children are completely toilet trained by the preschool years (Hockenberry and Wilson, 2015).

Large- and fine-muscle coordination improves. Preschoolers run well, walk up and down steps with ease, and learn to hop. By 5 years they usually skip on alternate feet, jump rope, and begin to skate and swim. Improving fine-motor skills allows intricate manipulations. They learn to copy crosses and squares. Triangles and diamonds are usually mastered between ages 5 and 6. Scribbling and drawing help to develop fine-muscle skills and the eye-hand coordination needed for the printing of letters and numbers.

Children need opportunities to learn and practice new physical skills. Nursing care of healthy and ill children includes an assessment of the availability of these opportunities. Although children with acute illnesses benefit from rest and exclusion from usual daily activities, children who have chronic conditions or who have been hospitalized for long periods need ongoing exposure to developmental opportunities. The parents and nurse weave these opportunities into the children's daily experiences, depending on their abilities, needs, and energy level.

Cognitive Changes

Maturation of the brain continues, with the most rapid growth occurring in the frontal lobe areas, where planning and organizing new activities and maintaining attention to tasks are paramount. Complete myelinization of the brain neurons does not occur until age 6 or 7 (Leifer, 2013).

Preschoolers demonstrate their ability to think more complexly by classifying objects according to size or color and by questioning. Children have increased social interaction, as is illustrated by the 5-year-old child who offers a bandage to a child with a cut finger. Children become aware of cause-and-effect relationships, as illustrated by the statement, "The sun sets because people want to go to bed." Early causal thinking is also evident in preschoolers. For example, if two events are related in time or space, children link them in a causal fashion. For example, the hospitalized child reasons, "I cried last night, and that's why the nurse gave me the shot." As children near age 5, they begin to use or learn to use rules to understand causation. They then begin to reason from the general to the particular. This forms the basis for more formal logical thought. The child now reasons, "I get a shot twice a day, and that's why I got one last night." Children in this stage also believe that inanimate objects have lifelike qualities and are capable of action, as seen through comments such as, "Trees cry when their branches get broken."

Preschoolers' knowledge of the world remains closely linked to concrete (perceived by the senses) experiences. Even their rich fantasy life is grounded in their perception of reality. The mixing of the two aspects often leads to many childhood fears, and adults sometimes misinterpret it as lying when children are actually presenting reality from their perspective. Preschoolers believe that, if a rule is broken, punishment results immediately. During these years they believe that a punishment is automatically connected to an act and do not yet realize that it is socially mediated (Perry et al., 2014).

The greatest fear of this age-group appears to be that of bodily harm; this is evident in children's fear of the dark, animals, thunderstorms, and medical personnel. This fear often interferes with their willingness to allow nursing interventions such as measurement of vital signs. Preschoolers cooperate if they are allowed to help the nurse measure the blood pressure of a parent or to manipulate the nurse's equipment.

Language. Preschoolers' vocabularies continue to increase rapidly; by the age of 6 children have 8000 to 14,000 words that they use to define familiar objects, identify colors, and express their desires and frustrations (Perry et al., 2014). Language is more social, and questions expand to "Why?" and "How come?" in the quest for information. Phonetically similar words such as *die* and *dye* or *wood* and *would* cause confusion in preschool children. Avoid such words when preparing them for procedures and assess comprehension of explanations.

Psychosocial Changes

The world of preschoolers expands beyond the family into the neighborhood where children meet other children and adults. Their curiosity and developing initiative lead to actively exploring the environment, developing new skills, and making new friends. Preschoolers have a surplus of energy that permits them to plan and attempt many activities that are beyond their capabilities such as pouring milk from a gallon container into their cereal bowls. Guilt arises within children when they overstep the limits of their abilities and think that they have not behaved correctly. Children who in anger wished that their sibling were dead experience guilt if that sibling becomes ill. Children need to learn that "wishing" for something to happen does not make it occur. Erikson (1963) recommends that parents help their children strike a healthy balance between initiative and guilt by allowing them to do things on their own while setting firm limits and providing guidance.

Sources of stress for preschoolers can include changes in caregiving arrangements, starting school, the birth of a sibling, parental marital distress, relocation to a new home, or an illness. During these times of stress preschoolers sometimes revert to bed-wetting or thumb sucking and want the parents to feed, dress, and hold them. These dependent behaviors are often confusing and embarrassing to parents. They benefit from the nurse's reassurance that they are the child's normal coping behaviors. Provide experiences that these children are able to master. Such successes help them return to their prior level of independent functioning. As language skills develop, encourage children to talk about their feelings. Play is also an excellent way for preschoolers to vent frustration or anger and is a socially acceptable way to deal with stress.

Play. The play of preschool children becomes more social after the third birthday as it shifts from parallel to associative play. Children playing together engage in similar if not identical activity; however, there is no division of labor or rigid organization or rules. Most 3-year-old children are able to play with one other child in a cooperative manner in which they make something or play designated roles such as mother and baby. By age 4 children play in groups of two or three, and by 5 years the group has a temporary leader for each activity.

During the preoperational stage of growth and development the child begins to engage in "make-believe" play (Piaget, 1952). Pretend play allows children to learn to understand others' points of view, develop skills in solving social problems, and become more creative. Some children have imaginary playmates. These playmates serve many purposes. They are friends when the child is lonely, they accomplish what the child is still attempting, and they experience what the child wants to forget or remember. Imaginary playmates are a sign of health and allow the child to distinguish between reality and fantasy.

Television (TV), videos, electronic games, and computer programs also help support development and the learning of basic skills. However, these should be only one part of the child's total play activities. The AAP (2014a) advises no more than 1 to 2 hours per day of educational, nonviolent TV programs, which should be supervised by parents or other responsible adults in the home. Limiting TV viewing will provide more time for children to read, engage in physical activity, and socialize with others (Hockenberry and Wilson, 2015).

Health Risks

As fine- and gross-motor skills develop and a child becomes more coordinated with better balance, falls become much less of a problem. Guidelines for injury prevention in the toddler also apply to the preschooler. Children need to learn about safety in the home, and parents need to continue close supervision of activities. Children at this age are great imitators; thus parental example is important. For instance, parental use of a helmet while bicycling sets an appropriate example for the preschooler.

Health Promotion

Little research has explored preschoolers' perceptions of their own health. Parental beliefs about health, children's bodily sensations, and their ability to perform usual daily activities help children develop attitudes about their health. Preschoolers are usually quite independent in washing, dressing, and feeding. Alterations in this independence influence their feelings about their own health.

Nutrition. Nutrition requirements for the preschooler vary little from those of the toddler. The average daily intake is 1800 calories. Parents often worry about the amount of food their child is consuming, and this is a relevant concern because of the problem of childhood obesity. However, the quality of the food is more important than quantity in most situations. Preschoolers consume about half of average adult portion sizes. Finicky eating habits are characteristic of the 4-year-old; however, the 5-year-old is more interested in trying new foods (CDC, 2014).

Sleep. Preschoolers average 12 hours of sleep a night and take infrequent naps. Sleep disturbances are common during these years. Disturbances range from trouble getting to sleep to nightmares to prolonging bedtime with extensive rituals. Frequently children have had an overabundance of activity and stimulation. Helping them slow down before bedtime usually results in better sleeping habits.

Vision. Vision screening usually begins in the preschool years and needs to occur at regular intervals. One of the most important tests is to determine the presence of nonbinocular vision or strabismus. Early detection and treatment of strabismus are essential by ages 4 to 6 to prevent amblyopia, the resulting blindness from disuse (Hockenberry and Wilson, 2015).

SCHOOL-AGE CHILDREN AND ADOLESCENTS

The developmental changes between ages 6 and 18 are diverse and span all areas of growth and development. Children develop, expand, refine, and synchronize physical, psychosocial, cognitive, and moral skills so the individual is able to become an accepted and productive member of society. The environment in which the individual develops skills also expands and diversifies. Instead of the boundaries of family and close

friends, the environment now includes the school, community, and church. With age-specific assessment, you need to review the appropriate developmental expectations for each age-group. You can promote health by helping children and adolescents achieve a necessary developmental balance.

SCHOOL-AGE CHILDREN

During these "middle years" of childhood, the foundation for adult roles in work, recreation, and social interaction is laid. In industrialized countries this **school-age** period begins when the child starts elementary school around the age of 6 years. Puberty, around 12 years of age, signals the end of middle childhood. Children make great developmental strides during these years as they develop competencies in physical, cognitive, and psychosocial skills.

The school or educational experience expands the child's world and is a transition from a life of relatively free play to one of structured play, learning, and work. The school and home influence growth and development, requiring adjustment by the parents and child. The child learns to cope with rules and expectations presented by the school and peers. Parents have to learn to allow their child to make decisions, accept responsibility, and learn from the experiences of life.

Physical Changes

The rate of growth during these early school years is slow and consistent, a relative calm before the growth spurt of adolescence. The school-age child appears slimmer than the preschooler as a result of changes in fat distribution and thickness. The average increase in height is 5 cm (2 inches) per year, and weight increases by 4 to 7 lbs (1.8 to 3.2 kg) per year. Many children double their weight during these middle childhood years, and most girls exceed boys in both height and weight by the end of the school years (Hockenberry and Wilson, 2015).

School-age children become more graceful during the school years because their large-muscle coordination improves and their strength doubles. Most children practice the basic gross-motor skills of running, jumping, balancing, throwing, and catching during play, resulting in refinement of neuromuscular function and skills. Individual differences in the rate of mastering skills and ultimate skill achievement become apparent during their participation in many activities and games. Fine-motor skills improve; and, as children gain control over fingers and wrists, they become proficient in a wide range of activities.

Most 6-year-old children are able to hold a pencil adeptly and print letters and words; by age 12 a child is able to make detailed drawings and write sentences in script. Painting, drawing, playing computer games, and modeling allow children to practice and improve newly refined skills. The improved fine-motor capabilities of youngsters in middle childhood allow them to become very independent in bathing, dressing, and taking care of other personal needs. They develop strong personal preferences in the way these needs are met. Illness and hospitalization threaten children's control in these areas. Therefore it is important to allow them to participate in care and maintain as much independence as possible. Children whose care demands restriction of fluids cannot be allowed to decide the amount of fluids they will drink in 24 hours. However, they can help decide the type of fluids and help keep a record of their intake.

Assessment of neurological development is often based on fine-motor coordination. Fine-motor coordination is critical to success in the typical American school, where children have to hold pencils and crayons and use scissors and rulers. The opportunity to practice these skills through schoolwork and play is essential to learning coordinated, complex behaviors.

As skeletal growth progresses, a child's body appearance and posture change. Earlier the child's posture was stoop shouldered, with slight lordosis and a prominent abdomen. The posture of a school-age child is more erect. It is essential to evaluate children, especially girls after the age of 12 years, for scoliosis, the lateral curvature of the spine.

Eye shape alters because of skeletal growth. This improves visual acuity, and normal adult 20/20 vision is achievable. Screening for vision and hearing problems is easier, and results are more reliable because school-age children more fully understand and cooperate with the test directions. The school nurse typically assesses the growth, visual, and auditory status of school-age children and refers those with possible deviations to a health care provider such as their family practitioner or pediatrician.

Cognitive Changes

According to Piaget, children begin transitioning into the concrete-operational stage of growth and development around the age of 7 when they begin to demonstrate logical, more concrete thinking. They become less egocentric and begin to understand that their thoughts and feelings may not be shared by others (Piaget, 1952). Cognitive changes provide the school-age child with the ability to think in a logical manner about the here and now and to understand the relationship between things and ideas. They are now able to use their developed thinking abilities to experience events without having to act them out (Hockenberry and Wilson, 2015). Their thoughts are no longer dominated by their perceptions; thus their ability to understand the world greatly expands.

School-age children have the ability to concentrate on more than one aspect of a situation. They begin to understand that others do not always see things as they do and even begin to understand another viewpoint. They now have the ability to recognize that the amount or quantity of a substance remains the same even when its shape or appearance changes. For instance, two balls of clay of equal size remain the same amount of clay even when one is flattened and the other remains in the shape of a ball.

The young child is able to separate objects into groups according to shape or color, whereas the school-age child understands that the same element can exist in two classes at the same time. By 7 or 8 years these children develop the ability to place objects in order according to their increasing or decreasing size (Hockenberry and Wilson, 2015). School-age children frequently have collections such as baseball cards or stuffed animals that demonstrate this new cognitive skill.

Language Development. Language growth is so rapid during middle childhood that it is no longer possible to match age with language achievements. Children improve their use of language and expand their structural knowledge. They become more aware of the rules of syntax, the rules for linking words into phrases and sentences. They also identify generalizations and exceptions to rules. They accept language as a means for representing the world in a subjective manner and realize that words have arbitrary rather than absolute meanings. Children begin to think about language, which enables them to appreciate jokes and riddles. They are not as likely to use a literal interpretation of a word; rather they reason about its meaning within a context (Hockenberry and Wilson, 2015).

Psychosocial Changes

Erikson (1963) identifies the developmental task for school-age children as industry vs. inferiority. During this time children strive to acquire competence and skills necessary for them to function as adults. School-age children who are positively recognized for success feel a sense of worth. Those faced with failure often feel a sense of mediocrity

FIGURE 12-6 School-age children gain a sense of achievement working and playing with peers. (From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 10, St Louis, 2015, Mosby.)

or unworthiness, which sometimes results in withdrawal from school and peers.

School-age children begin to define themselves on the basis of internal more than external characteristics. They begin to define their self-concept and develop self-esteem, an overall self-evaluation. Interaction with peers allows them to define their own accomplishments in relation to others as they work to develop a positive self-image (Perry et al., 2014).

According to Piaget, school-age children around the age of 11 may begin to enter the fourth and final stage of intellectual development, formal operations. In this stage they begin to ponder abstract relationships. They can formulate hypotheses and consider different possibilities. Piaget believed that this was the final stage of cognitive development and that the continued intellectual development in teenagers and adults depended on the accumulation of knowledge (Piaget, 1952).

Peer Relationships. Group and personal achievements become important to the school-age child. Success is important in physical and cognitive activities. Play involves peers and the pursuit of group goals. Although solitary activities are not eliminated, group play overshadows them. Learning to contribute, collaborate, and work cooperatively toward a common goal becomes a measure of success (Figure 12-6).

The school-age child prefers same-sex to opposite-sex peers. In general, girls and boys view the opposite sex negatively. Peer influence becomes quite diverse during this stage of development. Clubs and peer groups become prominent. School-age children often develop "best friends" with whom they share secrets and with whom they look forward to interacting on a daily basis. Group identity increases as the school-age child approaches adolescence.

Sexual Identity. Freud described middle childhood as the latency period because he believed that children of this period had little interest in their sexuality. Today many researchers believe that school-age children have a great deal of curiosity about their sexuality. Some experiment, but this play is usually transitory. Children's curiosity about adult magazines or meanings of sexually explicit words is also an example of their sexual interest. This is the time for them to have exposure to sex education, including sexual maturation, reproduction, and relationships (Hockenberry and Wilson, 2015).

Stress. Today's children experience more stress than children in earlier generations. Stress comes from parental expectations; peer expectations; the school environment; and violence in the family, school, or community. Some school-age children care for themselves before or after school without adult supervision. Latchkey children sometimes feel increased stress and are at greater risk for injury and unsafe behaviors (Hockenberry and Wilson, 2015). A nurse helps the child cope with stress by helping the parents and child identify potential stressors and designing interventions to minimize stress and the child's stress response. Deep-breathing techniques, positive imagery, and progressive relaxation of muscle groups are interventions that most children can learn (see Chapter 38). Include the parent, child, and teacher in the intervention for maximal success.

Health Risks

Accidents and injuries are a major health problem affecting school-age children. They now have more exposure to various environments and less supervision, but their developed cognitive and motor skills make them less likely to suffer from unintentional injury. Some school-age children are risk takers and attempt activities that are beyond their abilities. Motor vehicle injuries as a passenger or pedestrian and bicycle injuries are among the most common in this age-group.

Infections account for the majority of all childhood illnesses; respiratory infections are the most prevalent. The common cold remains the chief illness of childhood. Certain groups of children are more prone to disease and disability, often as a result of barriers to health care. Poverty and the prevalence of illness are highly correlated. Access to care is often very limited, and health promotion and preventive health measures are minimal.

Health Promotion

Perceptions. During the school-age years identity and self-concept become stronger and more individualized. Perception of wellness is based on readily observable facts such as presence or absence of illness and adequacy of eating or sleeping. Functional ability is the standard by which personal health and the health of others are judged. Six-year-olds are aware of their body and modest and sensitive about being exposed. Nurses need to provide for privacy and offer explanations of common procedures.

Health Education. The school-age period is crucial for the acquisition of behaviors and health practices for a healthy adult life. Because cognition is advancing during the period, effective health education must be developmentally appropriate. Promotion of good health practices is a nursing responsibility. Programs directed at health education are frequently organized and conducted in the school. Effective health education teaches children about their bodies and how the choices they make impact their health (Hockenberry and Wilson, 2015). During these programs focus on the development of behaviors that positively affect children's health status.

Health Maintenance. Parents need to recognize the importance of annual health maintenance visits for immunizations, screenings, and dental care. When their school-age child reaches 10 years of age, parents need to begin discussions in preparation for upcoming pubertal changes. Topics include introductory information regarding menstruation, sexual intercourse, reproduction, and **sexually transmitted infections (STIs)**. Human papilloma virus (HPV) is a widespread virus that will infect over 50% of males and females in their lifetime (AAP, 2015b). For many individuals HPV clears spontaneously, but for others it can cause significant consequences. Females can develop cervical, vaginal, and vulvar cancers and genital warts; and males can develop genital warts. Since it is not possible to determine who will or will not develop disease from the virus, the Centers for Disease Control and

Prevention (CDC, 2013b), along with the AAP, recommends routine HPV vaccination for girls ages 11 to 12 and for young women ages 13 through 26 who have not already been vaccinated. It is further recommended that HPV vaccine be given to boys and young men ages 9 to 26 years.

Safety.   Because accidents such as fires and car and bicycle crashes are the leading cause of death and injury in the school-age period, safety is a priority health teaching consideration. Educate children about safety measures to prevent accidents. At this age encourage children to take responsibility for their own safety, such as wearing helmets during bike riding.

Nutrition.   Growth often slows during the school-age period as compared to infancy and adolescence. School-age children are developing eating patterns that are independent of parental supervision. The availability of snacks and fast-food restaurants makes it increasingly difficult for children to make healthy choices. The prevalence of obesity among children 6 to 11 years of age increased from 6.5% in 1980 to 18% in 2012. In addition, the incidence of adolescents ages 12 to 19 years who were obese increased from 5% to almost 21% during the same period of time (CDC, 2014). Childhood obesity has become a prominent health problem, resulting in increased risk for hypertension, diabetes, coronary heart disease, fatty liver disease, pulmonary complications such as sleep apnea, musculoskeletal problems, dyslipidemia, and potential for psychological problems. Studies have found that overweight children are teased more often, less likely to be chosen as a friend, and more likely to be thought of as lazy and sloppy by their peers (Hockenberry and Wilson, 2015). Nurses contribute to meeting national policy goals by promoting healthy lifestyle habits, including nutrition. School-age children need to participate in educational programs that enable them to plan, select, and prepare healthy meals and snacks. Children need adequate caloric intake for growth throughout childhood accompanied by activity for continued gross-motor development.

ADOLESCENTS

Adolescence is the period during which the individual makes the transition from childhood to adulthood, usually between ages 13 and 20 years. The term *adolescent* usually refers to psychological maturation of the individual, whereas **puberty** refers to the point at which reproduction becomes possible. The hormonal changes of puberty result in changes in the appearance of the young person, and cognitive development results in the ability to hypothesize and deal with abstractions. Adjustments and adaptations are necessary to cope with these simultaneous changes and the attempt to establish a mature sense of identity. In the past many referred to adolescence as a stormy and stressful period filled with inner turmoil, but today it is recognized that most teenagers successfully meet the challenges of this period.

Your understanding of development provides a unique perspective for helping teenagers and parents anticipate and cope with the stresses of adolescence. Nursing activities, particularly education, promote healthy development. These activities occur in a variety of settings; and you can direct them at the adolescent, parents, or both. For example, a nurse conducts seminars in a high school to provide practical suggestions for solving problems of concern to a large group of students such as treating acne or making responsible decisions about drugs or alcohol use. Similarly a group education program for parents about how to cope with teenagers would promote parental understanding of adolescent development.

Physical Changes

Physical changes occur rapidly in adolescence. Sexual maturation occurs with the development of primary and secondary sexual characteristics. The four main physical changes are:
1. Increased growth rate of skeleton, muscle, and viscera.
2. Sex-specific changes such as changes in shoulder and hip width.
3. Alteration in distribution of muscle and fat.
4. Development of the reproductive system and secondary sex characteristics.

Wide variation exists in the timing of physical changes associated with puberty between sexes and within the same sex.

Girls generally have prepubescent changes 1 to 2 years before boys do. There is also evidence that African-American girls develop at a younger age than Caucasian girls. Although not clear, this phenomenon is believed to be influenced by being overweight and environmental factors (Perry et al., 2014). The rates of height and weight gain are usually proportional, and the sequence of pubertal growth changes is the same in most individuals.

Hormonal changes within the body create change when the hypothalamus begins to produce gonadotropin-releasing hormones that stimulate ovarian cells to produce estrogen and testicular cells to produce testosterone. These hormones contribute to the development of secondary sex characteristics such as hair growth and voice changes and play an essential role in reproduction. The changing concentrations of these hormones are also linked to acne and body odor. Understanding these hormonal changes enables you to reassure adolescents and educate them about body care needs.

Being like peers is extremely important for adolescents (Figure 12-7). Any deviation in the timing of their physical changes is extremely difficult for them to accept. Therefore provide emotional support for those undergoing early or delayed puberty. Even adolescents whose physical changes are occurring at the normal times seek confirmation of and reassurance about their normalcy.

Height and weight increases usually occur during the prepubertal growth spurt, which peaks in girls at about 12 years and boys at about 14 years. Girls' height increases 5 to 20 cm (2 to 8 inches), and weight increases by 15 to 55 lbs (6.8 to 25 kg). Boys' height increases approximately 10 to 30 cm (4 to 12 inches), and weight increases by 15 to 65 lbs (6.8 to 29.5 kg). Individuals gain the final 20% to 25% of their height and 50% of their weight during this time period (Hockenberry and Wilson, 2015).

FIGURE 12-7 Peer interactions help increase self-esteem during puberty. (©Petrenko Andriy.)

Girls attain 90% to 95% of their adult height by menarche (the onset of menstruation) and reach their full height by 16 to 17 years of age, whereas boys continue to grow taller until 18 to 20 years of age. Fat is redistributed into adult proportions as height and weight increase, and gradually the adolescent torso takes on an adult appearance. Although individual and sex differences exist, growth follows a similar pattern for both sexes. Personal growth curves help the nurse assess physical development. However, the individual's sustained progression along the curve is more important than a comparison to the norm.

Cognitive Changes

The adolescent develops the ability to determine and rank possibilities, solve problems, and make decisions through logical operations. The teenager thinks abstractly and deals effectively with hypothetical problems. When confronted with a problem, the adolescent considers an infinite variety of causes and solutions. For the first time the young person moves beyond the physical or concrete properties of a situation and uses reasoning powers to understand the abstract. School-age individuals think about what is, whereas adolescents are able to imagine what might be.

Adolescents are now able to think in terms of the future rather than just current events. These newly developed abilities allow an individual to have more insight and skill in playing video, computer, and board games that require abstract thinking and deductive reasoning about many possible strategies. A teenager even solves problems requiring simultaneous manipulation of several abstract concepts. Development of this ability is important in the pursuit of an identity. For example, newly acquired cognitive skills allow the teenager to define appropriate, effective, and comfortable sex-role behaviors and to consider their impact on peers, family, and society. A higher level of cognitive functioning makes the adolescent receptive to more detailed and diverse information about sexuality and sexual behaviors. For example, sex education includes an explanation of physiological sexual changes and birth control measures.

Adolescents also develop the ability to understand how an individual's ideas or actions influence others. This complex development of thought leads them to question society and its values. Although adolescents have the capability to think as well as an adult, they do not have experiences on which to build. It is common for teenagers to consider their parents too narrow minded or materialistic. At this time adolescents believe that they are unique and the exception, giving rise to their risk-taking behaviors. In other words, they think that they are invincible. For example, an adolescent might state that he or she "is able to drive fast and not have an accident."

Language Skills. Language development is fairly complete by adolescence, although vocabulary continues to expand. The primary focus becomes communication skills that an adolescent uses effectively in various situations. Adolescents need to communicate thoughts, feelings, and facts to peers, parents, teachers, and other people of authority. The skills used in these diverse communication situations vary. Adolescents need to select the people with whom to communicate, decide on the exact message, and choose the way to transmit it. For example, how teenagers tell parents about failing grades is not the same as how they tell friends. Good communication skills are critical for adolescents in overcoming peer pressure and unhealthy behaviors. The following are some hints for communicating with adolescents:

- Do not avoid discussing sensitive issues. Asking questions about sex, drugs, and school opens the channels for further discussion.
- Ask open-ended questions (see Chapter 24).
- Look for the meaning behind their words or actions.
- Be alert to clues to their emotional state.
- Involve other individuals and resources when necessary.

Psychosocial Changes

The search for personal identity is the major task of adolescent psychosocial development. Teenagers establish close peer relationships or remain socially isolated. Erikson (1963) sees identity (or role) confusion as the prime danger of this stage and suggests that the cliquish behavior and intolerance of differences seen in adolescent behavior are defenses against identity confusion (Erikson, 1968). Adolescents work at becoming emotionally independent from their parents while retaining family ties. They are often described as being ambivalent. They love and hate their parents. In addition, they need to develop their own ethical systems based on personal values. They need to make choices about vocation, future education, and lifestyle. The various components of total identity evolve from these tasks and compose adult personal identity that is unique to the individual.

Sexual Identity. Physical changes of puberty enhance achievement of sexual identity. The physical evidence of maturity encourages the development of masculine and feminine behaviors. If these physical changes involve deviations, the person has more difficulty developing a comfortable sexual identity. Adolescents depend on these physical clues because they want assurance of maleness or femaleness and they do not wish to be different from peers. Without these physical characteristics, achieving sexual identity is difficult.

Group Identity. Adolescents seek a group identity because they need esteem and acceptance. Similarity in dress or speech is common in teenage groups. Peer groups provide the adolescent with a sense of belonging, approval, and the opportunity to learn acceptable behavior. Popularity with opposite-sex and same-sex peers is important. The strong need for group identity seems to conflict at times with the search for personal identity. It is as though adolescents require close bonds with peers so they later achieve a sense of individuality.

Family Identity. The movement toward stronger peer relationships is contrasted with adolescents' movements away from parents. Although financial independence for adolescents is not the norm in American society, many work part-time, using their income to bolster independence. When they cannot have a part-time job because of studies, school-related activities, and other factors, parents can provide allowances for clothing and incidentals, which encourage them to develop decision-making and budgeting skills.

Some adolescents and families have more difficulty during these years than others. Adolescents need to make choices, act independently, and experience the consequences of their actions. Nurses help families consider appropriate ways for them to foster the independence of their adolescent while maintaining family structure.

Health Identity. Another component of personal identity is perception of health. This component is of specific interest to health care providers. Healthy adolescents evaluate their own health according to feelings of well-being, ability to function normally, and absence of symptoms (Hockenberry and Wilson, 2015). They also often include health maintenance and health promotion behaviors as important concerns.

Therefore interventions to improve health perception concentrate on the adolescent period. The rapid changes during this period make health promotion programs especially crucial. Adolescents try new

roles, begin to stabilize their identity, and acquire values and behaviors from which their adult lifestyle will evolve. They are able to identify behaviors such as smoking and substance abuse as threatening to health in general terms but frequently tend to underestimate the effect of the potentially negative consequences of their own actions (Hockenberry and Wilson, 2015).

Health Risks

Accidents. Accidents remain the leading cause of death in adolescence. Motor vehicle accidents, which are the most common cause of death, resulted in 74% of all unintentional deaths among teens 10 to 19 years (Hockenberry and Wilson, 2015). Such accidents are often associated with alcohol intoxication or drug abuse. Bicycling fatalities were 4 to 7 times more likely to occur in males than females. Other frequent causes of accidental death in teenagers are drowning and the use of firearms. Adolescents think that they are indestructible, which leads to risk-taking behaviors. The use of alcohol precedes many injuries, and adolescents continue to be both the victims and perpetrators of violence. An objective for Healthy People 2020 is to reduce the percentage of middle and public high schools that have violent incidents (USDHHS, 2014a).

Violence and Homicide. Homicide is the second leading cause of death in the 15- to 24-year-old age-group, and for African-American teenagers it is the most likely cause of death (National Institutes of Health, 2012). Results from the Youth Risk Behavior Surveillance System show that in 2013 17.9% of high school students had carried a weapon (e.g., gun, club, or knife) at some point during the preceding 30 days (CDC, 2013a). Individuals 12 years of age and older are most likely to be killed by an acquaintance or gang member and most often with a firearm. Because having a gun in the home raises the risk of homicide and suicide for adolescents, include assessment of gun presence in the home when counseling families (Hockenberry and Wilson, 2015).

Violence among adolescents has become a national concern (Box 12-2). Statistics show that in 2012 52 out of every 1000 high-school students were the victims of violence at school (USDEIES, 2012). This violence is not just limited to physical assaults and fighting, threats and intimidation, sexual harassment, or bullying. It can also include theft. Nurses working with adolescents need to be aware of the potential for school violence and include screening questions when providing health care, regardless of the setting.

Suicide. Suicide is a major leading cause of death in adolescents 15 to 24 years of age (CDC, 2011). In recent statistics reported by the CDC, 16% of high-school students indicated that they had seriously contemplated suicide in the previous 12 months (CDC, 2012). Depression and social isolation commonly precede a suicide attempt, but suicide probably results from a combination of several factors. Nurses must be able to identify the factors associated with adolescent suicide risk and precipitating events. The following warning signs often occur for at least a month before suicide is attempted:
- Decrease in school performance
- Withdrawal
- Loss of initiative
- Loneliness, sadness, and crying
- Appetite and sleep disturbances
- Verbalization of suicidal thought

Make immediate referrals to mental health professionals when assessment suggests that adolescents are considering suicide. Guidance helps them focus on the positive aspects of life and strengthen coping abilities.

BOX 12-2 EVIDENCE-BASED PRACTICE
Prevention Programs for School-Based Violence

PICO Question: For middle- and high-school students, are classroom-based curricular programs that promote prosocial behaviors and attitudes compared with efforts to improve the social and interpersonal climate of a school more effective in reducing school violence?

Evidence Summary
School violence is a complex issue and continues to be a problem in the United States. School safety research now includes a broader range of behaviors, including aggression, violence, and bullying (Astor et al., 2010). According to data from the Centers for Disease Control and Prevention (CDC, 2013a), the prevalence of being bullied on school property was as high as 27.9%. Bullying is considered to be one of the greatest public health concerns to youth in the United States. It not only poses one of the greatest health risks, but its effects are both immediate and long term and can developmentally affect the functioning of individuals across the life span (American Educational Research Association, 2013). Students who have been bullied experience higher rates of physical and mental health problems, including depression and anxiety. They also have issues with social adjustment, which can persist into adulthood (Ttofi et al., 2011). Bullying can encompass many forms such as physical or verbal aggression, including social exclusion or humiliation. It can be mild, moderate, or severe (Espelage et al., 2013). It can take place in face-to-face confrontations or through digital media (cyber-bullying). For instance, recent research has revealed that students who engage in school violence are also more likely to have insufficient sleep (Hildebrand et al., 2013).

One approach that schools take is to strengthen school safety through target hardening and zero-tolerance policies. Target hardening makes schools more difficult targets through architectural design, security cameras, and other safety measures (Astor et al., 2010). The other approach uses educational programs, including social skills training, conflict resolution and peer mediation, sleep interventions, programs to enhance school climate, and youth development programs that help students engage in community activities. Classroom-based curricular programs are more effective when offered to students in a positive school environment that fosters relationships between students and school personnel (Johnson et al., 2011).

Application to Nursing Practice
- Ongoing school violence assessment is critical to providing a healthy school environment (Johnson et al., 2011).
- Educate parents and children about the signs of cyber-bullying such as mean or hateful emails and inappropriate social media (Espelage et al., 2013).
- Teach parents how to place safety controls on home computers and smartphones and tablets (Espelage et al., 2013).
- Focus on the importance of a good night's sleep (Hildebrand et al., 2013)
- Work with educators and students to provide an environment that promotes adolescent health. (American Educational Research Association, 2013).

Substance Abuse. Substance abuse is a concern for all who work with adolescents. Adolescents often believe that mood-altering substances create a sense of well-being or improve level of performance. All adolescents are at risk for experimental or recreational substance use, but those who have dysfunctional families are more at risk for chronic use and physical dependency. Some adolescents believe that substance use makes them more mature. They further believe that they will look and feel better with drug use (Hockenberry and Wilson, 2015). Tobacco use continues to be a problem among adolescents; and,

although its use is declining, 3 out of 10 adolescents are active smokers at the time of high-school graduation.

Eating Disorders. Adolescent overweight and obesity are current concerns in the United States, and most teens try dieting at some time to control weight. Unfortunately the number of eating disorders is on the rise in adolescent girls; thus the benefits of a healthy diet should be discussed with all adolescents. Routine nutritional screening should be a part of the health care provided to all adolescents. Areas to include in the assessment are past and present diet history, food records, eating habits, attitudes, health beliefs, and socioeconomic and psychosocial factors (Hockenberry and Wilson, 2015).

Anorexia nervosa and bulimia are two eating disorders that appear in adolescence. Anorexia nervosa is a clinical syndrome with both physical and psychosocial components that involves the pursuit of thinness through starvation. People with anorexia nervosa have an intense fear of gaining weight and refuse to maintain body weight at the minimal normal weight for their age and height. Bulimia nervosa is most identified with binge eating and behaviors to prevent weight gain. Behaviors include self-induced vomiting, misuse of laxatives and other medications, and excessive exercise. Unlike anorexia, bulimia occurs within a normal weight range; thus it is much more difficult to detect. Because adolescents rarely volunteer information about behaviors to prevent weight gain, it is important to take a thorough dietary history. If left undetected and untreated, these disorders lead to significant morbidity and mortality (Grodner et al., 2012; Hockenberry and Wilson, 2015).

Sexually Transmitted Infections. Sexually transmitted infections (STIs) annually affect 3 million sexually active adolescents. This high degree of incidence makes it imperative that sexually active adolescents be screened for STIs, even when they have no symptoms. The annual physical examination of a sexually active adolescent includes a thorough sexual history and a careful examination of the genitalia so STIs are not missed. Be proactive by using the interview process to identify risk factors in the adolescent and provide education to prevent STIs, including human immunodeficiency virus (HIV), HPV, and unwanted pregnancies (Hockenberry and Wilson, 2015). As discussed earlier for school-age children, immunization for HPV infection should be considered at this time if not already administered.

Pregnancy. Adolescent pregnancy continues to be a major social challenge for our nation. The United States has the highest rate of teenage pregnancy and childbearing annually compared to other industrialized nations (Hockenberry and Wilson, 2015). Adolescent pregnancy occurs across socioeconomic classes, in public and private schools, among all ethnic and religious backgrounds, and in all parts of the country. Teenage pregnancy with early prenatal supervision is less harmful to both mother and child than earlier believed. Pregnant teens need special attention to nutrition, health supervision, and psychological support. Adolescent mothers also need help in planning for the future and obtaining competent day care for their infants.

Health Promotion

Health Education. Community and school-based health programs for adolescents focus on health promotion and illness prevention. Nurses need to be sensitive to the emotional cues from adolescents before initiating health teaching to know when the teen is ready to discuss concerns. In addition, discussions with adolescents need to be private and confidential. Adolescents define health in much the same way as adults and look for opportunities to reach their physical, mental, and emotional potential. Large numbers of school-based clinics have

been developed and implemented to respond to adolescents' needs. Adolescents are much more likely to use these health care services if they encounter providers who are caring and respectful (Hockenberry and Wilson, 2015).

Nurses play an important role in preventing injuries and accidental deaths. For example, urging adolescents to discuss alternatives to driving when under the influence of drugs or alcohol prepares them to consider alternatives when such an occasion arises. As a nurse, identify adolescents at risk for abuse, provide education to prevent accidents related to substance abuse, and provide counseling to those in rehabilitation.

Minority Adolescents. By the next century estimates predict that minorities as a group will become the majority. African-American, Hispanic, Latino, Asian, Native American, and Alaska Native American adolescents are the fastest-growing segment in the U.S. population. Minority adolescents experience a greater percentage of health problems and barriers to health care (Hockenberry and Wilson, 2015). Issues of concern for these adolescents living in a high-risk environment include learning or emotional difficulties, death related to violence, unintentional injuries, increased rate for adolescent pregnancy, STIs, HIV infection, and acquired immunodeficiency syndrome (AIDS). Poverty is a major factor negatively affecting the lives of minority adolescents. Limited access to health services is common. Nurses are able to make a significant contribution to improving access to appropriate health care for adolescents. With knowledge about various cultures and the means to care for minority adolescents, nurses act as advocates to ensure accessibility of appropriate services.

Gay, Lesbian, and Bisexual Adolescents. Researchers have studied development of a gay or lesbian identity in adults, but there are limited studies related to adolescents. It is widely known that, although some adolescents participate in same-gender sexual activity, they do not necessarily become homosexual as adults (Hockenberry and Wilson, 2015). Adolescents who believe that they have a homosexual or bisexual orientation often try to keep it hidden to avoid any associated stigma. This increases their vulnerability to depression and suicide. The teens who choose to disclose a homosexual or bisexual orientation become at risk for violence, harassment, and family abuse. If a teen chooses to disclose sexual orientation to you, help the adolescent construct a safety plan before telling his or her family or friends in case the response is not supportive (Hockenberry and Wilson, 2015). One of the Healthy People 2020 objectives is to increase the percentage of middle and high schools that prohibit harassment based on a student's sexual orientation or gender identity (USDHHS, 2014a).

> ### KEY POINTS
>
> - A developmental perspective helps a nurse understand commonalities and variations in each stage and the impact they have on a patient's health.
> - During critical periods of development, a multitude of factors foster or hinder optimal physical, cognitive, and psychosocial development.
> - In children, physiological, cognitive, and psychosocial development continues from conception through adolescence; thus be familiar with normal parameters to determine potential problems and identify ways to promote normal development.
> - The most rapid period of growth and development occurs during infancy.

- The toddler's development of fine- and gross-motor skills supports the move toward independence.
- Preschoolers interpret language literally and are unable to see another's point of view.
- Physical growth during the school years is slow and steady until the skeletal growth spurt just before puberty.
- The major psychosocial developmental task of the school-age child is the development of a sense of industry or competency.
- Adolescence begins with puberty, when primary sexual characteristics begin to develop and secondary sexual characteristics complete development.
- Adolescents are able to solve complex mental problems, which includes use of deductive reasoning.
- Accidents are the major cause of death in all age-groups.
- Sexually transmitted diseases are the most common communicable diseases among adolescents.

▌ CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You are caring for 12-year-old Elizabeth who has been hospitalized for an appendectomy. Her mother tells you that she is concerned about her lack of physical development compared to her peers. As a nurse you know that adolescents are preoccupied with their bodies and develop individual images of what they think they should look like. You are also aware that adolescents define health in terms of not just absence of illness but also being able to live up to one's physical, mental, and social potential and they are influenced by their peers.

1. What would you want to discuss concerning the onset of puberty with Elizabeth?
2. How would you discuss smoking with Elizabeth?
3. How will Elizabeth's cognitive and psychosocial development direct your teaching?

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

▌ REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. In an interview with a pregnant patient, the nurse discussed the three risk factors that have been cited as having a possible effect on prenatal development. They are:
   1. Nutrition, stress, and mother's age.
   2. Prematurity, stress, and mother's age.
   3. Nutrition, mother's age, and fetal infections.
   4. Fetal infections, prematurity, and placenta previa.
2. A parent has brought her 6-month-old infant in for a well-child check. Which of her statements indicates a need for further teaching?
   1. "I can start giving her whole milk at about 12 months."
   2. "I can continue to breastfeed for another 6 months."
   3. "I've started giving her plenty of fruit juice as a way to increase her vitamin intake."
   4. "I can start giving her solid food now."
3. The type of injury to which a child is most vulnerable at a specific age is most closely related to which of the following?
   1. Provision of adult supervision
   2. Educational level of the parent
   3. Physical health of the child
   4. Developmental level of the child

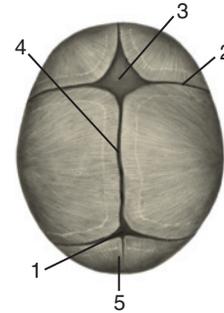
4. Which approach would be best for a nurse to use with a hospitalized toddler?
   1. Always give several choices.
   2. Set few limits to allow for open expression.
   3. Use noninvasive methods when possible.
   4. Establish a supportive relationship with the mother.
5. A nurse is providing information on prevention of sudden infant death syndrome (SIDS) to the mother of a young infant. Which of the following statements indicates that the mother has a good understanding? (Select all that apply.)
   1. "I won't use a pacifier to help my baby sleep."
   2. "I'll be sure that my baby doesn't spend any time sleeping on her abdomen."
   3. "I'll place my baby on her back for sleep."
   4. "I'll be sure to keep my baby's room cool."
   5. "I'll keep a crib bumper in the bed to prevent drafts."
6. Sequence the skills in the expected order of gross-motor development in an infant beginning with the earliest skill:
   1. Move from prone to sitting unassisted
   2. Sit down from standing position
   3. Sit upright without support
   4. Roll from abdomen to back
   5. Can turn from side to back
7. Parents are concerned about their toddler's negativism. To avoid a negative response, which of the following is the best way for a nurse to demonstrate asking the toddler to eat his or her lunch?
   1. Would you like to eat your lunch now?
   2. When would you like to eat your lunch?
   3. Would you like apple slices or applesauce with your sandwich?
   4. Would you like to sit at the big table to eat?
8. When nurses are communicating with adolescents, they should:
   1. Be alert to clues to their emotional state.
   2. Ask closed-ended questions to get straight answers.
   3. Avoid looking for meaning behind adolescents' words or actions.
   4. Avoid discussing sensitive issues such as sex and drugs.
9. Which of the following statements is most descriptive of the psychosocial development of school-age children?
   1. Boys and girls play equally with each other.
   2. Peer influence is not yet an important factor to the child.
   3. They like to play games with rigid rules.
   4. Children frequently have "best friends."
10. You are caring for a 4-year-old child who is hospitalized for an infection. He tells you that he is sick because he was "bad." Which is the most correct interpretation of his comment?
    1. Indicative of extreme stress
    2. Representative of his cognitive development
    3. Suggestive of excessive discipline at home
    4. Indicative of his developing sense of inferiority
11. At a well-child examination, the mother comments that her toddler eats little at mealtime, will only sit briefly at the table, and wants snacks all the time. Which of the following should the nurse recommend?
    1. Provide nutritious snacks.
    2. Offer rewards for eating at mealtimes.
    3. Avoid snacks so she is hungry at mealtime.
    4. Explain to her firmly why eating at mealtime is important.
12. An 8-year-old child is being admitted to the hospital from the emergency department with an injury from falling off her bicycle. Which of the following will most help her adjust to the hospital?

1. Explain hospital routines such as mealtimes to her.
2. Use terms such as "honey" and "dear" to show a caring attitude.
3. Explain when her parents can visit and why siblings cannot come to see her.
4. Since she is young, orient her parents to her room and hospital facility.

13. A school nurse is counseling an obese 10-year-old child. Which factors would be important to consider when planning an intervention to support the child's health? (Select all that apply.)
   1. Consider both the child and the family when addressing the issue.
   2. Consider the use of medications to suppress the appetite.
   3. First plan for weight loss through dieting and then add activity as tolerated.
   4. Plan food intake to allow for growth.
   5. Consider consulting a bariatric surgeon if other measures fail.

14. You are working in an adolescent health center when a 15-year-old patient shares with you that she thinks she is pregnant and is worried that she may now have a sexually transmitted infection (STI). Her pregnancy test is negative. What is your next priority of care?
   1. Contact her parents to alert them of her need for birth control.
   2. Refer her to a primary health care provider to obtain a prescription for birth control.

3. Counsel her on safe sex practices.
4. Ask her to have her partner come to the clinic for sexually transmitted infection testing.

15. A 4-month-old infant has not been feeling well for 2 days. His mother has brought him to the clinic to be seen by his health care provider. Which number identifies the area of the infant's head where the nurse can assess for dehydration?
   1. 1
   2. 2
   3. 3
   4. 4
   5. 5


Answers: 1. 1; **2.** 3; **3.** 4; **4.** 4; **5.** 2, 3, 4; **6.** 5, 4, 3, 1, 2; **7.** 3; **8.** 1; **9.** 4; **10.** 2; **11.** 1; **12.** 1; **13.** 1, 4; **14.** 3; **15.** 3.

Young and Middle Adults

Young and middle adulthood includes periods of challenges, rewards, and crises. Challenges often include the demands of working and raising families, although there are many rewards with these as well. Adults also face crises such as caring for their aging parents, the possibility of job loss in a changing economic environment, and dealing with their own developmental needs and those of their family members.

Classic works by developmental theorists such as Levinson et al. (1978), Diekelmann (1976), Erikson (1963, 1982), and Havighurst (1972) attempted to describe the phases of young and middle adulthood and related developmental tasks (see Chapter 11 for an in-depth discussion of developmental theories). More recent work has identified an additional phase of development in the young adult: emerging adulthood (Arnett, 2000; Grusec and Hastings, 2007; Jensen, 2011).

Faced with a societal structure that differs greatly from the norms of 20 or 30 years ago, both men and women are assuming different roles in today's society. Men were traditionally the primary supporter of the family. Today many women pursue careers and contribute significantly to their families' incomes. In 2012 59% of women 16 years and older participated in the U.S. labor force and constituted 46% of all U.S. workers in the U.S. labor force. Forty percent of employed women worked in management or professional occupations, and almost 30% of businesses in the United States were owned by women. In addition, 29% of women 25 years or older had completed four or more years of college, and 84.5% of women 18 years and older were living above the poverty level (Institute for Women's Policy Research [IWPR], 2014a). However, women in the United States are paid 77 cents for every dollar earned by men, a gender wage gap of 23% (IWPR, 2014b).

Developmental theories provide a basis for understanding the life events and developmental tasks of the young and middle adult. Patients present challenges to nurses who themselves are often young or middle adults coping with the demands of their respective developmental period. Nurses need to recognize the needs of their patients even if they are not experiencing the same challenges and events.

YOUNG ADULTS

Young adulthood is identified by some authors as the period between the late teens and the mid to late 30s (Edelman et al., 2014). In the past several decades, the period of life called **emerging adulthood** has been identified as lasting from about ages 18 to 25 (Grusec and Hastings, 2007; Jensen, 2011). This newly identified stage of development has been described as neither extended adolescence, since it is much freer from parental control and much more a period of independent exploration, nor young adulthood since most young people in their twenties have not made the transitions historically associated with adult status, especially marriage and parenthood. It is estimated that in 2013 young adults 20 to 34 years of age made up approximately 24% of the population (U.S. Census Bureau, 2014). According to the Pew Research Center (2011, 2013), today's young adults are history's first "always-connected" generation, with digital technology and social media major aspects of their lives. They adapt well to new experiences, are more ethnically and racially diverse than previous generations, and are the least overtly religious American generation in modern times. Young adults increasingly move away from their families of origin, establish career goals, and decide whether to marry or remain single and whether to begin

families; however, often these goals may be delayed because increased numbers of young adults pursue higher education and economic conditions.

Physical Changes

The young adult usually completes physical growth by the age of 20. An exception to this is the pregnant or lactating woman. The physical, cognitive, and psychosocial changes and the health concerns of the pregnant woman and the childbearing family are extensive.

Young adults are usually quite active, experience severe illnesses less frequently than older age-groups, tend to ignore physical symptoms, and often postpone seeking health care. Physical strength typically peaks in early adulthood, and physical characteristics of young adults begin to change as middle age approaches. Physical changes are minimal during this developmental phase; however, weight and muscle mass may change as a result of diet, exercise, and lifestyle. Assessment findings are generally within normal limits unless an illness is present.

Cognitive Changes

Critical thinking habits increase steadily through the young- and middle-adult years. Formal and informal educational experiences, general life experiences, and occupational opportunities dramatically increase the individual's conceptual, problem-solving, and motor skills.

Identifying an occupational direction is a major task of young adults. When people know their skills, talents, and personality characteristics, educational preparation and occupational choices are easier and more satisfying. An associate's degree, bachelor's degree, or graduate degree is the most significant source of postsecondary education for many of the fastest-growing occupations (U.S. Department of Labor, 2014).

An understanding of how adults learn helps the nurse develop patient education plans (see Chapter 25). Adults enter the teaching-learning situation with a background of unique life experiences, including illness. Therefore always view them as individuals. Their adherence to regimens such as medications, treatments, or lifestyle changes such as smoking cessation involves decision-making processes. When determining the amount of information that an individual needs to make decisions about the prescribed course of therapy, consider factors that possibly affect his or her adherence to the regimen, including educational level, socioeconomic factors, and motivation and desire to learn.

Because young adults are continually evolving and adjusting to changes in the home, workplace, and personal lives, their decision-making processes need to be flexible. The more secure young adults are in their roles, the more flexible and open they are to change. Insecure people tend to be more rigid in making decisions.

Psychosocial Changes

The emotional health of a young adult is related to an individual's ability to address and resolve personal and social tasks. The young adult is often caught between wanting to prolong the irresponsibility of adolescence and assume adult commitments. However, certain patterns or trends are relatively predictable. Between the ages of 23 and 28, the person refines self-perception and ability for intimacy. From 29 to 34 the person directs enormous energy toward achievement and mastery of the surrounding world. The years from 35 to 43 are a time of vigorous examination of life goals and relationships. People make changes in personal, social, and occupational areas. Often the stresses of this reexamination results in a "midlife crisis" in which marital partner, lifestyle, and occupation change.

Ethnic and gender factors have a sociological and psychological influence in an adult's life, and these factors pose a distinct challenge for nursing care. Each person holds culture-bound definitions of health and illness. Nurses and other health professionals bring with them distinct practices for the prevention and treatment of illness. Knowing too little about a patient's self-perception or beliefs regarding health and illness creates conflict between a nurse and patient. Changes in the traditional role expectations of both men and women in young and middle adulthood also lead to greater challenges for nursing care. For example, women often continue to work during the childrearing years, and many women struggle with the enormity of balancing three careers: wife, mother, and employee. This is a potential source of stress for the adult working woman. Men are more aware of parental and household responsibilities and find themselves having more responsibilities at home while achieving their own career goals (Fortinash and Holoday Worret, 2012). An understanding of ethnicity, race, and gender differences enables a nurse to provide individualized care (see Chapter 9).

Support from a nurse, access to information, and appropriate referrals provide opportunities for achievement of a patient's potential. Health is not merely the absence of disease but involves wellness in all human dimensions. The nurse acknowledges the importance of a young adult's psychosocial needs and needs in all other dimensions. The young adult needs to make decisions concerning career, marriage, and parenthood. Although each person makes these decisions based on individual factors, a nurse needs to understand the general principles involved in these aspects of psychosocial development while assessing the young adult's psychosocial status.

Lifestyle. Family history of cardiovascular, renal, endocrine, or neoplastic disease increases a young adult's risk of illness. Your role in health promotion is to identify modifiable factors that increase the young adult's risk for health problems and provide patient education and support to reduce unhealthy lifestyle behaviors (Lin et al., 2014).

A personal lifestyle assessment (see Chapter 6) helps nurses and patients identify habits that increase the risk for cardiac, malignant, pulmonary, renal, or other chronic diseases. The assessment includes general life satisfaction, hobbies, and interests; habits such as diet, sleeping, exercise, sexual habits, and use of caffeine, tobacco, alcohol, and illicit drugs; home conditions and pets; economics, including type of health insurance; occupational environment, including type of work and exposure to hazardous substances; and physical or mental stress. Military records, including dates and geographical area of assignments, may also be useful in assessing the young adult for risk factors. Prolonged stress from lifestyle choices increases wear and tear on the adaptive capacities of the body. Stress-related diseases such as ulcers, emotional disorders, and infections sometimes occur (see Chapter 38).

Career. A successful vocational adjustment is important in the lives of most men and women. Successful employment not only ensures economic security; it also leads to fulfillment, friendships, social activities, support, and respect from co-workers.

Some young adults choose a two-career family, which has benefits and liabilities. In addition to increasing the family's financial base, the person who works outside the home is able to expand friendships, activities, and interests. However, stress exists in a two-career family as well. These stressors result from a transfer to a new city; increased expenditures of physical, mental, or emotional energy; child care demands; or household needs. To avoid stress in a two-career family, partners should share all responsibilities. For example, some families may decide to limit recreational expenses and instead hire someone to

do routine housework. Others set up an equal division of household, shopping, and cooking duties.

Sexuality. The development of secondary sex characteristics occurs during the adolescent years (see Chapter 12). Physical development is accompanied by sexual maturation. The young adult usually has emotional maturity to complement the physical ability and therefore is able to develop mature sexual relationships and establish intimacy. Young adults who have failed to achieve the developmental task of personal integration sometimes develop relationships that are superficial and stereotyped (Fortinash and Holoday Worret, 2012).

The classic work of Masters and Johnson (1970) contributed important information about the physiological characteristics of the adult sexual response (see Chapter 35). The psychodynamic aspect of sexual activity is as important as the type or frequency of sexual intercourse to young adults. To maintain total wellness, encourage adults to explore various aspects of their sexuality and be aware that their sexual needs and concerns change. As the rate of early initiation of sexual intercourse continues to increase, young adults are at risk for sexually transmitted infections (STIs). Consequently there is an increased need for education regarding the mode of transmission, prevention, and symptom recognition and management for STIs.

Childbearing Cycle. Conception, pregnancy, birth, and the **puerperium** are major phases of the childbearing cycle. The changes during these phases are complex. Childbirth education classes can prepare pregnant women, their partners, and other support people to participate in the birthing process (Figure 13-1). Some health care agencies provide either professional labor support or a lay **doula**, a support person to be present during labor to assist women who have no other source of support. The stress that many women experience after childbirth may have a significant impact on postpartum women's health (Box 13-1).

Types of Families. During young adulthood most individuals experience singlehood and the opportunity to be on their own. Those who eventually marry or establish long-term partnerships encounter several changes as they take on new responsibilities. For example, many couples choose to become parents (Figure 13-2). Some young adults choose alternative lifestyles. Chapter 10 reviews forms of families.

FIGURE 13-1 Nurse providing Lamaze class for expectant young adults.

Singlehood. Social pressure to get married is not as great as it once was, and many young adults do not marry until their late 20s or early 30s or not at all. For young adults who remain single, parents and siblings become the nucleus for a family. Some view close friends and associates as "family." One cause for the increased single population is the expanding career opportunities for women. Women enter the job market with greater career potential and have greater opportunities for financial independence. More single individuals are choosing to live together outside of marriage and become parents either biologically or

BOX 13-1 EVIDENCE-BASED PRACTICE

Assessing for Postpartum Depression

PICO Question: Do psychosocial factors have an influence on the prevalence of postpartum depression (PPD) in young adult women?

Evidence Summary

A woman often experiences dramatic physical and psychosocial changes during the postpartum period that impact health, with up to 85% of women experiencing some type of mood disturbance. For most women these transient symptoms are referred to as *postpartum blues* (Dennis C et al., 2012; Venkatesh et al., 2014). Common symptoms of postpartum blues, including rapidly fluctuating mood, tearfulness, irritability, and anxiety, are generally mild (Guille et al., 2013). Approximately 9% to 16% of women experience a more persistent form of postpartum depression (PPD) after the birth of a baby, and 0.1% to 0.2% of postpartum women experience postpartum psychosis (Drake et al., 2014; Glover et al., 2014). The onset of postpartum psychosis carries a high risk of suicide and infanticide (murder of an infant). The onset is abrupt and severe, with clinical manifestations of delusions, hallucinations, thoughts of harming or killing the baby, unwillingness to eat or sleep, frantic energy, risk of suicide, and severe depressive symptoms.

Research findings indicate several risk factors for the development of postpartum mood disorder, including stress, fatigue, quality of relationship with the father of the baby, social support, birth of a preterm or low-birth-weight infant, young maternal age, and race and ethnicity (Camp, 2013; Liu and Tronick, 2013). Studies also show that PPD may have a negative impact on the maternal-infant relationship, infant development, and long-term child behavior (Horowitz et al., 2013; Jarosinski and Pollard, 2014). Postpartum psychosis is an extremely serious and rare postpartum mood disorder, and it is considered a psychiatric emergency.

Successful treatment of PPD depends on early identification and intervention. Clinical assessment of pregnant and postpartum women that is guided by the major predictors of PPD can help nurses identify women most at risk. Subsequently intervention can be initiated before the occurrence of depressive symptoms.

Application to Nursing Practice
- Assess for potential postpartum stressors such as fatigue, first-time mother, previous postpartum stress, or feeling of social isolation (Camp, 2013; Liu and Tronick, 2013).
- Identify sources of social support for new mothers after they are discharged from the hospital with their babies such as new-mother visits, young-mother groups, and mom's–day out activities (Horowitz et al., 2013; Jarosinski and Pollard, 2014).
- Create culturally appropriate primary prevention strategies for stressors that new mothers encounter (Horowitz et al., 2013; Jarosinski and Pollard, 2014).
- Educate new mothers and their families on the risks for and signs and symptoms of postpartum stress and PPD (Camp, 2013).
- Provide new mothers with information on health care and community resources for use during the postpartum period.

FIGURE 13-2 Parent-child nurturing is important in adapting to a newborn. (From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 10, St Louis, 2015, Mosby.)

through adoption. Similarly many married couples choose to separate or divorce if they find their marital situation unsatisfactory.

Parenthood. The availability of contraception makes it easier for today's couples to decide when and if to start a family. Social pressures may encourage a couple to have a child or influence them to limit the number of children they have. Economic considerations frequently enter into the decision-making process because of the expense of childrearing. General health status and age are also considerations in decisions about parenthood because couples are getting married later and postponing pregnancies, which often results in smaller families.

Alternative Family Structures and Parenting. Changing norms and values about family life in the United States reveal basic shifts in attitudes about family structure. The trend toward greater acceptance of cohabitation without marriage is a factor in the greater numbers of infants being born to single women. In addition, approximately 6 million American children and adults have a lesbian, gay, bisexual, or transgender (LGBT) parent. More than 111,000 same-sex households include children under the age of 18 (Gates, 2013). The American Academy of Pediatrics (AAP), in recognizing the needs of gay and lesbian parents and their children, published a policy statement supporting adoption of children and the parenting role by same-sex parents (AAP, 2013). However, many times parents from alternative family structures still feel a lack of support and even bias from the health care system (Nicol et al., 2013).

Hallmarks of Emotional Health. Most young adults have the physical and emotional resources and support systems to meet the many challenges, tasks, and responsibilities they face. During psychosocial assessment of young adults, assess for 10 hallmarks of emotional health (Box 13-2) that indicate successful maturation in this developmental stage.

Health Risks

Health risk factors for a young adult originate in the community, lifestyle patterns, and family history. The lifestyle habits that activate the stress response (see Chapter 38) increase the risk of illness. Smoking

---

BOX 13-2   Ten Hallmarks of Emotional Health

1. A sense of meaning and direction in life
2. Successful negotiation through transitions
3. Absence of feelings of being cheated or disappointed by life
4. Attainment of several long-term goals
5. Satisfaction with personal growth and development
6. When married, feelings of mutual love for partner; when single, satisfaction with social interactions
7. Satisfaction with friendships
8. Generally cheerful attitude
9. No sensitivity to criticism
10. No unrealistic fears

---

is a well-documented risk factor for pulmonary, cardiac, and vascular diseases in smokers and the individuals who receive secondhand smoke. Inhaled cigarette pollutants increase the risk of lung cancer, emphysema, and chronic bronchitis. The nicotine in tobacco is a vasoconstrictor that acts on the coronary arteries, increasing the risk of angina, myocardial infarction, and coronary artery disease. Nicotine also causes peripheral vasoconstriction and leads to vascular problems.

Family History. A family history of a disease puts a young adult at risk for developing it in the middle- or older-adult years. For example, a young man whose father and paternal grandfather had myocardial infarctions (heart attacks) in their 50s has a risk for a future myocardial infarction. The presence of certain chronic illnesses such as diabetes mellitus in the family increases the family member's risk of developing a disease. Regular physical examinations and screening are necessary at this stage of development. Since certain condition such as high blood pressure, high blood sugar, and high cholesterol levels may not have any symptoms in the early stages, having physical examinations and simple blood tests to screen for these conditions is important to assess the risk of current and future medical problems. Genomic science and resultant technologies have also facilitated new ways to identify people at risk for chronic disease through the use of genetic screening. Understanding the role genomics plays in the health of individuals and families enables clinicians to better advise young adults related to current and future health care.

Personal Hygiene Habits. As in all age-groups, personal hygiene habits in the young adult are risk factors. Sharing eating utensils with a person who has a contagious illness increases the risk of illness. Poor dental hygiene increases the risk of periodontal disease. Individuals avoid gingivitis (inflammation of the gums) and periodontitis (loss of tooth support) through oral hygiene (see Chapter 40).

Violent Death and Injury. Violence is a common cause of mortality and morbidity in the young-adult population. Factors that predispose individuals to violence, injury, or death include poverty, family breakdown, child abuse and neglect, drug involvement (dealing or illegal use), repeated exposure to violence, and ready access to guns. It is important for the nurse to perform a thorough psychosocial assessment, including such factors as behavior patterns, history of physical and substance abuse, education, work history, and social support systems to detect personal and environmental risk factors for violence. Death and injury primarily occur from physical assaults, motor vehicle or other accidents, and suicide attempts in young adults.

Intimate partner violence (IPV), formerly referred to as domestic violence, is a global public health problem. It exists along a continuum

from a single episode of violence to ongoing battering (Dudgeon and Evanson, 2014). IPV often begins with emotional or mental abuse and may progress to physical or sexual assault. Each year women in the United States experience approximately 4.8 million intimate partner–related physical assaults and rapes, and men are the victims of approximately 2.9 intimate partner–related physical assaults. Physical injuries from IPV range from minor cuts and bruises to broken bones, internal bleeding, and head trauma. IPV is linked to such harmful health behaviors as smoking, alcohol abuse, drug use, and risky sexual activity. Risk factors for the perpetration of IPV include using drugs or alcohol, especially heavy drinking; unemployment; low self-esteem; antisocial or borderline personality traits; desire for power and control in relationships; and being a victim of physical or psychological abuse (Bonomi et al., 2014; DeWall and Way, 2014; Dudgeon and Evanson, 2014). The greatest risk of violence occurs during the reproductive years. A pregnant woman has a 35.6% greater risk of being a victim of IPV than a nonpregnant woman. Women experiencing IPV may be more likely to delay prenatal care and are at increased risk for multiple poor maternal and infant health outcomes such as low maternal weight gain, infections, high blood pressure, vaginal bleeding, and delivery of a preterm or low-birth-weight infant.

QSEN **QSEN: BUILDING COMPETENCY IN PATIENT-CENTERED CARE** You are caring for Joan, a 25-year-old patient who has come to the clinic complaining of insomnia. Throughout the assessment interview Joan is slightly withdrawn, speaks quietly, and does not make eye contact. She does not work outside the home; and she acknowledges that her relationship with her husband, an engineer who lost his job as a result of downsizing 6 months ago, is "not going well." Physical examination reveals scratches and bruises on Joan's breasts, abdomen, and back. Which assessment questions, approaches, and tools do you use to determine whether Joan is a victim of IPV and, if so, how to help her?

ⓔ Answers to QSEN Activities can be found on the Evolve website.

Substance Abuse. Substance abuse directly or indirectly contributes to mortality and morbidity in young adults. Intoxicated young adults are often severely injured in motor vehicle accidents, resulting in death or permanent disability to other young adults.

Dependence on stimulant or depressant drugs sometimes results in death. Overdose of a stimulant drug ("upper") stresses the cardiovascular and nervous systems to the extent that death occurs. The use of depressants ("downers") leads to an accidental or intentional overdose and death.

Caffeine is a naturally occurring legal stimulant that is readily available in carbonated beverages; chocolate-containing foods; coffee and tea; and over-the-counter medications such as cold tablets, allergy and analgesic preparations, and appetite suppressants. It is the most widely ingested stimulant in North America. Caffeine stimulates catecholamine release, which in turn stimulates the central nervous system; it also increases gastric acid secretion, heart rate, and basal metabolic rate. This alters blood pressure, increases diuresis, and relaxes smooth muscle. Consumption of large amounts of caffeine results in restlessness, anxiety, irritability, agitation, muscle tremor, sensory disturbances, heart palpitations, nausea or vomiting, and diarrhea in some individuals.

Substance abuse is not always diagnosable, particularly in its early stages. Nonjudgmental questions about use of legal drugs (prescribed drugs, tobacco, and alcohol), soft drugs (marijuana), and more problematic drugs (cocaine or heroin) are a routine part of any health assessment. Obtain important information by making specific inquiries about past medical problems, changes in food intake or sleep patterns, or problems of emotional lability. Reports of arrests because of driving while intoxicated, wife or child abuse, or disorderly conduct are reasons to investigate the possibility of drug abuse more carefully.

Human Trafficking. Runaway and homeless youth and young adults have gained recognition as a significant and growing social problem (Benoit-Bryan, 2013). In particular, this population sometimes turns to illegal and dangerous activities to survive and may be at high risk for human trafficking (Derluyn, 2010; Pergamit and Ernst, 2010). The United Nations Office on Drugs and Crime (n.d.) defines human trafficking as the recruitment, transport, transfer, harboring, or receipt of a person by threat or use of force for the purpose of exploitation. Although human trafficking is often a hidden crime and accurate statistics are difficult to obtain, estimates indicate that over 80% of trafficking victims are female and 50% are children. Approximately 75% to 80% of human trafficking is for sex.

Unplanned Pregnancies. Unplanned pregnancies are a continued source of stress that may result in adverse health outcomes for the mother, infant, and family. Often young adults have educational and career goals that take precedence over family development. Interference with these goals affects future relationships and parent-child relationships.

Determination of situational factors that affect the progress and outcome of an unplanned pregnancy is important. Exploration of problems such as financial, career, and living accommodations; family support systems; potential parenting disorders; depression; and coping mechanisms is important in assessing the woman with an unplanned pregnancy.

Sexually Transmitted Infections. STIs are a major health problem in young adults. Examples of STIs include syphilis, chlamydia, gonorrhea, genital herpes, human papillomavirus (HPV), and acquired immunodeficiency syndrome (AIDS). STIs have immediate physical effects such as genital discharge, discomfort, and infection. They also lead to chronic disorders, terminal illnesses, infertility, or even death. They remain a major public health problem for sexually active people, with almost half of all new infections occurring in men and women younger than 24 years of age (USDHHS, CDC, 2014). In 2011 and 2012, 20- to 24-year-old men had the highest rate of chlamydia among men (1350.4 per 100,000 population); chlamydia rates in men of this age-group increased slightly from the previous year. Safe and effective vaccines have been developed for some STIs. For example HPV, which can cause several types of cancer, can be prevented through vaccination with Gardasil or Cervarix, both Food and Drug Administration (FDA)–approved vaccines for the prevention of HPV.

Environmental or Occupational Factors. A common environmental or occupational risk factor is exposure to work-related hazards or agents that cause diseases and cancer (Table 13-1). Examples include lung diseases such as silicosis from inhalation of talcum and silicon dust and emphysema from inhalation of smoke. Cancers resulting from occupational exposures may involve the lung, liver, brain, blood, or skin. Questions regarding occupational exposure to hazardous materials should be a routine part of your assessment.

Health Concerns

Health Promotion. Lifestyles (e.g., use of tobacco or alcohol) of young adults may put them at risk for illnesses or disabilities during their middle- or older-adult years. Young adults are also genetically susceptible to certain chronic diseases such as diabetes mellitus and familial hypercholesterolemia (Huether and McCance, 2013). Some

TABLE 13-1 Occupational Hazards/Exposures Associated with Diseases and Cancers

Job Category	Occupational Hazard/Exposure	Work-Related Condition/Cancer
Agricultural workers	Pesticides, infectious agents, gases, sunlight	Pesticide poisoning, "farmer's lung," skin cancer
Anesthetists	Anesthetic gases	Reproductive effects, cancer
Automobile workers	Asbestos, plastics, lead, solvents	Asbestosis, dermatitis
Carpenters	Wood dust, wood preservatives, adhesives	Nasopharyngeal cancer, dermatitis
Cement workers	Cement dust, metals	Dermatitis, bronchitis
Dry cleaners	Solvents	Liver disease, dermatitis
Dye workers	Dyestuffs, metals, solvents	Bladder cancer, dermatitis
Glass workers	Heat, solvents, metal powders	Cataracts
Hospital workers	Infectious agents, cleansers, latex gloves, radiation	Infections, latex allergies, unintentional injuries
Insulators	Asbestos, fibrous glass	Asbestosis, lung cancer, mesothelioma
Jackhammer operators	Vibration	Raynaud's phenomenon
Lathe operators	Metal dusts, cutting oils	Lung disease, cancer
Office computer workers	Repetitive wrist motion on computers, eyestrain	Tendonitis, carpal tunnel syndrome, tenosynovitis

From Stanhope M, Lancaster J: *Foundations of nursing in the community,* ed 3, St Louis, 2010, Mosby.

FIGURE 13-3 The ability to handle day-to-day challenges at work minimizes stress.

diseases that may appear in later years are avoidable if identified early. Encourage adults to perform monthly skin, breast, or male genital self-examination (see Chapter 31). Breast cancer is the most common major cancer among women in the United States, with a steadily increasing incidence. A nurse's role is extremely important in educating female patients about breast self-examinations (BSEs) and the current breast screening recommendations. Encourage routine assessment of the skin for recent changes in color or presence of lesions and changes in their appearance. Prolonged exposure to ultraviolet rays of the sun by adolescents and young adults increase the risk for development of skin cancer later in life. Crohn's disease, a chronic inflammatory disease of the small intestine, most commonly occurs between 15 and 35 years of age. Many young adults have misconceptions regarding transmission and treatment of STIs. Encourage partners to know one another's sexual history and practices. Be alert for STIs when patients come to clinics with complaints of urological or gynecological problems (see Chapter 35). Assess young adults for knowledge and use of safe sex practices and genital self-examinations. Provide information on safe sex practice (e.g., use of condoms and having only one sex partner).

Psychosocial Health. The psychosocial health concerns of the young adult are often related to job and family stressors. As noted in Chapter 38, stress is valuable because it motivates a patient to change. However, if the stress is prolonged and the patient is unable to adapt to the stressor, health problems develop. Ninety percent of cases of eating disorders such as anorexia nervosa and bulimia nervosa begin during adolescence and young adulthood (Skinner et al., 2012). Some

mental health disorders such as high levels of depression also begin in this age-group. These conditions may manifest during young adulthood, but symptoms and treatment may continue into middle adulthood and beyond (Smink et al., 2012).

Job Stress. Job stress can occur every day or from time to time. Most young adults are able to handle day-to-day crises (Figure 13-3). Situational job stress occurs when a new boss enters the workplace, a deadline is approaching, or the worker has new or greater numbers of responsibilities. A recent trend in today's business world and a risk factor for job stress is corporate downsizing, leading to increased responsibilities for employees with fewer positions within the corporate structure. Job stress also occurs when a person becomes dissatisfied with a job or the associated responsibilities. Because individuals perceive jobs differently, the types of job stressors vary from patient to patient. Your assessment of a young adult includes a description of the usual work performed. Job assessment also includes conditions and hours, duration of employment, changes in sleep or eating habits, and evidence of increased irritability or nervousness.

Family Stress. Because of the multiplicity of changing relationships and structures in the emerging young-adult family, stress is frequently high (see Chapter 10). Situational stressors occur during events such as births, deaths, illnesses, marriages, and job losses. Stress is often related to a number of variables, including the career paths of both husband and wife, and leads to dysfunction in the young-adult family. This is reflected in the fact that the highest divorce rate occurs during the first 3 to 5 years of marriage for young adults under the age of 30. When a patient seeks health care and presents stress-related symptoms, the nurse needs to assess for the occurrence of a life-change event.

Each family member has certain predictable roles or jobs. These roles enable a family to function and be an effective part of society. When they change as a result of illness, a situational crisis often occurs. Assess environmental and familial factors, including support systems and coping mechanisms commonly used by family members.

Infertility. According to the American Society for Reproductive Medicine (n.d.), an **infertility** evaluation is not undertaken until a couple has unprotected intercourse for about 12 months with the failure to conceive. An estimated 10% to 15% of reproductive couples

are infertile, and many are young adults. However, approximately half of the couples evaluated and treated in infertility clinics become pregnant. In about 15% of infertile couples the cause is unknown. Female factors such as ovulatory dysfunction or a pelvic factor are responsible for infertility in 50% of couples, and infertility in 35% of couples is caused by a male factor such as sperm and semen abnormalities. For some infertile couples a nurse is the first resource they identify. Nursing assessment of the infertile couple includes comprehensive histories of both the male and female partners to determine factors that have affected fertility and pertinent physical findings (Murray and McKinney, 2014).

Obesity. Obesity is a major health problem in young adults and is recognized as a risk factor for other health problems later in life. It is influenced by poor diet and inactivity and has been linked to the development of conditions such as type 2 diabetes, hypertension, high cholesterol, asthma, joint problems, psoriatic arthritis, and poor health status (Berge et al., 2014; Vranian et al., 2013). Nursing assessment of diet and physical activity of young adults is an important part of data collection. All young adults should be counseled about the benefits of a healthful diet and physical activity.

Exercise. People of all ages, both male and female, benefit from regular physical activity; however, young adults are spending increasingly more time with technology and less time engaged in physical activity. Exercise in young adults is important to prevent or decrease the development of chronic health conditions such as high blood pressure, obesity, and diabetes that develop later in life. Exercise improves cardiopulmonary function by decreasing blood pressure and heart rate; increases the strength and size of muscles; and decreases fatigability, insomnia, tension, and irritability. Conduct a thorough musculoskeletal assessment and exercise history to develop a realistic exercise plan. Encourage regular exercise within the patient's daily schedule.

Pregnant Woman and the Childbearing Family. A developmental task for many young adult couples is the decision to begin a family. Although the physiological changes of pregnancy and childbirth occur only in the woman, cognitive and psychosocial changes and health concerns affect the entire childbearing family, including the baby's father, siblings, and grandparents. Single-parent families and young single mothers tend to be particularly vulnerable, both economically and socially.

Health Practices. Women who are anticipating pregnancy benefit from good health practices before conception; these include a balanced diet, folic acid, exercise, dental checkups, avoidance of alcohol, and cessation of smoking.

Prenatal Care. **Prenatal care** is the routine examination of the pregnant woman by an obstetrician or advanced practice nurse such as a nurse practitioner or certified nurse midwife. Prenatal care includes a thorough physical assessment of the pregnant woman during regularly scheduled intervals; provision of information regarding STIs, other vaginal infections, and urinary infections that adversely affect the fetus; and counseling about exercise patterns, diet, and child care. Regular prenatal care addresses health concerns that may arise during the pregnancy.

Physiological Changes. The physiological changes and needs of the pregnant woman vary with each trimester. Be familiar with them, their causes, and implications for nursing. All women experience some physiological changes in the first trimester. For example, they commonly have morning sickness, breast enlargement and tenderness, and fatigue. During the second trimester growth of the uterus and fetus results in some of the physical signs of pregnancy. During the third

trimester increases in **Braxton Hicks contractions** (irregular, short contractions), fatigue, and urinary frequency occur.

Postpartum. Postpartum is a period of approximately 6 weeks after delivery. During this time the woman's body reverts to its prepregnant physical status. Determine the woman's knowledge of and ability to care for both herself and her newborn baby. Assessment of parenting skills and maternal-infant interactions is particularly important. The process of **lactation** or breastfeeding offers many advantages to both the new mother and baby. For the inexperienced mother breastfeeding can be a source of anxiety and frustration. Be alert for signs that the mother needs information and assistance.

Needs for Education. The entire childbearing family needs education about pregnancy, labor, delivery, breastfeeding, and integration of the newborn into the family structure.

Psychosocial Changes. Like the physiological changes of pregnancy, psychosocial changes occur at various times during the 9 months of pregnancy and in the puerperium. Table 13-2 summarizes the major categories of psychosocial changes and implications for nursing intervention.

TABLE 13-2 Major Psychosocial Changes During Pregnancy

Category	Implications for Nursing
Body image	Morning sickness and fatigue contribute to poor body image. Woman feels big, awkward, and unattractive during third trimester when fetus is growing more rapidly. Increase in breast size sometimes makes the woman feel more feminine and sexually appealing. Woman takes extra time with hygiene and grooming, trying new hairstyles and makeup. Woman begins to "show" during the second trimester and starts to plan maternity wardrobe. Woman has general feeling of well-being when she feels the baby move and hears the heartbeat.
Role changes	Both partners think about and have feelings of uncertainty about impending role changes. Both partners have feelings of ambivalence about becoming parents and concern about ability to be parents.
Sexuality	Woman needs reassurance that sexual activity will not harm fetus. Woman's desire for sexual activity is influenced by body image. Woman desires cuddling and holding rather than sexual intercourse.
Coping mechanisms	Woman needs reassurance that childbirth and childrearing are natural and positive experiences but are also stressful. Woman is often unable to cope with particular stressors such as finding new housing, preparing the nursery, or participating in childbirth classes.
Stresses during puerperium	Woman returns home from hospital fatigued and unfamiliar with infant care. Woman experiences physical discomfort or feelings of anxiety or depression. Woman must return to work soon after delivery with subsequent feelings of guilt, anxiety, or possibly a sense of freedom or relief.

Health Concerns. The pregnant woman and her partner have many health questions. For example, they wonder whether the pregnancy and baby will be normal. Proper prenatal care has the potential to identify risks and pregnancy problems and meet the majority of the expectant mother's emotional and physical health needs.

Acute Care. Young adults typically require acute care for accidents, substance abuse, exposure to environmental and occupational hazards, stress-related illnesses, respiratory infections, gastroenteritis, influenza, urinary tract infections, and minor surgery. An acute minor illness causes a disruption in life activities of young adults and increases stress in an already hectic lifestyle. Dependency and limitations posed by treatment regimens also increase frustration. To give them a sense of maintaining control of their health care choices, it is important to keep them informed about their health status and involve them in health care decisions.

Restorative and Continuing Care. Chronic conditions are not common in young adulthood, but they sometimes occur. Chronic illnesses such as hypertension, coronary artery disease, and diabetes have their onset in young adulthood but may not be recognized until later in life. Causes of chronic illness and disability in the young adult include accidents, multiple sclerosis, rheumatoid arthritis, AIDS, and cancer. Chronic illness or disability threatens a young adult's independence and results in the need to change personal, family, and career goals. Nursing interventions for the young adult faced with chronic illness or disability need to focus on problems related to sense of identity, establishing independence, reorganizing intimate relationships and family structure, and launching a chosen career.

MIDDLE ADULTS

The U.S. Census Bureau (2014) predicted that in 2013 39.6% of the population would be middle-age adults between the ages of 35 and 64. In middle adulthood an individual makes lasting contributions through involvement with others. Generally the middle-adult years begin around the early to mid-30s and last through the late 60s, corresponding to Levinson's developmental phases of "settling down" and the "payoff years." During this period personal and career achievements have often already been experienced. Many middle adults find particular joy in helping their children and other young people become productive and responsible adults (see Chapter 11 for Erikson's Theory of Psychosocial Development) (Figure 13-4). They also begin to help aging parents while being responsible for their own children, placing

FIGURE 13-4 Middle adults enjoy helping young people become productive and responsible adults.

them in the sandwich generation. Using leisure time in satisfying and creative ways is a challenge that, if met satisfactorily, enables middle adults to prepare for retirement.

Although most middle adults have achieved socioeconomic stability, recent trends in corporate downsizing have left many either jobless or forced to accept lower-paying jobs. According to the U.S. Census Bureau (2013), the real median household income in the United States was not statistically different from 2011 to 2012; however, in 2012 the real median household income was 8.3% lower than in 2007, the year before the most recent recession, and the poverty rate was 2.5% higher.

Men and women need to adjust to inevitable biological changes. As in adolescence, middle adults use considerable energy to adapt self-concept and body image to physiological realities and changes in physical appearance. High self-esteem, a favorable body image, and a positive attitude toward physiological changes occur when adults engage in physical exercise, balanced diets, adequate sleep, and good hygiene practices that promote vigorous, healthy bodies.

Physical Changes

Major physiological changes occur between 40 and 65 years of age. Because of this it is important to assess the middle adult's general health status. A comprehensive assessment offers direction for health promotion recommendations and planning and implementing any acutely needed interventions. The most visible changes during middle adulthood are graying of the hair, wrinkling of the skin, and thickening of the waist. Decreases in hearing and visual acuity are often evident during this period. Often these physiological changes during middle adulthood have an impact on self-concept and body image. Table 13-3 summarizes abnormal findings to consider when conducting a physical examination (see Chapter 31). The most significant physiological changes during middle age are menopause in women and the climacteric in men.

Perimenopause and Menopause. Menstruation and ovulation occur in a cyclical rhythm in women from adolescence into middle adulthood. Perimenopause is the period during which ovarian function declines, resulting in a diminishing number of ova and irregular menstrual cycles; it generally lasts 1 to 3 years. Menopause is the disruption of this cycle, primarily because of the inability of the neurohormonal system to maintain its periodic stimulation of the endocrine system. The ovaries no longer produce estrogen and progesterone, and the blood levels of these hormones drop markedly. Menopause typically occurs between 45 and 60 years of age (see Chapter 35). Approximately 10% of women have no symptoms of menopause other than cessation of menstruation, 70% to 80% are aware of other changes but have no problems, and approximately 10% experience changes severe enough to interfere with activities of daily living.

Climacteric. The climacteric occurs in men in their late 40s or early 50s (see Chapter 35). Decreased levels of androgens cause climacteric. Throughout this period and thereafter a man is still capable of producing fertile sperm and fathering a child. However, penile erection is less firm, ejaculation is less frequent, and the refractory period is longer.

Cognitive Changes

Changes in the cognitive function of middle adults are rare except with illness or trauma. Some middle adults enter educational or vocational programs to prepare themselves with new skills and information for entering the job market or changing jobs.

TABLE 13-3 Abnormal Physical Assessment Findings in the Middle Adult

Body System	Assessment Findings	Body System	Assessment Findings
Integument	Very thin skin Rough, flaky, dry skin Lesions	Breasts—female	Recent increase in size of one breast Pigskin like or orange-peel appearance Redness or painful breasts
Scalp and hair	Excessive generalized hair loss or patchy hair loss Excessive scaliness	Breasts—male	Soft, fatty enlargement of breast tissue
Head and neck	Large, thick skull and facial bones Asymmetry in movement of head and/or neck Drooping of one side of the face	Abdomen	Bruises, areas of local discoloration; purple discoloration; pale, taut skin Generalized abdominal distention Hypoactive, hyperactive, decreased, or absent bowel sounds
Eyes	Reduced peripheral vision Asymmetrical position of the light reflex Drooping of the upper lid (ptosis) Redness or crusting around the eyelids	Female genitalia	Asymmetrical labia Swelling, pain, or discharge from Bartholin's glands Decreased tone of vaginal musculature Cervical enlargement or projection into the vagina Reddened areas or lesions in the vagina
Ears	Discharge of any kind Reddened, swollen ear canals	Male genitalia	Rashes, lesions, or lumps on skin of shaft of penis Discharge from penis Enlarged scrotal sac Bulges that appear at the external inguinal ring or femoral canal when the patient bears down
Nose, sinuses, and throat	Nasal tenderness Occlusion of nostril Swollen and pale pink or bluish-gray nasal mucosa Sinuses tender to palpation or on percussion Asymmetrical movement or loss of movement of uvula Tonsils red or enlarged	Musculoskeletal system	Uneven weight bearing Decreased range of joint motion; swollen, red, or enlarged joint; painful joints Decreased strength against resistance
Thorax and lungs	Unequal chest expansion Unequal fremitus, hyperresonance, diminished or absent breath sounds Adventitious lung sounds such as crackles and wheezes	Neurological system	Lethargy Inadequate motor responses Abnormal sensory system responses: inability to smell certain aromas, loss of visual fields, inability to feel and correctly identify facial stimuli, absent gag reflex
Heart and vascular system	Pulse inequality, weak pulses, bounding pulses, or variations in strength of pulse from beat to beat Bradycardia or tachycardia Hypertension Hypotension		

Psychosocial Changes

The psychosocial changes in the middle adult involve expected events such as children moving away from home and unexpected events such as a marital separation or the death of a close friend.

You need to assess for major life changes and the impact that the changes have on the middle adult's state of health. Include individual psychosocial factors such as coping mechanisms and sources of social support in your assessment.

In the middle-adult years, as children depart from the household, the family enters the post-parental family stage. Time and financial demands on the parents decrease, and the couple faces the task of redefining their own relationship. It is during this period that many middle adults take on healthier lifestyles. Assessment of health promotion needs for the middle adult includes adequate rest, leisure activities, regular exercise, good nutrition, reduction or cessation in the use of tobacco or alcohol, and regular screening examinations. Assessment of the middle adult's social environment is also important, including relationship concerns; communication and relationships with children, grandchildren, and aging parents; and caregiver concerns with their own aging or disabled parents.

Career Transition. Career changes occur by choice or as a result of changes in the workplace or society. In recent decades middle adults change occupations more often for a variety of reasons,

including limited upward mobility, decreasing availability of jobs, and seeking an occupation that is more challenging. In some cases downsizing, technological advances, or other changes force middle adults to seek new jobs. Such changes, particularly when unanticipated, result in stress that affects health, family relationships, self-concept, and other dimensions.

Sexuality. After the departure of their last child from the home, many couples recultivate their relationships and find increased marital and sexual satisfaction during middle age. The onset of menopause and the climacteric affect the sexual health of the middle adult. Some women may desire increased sexual activity because pregnancy is no longer possible. Menopausal women also experience vaginal dryness and dyspareunia or pain during sexual intercourse (see Chapter 35).

During middle age a man may notice changes in the strength of his erection and a decrease in his ability to experience repeated orgasm. Other factors influencing sexuality during this period include work stress, diminished health of one or both partners, and the use of prescription medications. For example, antihypertensive agents have side effects that influence sexual desire or functioning. Antihypertensive drugs represent one of the most implicated classes of drugs that cause erectile dysfunction (ED) in men. Patients who take beta blockers or diuretics exhibit significantly worse ED than patients receiving newer

drugs such as angiotensin receptor blockers, angiotensin converting enzyme (ACE) inhibitors, and calcium antagonists for hypertension (Manolis and Doumas, 2012). Sometimes both partners experience sexual dysfunction caused by stresses related to sexual changes or a conflict between their sexual needs and self-perceptions and social attitudes or expectations (see Chapter 35).

Family Psychosocial Factors. Psychosocial factors involving the family include the stresses of singlehood, marital changes, transition of the family as children leave home, and the care of aging parents.

Singlehood. Many adults over 35 years of age in the United States have never been married. Many of these are college-educated people who have embraced the philosophy of choice and freedom, delayed marriage, and delayed parenthood. Some middle adults choose to remain single but also opt to become parents either biologically or through adoption. Many single middle adults have no relatives but share a family type of relationship with close friends or work associates. Consequently some single middle adults feel isolated during traditional "family" holidays such as Thanksgiving or Christmas. In times of illness middle adults who choose to remain single and childless have to rely on other relatives or friends, increasing caregiving demands of family members who also have other responsibilities. Nursing assessment of single middle adults needs to include a thorough assessment of psychosocial factors, including an individual's definition of family and available support systems.

Marital Changes. Marital changes occurring during middle age include death of a spouse, separation, divorce, and the choice of remarrying or remaining single. A widowed, separated, or divorced patient goes through a period of grief and loss in which it is necessary to adapt to the change in marital status. Normal grieving progresses through a series of phases, and resolution of grief often takes a year or more. You need to assess the level of coping of the middle adult to the grief and loss associated with certain life changes (see Chapter 37).

Family Transitions. The departure of the last child from the home is also a stressor. Many parents welcome freedom from childrearing responsibilities, whereas others feel lonely or without direction. *Empty nest syndrome* is the term used to describe the sadness and loneliness that accompany children leaving home. Eventually parents need to reassess their marriage and try to resolve conflicts and plan for the future. Occasionally this readjustment phase leads to marital conflicts, separation, and divorce (see Chapter 10).

Care of Aging Parents. Increasing life spans in the United States and Canada have led to increased numbers of older adults in the population. Therefore greater numbers of middle adults need to address the personal and social issues confronting their aging parents. Many middle adults find themselves caught between the responsibilities of caring for dependent children and those of caring for aging and ailing parents. Thus they find themselves in the sandwich generation, in which the challenges of caregiving can be stressful. The needs of family caregivers are being given more emphasis in the health care system.

Housing, employment, health, and economic realities have changed the traditional social expectations between generations in families. The middle-adult and older-adult parents often have conflicting relationship priorities when the older adult strives to remain independent. Negotiations and compromises help to define and resolve problems. Nurses deal with middle and older adults in the community, long-term care facilities, and hospitals. They help identify the health needs of both groups and assist the multigenerational family in determining the health and community resources available to them as they make decisions and plans. They evaluate family relationships to determine family members' perceptions of responsibility and loyalty in relation to caring

for older-adult members. Assessment of environmental resources (e.g., number of rooms in the house or stairwells) in relation to the complexity of health care demands for the older adult is also important.

Health Concerns

Health Promotion and Stress Reduction. Because middle adults experience physiological changes and face certain health realities, their perceptions of health and health behaviors are often important factors in maintaining health. Today's complex world makes individuals more prone to stress-related illnesses such as heart attacks, hypertension, migraine headaches, ulcers, colitis, autoimmune disease, backache, arthritis, and cancer. When adults seek health care, nurses focus on the goal of wellness and guide patients to evaluate health behaviors, lifestyle, and environment.

Throughout life people have many stressors (see Chapter 38). After identifying these stressors, work with your patient to intervene and modify the stress response. Specific interventions for stress reduction fall into three categories. First minimize the frequency of stress-producing situations. Together with the patient identify approaches to preventing stressful situations such as habituation, change avoidance, time blocking, time management, and environmental modification. Second, increase stress resistance (e.g., increase self-esteem, improve assertiveness, redirect goal alternatives, and reorient cognitive appraisal). Finally avoid the physiological response to stress. Use relaxation techniques, imagery, and biofeedback to recondition the patient's response to stress.

Obesity. Obesity is a growing, expensive health concern for middle adults. It can reduce quality of life and increase risk for many serious chronic diseases and premature death. A new Healthy People 2020 (USDHHS, 2011) goal relates to improvement of health-related quality of life and well-being, including physical well-being. Health consequences of obesity include high blood pressure, high blood cholesterol, type 2 diabetes, coronary heart disease, osteoarthritis, and obstructive sleep apnea. Continued focus on the goal of health-related quality of life helps patients evaluate health behaviors and lifestyle that contribute to obesity during the middle-adult years. Counseling related to physical activity and nutrition is an important component of the plan of care for patients who are overweight and obese.

Forming Positive Health Habits. A habit is a person's usual practice or manner of behavior. Frequent repetition reinforces this behavior pattern until it becomes an individual's customary way of behaving. Some habits support health (e.g., exercise and brushing and flossing the teeth each day). Other habits involve risk factors to health (e.g., smoking or eating foods with little or no nutritional value. Evidence indicates that vitamin D and calcium play key roles in bone health and the prevention of osteopenia and osteoporosis in middle-age women (Institute of Medicine, 2011).

During assessment a nurse frequently obtains data indicating positive and negative health behaviors by a patient. Examples of positive health behaviors include regular exercise, adherence to good dietary habits, avoidance of excess consumption of alcohol, participation in routine screening and diagnostic tests for disease prevention and health promotion (e.g., laboratory screening for serum cholesterol or mammography), and lifestyle changes to reduce stress. You help patients maintain habits that protect health and offers healthier alternatives to poor habits.

Health teaching and counseling often focus on improving health habits. The more you understand the dynamics of behavior and habits, the more likely it is that your interventions will help patients achieve or reinforce health-promoting behaviors.

BOX 13-3   Barriers to Change

External Barriers
- Lack of facilities
- Lack of materials
- Lack of social supports
- Lack of motivation

Internal Barriers
- Lack of knowledge
- Insufficient skills to change health habits
- Undefined short- and long-term goals

To help patients form positive health habits, you act as a teacher and facilitator. By providing information about how the body functions and how patients form and change habits, patients' levels of knowledge regarding the potential impact of behavior on health are raised. You cannot change your patients' habits. They have control of and are responsible for their own behaviors. Explain psychological principles of changing habits and offer information about health risks. Offer positive reinforcement (such as praise and rewards) for health-directed behaviors and decisions. Such reinforcement increases the likelihood that the behavior will be repeated. However, ultimately a patient decides which behaviors will become habits of daily living.

Help middle adults consider factors such as avoidance of STIs, prevention of substance abuse, and accident prevention in relation to decreasing health risks. For example, provide patients with factual information on STI causes, symptoms, and transmission. Discuss methods of protection during sexual activity with a patient in an open and nonjudgmental manner and reinforce the importance of practicing safe sex (see Chapter 35). Provide counseling and support for patients seeking treatment for substance abuse. Help them recognize and alter unsafe and potential health hazards. In addition, encourage them to express their feelings so they become proficient in solving problems and recognizing risk factors themselves. Barriers to change exist (Box 13-3). Unless you minimize or eliminate these barriers, it is futile to encourage a patient to take action.

Health Literacy. Health literacy is defined as the cognitive and social skills that determine the motivation and ability of individuals to gain access to, understand, and use information in ways that promote and maintain good health (see Chapter 25). Health education materials such as medical instructions, consent forms, and questionnaires are often given to patients without consideration of their level of health literacy. It is estimated that nearly half of the American adult population functions at or below a basic health literacy level (Sorensen et al., 2012; Willens et al., 2013). A person with an adequate level of health literacy has the ability to take responsibility for his or her own health. Lower health literacy may impact the ability to understand basic written health information or read a prescription bottle correctly. People with low health literacy may not be able to self-manage their health with lifestyle risk-factor modification to prevent the development of chronic diseases (Dennis S et al., 2012).

Psychosocial Health

Anxiety. Anxiety is a critical maturational phenomenon related to change, conflict, and perceived control of the environment. Adults often experience anxiety in response to the physiological and psychosocial changes of middle age. Such anxiety motivates the adult to rethink life goals and stimulates productivity. However, for some adults this anxiety precipitates psychosomatic illness and preoccupation with

death. In this case a middle adult views life as being half or more over and thinks in terms of the time left to live.

Clearly a life-threatening illness, marital transition, or job stressor increases the anxiety of a patient and family. Use crisis intervention or stress-management techniques to help a patient adapt to the changes of the middle-adult years (see Chapter 38).

Depression. Depression is a mood disorder that manifests itself in many ways. Although the most frequent age of onset is between ages 25 and 44, it is common among adults in the middle years and has many causes. The risk factors for depression include being female; disappointments or losses at work, at school, or in family relationships; departure of the last child from the home; and family history. In fact, the incidence of depression in women is twice that of men. People experiencing mild depression describe themselves as feeling sad, blue, downcast, down in the dumps, and tearful. Other symptoms include alterations in sleep patterns such as difficult sleeping (insomnia) or sleeping too much (hypersomnia), irritability, feelings of social disinterest, and decreased alertness. Physical changes such as weight gain or loss, headaches, or feelings of fatigue regardless of the amount of rest are also depressive symptoms. Individuals with depression that occurs during the middle years commonly experience moderate-to-high anxiety and have physical complaints. Mood changes and depression are common occurrences during menopause. The abuse of alcohol or other substances makes depression worse. Nursing assessment of a middle adult diagnosed with depression includes focused data collection regarding individual and family history of depression, mood changes, cognitive changes, behavioral and social changes, and physical changes. Collect assessment data from both the patient and the patient's family because family data are often particularly important, depending on the level of depression the middle adult is experiencing.

Community Health Programs. Community health programs offer services to prevent illness, promote health, and detect disease in the early stages. Nurses make valuable contributions to the health of the community by taking an active part in planning screening and teaching programs and support groups for middle adults (see Chapter 3).

Family planning, birthing, and parenting skills are program topics in which adults are usually interested. Health screening for diabetes, hypertension, eye disease, and cancer is a good opportunity for a nurse to perform assessment and provide health teaching and health counseling.

Health education programs promote changes in behavior and lifestyle. As a health teacher, offer information that enables patients to make decisions about health practices within the context of health promotion for young-to-middle adults. Make sure that educational programs are culturally appropriate. Changes to more positive health practices during young and middle adulthood lead to fewer or less complicated health problems as an older adult. During health counseling, collaborate with your patient to design a plan of action that addresses his or her health and well-being. Through objective problem solving you can help your patient grow and change.

Acute Care. Acute illnesses and conditions experienced in middle adulthood are similar to those of young adulthood. However, injuries and acute illnesses in middle adulthood require a longer recovery period because of the slowing of healing processes. In addition, they are more likely to become chronic conditions. For middle adults in the sandwich generation, stress levels also increase as they balance responsibilities related to employment, family life, care of children, and care of aging parents while recovering from an injury or acute illness.

Restorative and Continuing Care.   Chronic illnesses such as diabetes mellitus, hypertension, rheumatoid arthritis, or multiple sclerosis affect the roles and responsibilities of a middle adult. Some results of chronic illness are strained family relationships, modifications in family activities, increased health care tasks, increased financial stress, the need for housing adaptation, social isolation, medical concerns, and grieving. The degree of disability and a patient's perception of both the illness and the disability determine the extent to which lifestyle changes occur. A few examples of the problems experienced by patients who develop debilitating chronic illness during adulthood include role reversal, changes in sexual behavior, and alterations in self-image. Along with the current health status of a middle adult living with a chronic illness, you need to assess the knowledge base of both the patient and family. This assessment includes the medical course of the illness and the prognosis for the patient. You need to determine the coping mechanisms of the patient and family. In addition, you need to assess adherence to treatment and rehabilitation regimens, evaluate the need for community and social services, and make appropriate referrals.

KEY POINTS

- Adult development involves orderly and sequential changes in characteristics and attitudes that adults experience over time.
- Many changes experienced by young adults are related to the natural process of maturation and socialization.
- Young adults are in a stable period of physical development, except for changes related to pregnancy.
- Cognitive development continues throughout the young- and middle-adult years.
- Emotional health of young adults is correlated with the ability to address and resolve personal and social problems.
- Pregnant women need to understand physiological changes occurring in each trimester.
- Psychosocial changes and health concerns during pregnancy and postpartum affect the parents, the siblings, and often the extended family.
- Midlife transition begins when a person becomes aware that physiological and psychosocial changes signify passage to another stage in life.
- Cognitive changes are rare in middle age except in cases of illness or physical trauma.
- Psychosocial changes for middle adults are often related to career transition, sexuality, marital changes, family transition, and care of aging parents.
- Health concerns of middle adults commonly involve stress-related illnesses, health assessment, adoption of positive health habits, and issues with health literacy.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

A 24-year-old patient who smokes two packs of cigarettes per day comes to a clinic to talk with you about quitting smoking. She began smoking when she was 14 years old. She states, "I just can't seem to kick the habit, no matter how hard I try. I'm smoking more now because of increased stress from my job."

1. What information do you need to know to help this patient quit smoking?

2. Which factors will have the greatest impact on health promotion related to smoking cessation in this patient?

3. Which steps should you take to help this patient decrease stress?

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. With the exception of pregnant or lactating women, the young adult has usually completed physical growth by the age of:
   1. 18.
   2. 20.
   3. 25.
   4. 30.
2. A nurse is completing an assessment on a male patient, age 24. Following the assessment, the nurse notes that his physical and laboratory findings are within normal limits. Because of these findings, nursing interventions are directed toward activities related to:
   1. Instructing him to return in 2 years.
   2. Instructing him in secondary prevention.
   3. Instructing him in health promotion activities.
   4. Implementing primary prevention with vaccines.
3. When determining the amount of information that a patient needs to make decisions about the prescribed course of therapy, many factors affect his or her compliance with the regimen, including educational level and socioeconomic factors. Which additional factor affects compliance?
   1. Gender
   2. Lifestyle
   3. Motivation
   4. Family history
4. A patient is laboring with her first baby, who is about to be delivered 2 weeks early. Her husband is in the military and might not get back in time, and both families are unable to be with her during labor. The doctor decides to call in which of the following people employed by the birthing area as a support person to be present during labor?
   1. Nurse
   2. Midwife
   3. Geneticist
   4. Lay doula
5. A single young adult interacts with a group of close friends from college and work. They celebrate birthdays and holidays together. In addition, they help one another through many stressors. These individuals are viewed as:
   1. Family.
   2. Siblings.
   3. Substitute parents.
   4. Alternative family structure.
6. Sharing eating utensils with a person who has a contagious illness increases the risk of illness. This type of health risk arises from:
   1. Lifestyle.
   2. Community.
   3. Family history.
   4. Personal hygiene habits.
7. A 50-year-old woman has elevated serum cholesterol levels that increase her risk for cardiovascular disease. One method to control this risk factor is to identify current diet trends and

describe dietary changes to reduce the risk. This nursing activity is a form of:
1. Referral.
2. Counseling.
3. Health education.
4. Stress-management techniques.

8. A 34-year-old female executive has a job with frequent deadlines. She notes that, when the deadlines appear, she has a tendency to eat high-fat, high-carbohydrate foods. She also explains that she gets frequent headaches and stomach pain during these deadlines. The nurse provides a number of options for the executive, and she chooses yoga. In this scenario yoga is used as a (n):
1. Outpatient referral.
2. Counseling technique.
3. Health promotion activity.
4. Stress-management technique.

9. A 50-year-old male patient is seen in the clinic. He tells a nurse that he has recently lost his job and his wife of 26 years has asked for a divorce. He has a flat affect. Family history reveals that his father committed suicide at the age of 53. The nurse assesses for the following:
1. Cardiovascular disease
2. Depression
3. Sexually transmitted infection
4. Iron deficiency anemia

10. Middle-age adults frequently find themselves trying to balance responsibilities related to employment, family life, care of children, and care of aging parents. People finding themselves in this situation are frequently referred to as being a part of:
1. The sandwich generation.
2. The millennial generation.
3. Generation X.
4. Generation Y.

11. Intimate partner violence (IPV) is linked to which of the following factors? (Select all that apply.)
1. Alcohol abuse
2. Marriage
3. Pregnancy
4. Unemployment
5. Drug use

12. Sexually transmitted infections (STIs) continue to be a major health problem in young adults. Men ages 20 to 24 years have the highest rate of which STI?
1. Chlamydia
2. Syphilis
3. Gonorrhea
4. Herpes zoster

13. Formation of positive health habits may prevent the development of chronic illness later in life. Which of the following are examples of positive health habits? (Select all that apply.)
1. Routine screening and diagnostic tests
2. Unprotected sexual activity
3. Regular exercise
4. Excess alcohol consumption
5. Consistent seat belt use

14. Chronic illness (e.g., diabetes mellitus, hypertension, rheumatoid arthritis) may affect a person's roles and responsibilities during middle adulthood. When assessing the health-related knowledge base of both the middle-age patient with a chronic illness and his family, your assessment includes which of the following? (Select all that apply.)
1. The medical course of the illness
2. The prognosis for the patient
3. Socioeconomic status
4. Coping mechanisms of the patient and family
5. The need for community and social services

15. A 45-year-old woman who is obese tells a nurse that she wants to lose weight. After conducting a thorough assessment, the nurse concludes that which of the following may be contributing factors to the woman's obesity? (Select all that apply.)
1. The woman works in an executive position that is very demanding.
2. The woman works out at the corporate gym at 5 AM two mornings per week.
3. The woman says that she has little time to prepare meals at home and eats out at least four nights a week.
4. The woman says that she tries to eat "low-cholesterol" foods to help lose weight.
5. The woman says that she vacations annually to reduce stress.

Answers: 1. 2; **2.** 3; **3.** 4; **4.** 5; **5.** 1; **6.** 4; **7.** 3; **8.** 4; **9.** 2; **10.** 1; **11.** 1,3,4,5; **12.** 1; **13.** 1,3,5; **14.** 1,2,4,5; **15.** 1,3,4.

Older Adults

OBJECTIVES

- Identify common myths and stereotypes about older adults.
- Discuss common developmental tasks of older adults.
- Describe common physiological changes of aging.
- Differentiate among delirium, dementia, and depression.
- Discuss issues related to psychosocial changes of aging.

- Describe the multifaceted aspects of elder mistreatment.
- Describe selected health concerns of older adults.
- Identify nursing interventions related to the physiological, cognitive, and psychosocial changes of aging.

People who are 65 years old are in the lower boundary for "old age" in demographics and social policy within the United States. However, many older adults consider themselves to be "middle-age" well into their seventh decade. Chronological age often has little relation to the reality of aging for an older adult. Each person ages in his or her own way. Every older adult is unique, and as a nurse you need to approach each one as an individual.

The number of older adults in the United States is growing quickly. In 2013 there were 43.1 million adults over age 65 in the United States, representing 13.7% of the population or one in seven Americans (AOA, 2013). This represents an increase of 7.6 million or 21% since 2002. Part of this increase is caused by the increase of the average life span. The aging of the baby-boom generation and the growth of the population segment over age 85 contribute to the projected increase in the number of older adults. The baby boomers were born between 1946 and 1964. The first baby boomers reached age 65 in 2011. As the large number of baby boomers age, the social and health care programs necessary to meet their needs must dramatically reform their services. The diversity of the population over age 65 is also increasing. In 2012 minorities (African-Americans, Hispanics, Asians, American Indians/Eskimos/Aleuts, and other Pacific Islanders) made up 21% of the population over age 65 (AOA, 2013). As a nurse, you need to take cultural diversity into account as you care for older adults. The challenge is to gain new knowledge and skills to provide culturally sensitive and linguistically appropriate care (see Chapter 9).

VARIABILITY AMONG OLDER ADULTS

The nursing care of older adults poses special challenges because of great variation in their physiological, cognitive, and psychosocial health. Older adults also vary widely in their levels of functional ability. Most older adults are active and involved members of their communities. A smaller number have lost the ability to care for themselves, are confused or withdrawn, and/or are unable to make decisions concerning their needs. Most older adults live in noninstitutional settings. In 2012 57% of older adults in noninstitutional settings lived with a spouse (45% of older women, 71% of older men) (AOA, 2013), 28% lived alone (35% of older women, 19% of older men); and only 3.5% of all older adults resided in institutions such as nursing homes or centers.

Aging does not automatically lead to disability and dependence. Most older people remain functionally independent despite the increasing prevalence of chronic disease. Nursing assessment provides valuable clues to the effects of a disease or illness on a patient's functional status. Chronic conditions add to the complexity of assessment and care of the older adult. Most older people have at least one chronic condition, and many have multiple conditions. The physical and psychosocial aspects of aging are closely related. A reduced ability to respond to stress, the experience of multiple losses, and the physical changes associated with normal aging combine to place people at high risk for illness and functional deterioration. Although the interaction

of these physical and psychosocial factors is often serious, do not assume that all older adults have signs, symptoms, or behaviors representing disease and decline or that these are the only factors you need to assess. You also need to identify an older adult's strengths and abilities during the assessment and encourage independence as an integral part of your plan of care (Kresevic, 2012).

MYTHS AND STEREOTYPES

Despite ongoing research in the field of **gerontology**, myths and stereotypes about older adults persist. These include false ideas about their physical and psychosocial characteristics and lifestyles. When health care providers hold negative stereotypes about aging, their action often negatively affect the quality of patient care. Although nurses are susceptible to these myths and stereotypes, they have the responsibility to replace them with accurate information.

Some people stereotype older adults as ill, disabled, and physically unattractive. Others believe that older adults are forgetful, confused, rigid, bored, and unfriendly and that they are unable to understand and learn new information. Yet specialists in the field of gerontology view centenarians, the oldest of the old, as having an optimistic outlook on life, good memories, broad social contacts and interests, and tolerance for others. Although changes in vision or hearing and reduced energy and endurance sometimes affect the process of learning, older adults are lifelong learners.

Stereotypes about lifestyles often include mistaken ideas about living arrangements and finances. Misconceptions about financial status range from beliefs that many are affluent to beliefs that many are poor. According to the U.S. Census Bureau, only 9.5% of people over age 65 had incomes below the poverty level. Older women report a significantly lower income than men. Poverty rates for older women are 11.6% compared with older men at 6.8% (U.S. Census Bureau, 2014).

In a society that values attractiveness, energy, and youth, these myths and stereotypes lead to the undervaluing of older adults. Some people equate worth with productivity; therefore they think that older adults become worthless after they leave the workforce. Others consider their knowledge and experience too outdated to have any current value. These ideas demonstrate **ageism**, which is discrimination against people because of increasing age, just as people who are racists and sexists discriminate because of skin color and gender. According to experts in the field of gerontology, ageism typically undermines the self-confidence of older adults, limits their access to care, and distorts caregivers' understanding of the uniqueness of each older adult. Always promote a positive perception regarding the aging process when you establish therapeutic relationships and show respect to older adults.

Current laws ban discrimination on the basis of age. The economic and political power of older adults challenges ageist views. Older adults are a significant proportion of the consumer economy. As voters and activists in various issues, they have a major influence in the formation of public policy. Their participation adds a unique perspective on social, economic, and technological issues because they have experienced almost a century of developments. In the past 100 years our nation has progressed from riding in horse-drawn carriages to tracking the adventures of the international space station. Gaslights and steam power have been replaced by electricity and nuclear power. Computers and copy machines replaced typewriters and carbon paper. Many older adults lived through or were born during the Great Depression of 1929. They also experienced two world wars and wars in Korea, Vietnam, and the Persian Gulf and are now experiencing the war on terrorism. They have seen changes in health care as the era of the family physician gave way to the age of specialization. After witnessing the government

initiatives establishing the Social Security system, Medicare, and Medicaid, older adults are currently living with the changes imposed by health care reform and the uncertainty of the future of Social Security and Medicare. Living through all of these events and changes, they have stories and examples of coping with change to share.

NURSES' ATTITUDES TOWARD OLDER ADULTS

It is important for you to assess your own attitudes toward older adults; your own aging; and the aging of your family, friends, and patients. Nurses' attitudes come from personal experiences with older adults, education, employment experiences, and attitudes of co-workers and employing institutions. Given the increasing number of older adults in health care settings, forming positive attitudes toward them and gaining specialized knowledge about aging and the health care needs of older adults are priorities for all nurses. Positive attitudes are based in part on a realistic portrayal of the characteristics and health care needs of older adults. It is critical for you to respect older adults and actively involve them in care decisions and activities. In the past institutional settings such as hospitals and nursing centers often treated older adults as objects rather than independent, dignified people. The time has come for nurses to recognize and address ageism by questioning prevailing negative attitudes and stereotypes and reinforcing the realities of aging as they care for older adults in all care settings.

DEVELOPMENTAL TASKS FOR OLDER ADULTS

Theories of aging are closely linked to the concept of developmental tasks appropriate for distinct stages of life (see Chapter 11). Although no two individuals age in the same way, either biologically or psychosocially, researchers have developed frameworks outlining developmental tasks for older adults (Box 14-1). These developmental tasks are common to many older adults and are associated with varying degrees of change and loss. The more common losses are of health, significant others, a sense of being useful, socialization, income, and independent living. How older adults adjust to the changes of aging is highly individualized. For some adaptation and adjustment are relatively easy. For others coping with aging changes requires the assistance of family, friends, and health care professionals. Be sensitive to the effect of losses on older adults and their families and be prepared to offer support.

Older adults need to adjust to the physical changes that accompany aging. The extent and timing of these changes vary by individual but, as body systems age, changes in appearance and functioning occur. These changes are not associated with a disease; they are normal. The presence of disease sometimes alters the timing of the changes or their impact on daily life. The section on physiological changes describes structural and functional changes of aging.

Some older adults, both men and women, find it difficult to accept aging. This is apparent when they understate their ages when asked,

---

BOX 14-1   Developmental Tasks for Older Adults

- Adjusting to decreasing health and physical strength
- Adjusting to retirement and reduced or fixed income
- Adjusting to death of a spouse, children, siblings, friends
- Accepting self as aging person
- Maintaining satisfactory living arrangements
- Redefining relationships with adult children and siblings
- Finding ways to maintain quality of life

adopt younger styles of clothing, or attempt to hide physical evidence of aging with cosmetics. Others deny their aging in ways that are potentially problematic. For example, some older adults deny functional declines and refuse to ask for help with tasks, placing their safety at great risk. Others avoid activities designed for their benefit such as senior citizens' centers and senior health promotion activities and thus do not receive the benefits these programs offer. Acceptance of personal aging does not mean retreat into inactivity, but it does require a realistic review of strengths and limitations.

Older adults retired from employment outside the home need to cope with the loss of a work role. Older adults who worked at home and the spouses of those who worked outside the home also face role changes. Some welcome retirement as a time to pursue new interests and hobbies, volunteer in their community, continue their education, or start a new career. Retirement plans for others include changing residence by moving to a different city or state or to a different type of housing within the same area. Reasons other than retirement also lead to changes of residence. For example, physical impairments sometimes require relocation to a smaller, single-level home or nursing center. A change in living arrangements for the older adult usually requires an extended period of adjustment, during which assistance and support from health care professionals, friends, and family members are necessary.

The majority of older adults cope with the death of a spouse. In 2013 36% of all older women were widows, and 12% of older men were widowers (AOA, 2013). Some older adults must cope with the death of adult children and grandchildren. All experience the deaths of friends. These deaths represent both losses and reminders of personal mortality. Coming to terms with them is often difficult. By helping older adults through the grieving process (Chapter 37), you help them resolve issues posed by the deaths of those close to them.

The redefining of relationships with children that occurred as the children grew up and left home continues as older adults experience the challenges of aging. A variety of issues sometimes occur, including control of decision making, dependence, conflict, guilt, and loss. How these issues surface in situations and how they are resolved depend in part on the past relationship between the older adult and their adult children. All the involved parties have past experiences and powerful emotions. When adult children become their parents' caregivers, they have to find ways to balance the demands of their own children and careers with the many challenges of family caregiving. As adult children and aging parents negotiate the aspects of changing roles, nurses are in the position to act as counselors for the entire family. Helping older adults maintain their quality of life is often a priority. What defines quality of life is unique for each person.

COMMUNITY-BASED AND INSTITUTIONAL HEALTH CARE SERVICES

As a nurse you will encounter older-adult patients in a wide variety of community and institutional health care settings. Outside of an acute care hospital, nurses care for older adults in private homes and apartments, retirement communities, adult day care centers, assisted-living facilities, and nursing centers (extended care, intermediate care, and skilled nursing facilities). Chapter 2 describes these settings and the services provided in detail.

Nurses help older adults and their families by providing information and answering questions as they make choices among care options. Your assistance is especially valuable when patients and families need to make decisions about moving to a nursing center. Some family caregivers consider nursing center placement when in-home care

BOX 14-2 FOCUS ON OLDER ADULTS

Selection of a Nursing Center or Home

An important step in the process of selecting a nursing center is to visit it. A quality nursing home has the following features:
- Does not feel like a hospital. It is a home, a place where people live. Residents are encouraged to personalize their rooms. Privacy is respected.
- Is Medicare and Medicaid certified.
- Has adequate, qualified staff members who have passed criminal background checks.
- Provides quality care, in addition to assistance with basic activities of daily living such as bathing, dressing, eating, oral hygiene, and toileting. Staff regularly help residents with social and recreational activities.
- Offers quality food and mealtime choices.
- Welcomes families when they visit the facility. Whether families wish to provide information, ask questions, participate in care planning, or help with social activities or physical care, staff always encourage family involvement.
- Is clean. There are no pervasive odors in the facility. The environment feels "homelike."
- Provides active communication from staff to patient and family.
- Attends quickly to resident requests. Staff are actively involved with assisting the residents. They focus on the person, not on the task.

Modified from the Centers for Medicare & Medicaid Services (CMS): *Your guide to choosing a nursing home or other long-term care,* Baltimore, MD, 2013, CMS, http://www.medicare.gov/Pubs/pdf/02174.pdf. Accessed March 25, 2015.

becomes increasingly difficult or when convalescence (recovery) from hospitalization requires more assistance than the family is able to provide. Although the decision to enter a nursing center is never final and a nursing center resident is sometimes discharged to home or another less-acute facility, many older adults view the nursing center as their final residence. Results of state and federal inspections of nursing centers are available to the public at the nursing center, on-line, and at the inspectors' offices. The best way to evaluate the quality of a nursing center in a community is for the patient and family to visit that facility and inspect it personally. The Centers for Medicare and Medicaid (CMS website (http://www.Medicare.gov/NHcompare) is an excellent resource for you to learn about the quality rating of a nursing center on the basis of the health inspections, staffing, and quality measures of the facility. It also offers a nursing center checklist. Box 14-2 summarizes some features to look for in a nursing center.

ASSESSING THE NEEDS OF OLDER ADULTS

Gerontological nursing requires creative approaches for maximizing the potential of older adults. With comprehensive assessment information regarding strengths, limitations, and resources, you and older adults identify needs and problems together. You select interventions with older adults to maintain their physical abilities and create environments for psychosocial and spiritual well-being (Chapter 36). To complete a thorough assessment, actively engage older adults and provide adequate time, allowing them to share important information about their health.

Nursing assessment takes into account three key points to ensure an age-specific approach: (1) the interrelation between physical and psychosocial aspects of aging, (2) the effects of disease and disability on functional status and, (3) tailoring the nursing assessment to an older person (Meiner, 2015). A comprehensive assessment of an older adult takes more time than the assessment of a younger adult because

of the longer life and medical history and the potential complexity of the history. During the physical examination allow rest periods as needed or conduct the assessment in several sessions if a patient has reduced energy or limited endurance. Remember to review both prescribed and over-the-counter medications carefully with each patient.

A patient's sensory changes also affect data gathering. Your choice of communication techniques depends on an older adult's visual or hearing impairments. If an older adult is unable to understand your visual or auditory cues, your assessment data will likely be inaccurate or misleading, leading you to incorrectly conclude that the older adult is confused. When a person has a hearing impairment, speak directly to the patient in clear, low-pitched tones and move to a quiet area to reduce background noise. When caring for people with visual impairments, sit or stand at eye level and face them. Always encourage the use of assistive devices such as glasses and hearing aids. Chapter 49 explains in detail techniques to use when communicating with older adults who have sensory deficits.

Memory deficits, if present, affect the accuracy and completeness of your assessment. Information contributed by a family member or other caregiver is sometimes necessary to supplement an older adult's recollection of past medical events and information about current self-care habits, medication adherence, and history of allergies and immunizations. Use tact when involving another person in the assessment interview. The additional person supplements information with the consent of the older adult, but the older adult remains the primary source of the interview.

During all aspects of an assessment, you are responsible for providing culturally competent care. Your ability to recognize and process your own biases related to ageism, social norms, and racism affects your ability to provide culturally competent care. See Chapter 9 for a detailed description of the components of a cultural assessment. During an assessment, use caution when interpreting the signs and symptoms of diseases and laboratory values. Historically researchers used younger populations to establish these signs and norms. However, the classic signs and symptoms of diseases are sometimes absent, blunted, or atypical in older adults (Smith and Cotter, 2012). This is especially true in the cases of bacterial infection, pain, acute myocardial infarction, and heart failure. The masquerading of disease is possibly caused by age-related changes in organ systems and homeostatic mechanisms, progressive loss of physiological and functional reserves, or coexisting acute or chronic conditions. As a result an older adult with a urinary tract infection (UTI) sometimes presents with confusion, incontinence, and only a slight elevation of body temperature (within normal limits) instead of having fever, dysuria, frequency, or urgency. Some older adults with pneumonia have tachycardia, tachypnea, and confusion with decreased appetite and functioning, without the more common symptoms of fever and productive cough. Instead of crushing, substernal chest pain and diaphoresis, some older adults experience a sudden onset of dyspnea often accompanied by anxiety and confusion when having a myocardial infarction. Variations from the usual norms for laboratory values are sometimes caused by age-related changes in cardiac, pulmonary, renal, and metabolic function.

It is important to recognize early indicators of acute illness in older adults. Note changes in mental status, occurrence and reason for falls, dehydration, decrease in appetite, loss of function, dizziness, and incontinence because these symptoms are not frequently present in younger adults. A key principle of providing age-appropriate nursing care is timely detection of these cardinal signs of illness so early treatment can begin (Box 14-3). Mental status changes commonly occur as a result of disease and psychological issues. Some mental changes are often drug related, caused by drug toxicity or adverse drug events. Falls are complex and often cause injury. They are sometimes costly and can

---

BOX 14-3 Examples of Altered Presentation of Illnesses in Older Adults Occurring in Various Health Care Settings

Hospital
- Confusion is not inevitable. Look for an acute illness, neurological events, new medication, or the presence of risk factors for delirium.
- Many hospitalized older adults suffer from chronic dehydration exacerbated by acute illness.
- Not all older adults have fevers with infection. Symptoms instead include increased respiratory rate, falls, incontinence, or confusion.

Nursing Home
- Health care providers often undertreat pain in older adults, especially those with dementia. Look for nonverbal cues or pain presence such as grimacing or resistance to care.
- Decline in functional ability (even a minor one such as the inability to sit upright in a chair) is a signal of new illness.
- Residents with less muscle mass—both the frail and the obese—are at a much higher risk for toxicity from protein-binding drugs such as phenytoin (Dilantin and others) and warfarin (Coumadin and others).
- New urinary and/or fecal incontinence is often a sign of the onset of a new illness.

Ambulatory Care
- Complaints of fatigue or decreased ability to do usual activities are often signs of anemia, thyroid problems, depression, or neurological or cardiac problems.
- Severe gastrointestinal problems in older adults do not always present with the same acute symptoms seen in younger patients. Ask about constipation, cramping sensations, and changes in bowel habits.
- Older adults reporting increased dyspnea and confusion, especially those with a cardiac history, need to go to the emergency department because these are the most common manifestations of myocardial infarction in this population.
- Depression is common among older adults with chronic illnesses. Watch for lack of interest in former activities, significant personal losses, or changes in role or home life.

Home Care
- Investigate all falls, focusing on balance, lower extremity strength, gait, and neurological issues (e.g., loss of sensation).
- Monitor older adults with late-stage heart disease for loss of appetite as an early symptom of impending heart failure.
- Drug-drug and drug-food interactions in older patients who are seeing more than one provider and taking multiple medications are common. Watch for signs of interactions.

---

be a common event for an older adult. You need to investigate every fall carefully to find out if it was the result of environmental causes or the symptom of a new-onset illness. Problems with the cardiac, respiratory, musculoskeletal, neurological, urological, and sensory body systems sometimes present with a fall as a chief symptom of a new-onset condition. Dehydration is common in older adults because of decreased oral intake related to a reduced thirst response and less free water as a consequence of a decrease in muscle mass. When vomiting and diarrhea accompany the onset of an acute illness, an older adult is at risk for further dehydration. Decrease in appetite is a common symptom with the onset of pneumonia, heart failure, and UTI. Loss of functional ability occurs in a subtle fashion over a period of time; or it occurs suddenly, depending on the underlying cause. Thyroid

disease, infection, cardiac or pulmonary conditions, metabolic disturbances, and anemia are common causes of functional decline. You play an essential role in early identification, referral, and treatment of health problems.

Physiological Changes

Perception of well-being defines quality of life. Understanding an older adult's perceptions about health status is essential for accurate assessment and development of clinically relevant interventions. Their concepts of health generally depend on personal perceptions of functional ability. Therefore older adults engaged in activities of daily living (ADLs) usually consider themselves healthy; whereas those who have physical, emotional, or social impairments that limit their activities perceive themselves as ill.

Some frequently observed physiological changes in older adults are normal (Table 14-1). The changes are not always pathological

processes in themselves, but they make older adults more vulnerable to some common clinical conditions and diseases. Some older adults experience all of these changes, and others experience only a few. The body changes continuously with age; and specific effects on particular older adults depend on health, lifestyle, stressors, and environmental conditions. You need to understand these normal, more common changes to provide appropriate care for older adults and help with adaptation to associated changes.

General Survey. Your general survey begins during the initial nurse-patient encounter and includes a quick but careful head-to-toe scan of the older adult that you document in a brief description (see Chapter 31). An initial inspection reveals if eye contact and facial expression are appropriate to the situation and if universal aging changes (e.g., facial wrinkles, gray hair, loss of body mass in the extremities, an increase of body mass in the trunk) are present.

TABLE 14-1	Common Physiological Changes with Aging at a Glance
System	**Common Changes**
Integumentary	Loss of skin elasticity with fat loss in extremities; pigmentation changes; glandular atrophy (oil, moisture, sweat glands); thinning hair, with hair turning gray-white (facial hair: decreased in men, increased in women); slower nail growth; atrophy of epidermal arterioles
Respiratory	Decreased cough reflex; decreased cilia; increased anterior-posterior chest diameter; increased chest wall rigidity; fewer alveoli, increased airway resistance; increased risk of respiratory infections
Cardiovascular	Thickening of blood vessel walls, narrowing of vessel lumen, loss of vessel elasticity, lower cardiac output, decreased number of heart muscle fibers, decreased elasticity and calcification of heart valves, decreased baroreceptor sensitivity, decreased efficiency of venous valves, increased pulmonary vascular tension, increased systolic blood pressure, decreased peripheral circulation
Gastrointestinal	Periodontal disease; decrease in saliva, gastric secretions, and pancreatic enzymes; smooth-muscle changes with decreased peristalsis and small intestinal motility; gastric atrophy; decreased production of intrinsic factor; increased stomach pH; loss of smooth muscle in the stomach; hemorrhoids; rectal prolapse; and impaired rectal sensation.
Musculoskeletal	Decreased muscle mass and strength, decalcification of bones, degenerative joint changes, dehydration of intervertebral disks, fat tissue increases
Neurological	Degeneration of nerve cells, decrease in neurotransmitters, decrease in rate of conduction of impulses
Sensory	
Eyes	Decreased accommodation to near/far vision (presbyopia), difficulty adjusting to changes from light to dark, yellowing of the lens, altered color perception, increased sensitivity to glare, smaller pupils
Ears	Loss of acuity for high-frequency tones (presbycusis), thickening of tympanic membrane, sclerosis of inner ear, buildup of earwax (cerumen)
Taste	Often diminished; often fewer taste buds
Smell	Often diminished
Touch	Decreased skin receptors
Proprioception	Decreased awareness of body positioning in space
Genitourinary	Fewer nephrons, 50% decrease in renal blood flow by age 80, decreased bladder capacity Male—enlargement of prostate Female—reduced sphincter tone
Reproductive	Male—sperm count diminished, smaller testes, erections less firm and slow to develop Female—decreased estrogen production, degeneration of ovaries, atrophy of vagina, uterus, breasts
Endocrine	General—alterations in hormone production with decreased ability to respond to stress Thyroid—diminished secretions Cortisol, glucocorticoids—increased antiinflammatory hormone Pancreas—increased fibrosis, decreased secretion of enzymes and hormones, decreased sensitivity to insulin
Immune System	Thymus decreases in size and volume T-cell function decreases Core temperature elevation is lowered

Modified from Jett K: Physiological changes. In Touhy T, Jett K: *Ebersole and Hess' gerontological nursing and healthy aging,* ed 4, St Louis, 2014, Mosby.

Integumentary System. With aging the skin loses resilience and moisture. The epithelial layer thins, and elastic collagen fibers shrink and become rigid. Wrinkles of the face and neck reflect lifelong patterns of muscle activity and facial expressions, the pull of gravity on tissue, and diminished elasticity. Spots and lesions are often present on the skin. Smooth, brown, irregularly shaped spots (age spots or senile lentigo) initially appear on the backs of the hands and on forearms. Small, round, red or brown cherry angiomas occur on the trunk. Seborrheic lesions or keratoses appear as irregular, round or oval, brown, watery lesions. Years of sun exposure contribute to the aging of the skin and lead to premalignant and malignant lesions. You need to rule out these three malignancies related to sun exposure when examining skin lesions: melanoma, basal cell carcinoma, and squamous cell carcinoma (see Chapter 31).

Head and Neck. The facial features of an older adult sometimes become more pronounced from loss of subcutaneous fat and skin elasticity. Facial features appear asymmetrical because of missing teeth or improperly fitting dentures. In addition, common vocal changes include a rise in pitch and a loss of power and range.

Visual acuity declines with age. This is often the result of retinal damage, reduced pupil size, development of opacities in the lens, or loss of lens elasticity. Presbyopia, a progressive decline in the ability of the eyes to accommodate from near to far vision, is common. Ability to see in darkness and adapt to abrupt changes from dark to light areas (and the reverse) is reduced. More ambient light is necessary for tasks such as reading and other ADLs. Older adults have increased sensitivity to the effects of glare. Pupils are smaller and react slower. Objects do not appear bright, but older adults have difficulty when coming from bright to dark environments. Changes in color vision and discoloration of the lens make it difficult to distinguish between blues and greens and among pastel shades. Dark colors such as blue and black appear the same. Diseases of the older eye include cataract, macular degeneration, diabetic retinopathy, and retinal detachment. Cataracts, a loss of the transparency of the lens, are a prevalent disorder among older adults. They normally result in blurred vision, sensitivity to glare, and gradual loss of vision. Chapter 49 outlines nursing interventions for helping patients adapt to their visual changes.

Auditory changes are often subtle. Most of the time older adults ignore the early signs of hearing loss until friends and family members comment on compensatory attempts such as turning up the volume on televisions or avoiding social conversations. A common age-related change in auditory acuity is presbycusis. Presbycusis affects the ability to hear high-pitched sounds and conversational speech and is typically bilateral, affecting more men than women. Before the nurse assumes presbycusis, it is necessary to inspect the external auditory canal for the presence of cerumen. Impacted cerumen, a common cause of diminished hearing acuity, is easy to treat.

Salivary secretion is reduced, and taste buds atrophy and lose sensitivity. An older adult is less able to differentiate among salty, sweet, sour, and bitter tastes. The sense of smell also decreases, further reducing taste. Health conditions, treatments, and/or medications often alter taste. It is often a challenge to promote optimal nutrition in an older patient because of the loss of smell and changes in taste.

Thorax and Lungs. Because of changes in the musculoskeletal system, the configuration of the thorax sometimes changes. Respiratory muscle strength begins to decrease, and the anteroposterior diameter of the thorax increases. Vertebral changes caused by osteoporosis lead to dorsal kyphosis, the curvature of the thoracic spine. Calcification of the costal cartilage causes decreased mobility of the ribs. The chest wall gradually becomes stiffer. Lung expansion decreases, and the person is less able to cough deeply. If kyphosis or chronic obstructive lung disease is present, breath sounds become distant. With these changes an older adult is more susceptible to pneumonia and other bacterial or viral infections.

Heart and Vascular System. Decreased contractile strength of the myocardium results in decreased cardiac output. The decrease is significant when an older adult experiences anxiety, excitement, illness, or strenuous activity. The body tries to compensate for decreased cardiac output by increasing the heart rate during exercise. However, after exercise it takes longer for an older adult's rate to return to baseline. Systolic and/or diastolic blood pressures are sometimes abnormally high. Although a common chronic condition, hypertension is not a normal aging change and predisposes older adults to heart failure, stroke, renal failure, coronary heart disease, and peripheral vascular disease.

Peripheral pulses frequently are still palpable but weaker in lower extremities. Older adults sometimes complain that their lower extremities are cold, particularly at night. Changes in the peripheral pulses in the upper extremities are less common.

Breasts. As estrogen production diminishes, the milk ducts of the breasts are replaced by fat, making breast tissue less firm. Decreased muscle mass, tone, and elasticity result in smaller breasts in older women. In addition, the breasts sag. Atrophy of glandular tissue coupled with more fat deposits results in a slightly smaller, less dense, and less nodular breast. Gynecomastia, enlarged breasts in men, is often the result of medication side effects, hormonal changes, or obesity. Both older men and women are at risk of breast cancer.

Gastrointestinal System and Abdomen. Aging leads to an increase in the amount of fatty tissue in the trunk. As a result, the abdomen increases in size. Because muscle tone and elasticity decrease, it also becomes more protuberant. Gastrointestinal function changes include a slowing of peristalsis and alterations in secretions. An older adult experiences these changes by becoming less tolerant of certain foods and having discomfort from delayed gastric emptying. Alterations in the lower gastrointestinal tract lead to constipation, flatulence, or diarrhea.

Reproductive System. Changes in the structure and function of the reproductive system occur as the result of hormonal alterations. Women experience a reduced responsiveness of the ovaries to pituitary hormones and a resultant decrease in estrogen and progesterone levels. This can cause dryness of the vaginal mucosa, causing irritation and pain with intercourse, and may also cause a decreased libido. Aging men typically experience an erection that is less firm and shorter acting and have a less forceful ejaculation (Yeager, 2015).

Testosterone lessens with age and sometimes leads to a loss of libido. Spermatogenesis begins to decline during the fourth decade and continues into the ninth. However, for both men and women sexual desires, thoughts, and actions continue throughout all decades of life. Less frequent sexual activity often results from illness, death of a sexual partner, or decreased socialization.

Urinary System. Hypertrophy of the prostate gland is frequently seen in older men. This hypertrophy enlarges the gland and places pressure on the neck of the bladder. As a result, urinary retention, frequency, incontinence, and UTIs occur. In addition, prostatic hypertrophy results in difficulty initiating voiding and maintaining a urinary stream. Benign prostatic hypertrophy is different from cancer of the prostate. Cancer of the prostate is the second leading cause of cancer

death in American men, behind only lung cancer. In 2014 the American Cancer Society estimated that one in seven men will be diagnosed with prostate cancer and 1 in 38 will die (ACS, 2015).

Urinary incontinence is an abnormal and typically embarrassing condition. Some men are afraid to discuss incontinence with their health care providers because they think that it is a "woman's disease." Older women, particularly those who have had children, experience stress incontinence, an involuntary release of urine that occurs when they cough, laugh, sneeze, or lift an object. This is a result of a weakening of the perineal and bladder muscles. Other types of urinary incontinence are urgency, overflow, functional, and mixed incontinence. The risk factors for urinary incontinence include age, menopause, diabetes, hysterectomy, stroke, and obesity.

Musculoskeletal System. With aging, muscle fibers become smaller. Muscle strength diminishes in proportion to the decline in muscle mass. Beginning in the 30s, bone density and bone mass decline in men and women. Older adults who exercise regularly do not lose as much bone and muscle mass or muscle tone as those who are inactive. Osteoporosis is a major public health threat. Fifty-four million Americans have osteoporosis or low bone mass, and approximately one in two women and one in four men over the age of 50 will break a bone because of osteoporosis (National Osteoporosis Foundation, n.d.). Postmenopausal women experience a greater rate of bone demineralization than older men. Women who maintain calcium intake throughout life and into menopause have less bone demineralization than women with low calcium intake. Older men with poor nutrition and decreased mobility are also at risk for bone demineralization.

Neurological System. A decrease in the number and size of neurons in the nervous system begins in the middle of the second decade. Neurotransmitters, chemical substances that enhance or inhibit nerve impulse transmission, change with aging as a result of the decrease in neurons. All voluntary reflexes are slower, and individuals often have less of an ability to respond to multiple stimuli. In addition, older adults frequently report alterations in the quality and the quantity of sleep (see Chapter 43), including difficulty falling asleep, difficulty staying asleep, difficulty falling asleep again after waking during the night, waking too early in the morning, and excessive daytime napping. These problems are believed to be caused by age-related changes in the sleep-wake cycle.

Functional Changes

Physical function is a dynamic process. It changes as individuals interact with their environments. Functional status in older adults includes the day-to-day ADLs involving activities within physical, psychological, cognitive, and social domains. A decline in function is often linked to illness or disease and its degree of chronicity. However, ultimately it is the complex relationship among all of these areas that influences an older adult's functional abilities and overall well-being.

Keep in mind that it may be difficult for older adults to accept the changes that occur in all areas of their lives, which in turn have a profound effect on functional status. Some deny the changes and continue to expect the same personal performance, regardless of age. Conversely some overemphasize them and prematurely limit their activities and involvement in life. The fear of becoming dependent is overwhelming for an older adult who is experiencing functional decline as a result of aging. Educate older adults to promote understanding of age-related changes, appropriate lifestyle adjustments, and effective coping. Factors that promote the highest level of function include a healthy, well-balanced diet; paced and appropriate activity; regularly scheduled visits with a health care provider; regular participation in meaningful

activities; use of stress-management techniques; and avoidance of alcohol, tobacco, or illicit drugs.

Functional status in older adults refers to the capacity and safe performance of ADLs and instrumental ADLs (IADLs). It is a sensitive indicator of health or illness in the older adult. ADLs (such as bathing, dressing, and toileting) and IADLs (such as the ability to write a check, shop, prepare meals, or make phone calls) are essential to independent living; therefore carefully assess whether or not an older adult has changed the way he or she completes these tasks. Occupational and physical therapists are your best resources for a comprehensive assessment. A sudden change in function, as evidenced by a decline or change in an older adult's ability to perform any one or combination of ADLs, is often a sign of the onset of an acute illness (e.g., pneumonia, UTI, or electrolyte imbalance) or worsening of a chronic problem (e.g., diabetes or cardiovascular disease) (Kresevic, 2012).

Consult with other health care providers who work in a range of different settings and are experts in functional assessment. Several standardized functional assessment tools are widely available. An online collection of the tools used most commonly with older adults is available at the geriatric nursing website of the Hartford Institute for Geriatric Nursing, www.ConsultGeriRN.org.

When you identify a decline in a patient's function, focus your nursing interventions on maintaining, restoring, and maximizing an older adult's functional status to maintain independence while preserving dignity.

Cognitive Changes

A common misconception about aging is that cognitive impairments are widespread among older adults. Because of this misconception, older adults often fear that they are, or soon will be, cognitively impaired. Younger adults often assume that older adults will become confused and no longer able to handle their affairs. Forgetfulness as an expected consequence of aging is a myth. Some structural and physiological changes within the brain are associated with cognitive impairment. Reduction in the number of brain cells, deposition of lipofuscin and amyloid in cells, and changes in neurotransmitter levels occur in older adults both with and without cognitive impairment. Symptoms of cognitive impairment such as disorientation, loss of language skills, loss of the ability to calculate, and poor judgment *are not* normal aging changes and require you to further assess patients for underlying causes. There are standard assessment forms for determining a patient's mental status, including the Mini-Mental State Exam-2 (MMSE-2), the Mini-Cog, and the Clock Drawing Test (Jett, 2014).

The three common conditions affecting cognition are **delirium**, **dementia**, and **depression** (Table 14-2). Distinguishing among these three conditions is challenging. Complete a careful and thorough assessment of older adults with cognitive changes to distinguish among them. Select appropriate nursing interventions that are specific to the cause of the cognitive impairment.

Delirium. Delirium, or acute confusional state, is a potentially reversible cognitive impairment that often has a physiological cause. Physiological causes include electrolyte imbalances, untreated pain, infection, cerebral anoxia, hypoglycemia, medication effects, tumors, subdural hematomas, and cerebrovascular infarction or hemorrhage. Delirium in older adults sometimes accompanies systemic infections and is often the presenting symptom for pneumonia or UTI. Sometimes it is also caused by environmental factors such as sensory deprivation or overstimulation, unfamiliar surroundings, or sleep deprivation or psychosocial factors such as emotional distress. Although it occurs in any setting, an older adult in the acute care setting is especially at risk because of predisposing factors (physiological, psychosocial, and

TABLE 14-2 **Comparison of Clinical Features of Delirium, Dementia, and Depression**

Clinical Feature	Delirium	Dementia	Depression
Onset	Sudden/abrupt; depends on cause	Insidious/slow and often unrecognized	Happens with major life changes; often abrupt but can be gradual
Course	Short, daily fluctuations in symptoms; worse at night, in darkness, and on awakening	Long, no diurnal effects; symptoms progressive yet relatively stable over time; some deficits with increased stress	Diurnal effects, typically worse in the morning; situational fluctuations but less than with delirium
Progression	Abrupt	Slow over months and years	Variable; rapid or slow but even
Duration	Hours to less than 1 month; longer if unrecognized and untreated	Months to years	At least 6 weeks; sometimes several months to years
Consciousness	Reduced/disturbed	Awake	Awake
Alertness	Fluctuates; lethargic or hypervigilant	Generally normal	Normal
Attention	Impaired; fluctuates; inattention; distractible	Generally normal	Minimal impairment but is easily distracted
Orientation	Generally impaired; severity varies	Generally normal to person but not to place or time	Selective disorientation
Memory	Recently and immediately impaired; forgetful; unable to recall or follow directions	Recent memory worsens first in disease process, and remote memory becomes progressively impaired	Selective or "patchy" impairment; "islands" of intact memory; evaluation often difficult because of low motivation
Thinking	Disorganized, distorted, fragmented, illogical; incoherent speech, either slow or accelerated	Difficulty with abstraction; thoughts diminished; judgment impaired; words difficult to find	Intact but with themes of hopelessness, helplessness, or self-deprecation
Perception	Distorted perceptions often accompanied by delusions and hallucinations; difficulty distinguishing between reality and misperceptions	Misperceptions usually absent	Intact; delusions and hallucinations absent except in severe cases
Psychomotor behavior	Variable; hypoactive, hyperactive, or mixed	Normal; some have apraxia	Variable; psychomotor retardation or agitation
Sleep/wake cycle	Disturbed; cycle reversed	Fragmented	Disturbed; usually early morning awakening
Associated features	Variable affective changes; symptoms of autonomic hyperarousal; exaggeration of personality type; associated with acute physical illness	Affect tends to be superficial, inappropriate, and labile (changing); attempts to hide deficits in intellect; personality changes, aphasia, agnosia sometimes present; lacks insight and has poor judgment	Affect depressed; dysphoric mood; exaggerated and detailed complaints; preoccupied with personal thoughts; insight present; verbal elaboration; somatic complaints; poor hygiene; neglect of self
Assessment	Distracted from task; makes numerous errors	Failings highlighted by family, frequent "near-miss" answers; struggles with test; great effort to find an appropriate reply; frequent requests for feedback on performance	Failings highlighted by individual, frequent "don't knows"; poor motivation, frequently gives up; indifferent toward test; does not care or attempt to find answer

Modified from Milisen K et al: Assessing cognitive function. In Boltz M et al: *Evidence-based geriatric nursing protocols for best practice,* ed 4, New York, 2012, Springer.

environmental) in combination with underlying medical conditions. Dementia is an additional risk factor that greatly increases the risk for delirium; it is possible for delirium and dementia to occur in a patient at the same time. The presence of delirium is a medical emergency and requires prompt assessment and intervention. Nurses are at the bedside 24/7 and in a position to recognize delirium development and report it. The cognitive impairment usually reverses once health care providers identify and treat the cause of delirium.

Dementia. Dementia is a generalized impairment of intellectual functioning that interferes with social and occupational functioning. It is an umbrella term that includes Alzheimer's disease, Lewy body disease, frontal-temporal dementia, and vascular dementia. Cognitive function deterioration leads to a decline in the ability to perform basic ADLs and IADLs. Unlike delirium, a gradual, progressive, irreversible cerebral dysfunction characterizes dementia. Because of the similarity between delirium and dementia, you need to assess carefully to rule out the presence of delirium whenever you suspect dementia.

Nursing management of older adults with any form of dementia always considers the safety and physical and psychosocial needs of the older adult and the family. These needs change as the progressive nature of dementia leads to increased cognitive deterioration. To meet the needs of older adults, individualize nursing care to enhance quality of life and maximize functional performance by improving cognition, mood, and behavior. Box 14-4 lists general nursing principles for care of older adults with cognitive changes. Support and education about Alzheimer's disease for patients, families, and professionals can be found at the Alzheimer's Association website (www.alz.org).

BOX 14-4 Principles for Nursing Care of Adults Who Are Cognitively Impaired

- Provide a comprehensive assessment to differentiate between a progressive or reversible etiology.
- Institute medical measures to correct underlying physiological alterations (e.g., infection, electrolyte imbalances, pain).
- Maximize safe function. Keep a routine, encourage activity and mobility, limit choices (e.g., clothes for dressing, what to eat), allow for rest.
- Provide unconditional positive regard. Be respectful and provide positive nonverbal communication.
- Use behaviors to gauge activity and stimulation. Watch for nonverbal signs of anxiety.
- Teach caregivers to listen to the behaviors that show stress (e.g., verbalizations such as repetition).
- Make sure that the environment is safe for mobility and promote wayfinding with pictures or cues. Try to identify patients who wander and remove the cause (e.g., pain, thirst, unfamiliar surroundings, new noises).
- Promote social interaction on the basis of abilities.
- Compensate for sensory deficits (e.g., hearing aids, glasses, dentures).
- Encourage fluid intake (make sure that fluids are accessible) and avoid long periods of giving nothing orally.
- Be vigilant for drug reactions or interactions; consider onset of new symptoms as an adverse reaction.
- Activate bed and chair alarms.
- Provide ongoing assistance to family caregivers; educate them in nursing care techniques and inform them about community resources.

Modified from Fletcher K: Dementia. In Capezuti et al: *Evidence-based geriatric nursing protocols for best practice,* ed 4, New York, 2012, Springer.

Depression. Older adults sometimes experience late-life depression, but it is not a normal part of aging. Depression is the most common, yet most undetected and untreated, impairment in older adulthood. It sometimes exists and is exacerbated in patients with other health problems such as stroke, diabetes, dementia, Parkinson's disease, heart disease, cancer, and pain-provoking diseases such as arthritis. Loss of a significant loved one or admission to a nursing center sometimes causes depression. Clinical depression is treatable. Treatment includes medication, psychotherapy, or a combination of both. Electroconvulsant therapy (ECT) is sometimes used for treatment of resistant depression when medications and psychotherapy do not help. Of special note, suicide attempts in older adults are often successful. In fact, white men age 85 and older have the highest suicide rate in the United States (National Institute of Mental Health, n.d.).

Psychosocial Changes

The psychosocial changes occurring during aging involve life transitions and loss. The longer people live, the more transitions and losses they experience. Life transitions, of which loss is a major component, include retirement and the associated financial changes, changes in roles and relationships, alterations in health and functional ability, changes in one's social network, and relocation. But the universal loss for older adults usually revolves around the loss of relationships through death.

It is important to assess both the nature of the psychosocial changes that occur in older adults as a result of life transitions and the loss and the adaptations to the changes. During your assessment ask how an older adult feels about self, self in relation to others, and self as one who is aging and which coping methods and skills have been beneficial. Areas to address during the assessment include family, intimate relationships, past and present role changes, finances, housing, social networks, activities, health and wellness, and spirituality. Specific topics related to these areas include retirement, social isolation, sexuality, housing and environment, and death.

Retirement. Many often mistakenly associate retirement with passivity and seclusion. In actuality it is a stage of life characterized by transitions and role changes and may occupy 30 or more years of one's life. This transition requires letting go of certain habits and structure and developing new ones (Touhy, 2012). The psychosocial stresses of retirement are usually related to role changes with a spouse or within the family and to loss of the work role. Sometimes problems related to social isolation and finances are present. The age of retirement varies; but, whether it occurs at age 55, 65, or 75, it is one of the major turning points in life.

Preretirement planning is an important advisable task. People who plan in advance for retirement generally have a smoother transition. Preretirement planning is more than financial planning. Planning begins with consideration of the "style" of retirement desired and includes an inventory of interests, current skills, and general health. Meaningful retirement planning is critical as the population continues to age.

Retirement affects more than just the retired. It affects the spouse, adult children, and even grandchildren. When the spouse is still working, the retired person faces time alone. There may be new expectations of the retired person. For example, a working spouse has new ideas about the amount of housework expected of the retired person. Problems develop when the plans of the retired person conflict with the work responsibilities of the working spouse. The roles of the retiree and the working spouse need clarification. Some adult children expect the retired person to always care for the grandchildren, forgetting that this is a time for the retired person to pursue other personal interests.

Loss of the work role has a major effect on some retired people. When so much of life has revolved around work and the personal relationships at work, the loss of the work role is sometimes devastating. Personal identity is often rooted in the work role, and with retirement individuals need to construct a new identity. They also lose the structure imposed on daily life when they no longer have a work schedule. The social exchanges and interpersonal support that occur in the workplace are lost. In the adjustment to retirement an older adult has to develop a personally meaningful schedule and a supportive social network.

Factors that influence a retired person's satisfaction with life are health status and sufficient income. Positive preretirement expectations also contribute to satisfaction in retirement. You can help the older adult and family prepare for retirement by discussing with them several key areas, including relations with spouse and children; meaningful activities and interests; building social networks; issues related to income; health promotion and maintenance; and long-range planning, including wills and advance directives.

Social Isolation. Many older adults experience social isolation. Isolation is sometimes a choice, the result of a desire not to interact with others. It is also a response to conditions that inhibit the ability or the opportunity to interact such as the lack of access to transportation. Although some older adults choose isolation or a lifelong pattern of reduced interaction with others, older adults who experience social isolation become vulnerable to its consequences. An older adult's vulnerability increases in the absence of the support of other adults, as occurs with loss of the work role or relocation to unfamiliar surroundings. Impaired sensory function, reduced mobility, and cognitive

changes all contribute to reduced interaction with others and often place an older adult at risk for isolation.

You assess patients' potential for social isolation by identifying their social network, access to transportation, and willingness and desire to interact with others. Use your findings to help a lonely older adult rebuild social networks and reverse patterns of isolation. Many communities have outreach programs designed to make contact with isolated older adults such as Meals on Wheels, which provides nutritional meals. Outreach programs such as daily telephone calls by volunteers or needs for activities such as social outings also meet socialization needs. Social service agencies in most communities welcome older adults as volunteers and provide the opportunity for them to serve while meeting their socialization or other needs. Churches, colleges, community centers, and libraries offer a variety of programs for older adults that increase the opportunity to meet people with similar activities, interests, and needs.

Sexuality. All older adults, whether healthy or frail, need to express their sexual feelings. Sexuality involves love, warmth, sharing, and touching, not just the act of intercourse. It plays an important role in helping the older adult maintain self-esteem. To help an older adult achieve or maintain sexual health, you need to understand the physical changes in a person's sexual response (see Chapter 35). You need to provide privacy for any discussion of sexuality and maintain a non-judgmental attitude. Open-ended questions inviting an older adult to explain sexual activities or concerns elicit more information than a list of closed-ended questions about specific activities or symptoms. Include information about the prevention of sexually transmitted infections when appropriate. Sexuality and the need to express sexual feelings remain throughout the human life span.

When considering an older adult's need for sexual expression, do not ignore the important need to touch and be touched. Touch is an overt expression with many meanings and is an important part of intimacy (Yeager, 2015). Touch complements traditional sexual methods or serves as an alternative sexual expression when physical intercourse is not desired or possible. Knowing an older adult's sexual needs allows you to incorporate this information into the nursing care plan. The sexual preferences of older adults are as diverse as those of the younger population. Clearly not all older adults are heterosexual; and research is emerging on older adult, lesbian, gay, bisexual, and transgender individuals and their health care needs. Nurses often find that they are called on to help other health care professionals understand the sexual needs of older adults and advise them. Not all nurses feel comfortable counseling older adults about sexual health and intimacy-related needs. Be prepared to refer older adults to an appropriate professional counselor.

Housing and Environment. The extent of older adults' ability to live independently influences housing choices. Changes in social roles, family responsibilities, and health status influence their living arrangements. Some choose to live with family members. Others prefer their own homes or other housing options near their families. Leisure or retirement communities provide older people with living and social opportunities in a one-generation setting. Federally subsidized housing, where available, offers apartments with communal, social, and in some cases food-service arrangements.

The goal of your assessment of a patient's environment is to consider resources that promote independence and functional ability. When helping older adults with housing needs, assess their activity level, financial status, access to public transportation and community activities, environmental hazards, and support systems. When helping patients consider housing choices, anticipate their future needs as much as possible. For example, a housing unit with only one floor and without exterior steps is a prudent choice for an older adult with severe arthritis who has already had lower-extremity joint replacement surgery and anticipates the need for future operations. Assessment of safety, a major component of an older adult's environment, includes risks within the environment and the older adult's ability to recognize and respond to the risks (see Chapter 27). Safety risks in the home include factors leading to injury such as water heaters set at excessively hot temperatures or environmental barriers such as throw rugs or slippery floor surfaces that contribute to falls. Assess if a person has a pet that could easily move around the person's feet to cause a fall. Assess lighting in the home. Is the light bright enough to see walkways and stairs, and is there a lit path to the bathroom at night? Assess the safety of the home and environment with a family caregiver present if possible (Touhy, 2014).

Housing and environment affect the health of older adults. The environment supports or hinders physical and social functioning, enhances or drains energy, and complements or taxes existing physical changes such as vision and hearing. For example, furnishings with red, orange, and yellow colors are easiest for older adults to see. Shiny waxed floors may appear to be wet or have a hole in them. Ensure that door frames and baseboards are an appropriate color that contrasts with the color of the wall to improve perception of the boundaries of halls and rooms, keeping in mind that older adults often have difficulty distinguishing among pastel shades and between green and blue. Walkways leading to the house need to be flat and even, and stairs need to have a color contrast at the edge of the step so an older person knows where the stair ends. Glare from highly polished floors, metallic fixtures, and a window is difficult for an older adult to tolerate.

Furniture needs to be comfortable and safe. Older adults need to examine furniture carefully for size, comfort, and function before purchasing it. They need to be able to easily get into and out of the furniture, and it needs to provide adequate back support. Test dining room chairs for comfort during meals and for height in relation to the table. Many older adults find that chairs with armrests make it easier while getting into and out of the chair. Older adults often prefer transferring out of a wheelchair to another chair for meals because some styles of wheelchairs do not allow a person to sit close enough to the table to eat comfortably. Raising the table to clear the wheelchair arms brings the table closer to the older adult but makes it too high to eat comfortably. To make getting out of bed easier and safer, ensure that the height of the bed allows an older adult's feet to be flat on the floor when he or she is sitting on the side of the bed.

QSEN **QSEN: BUILDING COMPETENCY IN SAFETY** Mr. Sousa is an energetic 76-year-old man who is ready for discharge from the hospital. He does not "look" 76 as he appears very fit and states that he is active in social activities and volunteering. He was admitted to the hospital 3 days ago for a right total knee replacement and is doing well after surgery; he now walks with the assistance of one person and is using a walker. He is able to walk to the bathroom and has walked 125 feet in the hallway 3 times today. He will get home health care and home physical therapy rather than going to the hospital rehabilitation unit. He insists on going home because of his dog, Benji, a black Labrador retriever. Mr. Sousa's daughter is going to pick up Benji from the boarding kennel and take him home. Mr. Sousa's wife of 50 years died recently, leaving him alone at home, but he has been getting along well. His daughter lives within 25 miles of his home and will visit him daily. When considering safety for this patient in the home setting, which assessment questions and teaching approaches and resources can you use to enhance his safety in the home environment?

ⓔ Answers to QSEN Activities can be found on the Evolve website.

Death. Part of one's life history is the experience of loss through the death of relatives and friends (see Chapter 37). This includes the loss of the older generations of families and sometimes, sadly, the loss of a child. However, death of a spouse or significant other is the loss that most affects the lives of older people. The death of a spouse affects older women more than men, a trend that will probably continue in the future. In spite of these experiences, do not assume that an older adult is comfortable with death. You play a key role in helping older adults understand the meaning of and cope with loss.

Current evidence supports that older people have a wide variety of attitudes and beliefs about death but fear of their own death is uncommon. Rather they are concerned with fear of being a burden, experiencing suffering, being alone, and the use of life-prolonging measures (Morgan and Upadhyaya, 2015). The stereotype that the death of an older adult is a blessing does not apply to every older adult. Even as death approaches, many older adults still have unfinished business and are not prepared for it. Families and friends are not always ready to let go of their older significant others. Older adults and family members or friends will often turn to you for assistance. Thus you need knowledge of the grieving process (see Chapter 37); excellent communication skills (see Chapter 24); understanding of legal issues and advance care planning (see Chapter 23); familiarity with community resources; and awareness of one's own feelings, limitations, and strengths as they relate to care of those confronting death.

Learning Needs

The complexities associated with managing chronic disease and the cognitive and sensory changes that may be associated with aging add to the challenges of teaching older adults. As you assess the various physical, cognitive, functional and psychosocial problems of older adults, it is important to also assess their associated learning needs. For example, during a cognitive and psychosocial assessment, you will learn information that indicates a patient's ability to follow a recommended treatment plan. When assessing a patient's medication history, have the patient describe when he or she takes the medication at home and what is the dosage. If a patient has slow responses or reaction time when performing physical activities, it will be necessary to consider these limitations when teaching new psychomotor skills. Older adults learn new information at a slower rate than younger adults due to a decline in fluid intelligence, which is defined as the reasoning and processing components of learning (Speros, 2009). In addition, an older adult has difficulty processing multiple bits of information at one moment. During your assessment, carefully consider a patient's learning needs and capability to learn.

ADDRESSING THE HEALTH CONCERNS OF OLDER ADULTS

As the population ages and life expectancy increases, emphasis on health promotion and disease prevention increases (see Chapter 6). The number of older adults becoming enthusiastic and motivated about these aspects of health is increasing. A number of national programs and projects address preventive practices in the older-adult population. The national initiative *Healthy People 2020* (Office of Disease Prevention and Health Promotion, 2015) has a number of major goals affecting the older adult population, including the following:

- Increase the number of older adults with one or more chronic conditions who report confidence in maintaining their conditions.
- Reduce the proportion of older adults who have moderate-to-severe functional limitations.

- Increase the proportion of older adults with reduced physical or cognitive function who engage in light, moderate, or vigorous leisure-term physical activities.
- Increase the proportion of older adults who receive diabetes self-management benefits.
- Increase the proportion of the health care workforce with geriatric certification.

The challenges of health promotion and disease prevention for older adults are complex and affect health care providers as well. Previous health care experiences, personal motivation, health beliefs, culture, health literacy, and non–health-related factors such as transportation and finances often create barriers for older adults. Barriers for health care providers include beliefs and attitudes about which services and programs to provide, their effectiveness and the lack of consistent guidelines, and absence of a coordinated approach. Your role is to focus interventions on maintaining and promoting patients' function and quality of life. You can empower older adults to make their own health care decisions and realize their optimum level of health, function, and quality of life (Meiner and Benzel-Lindley, 2015). Always be open to recognizing an older adult's concerns so you can adjust a plan of care accordingly. Although various interventions cross all three levels of care (i.e., health promotion, acute care, and restorative care), some approaches are unique to each level.

Educating Older Adults

Inadequate health literacy disproportionately affects older adults in the United States, causing misunderstanding of health information and subsequent nonadherence (Speros, 2009). The World Health Organization (2015) defines health literacy as the cognitive and social skills that determine the motivation and ability of individuals to gain access to, understand, and use information in ways that promote and maintain good health. To enhance comprehension and bring about positive health behavior changes, a nurse must use *more than words* when teaching older adults (Speros, 2009). Instead a nurse must know how to adapt routine patient education strategies to effectively meet the specific learning needs of elderly patients. Consider the need for learning new medications. Retrieving prescriptions and referrals, selecting providers from a list of names and addresses, calculating when to take multiple medications, interpreting medical terminology, comparing different insurance plans, and sifting through the myriad of health-related information available in magazines, on the Internet, and on television are just a few of the complex thought processes involved in selecting, understanding, and using health-related information about medications (Speros, 2009).

Box 14-5 summarizes teaching strategies to use for promoting an older adult's learning.

Health Promotion and Maintenance: Physiological Concerns

The desire of older adults to participate in health promotion activities varies. Therefore use an individualized approach, taking into account a person's beliefs about the importance of staying healthy and remaining independent. The Federal Interagency Forum on Aging-Related Statistics (2012) reported that 36% of older people 65 years and older reported a functional limitation (i.e., difficulty in hearing, vision, cognition, ambulation, self-care, or independent living), with older women reporting higher levels of functional limitations than men. Some of these disabilities are relatively minor, but others cause people to require assistance to meet important personal needs. The incidence of disability increases with age. Limitations in ADLs limit the ability to live independently. The ADL limitations most often reported include

Adapting Instruction for Older Adults with Health Literacy Limitations

Objectives
- Patient will verbalize understanding of instructional content using Teach Back.
- Patient will demonstrate psychomotor skills.

Teaching Strategies
- Schedule teaching sessions in midmorning, when energy levels are high. Several brief teaching sessions on different days are more appropriate than one lengthy session that might fatigue the patient.
- Minimize use of medical terminology and replace with lay terms when possible.
- Allow additional time for the older adult to process new information by pausing after presenting each new concept or bit of information.
- Link new knowledge or skills to clearly identifiable past experiences. Reminiscing and storytelling help the older adult reconnect with lived experiences and serve as a valuable strategy to facilitate learning (e.g., explaining the use of an assist device and reviewing what occurred when a spouse had to a learn similar skill).
- Keep the content practical and relevant to the older adult's daily activities, social structure, and physical function. Emphasize safety and maintaining independence.
- Help the older adult focus during each interaction by minimizing distractions, limiting the message to a few (five or fewer) essential key points, and avoiding extraneous information.
- Speak slowly, but not so slowly that the patient becomes distracted or bored. Face the patient when speaking, and sit at the same level as the patient.
- Encourage the older adult to invite a family member or trusted friend to attend and actively participate in each teaching session.

Evaluation
- Validate understanding by using the Teach Back technique before moving on.
- Be sure the patient is able to demonstrate and do psychomotor skills independently.

Modified from Speros CI: More than words: promoting health literacy in older adults. *Online J Issue Nurs* 14(3):Manuscript 5, Sept 30, 2009; and Touhy T: Social, psychological, spiritual, and cognitive aspects of aging. In Touhy T, Jett K: *Ebersole and Hess' gerontological nursing and healthy aging*, ed 4, St Louis, 2014, Mosby.

FIGURE 14-1 This older adult works part time at a sporting goods store.

- Regular dental visits
- Smoking cessation
- Stress management
- Socialization
- Good handwashing
- Regular check-ups with health care providers
- Immunization for seasonal influenza, tetanus, diphtheria and pertussis, shingles, and pneumococcal disease

Those who die from influenza are predominately older adults. Providers strongly recommend annual immunization of all older adults for influenza, with special emphasis on residents of nursing homes or residential or long-term care facilities. Not all older adults are current with their booster injections, and some never received the primary series of injections. Ask them about the current status of all immunizations, provide information about the immunizations, and make arrangements for them to receive immunizations as needed.

Most older adults are interested in their health and are capable of taking charge of their lives. They want to remain independent and prevent disability (Figure 14-1). Initial screenings establish baseline data that you use to determine wellness, identify health needs, and design health maintenance programs. Following initial screening sessions, share with older adults information on nutrition, exercise, medications, and safety precautions. You can also provide information on specific conditions such as hypertension, arthritis, or self-care procedures such as foot and skin care. By providing information about health promotion and self-care, you significantly improve the health and well-being of older adults.

Heart Disease. Heart disease is the leading cause of death in older adults, followed by cancer, chronic lung disease, and stroke (Murphy et al., 2013). Common cardiovascular disorders are hypertension and coronary artery disease. Hypertension is a silent killer because older adults are often unaware that their pressure is elevated (see Chapter 30). The fact that hypertension is common does not make it normal or harmless. Although one in three of Americans have elevated blood pressure, only one half of those have the condition under control. Treatment is linked to reduced incidence of myocardial infarction, chronic kidney disease, stroke, and heart failure. In coronary artery disease, partial or complete blockage of one or more coronary arteries leads to myocardial ischemia and myocardial infarction. The risk factors for both hypertension and coronary artery disease include smoking, obesity, lack of exercise, and stress. Additional risk factors for coronary artery disease include hypertension, hyperlipidemia, and diabetes mellitus. Nursing interventions for hypertension and coronary

walking, showering and bathing, getting in and out of bed and chair, dressing, toileting, and eating. There is a strong relationship between disability status and reported health status. The effect of chronic conditions on the lives of older adults varies widely, but in general chronic conditions further diminish well-being and a sense of independence. Direct nursing interventions at managing these conditions and educating family caregivers in ways to give appropriate support. You also need to focus interventions on prevention. General preventive measures to recommend to older adults include:
- Participation in screening activities (e.g., blood pressure, mammography, Papanicolaou [Pap] smears, depression, vision and hearing, colonoscopy)
- Regular exercise
- Weight reduction if overweight
- Eating a low-fat, well-balanced diet
- Moderate alcohol use

artery disease address weight reduction, exercise, dietary changes, limiting salt and fat intake, stress management, and smoking cessation. Patient teaching also includes information about medication management, blood-pressure monitoring, and the symptoms indicating the need for emergency care.

Cancer. Malignant neoplasms are the second most common cause of death among older adults. Nurses educate older adults about early detection, treatment, and cancer risk factors. Examples include smoking cessation, teaching breast self-examination (see Chapter 31), and encouraging all older adults to have annual screening for fecal occult blood with a rectal examination. It is also important to educate older adults about the signs of cancer and encourage prompt reporting of nonhealing skin lesions, unexpected bleeding, change in bowel habits, nagging cough, lump in breast or another part of body, change in a mole, difficulty swallowing, and unexplained weight loss. Cancer is difficult to detect because providers often mistake symptoms as part of the normal aging process or signs of a person's chronic disease. You need to carefully distinguish between signs of normal aging and signs of pathological conditions.

Chronic Lung Disease. Chronic lung disease, specifically chronic obstructive pulmonary disease (COPD) is the third leading cause of death in those 65 and older. More women than men die from COPD (American Lung Association, 2014). Lung injury from tobacco smoke leads to the development of COPD, causing airflow blockage and breathing-related difficulty. Tobacco smoke is a key factor in the development and progression of COPD. It is important to provide patients with information about quit smoking programs. In addition, depending on the severity of a patient's disease, you will teach a patient about proper exercise, how to use inhalers, and techniques for the removal of mucus from the airways (see Chapter 41). Exercise training is a major component of pulmonary rehabilitation programs today and is an established safe and effective intervention for improving patients' physical capacity and quality of life (American College of Sports Medicine, n.d.).

Stroke (Cerebrovascular Accident). Cerebrovascular accidents (CVAs) are the fourth leading cause of death in the United States and occur as brain ischemia (inadequate blood supply to areas of brain caused by arterial blockage) or brain hemorrhage (subarachnoid or intercerebral bleeds). Risk factors include hypertension, hyperlipidemia, diabetes mellitus, history of transient ischemic attacks, and family history of cardiovascular disease. CVAs often impair a person's functional abilities and lead to loss of independence and nursing home admission. The scope of nursing interventions ranges from teaching older adults about risk-reduction strategies to teaching family caregivers the early warning signs of a stroke and ways to support a patient during recovery and rehabilitation.

Smoking. Cigarette smoking is a risk factor for the four most common causes of death: heart disease, cancer, lung disease, and stroke. Smoking is the most preventable cause of disease and death in the United States. Smoking cessation is a health promotion strategy for older adults just as it is for younger adults. Older smokers still benefit from smoking cessation. In addition to reducing risk, it sometimes stabilizes existing conditions such as COPD and coronary artery disease. Smoking cessation after age 50 reduces the risk of dying prematurely by 50% compared with those who continue to smoke (NCI, 2014). Smoking cessation programs include individual, group, and telephone counseling and the use of nicotine (gum and patch) or non-nicotine medications. If a patient rejects smoking cessation, suggest at

least a reduction in smoking. Finally set a quit or reduction date and a follow-up visit with the older adult to discuss the quit attempt. At follow-up visits, offer encouragement and assistance in modifying the plan as necessary.

Alcohol Abuse. Alcoholism is sometimes found in older adults. Studies of alcohol abuse in older adults report two patterns: a lifelong pattern of continuous heavy drinking and a pattern of heavy drinking that begins late in life. Frequently cited causes of excessive alcohol use include depression, loneliness, and lack of social support.

Alcohol abuse is often under-identified in older adults. The clues to creating suspicion of alcohol abuse are subtle; coexisting dementia or depression sometimes complicates your assessment. Your suspicion of alcohol abuse increases when there is a history of repeated falls and accidents, social isolation, recurring episodes of memory loss and confusion, failure to meet home and work obligations, a history of skipping meals or medications, and difficulty managing household tasks and finances. When you suspect that an older adult is abusing alcohol, realize that a variety of treatment needs are available. Treatment includes age-specific approaches that acknowledge the stresses experienced by an older adult and encourage involvement in activities that match his or her interests and increase feelings of self-worth. Identifying and treating coexisting depression is also important. The continuum of interventions ranges from simple education about risks to formalized treatment programs that include pharmacotherapy, psychotherapy, and rehabilitation.

Nutrition. Lifelong eating habits and situational factors influence how older adults meet their needs for good nutrition. Lifelong eating habits based in tradition, cultural habits and preferences, and religion influence food choices and how people prepare their food. Situational factors affecting nutrition include access to grocery stores, finances, physical and cognitive capability for food preparation, and a place to store food and prepare meals. Older adults' levels of activity and clinical conditions affect their nutritional needs. Level of activity has implications for the total amount of required calories. Older adults who are sedentary usually need fewer calories than those who are more active. However, activity alone does not determine caloric requirements. Patients often need additional calories in clinical situations such as recovery from surgery, whereas fewer calories are necessary when an older adult has diabetes or is overweight. Always consult with a clinical dietitian when planning nutritional interventions for your patients.

Healthy nutrition for older adults includes appropriate caloric intake and limited intake of fat, salt, refined sugars, and alcohol. Protein intake is sometimes lower than recommended if older adults have reduced financial resources or limited access to grocery stores. Difficulty chewing meat because of poor dentition or poor-fitting dentures also limits protein intake. Fat and sodium intake is sometimes higher than usual because of quick and convenient frozen meals or the substitution of fast-food restaurant meals for meals prepared at home. Home-prepared meals that are fried or made with canned goods also are high in fat and sodium. Some use extra salt and sugar while cooking or at the table to compensate for a diminished sense of taste. Older adults with dementia have special nutritional needs. As their memory and functional skills decline with the progression of dementia, they lose the ability to remember when to eat, how to prepare food, and how to feed themselves. Caloric needs sometimes increase because of the energy expended in pacing and wandering activities. When caring for older adults with dementia, routinely monitor weight and food intake, serve food that is easy to eat such as finger foods (e.g., chicken strips, sandwiches, cut-up vegetables, and fruit), provide assistance with eating, and offer food supplements that the patient likes and are

easy to swallow. Home-delivered meals are an excellent source of nutrition for older adults.

Dental Problems. Dental problems with natural teeth and dentures are common in older adults. Dental caries, gingivitis, broken or missing teeth, and ill-fitting or missing dentures affect nutritional adequacy, cause pain, and lead to infection. Dentures are a frequent problem because the cost is not covered by Medicare and dentures tend to be quite expensive. Help prevent dental and gum disease through education about routine dental care (see Chapter 40).

Exercise. Encourage older adults to maintain physical exercise and activity. The primary benefits of exercise include maintaining and strengthening functional ability and promoting a sense of enhanced well-being. Regular daily exercise such as walking builds endurance, increases muscle tone, improves joint flexibility, strengthens bones, reduces stress, and contributes to weight loss. Other benefits include improvement of cardiovascular function, improved plasma lipoprotein profiles, increased metabolic rate, increased gastrointestinal transit time, prevention of depressive illness, and improved sleep quality. Older adults who participate in group exercise programs, individually tailored balance and strength programs, or planned walking programs often experience improved mobility, gait, and balance, resulting in fewer falls (CDC, 2015a).

Consult with physical therapists and a patient's health care provider to plan an exercise program that meets physical needs and is one the patient enjoys. Consider a patient's physical limitations and encourage him or her to stick with the exercise program. Many factors influence an individual's willingness to participate in an exercise program. These include general beliefs about benefits of exercise, past experiences with exercise, personal goals, personality, and any unpleasant sensations associated with exercise.

Walking is the preferred exercise of many older adults (Figure 14-2). Walking and other low-impact exercises such as riding a stationary exercise bicycle or water exercises in a swimming pool protect the musculoskeletal system and joints. Include other exercises in the older adult's ADLs. For example, have an older adult perform arm and leg circles while watching television. Before beginning an exercise program, all older adults need to have a physical examination. Exercise programs for sedentary older adults who have not been exercising regularly need

to begin conservatively and progress slowly. Safety considerations include wearing good support shoes and appropriate clothing, drinking water before and after exercising, avoiding outdoor exercise when the weather is very warm or very cold, and exercising with a partner. Instruct older adults to stop exercising and seek help if they experience chest pain or tightness, shortness of breath, dizziness or light-headedness, joint pain, or palpitations during exercise.

Falls. Falls are a safety concern of many older adults. A large research study of over 12,000 people over the age of 65 living in the community found that approximately 23% fell, yet less than half discussed it with their health care provider (Stevens et al., 2012). Fall-related injuries are often associated with a patient's preexisting medical conditions such as osteoporosis and bleeding tendencies. Hospitalization and placement in a nursing center for rehabilitation or long-term placement is sometimes necessary after a fall. In 2013 2.5 million nonfatal falls among older adults were treated in emergency departments, and more than 734,000 of these patients were hospitalized. The direct medical costs of those falls adjusted for inflation was $34 billion (CDC, 2015b). The most common injuries in older adults include fractures of the spine, hip, forearm, leg, ankle, pelvis, upper arm, and hand. Older adults who have fallen will often develop a fear of falling, which in turn often causes them to walk less naturally or to limit their activities, leading to reduced mobility and loss of physical fitness. See Chapter 39 for a complete description of fall-prevention interventions. Box 14-6 summarizes both intrinsic and extrinsic risk factors leading to falls.

Sensory Impairments. Because of common sensory impairments experienced by older adults, you need to promote existing sensory function and be sure that patients live in safe environments. Whenever you provide care activities, make sure that patients wear assist devices such as a hearing aid or glasses so they can fully

FIGURE 14-2 This couple enjoys walking together.

BOX 14-6   Risk Factors for Falls in Older Adults

Intrinsic Factors
- History of a previous fall
- Impaired vision
- Postural hypotension or syncope
- Conditions affecting mobility such as arthritis, lower extremity muscle weakness, peripheral neuropathy, foot problems
- Conditions affecting balance and gait
- Alterations in bladder function such as frequency or urge incontinence and nocturia
- Cognitive impairment, agitation, and confusion
- Adverse medication reactions (sedatives, hypnotics, anticonvulsants, opioids)
- Slowed reaction times
- Deconditioning

Extrinsic Factors
- Environmental hazards outside and within the home such as poor lighting, slippery or wet flooring, items on floor that are easy to trip over, furniture placement and other obstacles to ambulation, and sidewalks and stairs in poor repair
- Inappropriate footwear
- Unfamiliar environment of a hospital room that contains barriers to movement (e.g., clutter, equipment, poor lighting at night)
- Improper use of assistive devices (e.g., canes, walkers, crutches)

participate in care. Chapter 49 describes in detail the nursing interventions used to maintain and improve sensory function.

Pain.   Pain is not a normal part of healthy aging. It is a symptom and a sensation of distress, alerting a person that something is wrong. It is prevalent in the older-adult population and may be acute or chronic. The consequences of persistent pain include depression, loss of appetite, sleep difficulties, changes in gait and mobility, and decreased socialization. Many factors influence the management of pain, including cultural influences on the meaning and expression of pain for older adults, fears related to the use of analgesic medications, and the problem of pain assessment with older adults who are cognitively impaired. Nurses caring for older adults have to advocate for appropriate and effective pain management (see Chapter 44). Again, the goal of nursing management of pain in older adults is to maximize function and improve quality of life.

Medication Use.   One of the greatest challenges for older adults is safe medication use. Medication categories such as analgesics, anticoagulants, antidepressants, antihistamines, antihypertensives, sedative-hypnotics, and muscle relaxants create a high likelihood of adverse effects in older adults. They are at risk for adverse medication effects because of age-related changes in the absorption, distribution, metabolism, and excretion of drugs, collectively referred to as the process of pharmacokinetics (see Chapter 32). Medications sometimes interact with one another, adding or negating the effect of another drug. Examples of adverse effects include confusion, impaired balance, dizziness, nausea, and vomiting. Because of these effects, some older adults are unwilling to take medications; others do not adhere to the prescribed dosing schedule, or they try to medicate themselves with herbal and over-the-counter medications.

Polypharmacy, the concurrent use of many medications, increases the risk for adverse drug effects (Box 14-7). Although polypharmacy often reflects inappropriate prescribing, the concurrent use of multiple medications is often necessary when an older adult has multiple acute and chronic conditions. For example, it is common for a patient to take more than one medication to control hypertension. Your role as a nurse is to ensure the greatest therapeutic benefit with the least amount of harm by educating patients about safe medication use. You need to question the efficacy and safety of combinations of prescribed medications by conferring with pharmacists or health care providers. Advocate for the older adult to prevent adverse reactions. Older adults often use over-the-counter or herbal medications. The mix of over-the-counter and herbal medications with prescription medications can create adverse reactions.

For some older adults safely managing medications is complex and often becomes overwhelming. This problem is even more complicated when limited health literacy is an issue. Some take their medications incorrectly because they do not understand the administration instructions, thereby complicating your assessment of medication effects and side effects. Medications that need to be taken more than once or twice a day are a concern because a patient may not remember to take them as scheduled. As a nurse you are in a position to help older-adult patients as they carry out this important self-care activity (see Chapter 32).

The cost of prescriptions is often prohibitive. The Medicare Prescription Drug Benefit, Medicare Part D, was created in 2003 as part of the Medicare Modernization Act of 2003. This is not one plan but a designation of many plans that are approved by the Center for Medicare and Medicaid Services (CMS, 2015). Although accompanied by a deductible dependent on the number and expense of the medications prescribed, this benefit is of great help to aging adults. In

---

BOX 14-7   EVIDENCE-BASED PRACTICE

Polypharmacy in Older Adults

PICO Question: Do older community-living adults experience fewer adverse outcomes when they are on a limited medication therapy compared with older adults who are exposed to polypharmacy?

Evidence Summary

Polypharmacy is an important factor for numerous health problems in older adults, including the risk for adverse drug events (ADEs), the inappropriate use of medications, functional decline, and falls. In a study sample of 1503 community-dwelling older adults that recorded 1650 falls, 42% were judged to be at risk for falls because of polypharmacy (Boffin et al., 2014). Another study of older adults found a correlation between functional decline and older adults with dementia taking five or more medications (Lau et al., 2011). Polypharmacy causes a higher incidence of drug-to-drug interactions, especially in older adults, because of changes in pharmacokinetics, including changes with drug distribution and absorption, metabolism, and liver and renal clearance of drugs. A study of Canadian emergency department visits found that 21.5% of older adults presenting to the emergency department with an ADE were admitted to the hospital. In addition, the study identified that the drug classes most often associated with causing harm and occurring out of proportion to the frequency prescribed were anticoagulants, opioids, antibiotics, cardiovascular drugs, and nonsteroidal antiinflammatory drugs (Bayoumi et al., 2014). Over-the-counter supplemental herbals, vitamins, and drugs may also precipitate an ADE. Many supplements contain active ingredients that can have strong effects in the body. Although many prescriptions may be needed for some individuals, more prudent care is needed to lessen the risks. Two tools are especially helpful to providers to guide appropriate prescribing for older adults. *Beers Criteria for Potentially*

Inappropriate Medication Use in Older Adults, a guideline developed originally in 1991 by the American Geriatrics Society and updated in 2012, (American Geriatrics Society, 2012) helps health care providers recognize drugs that have high association with ADEs. A Screening Tool of Older Person's Prescriptions and a Screening Tool to Alert Doctors to Right Treatment (STOPP-START) also screen for drug interactions and potentially inappropriate prescribing in older adults (Lam and Cheung, 2012). Using both sets of criteria, a study of 624 patients age 65 and older at time of hospital discharge showed that 22.9% had a potentially inappropriate prescription (PIP) using the Beer's criteria and 38.4% had a PIP using the STOPP-START criteria. PIP frequency also increased with the number of drugs prescribed (Hudhra et al., 2014).

Application to Nursing Practice

- Have patients and family caregivers ensure that one provider knows all medications that a patient is prescribed. This is especially important if a patient sees several physicians.
- Consider a possible ADE when a patient develops a new behavior or clinical change; consult the physician and a clinical pharmacist.
- Reconcile medications at the time of hospital admission and discharge to identify potentially inappropriate prescriptions.
- Review herbal supplements, vitamins, and over-the-counter medications in combination with prescription drugs for potential ADEs.
- Review older adults' medications in long-term settings routinely (e.g., monthly).
- Use nonpharmacological treatments known to be effective when possible.

addition, you advocate for patients who need certain medications by working with pharmacies or drug companies to provide the needed medication at less cost. Often a generic medication that will provide the desired effect is available at a reduced cost.

Work collaboratively with older adults to ensure safe and appropriate use of all medications, both prescribed and over-the-counter. Teach an older adult the names of all medications that he or she is taking, when and how to take them, and desirable and undesirable effects. Pill organizers and medication calendars help older adults track their doses. Explain how to avoid adverse effects and/or interactions of medications and how to establish and follow an appropriate self-administration pattern. Strategies for reducing the risk for adverse medication effects include reviewing the medications with older adults at each visit, examining for potential interactions with food or other medications, simplifying and individualizing medication regimens, taking every opportunity to inform older adults and their family caregivers about all aspects of medication use, and encouraging older adults to question their health care providers about all prescribed and over-the-counter medications.

When health care providers use medications to manage confusion, special care is necessary. Sedatives and tranquilizers sometimes prescribed for older adults who are acutely confused often cause or exacerbate confusion and increase risks for falls or other injuries. Carefully monitor patients who receive these medications, taking into account age-related changes in body systems that affect pharmacokinetic activity. When confusion has a physiological cause (such as an infection), health care providers need to treat the cause rather than the confused behavior. When confusion varies by time of day or is related to environmental factors, use creative, nonpharmacological measures such as making the environment more meaningful, providing adequate light, encouraging use of assistive devices, or even calling friends or family members to let older adults hear reassuring voices.

Health Promotion and Maintenance: Psychosocial Health Concerns

Interventions supporting the psychosocial health of older adults resemble those for other age-groups. However, some interventions are more crucial for older adults experiencing social isolation; cognitive impairment; or stresses related to retirement, relocation, or approaching death.

Elder Mistreatment. Elder mistreatment is complex and multifaceted and encompasses a broad range of abuses. It is found across all areas of nursing practice and socioeconomic settings. Consequently there is a strong likelihood that you will encounter elder mistreatment. Your ability to screen and assess for it is essential to the safety, health, and well-being of the older adult.

Elder mistreatment is defined as "intentional actions that cause harm or create serious risk of harm (whether harm is intended) to a vulnerable elder by a caregiver or other person who is in a trust relationship to the elder" (NRC, 2003). Types of elder mistreatment include physical abuse, emotional abuse, financial exploitation, sexual abuse, neglect (intentional and unintentional), and abandonment (Table 14-3). Although cases remain under-reported, data suggest that 10% of older adults in the United States experience some form of elder mistreatment (IOM and NRC, 2014). It is also common for vulnerable older adults to experience a combination of the various types of abuse.

Most perpetrators are relative caregivers, making abuse cases more complex to identify because of denial, fear of reporting, and the refusal of community services. Higher rates of elder mistreatment occur when there is a greater reliance on the caregiver because of functional and cognitive impairment. Low social support affects reports of mistreatment. One study found that reports of mistreatment tripled when there were poor social supports in place such as low income,

TABLE 14-3   Elder Mistreatment—Types, Descriptions, and Examples

Type	Description	Examples
Physical abuse	Inflicting or threatening to inflict physical pain or injury on a vulnerable older adult or depriving him or her of a basic need	Hitting, beating, pushing, slapping, kicking, physical restraint, inappropriate use of drugs, fractures, lacerations, rope burns, untreated injuries
Psychosocial/ emotional abuse	Verbal and nonverbal acts that inflict mental pain, anguish, and distress	Insults, threats, humiliation, intimidation, harassment, social isolation
Financial exploitation	Illegal taking, misuse, or concealment of funds, property, or assets of a vulnerable elder	Cashing check without authorization or permission, forging a signature, stealing money or possessions, coercing a signature on a financial document, forcing or improper use of guardianship or power of attorney, unpaid bills
Sexual abuse	Nonconsensual sexual contact or activity of any kind; coercing an elder to witness sexual behaviors	Unwanted touching, rape, sodomy, forced watching of pornography, coerced nudity, sexually explicit photography
Caregiver neglect	Refusal or failure by those responsible to fulfill caregiving activities, duties, protection, or obligations; may be intentional or unintentional because of lack of resources or education	Refusal or failure to provide basic necessities such as food, water, clothing, shelter, personal hygiene, or medication; unsafe and unclean living conditions, soiled bedding, animal or insect infestation
Abandonment	Desertion of a vulnerable elder by anyone who has assumed the responsibility for care or custody of that person	Desertion at a hospital, nursing facility, or public location such as a shopping center
Self-neglect	Behavior of an older adult that threatens his or her own well-being or safety; disregard of one's personal health or environment, causing unmet needs	Refusal or failure to provide oneself with basic necessities such as food, water, clothing, shelter, personal hygiene, medication, safety

Modified from the National Center on Elder Abuse, Administration on Aging: *Frequently asked questions,* n.d. http://www.ncea.aoa.gov/faq/index.aspx. Accessed March 30, 2015; and Fulmer T, Greenbery S: *Elder mistreatment & abuse,* 2015, http://consultgerirn.org/resources. Accessed March 30, 2015.

unemployment in the family, traumatic events, and little or no involvement of social services (Acierno et al., 2010). Vulnerable older adults may not reach out for help for fear of further retribution, fear of nursing home placement, or because they have become completely isolated from others. They may feel foolish or blame themselves for allowing someone to mistreat them or not want to get caregivers in legal or financial trouble (Bond and Butler, 2013).

Elder mistreatment has become the focus of national and international organizations, public and social policy, and research. Established by the U.S. Administration on Aging, the National Center for Elder Abuse (NCEA) is a resource center dedicated to the prevention of elder mistreatment. The Elder Justice Act of 2009 is widely regarded as the most comprehensive bill ever passed to address and battle elder mistreatment, providing federal funding to state Adult Protective Services (APS). In most states APS caseworkers are the first responders to reports of abuse, neglect, and exploitation of vulnerable adults. Services include receiving reports of adult abuse, exploitation or neglect, investigating these reports, case management, monitoring, and evaluation. In addition to casework services, APS arranges medical, social, economic, legal, housing, and law enforcement or other protective emergency or supportive services (National Center on Elder Abuse, n.d.).

As a nurse you are in a unique position to screen for elder mistreatment and assess for physical and emotional signs of abuse. A necessary part of your assessment is completing the interview and assessment privately away from the caregiver. It is definitely a "red flag" if the caregiver refuses to leave the room or area so you can ask questions confidentially. State laws differ on reporting and investigation of elder mistreatment. However, if you suspect that an older adult is being mistreated, it is your responsibility to know the reporting provisions of your jurisdiction (Falk et al., 2012).

Therapeutic Communication. Therapeutic communication skills enable you to perceive and respect the older adult's uniqueness and health care expectations. Attentive nurses provide care in a timely fashion, meeting a patient's expressed or unexpressed needs. A caring nurse expresses attitudes of concern, kindness, and compassion. Knowledgeable nurses not only demonstrate procedural competence but recognize needs and relay information skillfully. Patients accept and respect nurses who meet these expectations and communicate effectively about concern for the older adult's welfare. However, you cannot simply enter an older adult's environment and immediately establish a therapeutic relationship. First you have to be knowledgeable and skilled in communication techniques (see Chapter 24). Sitting down and engaging an older adult eye to eye goes a long way in establishing a therapeutic relationship.

Touch. Touch is a therapeutic tool that you use to help comfort older adults. It provides sensory stimulation, induces relaxation, provides physical and emotional comfort, conveys warmth, and communicates interest. It is a powerful physical expression of a relationship. In addition, gentle touch is a technique to use when administering any type of procedure that requires physical contact or repositioning and moving a patient.

Older adults are often deprived of touch when separated from family or friends. An older adult who is isolated, dependent, or ill; who fears death; or who lacks self-esteem has a greater need for touch. You recognize touch deprivation by behaviors as simple as an older adult reaching for the nurse's hand or standing close to the nurse. Unfortunately older men are sometimes wrongly accused of sexual advances when they reach out to touch others. When you use touch, be aware of cultural variations and individual preferences (see Chapters 7 and 9). Use touch to convey respect and sensitivity. Do not use it in a condescending way such as patting an older adult on the head. When you reach out to an older adult, do not be surprised if he or she reciprocates.

Reality Orientation. Reality orientation is a communication technique that makes an older adult more aware of time, place, and person. The purposes of reality orientation include restoring a sense of reality; improving the level of awareness, promoting socialization; elevating independent functioning; and minimizing confusion, disorientation, and physical regression. Although you use reality orientation techniques in any health care setting, they are especially useful in the acute care setting. The older adult experiencing a change in environment, surgery, illness, or emotional stress is at risk for becoming disoriented. Environmental changes such as bright lights, unfamiliar noises, and lack of windows in specialized units of a hospital often lead to disorientation and confusion. Absence of familiar caregivers is also disorienting. The use of anesthesia, sedatives, tranquilizers, analgesics, and physical restraints in older patients increases disorientation. Anticipate and monitor for disorientation and confusion as possible consequences of hospitalization, relocation, surgery, loss, or illness and incorporate interventions on the basis of reality orientation into the plan of care.

The principles of reality orientation offer useful guidelines for communicating with individuals who are acutely confused. The key elements of reality orientation include frequent reminders of person, place, and time; the use of familiar environmental aids such as clocks, calendars, and personal belongings; and stability of the environment, routine, and staff. However, do not continue to reorient older adults with chronic cognitive impairment. Communication is always respectful, patient, and calm. Answer questions from the older adult simply and honestly with sensitivity and a caring attitude.

Validation Therapy. Validation therapy is an alternative approach to communication with an older adult who is confused. Whereas reality orientation insists that the confused older adult agree with statements of time, place, and person, validation therapy accepts the description of time and place as stated by the older adult. Older adults with dementia are less likely to benefit and more likely to become agitated by a caregiver's insistence on the "correct" time, place, and person. In validation therapy you do not challenge or argue with statements and behaviors of the older adult. They represent an inner need or feeling. For example, a patient insists that the day is actually a different day because of high anxiety. The appropriate nursing intervention is to recognize and address that inner need or feeling. Validation does not involve reinforcing the older adult's misperceptions; it reflects sensitivity to hidden meanings in statements and behaviors. By listening with sensitivity and validating what the patient is expressing, you convey respect, reassurance, and understanding. Validating or respecting older adults' feelings in the time and place that is real to them is more important than insisting on the literally correct time and place.

Reminiscence. Reminiscence is recalling the past. Many older adults enjoy sharing past experiences. As a therapy, reminiscence uses the recollection of the past to bring meaning and understanding to the present and resolve current conflicts. Looking back to positive resolutions of problems reminds an older adult of coping strategies used successfully in the past. Reminiscing is also a way to express personal identity. Reflection on past achievements supports self-esteem. For some older adults the process of looking back on past events uncovers new meanings for those events.

During the assessment process use reminiscence to assess self-esteem, cognitive function, emotional stability, unresolved conflicts, coping ability, and expectations for the future. For example, have a patient talk about a previous loss to assess coping. You can also reminisce during direct care activities. Taking time to ask questions about past experiences and listening attentively conveys to an older adult your attitudes of respect and concern.

Although many use reminiscence in a one-on-one situation, it is also used as a group therapy for older adults who are cognitively impaired or depressed. You begin by organizing the group and selecting strategies to start a conversation. For example, you ask the group to discuss family activities or childhood memories, adapting questions to the group's size, structure, process, goals, and activities to meet its members' needs.

Body-Image Interventions. The way that older adults present themselves influences body image and feelings of isolation (see Chapter 34). Some physical characteristics of older adulthood such as distinguished-looking gray hair are socially desirable. Other features such as a lined face that displays character or wrinkled hands that show a lifetime of hard work are also impressive. However, too often society sees older people as incapacitated, deaf, obese, or shrunken in stature. Consequences of illness and aging that threaten an older adult's body image include invasive diagnostic procedures, pain, surgery, loss of sensation in a body part, skin changes, and incontinence. The use of devices such as dentures, hearing aids, artificial limbs, indwelling catheters, ostomy devices, and enteral feeding tubes also affects body image.

You need to consider the importance to an older adult of presenting a socially acceptable image. When older adults have acute or chronic illnesses, the related physical dependence makes it difficult for them to maintain body image. You influence an older adult's appearance by helping with grooming and hygiene. It takes little effort to help an older adult comb hair, clean dentures, shave, or change clothing. He or she does not choose to have an objectionable appearance. Be sensitive to odors in the environment. Odors created by urine and some illnesses are often present. By controlling odors you may prevent visitors from shortening their stay or not coming at all.

OLDER ADULTS AND THE ACUTE CARE SETTING

Older adults in the acute care setting need special attention to help them adjust to the acute care environment and meet their basic needs. The acute care setting poses increased risk for adverse events such as delirium, dehydration, malnutrition, health care–associated infections (HAIs), urinary incontinence, and falls. The risk for delirium increases when hospitalized older adults experience immobilization, sleep deprivation, infection, dehydration, pain, sensory impairment, drug interactions, anesthesia, and hypoxia. Nonmedical causes of delirium include placement in unfamiliar surroundings, unfamiliar staff, bed rest, separation from supportive family members, and stress. Impaired vision or hearing contributes to confusion and interferes with attempts to reorient an older adult. When the prevention of delirium fails, nursing management begins with identifying and treating the cause. Supportive interventions include encouraging family visits, providing memory cues (clocks, calendars, and name tags), and compensating for sensory deficits. Reality orientation techniques are often useful.

Older adults are at greater risk for dehydration and malnutrition during hospitalization because of standard procedures such as limiting food and fluids in preparation for diagnostic tests and medications that decrease appetite. The risk for dehydration and malnutrition increases when older adults are unable to reach beverages or feed themselves while in bed or connected to medical equipment. Interventions include getting the patient out of bed, providing beverages and snacks frequently, and including favorite foods and beverages in the diet plan.

The increased risk for HAIs in older adults is associated with the decreased immune system response related to advancing age in addition to other chronic conditions that make older adults more susceptible. UTIs are the most common type of HAI. Approximately 75% of UTIs acquired in hospitals result from the use of urinary catheters (CDC, 2015c). Other HAIs include central-line bloodstream infection, surgical site infection, *Clostridium difficile,* and hospital-acquired pneumonia. The leading preventive measure is hand hygiene combined with proper isolation policy and procedures to prevent and control the transmission of infection (see Chapter 29).

Older hospitalized adults are at risk for becoming incontinent of urine (transient incontinence). Causes of incontinence include delirium, untreated UTI, medications, restricted mobility, or need for assistance to get to the bathroom. Interventions to decrease incontinence include individualized care planning to provide voiding opportunities and modification of the environment to improve access to the toilet. Avoid indwelling urinary catheterization and promote measures to prevent skin breakdown (see Chapter 46).

The increased risk for skin breakdown and the development of pressure ulcers is related to changes in aging skin and to situations that occur in the acute care setting such as immobility, incontinence, and malnutrition. The key points in the prevention of skin breakdown are avoiding pressure with proper positioning and use of a support surface on the basis of risk status, reducing shear forces and friction, providing meticulous skin care and moisture management, and providing nutritional support (see Chapter 48).

Older adults in the acute care setting are also at greater risk for falling and sustaining injuries. The cause of a fall is typically multifactorial and composed of intrinsic or extrinsic factors (see Box 14-6). Sedative and hypnotic medications increase unsteadiness. Lower extremity weakness and general fatigue and deconditioning can make it difficult for a patient to get out of bed. Once the patient does get out of bed, often he or she is very unsteady and prone to falling. Medications causing orthostatic hypotension also increase the risk for falls because the blood pressure drops when an older adult gets out of a bed or chair. The increase in urine output from diuretics increases the risk for falling by increasing the number of attempts to get out of bed to void. Attempts to get out of bed when physically restrained sometimes lead to injury when an older adult becomes entangled in the restraint. Equipment such as wires from monitors, intravenous tubing, urinary catheters, and other medical devices become obstacles to safe ambulation. Impaired vision prevents an older adult from seeing tripping hazards such as trash cans. Many hospitals have significantly decreased restraint use and the incidence of falls by implementing frequent hourly rounds focusing on toileting needs, pain management, and personal needs of the patients. Other interventions to reduce the risk for falling in a health care setting are discussed in Chapter 39.

OLDER ADULTS AND RESTORATIVE CARE

Restorative care refers to two types of ongoing care: the continuation of the recovery from acute illness or surgery that began in the acute care setting and support of chronic conditions that affect day-to-day functioning. Both types of restorative care take place in private homes and long-term care settings.

Interventions during convalescence from acute illness or surgery aim at regaining or improving patients' prior level of independence in ADLs. Continue interventions that began in the acute care setting and

later modify them as convalescence progresses. To achieve this continuation, ensure that discharge information provided by the acute care setting includes information on required ongoing interventions (e.g., exercise routines, wound care routines, medication schedules, and blood glucose monitoring). Interventions also need to address the restoration of interpersonal relationships and activities at either their previous level or the level desired by the older adult. When restorative care addresses chronic conditions, the goals of care include stabilizing the chronic condition, promoting health, and promoting independence in ADLs.

Interventions to promote independence in ADLs address a person's physical and cognitive ability and safety. The physical ability to perform ADLs requires strength, flexibility, and balance. You need to make accommodations for impairments of vision, hearing, and touch. The cognitive ability to perform ADLs requires the ability to recognize, judge, and remember. Cognitive impairments such as dementia interfere with safe performance of ADLs, although an older adult is still physically capable of the activities. Adapt interventions to promote independence in ADLs to meet the needs and lifestyle of the older adult. Although safety is paramount, an older adult needs to be able to perform ADLs with a level of risk that is acceptable to him or her. Collaborate with an occupational therapist, who is trained in selecting the correct type of assist devices for patients.

Beyond basic ADLs, you need to support an older adult's ability to perform IADLs such as using a telephone, doing laundry, cleaning the home or apartment, handling money, paying bills, and driving an automobile. To live independently at home or in an apartment, older adults need to be able to perform IADLs, purchase services by outside workers, or have a supportive network of family and friends who help with these tasks. Occupational therapists are an important resource for helping people adapt when IADLs are difficult to perform. Also, it might be appropriate to have a family caregiver assume more responsibility by completing IADLs for patients.

Restorative care measures focus on activities that allow older adults to remain functional within their living environments. Collaborate with an older adult to establish priorities of care and patient goals, determine expected outcomes, and select appropriate interventions. Patient collaboration promotes a patient's understanding about care and minimizes conflicts. Consideration of an older adult's lifetime experiences, values, and sociocultural patterns serves as the basis for planning individual care. When an older adult's cognitive status prevents participation in health care decisions, you need to include the family caregivers. Family and friends are rich sources of data because they knew the older adult before the impairment. Frequently they provide explanations for the older adult's behaviors and suggest methods of management. Thoughtful assessment and planning lead to goals of care that consider the influence of normal aging changes, facilitate an optimal level of comfort and coping, and promote independence in self-care activities.

KEY POINTS

- Nursing care of older adults poses special challenges because of great variation in their physiological, cognitive, and psychosocial health.
- When health care providers hold negative stereotypes about aging, these stereotypes can negatively affect the quality of patient care.
- The best way to evaluate the quality of a nursing center in a community is for a patient and family to visit that facility and inspect it personally.
- A comprehensive assessment of an older adult may take more time than the assessment of a younger adult because of the longer life

and medical history, the potential complexity of the history, and the time it takes for an older adult to respond to questions.
- Classic signs and symptoms of diseases are sometimes absent, blunted, or atypical in older adults.
- Normal physiological changes of aging are not pathological processes, but they make older adults more vulnerable to some common clinical conditions and diseases.
- A sudden change in function, as evidenced by a decline or change in an older adult's ability to perform any one or combination of ADLs or IADLs, is often a sign of the onset of an acute illness.
- Symptoms of cognitive impairment such as disorientation, loss of language skills, and poor judgment are not normal aging changes and require you to further assess patients for underlying causes.
- Assess a patient's potential for social isolation by identifying social networks, access to transportation, and willingness and desire to interact with others.
- General preventive health measures for older adults include routine health screening; regular exercise; weight reduction if overweight; eating a low-fat, well-balanced diet; moderate alcohol use; regular dental visits; smoking cessation; and immunization.
- Polypharmacy, the concurrent use of many medications, increases the risk for adverse drug effects, inappropriate use of medications, and falls in older adults.
- Elder mistreatment is found across all areas of nursing practice and socioeconomic settings and includes physical, emotional, and sexual abuse; financial exploitation; caregiver neglect; self neglect; and abandonment.
- Reminiscence uses the recollection of the past to bring meaning and understanding to the present and resolve current conflicts.
- Acute care settings place older adults at risk for delirium, dehydration, malnutrition, HAIs, and falls.
- Restorative nursing interventions stabilize chronic conditions, promote health, and promote independence in basic and instrumental ADLs.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mrs. Kaven is an alert 81-year-old woman who is admitted to the hospital following emergency surgery for a hip pinning of a hip fracture secondary to a fall at her home. Her other medical problems are hypertension, hypothyroidism, and anxiety disorder for which she takes a diuretic and thyroid replacement medication. She has had bilateral knee replacements in the past. She is a retired bookkeeper, a widow living independently at her home, and usually very active. She drives, plays cards weekly with her friends, and participates in church activities twice a week. She hires help for household cleaning and yard work. She wears glasses, has uncorrected cataracts, and uses a cane.

You are assigned to care for her on her first postoperative day after the hip pinning. You learn in report that Mrs. Kaven has been receiving opioids for postoperative pain, with her last pain rating a 5 on a scale of 0 to 10. She has intravenous fluids for hydration for the first 24 hours. She has an indwelling urinary catheter. The night nurse reports that Mrs. Kaven was restless all night and slept very little and that she had even tried to get out of bed. Her ordered pain medication did not help her to sleep. You enter Mrs. Kaven's room and find her picking at the air and talking to herself as she tries to eat her breakfast. She is not wearing her glasses. She is oriented to self only. As you do your shift assessment, you recognize signs of delirium.

1. During your assessment, which conditions prompt you to suspect that the patient has delirium?
2. Mrs. Kaven's good friend comes to visit. She is concerned that Mrs. Kaven is confused. She asks you if there is anything she can do to help Mrs. Kaven be less confused. How do you respond to the friend?
3. Explain the approach that Mrs. Kaven's health care providers will use to reverse her delirium. Give some examples of these approaches.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nursing student is caring for a 78-year-old patient with multiple sclerosis. The patient has had an indwelling Foley catheter in for 3 days. Eight hours ago the patient's temperature was 37.1°C (98.8°F). The student reports her recent assessment to the registered nurse (RN): the patient's temperature is 37.2°C (99°F); the Foley catheter is still in place, draining dark urine; and the patient is uncertain what time of day it is. From what the RN knows about presentation of symptoms in older adults, what should he recommend first?
   1. Tell the student that temporary confusion is normal and simply requires reorientation
   2. Tell the student to increase the patient's fluid intake since the urine is concentrated
   3. Tell the student that her assessment findings are normal for an older adult
   4. Tell the student that he will notify the patient's health care provider of the findings and recommend a urine culture

2. A patient's family member is considering having her mother placed in a nursing center. The nurse has talked with the family before and knows that this is a difficult decision. Which of the following criteria does the nurse recommend in choosing a nursing center? (Select all that apply.)
   1. The center needs to be clean, and rooms should look like a hospital room.
   2. Adequate staffing is available on all shifts.
   3. Social activities are available for all residents.
   4. The center provides three meals daily with a set menu and serving schedule.
   5. Staff encourage family involvement in care planning and assisting with physical care.

3. A nurse conducted an assessment of a new patient who came to the medical clinic. The patient is 82 years old and has had osteoarthritis for 10 years and diabetes mellitus for 20 years. He is alert but becomes easily distracted during the assessment. He recently moved to a new apartment, and his pet beagle died just 2 months ago. He is most likely experiencing:
   1. Dementia.
   2. Depression.
   3. Delirium.
   4. Hypoglycemic reaction.

4. The nurse is completing a health history with the daughter of a newly admitted patient who is confused and agitated. The daughter reports that her mother was diagnosed with Alzheimer's disease 1 year ago but became extremely confused last evening and was hallucinating. She was unable to calm her, and her mother thought she was a stranger. On the basis of this history, the nurse suspects that the patient is experiencing:
   1. Delirium.
   2. Depression.
   3. New-onset dementia.
   4. Worsening dementia.

5. Sexuality is maintained throughout our lives. Which of the following answers best explains sexuality in an older adult?
   1. When the sexual partner passes away, the survivor no longer feels sexual.
   2. A decrease in an older adult's libido occurs.
   3. Any outward expression of sexuality suggests that the older adult is having a developmental problem.
   4. All older adults, whether healthy or frail, need to express sexual feelings.

6. Older adults frequently experience a change in sexual activity. Which best explains this change?
   1. The need to touch and be touched is decreased.
   2. The sexual preferences of older adults are not as diverse.
   3. Physical changes usually do not affect sexual functioning.
   4. Frequency and opportunities for sexual activity may decline.

7. The nurse sees a 76-year-old woman in the outpatient clinic. She states that she recently started noticing a glare in the lights at home. Her vision is blurred; and she is unable to play cards with her friends, read, or do her needlework. The nurse suspects that the woman may have:
   1. Presbyopia.
   2. Presbycusis
   3. Cataract(s).
   4. Depression.

8. A nurse is caring for a patient preparing for discharge from the hospital the next day. The patient does not read. His family caregiver will be visiting before discharge. What can the nurse do to facilitate the patient's understanding of his discharge instructions? (Select all that apply.)
   1. Yell so the patient can hear you.
   2. Sit facing the patient so he is able to watch your lip movements and facial expressions.
   3. Present one idea or concept at a time.
   4. Send a written copy of the instructions home with him and tell him to have the family review them.
   5. Include the family caregiver in the teaching session.

9. A 63-year-old patient is retiring from his job at an accounting firm where he was in a management role for the past 20 years. He has been with the same company for 42 years and was a dedicated employee. His wife is a homemaker. She raised their five children, babysits for her grandchildren as needed, and belongs to numerous church committees. What are the major concerns for this patient? (Select all that apply.)
   1. The loss of his work role
   2. The risk of social isolation
   3. A determination if the wife will need to start working
   4. How the wife expects household tasks to be divided in the home in retirement
   5. The age the patient chose to retire

10. A nurse is assessing an older adult brought to the emergency department following a fall and wrist fracture. She notes that the patient is very thin and unkempt, has a stage 3 pressure ulcer to her coccyx, and has old bruising to the extremities in addition to her new bruises from the fall. She defers all of the questions to her caregiver son who accompanied her to the hospital. The nurse's next step is to:
    1. Call social services to begin nursing home placement.
    2. Ask the son to step out of the room so she can complete her assessment.

3. Call adult protective services because you suspect elder mistreatment.
4. Assess patient's cognitive status.

11. A nurse is participating in a health and wellness event at the local community center. A woman approaches and relates that she is worried that her widowed father is becoming more functionally impaired and may need to move in with her. The nurse inquires about his ability to complete activities of daily living (ADLs). ADLs include independence with: (Select all that apply.)
   1. Driving.
   2. Toileting.
   3. Bathing.
   4. Daily exercise.
   5. Eating.

12. During a home health visit a nurse talks with a patient and his family caregiver about the patient's medications. The patient has hypertension and renal disease. Which of the following findings place him at risk for an adverse drug event? (Select all that apply.)
   1. Taking two medications for hypertension
   2. Taking a total of eight different medications during the day
   3. Having one physician who reviews all medications
   4. Patient's health history of renal disease
   5. Involvement of the caregiver in helping with medication administration

13. The nurse is completing an admission assessment with an 80-year-old man who experienced a hip fracture following a fall. He is alert, lives alone, and has very poor hygiene. He reports a 20-pound weight loss in the last 6 months following his wife's death, as well as estrangement from his only child. He admits to falls before this most recent fall. What should the nurse suspect?

   1. Dementia.
   2. Elder abuse.
   3. Delirium.
   4. Alcohol abuse.

14. The nurse is working with an older adult after an acute hospitalization. The goal is to help this person be more in touch with time, place, and person. Which intervention will likely be most effective?
   1. Reminiscence
   2. Validation therapy
   3. Reality orientation
   4. Body image interventions

15. A 71-year-old patient enters the emergency department after falling down stairs in the home. The nurse is conducting a fall history with the patient and his wife. They live in a one-level ranch home. He has had diabetes for over 15 years and experiences some numbness in his feet. He wears bifocal glasses. His blood pressure is stable at 130/70. The patient does not exercise regularly and states that he experiences weakness in his legs when climbing stairs. He is alert, oriented, and able to answer questions clearly. What are the fall risk factors for this patient? (Select all that apply.)
   1. Impaired vision
   2. Residence design
   3. Blood pressure
   4. Leg weakness
   5. Exercise history

Answers: 1. 4; 2. 2, 3, 5; 3. 4, 1; 5. 4; 6. 4; 7. 3; 8. 2, 3, 5; 9. 1, 4; 10. 2; 11. 2, 3, 5; 12. 2, 4; 13. 2, 4; 14. 3; 15. 1, 4, 5.

Critical Thinking in Nursing Practice

As a nursing student you are just beginning to learn how to make clinical judgments or decisions about the patients and their families in your care. Clinical judgment is an essential skill that involves the interpretation of a patient's needs, concerns, or health problems and the decision to take action or not, to use or modify standard approaches, or to improvise new approaches on the basis of a patient's response (Tanner, 2006). Harjai and Tiwari (2009) explain it this way, "Contemporary nursing practice needs effective thinkers and decision makers who are capable of analyzing clinical data, medical and nursing knowledge, and environmental data, translating the analyses into lifesaving interventions" (p. 305). Sound clinical judgment is associated with your ability to think critically. You apply it each day in your practice as a nurse.

Consider this example of critical thinking. The computer you are using flashes an error warning on the screen. You think about the steps you made before the error; consider the possible problem; and correct a key stroke, change a function, or maybe reboot the computer on the basis of your logic and reasoning skills. You consider what you know about computing, your past experiences in using computers, your experience with the same error in the past, and how you feel at the moment (stressed or hurried, calm and insightful) as you decide how to correct the error. You use a very similar critical thinking approach when you care for patients. However, you apply knowledge, clinical experiences, and professional standards when thinking critically and making decisions about patient care.

As you develop professionally, it is important to acquire critical thinking skills that allow you to face each new patient care experience or problem with open-mindedness, creativity, confidence, and continual inquiry. When a patient develops a new set of symptoms, asks you to offer comfort, or requires a procedure, it is important to think critically and make sensible judgments so the patient receives the best nursing care possible. Critical thinking is not a simple step-by-step, linear process that you learn overnight. It is a process gained only through experience, commitment, and an active curiosity toward learning. Thus this chapter leads you to think about and understand the thinking processes used in clinical judgment to help you improve your decision making and the ability to identify patient problems (Croskerry and Nimmo, 2011).

CLINICAL JUDGMENT IN NURSING PRACTICE

Registered nurses (RNs) are responsible for making accurate and appropriate clinical decisions or judgments. Clinical decision making separates RNs from technicians. For example, an RN observes for changes in patients, recognizes potential problems, identifies new problems as they arise, and takes immediate action when a patient's clinical condition worsens. Technical personnel are directed by nurses to perform certain aspects of care and report back any important observations to keep RNs informed. The RN is responsible for making decisions on the basis of clinical information. An RN relies on

knowledge and experience when deciding if a patient is having complications that call for notification of a health care provider or if a teaching plan for a patient is ineffective and needs revision. Tanner (2006) describes clinical judgment or decision making as complex, requiring flexibility and the ability to know and recognize subtle changes or aspects of an undefined clinical situation. When a clinical situation develops (such as a patient experiencing pain, an adverse effect of a medication, or a serious drop in blood pressure), the RN must learn to recognize it, interpret the meaning, and respond appropriately.

Most patients have health care problems for which there are no clear textbook solutions. Each patient's health problems are unique, a product of the patient's physical health, lifestyle, culture, relationship with family and friends, living environment, and experiences. Thus as a nurse you do not always have a clear picture of a patient's needs and the appropriate actions to take when first meeting a patient. Instead you must learn to question, wonder, and explore different perspectives and interpretations to find a solution that benefits the patient. With experience you learn to creatively seek new knowledge, act quickly when events change, and make quality decisions for patients' well-being. You will find nursing to be rewarding and fulfilling through the clinical judgments you make.

CRITICAL THINKING DEFINED

Mr. Lawson is a 68-year-old patient who had abdominal surgery for a colon resection and removal of a tumor yesterday. His nurse, Tonya, finds the patient lying supine in bed with arms held tightly over his abdomen. His facial expression is tense. When Tonya checks the patient's surgical wound, she notes that he winces when she gently places her hands to palpate around the surgical incision. She asks Mr. Lawson when he last turned onto his side, and he responds, "Not since last night." Tonya asks Mr. Lawson if he is having pain around his incision, and he nods yes, saying, "It hurts too much to move." Tonya assesses Mr. Lawson with a pain-rating scale and finds that his pain is at a 7 on a scale of 0 to 10. Tonya considers the information she observed and learned from the patient to determine that he is in pain and has reduced mobility because of it. She decides to take action by administering an analgesic to relieve his pain so she can turn him more frequently and begin to get him out of bed for his recovery.

In the case example Tonya observes the patient's clinical situation; asks questions; considers knowledge gained from caring for previous patients with colon resection, postoperative pain, and risks from immobility; and takes action. Tonya makes a clinical decision by applying **critical thinking**, the ability to think in a systematic and logical manner with openness to question and reflect on the reasoning process. Critical thinking involves open-mindedness, continual inquiry, and perseverance, combined with a willingness to look at each unique patient situation and determine which identified assumptions are true and relevant. A nurse learns to recognize that a patient problem exists, analyzes information about the problem (e.g., clinical data, observation of patient behavior), evaluates the information (reviewing assumptions and evidence), and makes conclusions so he or she can act appropriately. A critical thinker considers what is important in each clinical situation, imagines and explores alternatives, considers ethical principles, and makes informed decisions about the care of patients.

Critical thinking is a way of thinking about a situation that always asks "Why?", "What am I missing?", "What do I really know about this patient's situation?", and "What are my options?" *Tonya knew that pain*

was likely going to be a problem because Mr. Lawson had extensive surgery. Her review of her observations and the patient's report of pain confirmed her knowledge that pain was a problem. Her options include giving Mr. Lawson an analgesic and waiting until it takes effect so she is able to reposition and make him more comfortable. Once he has less acute pain, Tonya offers to teach Mr. Lawson some relaxation exercises to maintain his comfort.

You begin to learn how to think critically early in your practice. For example, as you learn about administering baths and other hygiene measures, take time to read your textbook, on-line resources, and the scientific literature about the concept of comfort. What are the criteria for comfort? How does a patient's culture affect perceptions of comfort? What are the many factors that promote comfort? The use of **evidence-based knowledge,** or knowledge based on research or clinical expertise, makes you an informed critical thinker. Thinking critically and learning about the concept of comfort prepares you to better anticipate your patients' needs, identify comfort problems quickly, and offer appropriate care. Critical thinking requires cognitive skills and the habit of asking questions, staying well informed, being honest in facing personal biases, and always being willing to reconsider and think clearly about issues (Facione, 1990). When core critical thinking skills are applied to nursing, they show the complex nature of clinical decision making (Table 15-1). Being able to apply all of these skills takes practice. You also need to have a sound knowledge base and thoughtfully consider what you learn when caring for patients.

Nurses who apply critical thinking in their work are able to see the big picture from all possible perspectives. They focus clearly on options for solving problems and making decisions rather than quickly and carelessly forming quick solutions (Kataoka-Yahiro and Saylor, 1994). Nurses who work in crisis situations such as the emergency department often act quickly when patient problems develop. However, even these nurses exercise discipline in decision making to avoid premature and inappropriate decisions. Learning to think critically helps you care for patients as their advocate, or supporter, and make better-informed choices about their care. Facione and Facione (1996) identified concepts for thinking critically (Table 15-2). Critical thinking is more than just problem solving. It is a continuous attempt to improve how to apply yourself when faced with problems in patient care.

Reflection

The ability to act on the basis of critical thinking comes with experience. When you care for patients, begin by thinking about previous situations and considering relevant issues: What did I notice before? How did I act? What could I have done differently? What should I do next time in the same situation? This is **reflection,** turning over a subject in the mind and thinking about it seriously. It involves purposeful thinking back or recalling a situation to discover its purpose or meaning. *For example, before Tonya makes a conclusion about Mr. Lawson's problems she thinks about previous surgical patients for whom she cared and how they responded to incisional pain. She recalls a patient who had a serious pulmonary embolus (clot in the lung) after surgery and how that pain differed from incisional pain. Reflecting on previous clinical situations prepares Tonya to act knowledgeably and quickly in caring for Mr. Lawson.* Research has shown that, when nurses reflect on past experiences, they perceive that their knowledge increases and their critical thinking moves to a higher level (Kaddoura, 2013).

Reflection is like instant replay. It is not intuitive. It involves playing back a situation in your mind and taking time to honestly review everything you remember about it. Reflective reasoning improves the accuracy of making diagnostic conclusions (Mamede et al., 2012). This means that, when you gather information about a patient, reflection on the meaning of your findings and exploration about what the

TABLE 15-1 Critical Thinking and Clinical Judgment Skills

Skill	Nursing Practice Applications
Interpretation	Be orderly in collecting data about patients. Apply reasoning while looking for patterns to emerge. Categorize the data (e.g., nursing diagnoses [see Chapter 17]). Gather additional data or clarify any data about which you are uncertain.
Analysis	Be open-minded as you look at information about a patient. Do not make careless assumptions. Does the data reveal a problem or trend that you believe is true, or are there other options?
Inference	Look at the meaning and significance of findings. Are there relationships among findings? Does the data about the patient help you see that a problem exists?
Evaluation	Look at all situations objectively. Use criteria (e.g., expected outcomes, pain characteristics, learning objectives) to determine results of nursing actions. Reflect on your own behavior.
Explanation	Support your findings and conclusions. Use knowledge and experience to choose strategies to use in the care of patients.
Self-regulation	Reflect on your experiences. Be responsible for connecting your actions with outcomes. Identify the ways you can improve your own performance. What will make you believe that you have been successful?

Modified from Facione P: *Critical thinking: a statement of expert consensus for purposes of educational assessment and instruction. The Delphi report: research findings and recommendations prepared for the American Philosophical Association,* ERIC Doc No. ED 315, Washington, DC, 1990, ERIC.; and Tanner CA: Thinking like a nurse: a research-based model of clinical judgment in nursing, *J Nurs Educ* 45(6):204, 2006.

TABLE 15-2 Concepts for a Critical Thinker

Concept	Critical Thinking Behavior
Truth seeking	Seek the true meaning of a situation. Be courageous, honest, and objective about asking questions.
Open-mindedness	Be tolerant of different views; be sensitive to the possibility of your own prejudices; respect the right of others to have different opinions.
Analyticity	Analyze potentially problematic situations; anticipate possible results or consequences; value reason; use evidence-based knowledge.
Systematicity	Be organized, focused; work hard in any inquiry.
Self-confidence	Trust in your own reasoning processes.
Inquisitiveness	Be eager to acquire knowledge and learn explanations even when applications of the knowledge are not immediately clear. Value learning for learning's sake.
Maturity	Multiple solutions are acceptable. Reflect on your own judgments; have cognitive maturity.

Modified from Facione N, Facione P: Externalizing the critical thinking in knowledge development and clinical judgment, *Nurs Outlook* 44(3):129, 1996.

BOX 15-1 Tips on Using Reflection

- Stop and think about what is going on with your patient. What do your assessment findings mean on the basis of what you have observed before with other patients? How do the findings compare with normal or baseline findings for the patient?
- Reflect carefully on any critical incidents (e.g., safety episodes, cardiac arrests, medication error, complex-care patient). What occurred? Which actions did you take? How did the patient respond? Did you think of taking any other options?
- Think about your feelings and the painful experiences you sometimes have. Realize that these emotions are real. How do they affect your care for others?
- At the end of each day after caring for a patient, take time to reflect. Ask yourself whether you achieved your original plan of care. If you did, why were you successful? If you did not, what were the barriers or problems? What would you do differently or the same?
- Keep all written care plans or clinical notes and papers. Use them frequently as a resource for care of future patients.
- Keep a personal journal and describe your feelings and experiences.

findings might mean improve your ability to problem solve. Reflection lessens the likelihood that reasoning is based on assumptions or guesswork. By reviewing your previous actions you see successes and opportunities for improvement. Always be cautious in using reflection. Reliance on it can block thinking and not allow you to look at newer evidence or subtle aspects of situations that you have not encountered. Box 15-1 summarizes tips on how to use reflection.

LEVELS OF CRITICAL THINKING IN NURSING

Your ability to think critically grows as you gain new knowledge and experience in nursing practice. Kataoka-Yahiro and Saylor (1994) developed a critical thinking model (Figure 15-1) that includes three levels: basic, complex, and commitment.

Basic Critical Thinking

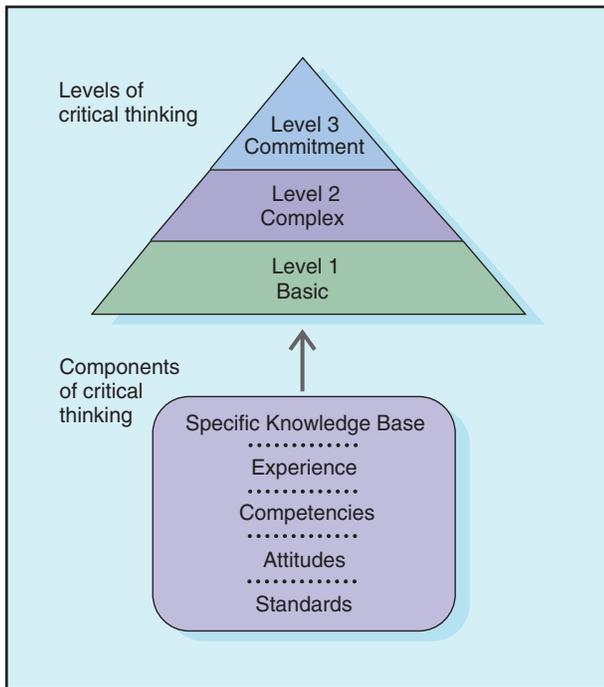
As a beginning student you make a conscious effort to apply critical thinking because initially you are more task oriented and trying to learn how to organize nursing care activities. At the basic level of critical thinking a learner trusts that experts have the right answers for every problem. Thinking is concrete and based on a set of rules or principles. For example, as a nursing student you use a hospital procedure manual to confirm how to change an intravenous (IV) dressing. You likely follow the procedure step by step without adjusting it to meet a patient's unique needs (e.g., positioning to minimize the patient's pain or mobility restrictions). You do not have enough experience to anticipate how to individualize the procedure when problems arise. At this level answers to complex problems seem to be either right or wrong (e.g., when the IV is not infusing correctly, it must not be positioned in the vein). Although there are other explanations, basic critical thinkers tend to think that one right answer usually exists for each problem. Basic critical thinking is an early step in developing reasoning (Kataoka-Yahiro and Saylor, 1994). A basic critical thinker learns to accept the diverse opinions and values of experts (e.g., instructors and staff nurse preceptors). However, inexperience, weak competencies, and inflexible attitudes restrict a person's ability to move to the next level of critical thinking.


FIGURE 15-1 Critical thinking model for nursing judgment. (Redrawn from Kataoka-Yahiro M, Saylor C: A critical thinking model for nursing judgment, *J Nurs Educ* 33(8):351, 1994. Modified from Glaser E: *An experiment in the development of critical thinking,* New York, 1941, Bureau of Publications, Teachers College, Columbia University; Miller M, Malcolm N: Critical thinking in the nursing curriculum, *Nurs Health Care* 11:67, 1990; Paul RW: The art of redesigning instruction. In Willsen J, Blinker AJA, editors: *Critical thinking: how to prepare students for a rapidly changing world,* Santa Rosa, Calif, 1993, Foundation for Critical Thinking; and Perry W: *Forms of intellectual and ethical development in the college years: a scheme,* New York, 1979, Holt, Rinehart, & Winston.)

Complex Critical Thinking

Complex critical thinkers begin to separate themselves from experts. For example, while inserting a feeding tube, you recognize that your patient cannot swallow easily. Thus you adapt how you insert it. You analyze the clinical situation and examine choices more independently. A person's thinking abilities and initiative to look beyond expert opinion begin to change. As a nurse you learn that alternative and perhaps conflicting solutions exist.

Consider Mr. Lawson's case. His pain was partially relieved after receiving an analgesic (rating of 4 on scale of 0 to 10), and Tonya has helped him out of bed and into a chair. However, the patient becomes restless, cannot get comfortable, and begins to feel short of breath. Tonya wonders if something other than the incision is causing Mr. Lawson's discomfort. She sits down next to him and asks, "Is the pain you're feeling now different from before I gave you your medication?" The patient tells her that the pain feels sharper, in his chest. Tonya quickly takes a set of vital signs. His heart rate, which was 88 and regular 1 hour ago, is now 102 and irregular. Tonya calls the physician and notifies her of the changes in Mr. Lawson's condition. Tonya thought outside of the box. Rather than assume that Mr. Lawson's continued pain was from his incision, she gathered more data and recognized that the patient possibly was experiencing a life-threatening condition, a pulmonary embolus.

In complex critical thinking each solution has benefits and risks that you weigh before making a final decision. There are options. Thinking becomes more creative and innovative. The complex critical thinker is willing to consider different options from routine procedures when complex situations develop. You learn to gather additional information and take a variety of different approaches for the same therapy.

Commitment

The third level of critical thinking is commitment (Kataoka-Yahiro and Saylor, 1994). At this level you anticipate when to make choices without assistance from others and accept accountability for decisions made. As a nurse you do more than just consider the complex alternatives that a problem poses. At the commitment level you choose an action or belief that is based on the available alternatives and support it. Sometimes an action is to not act or to delay an action until a later time. You choose to delay as a result of your experience and knowledge. Because you take accountability for the decision, you consider the results of the decision and determine whether it was appropriate.

CRITICAL THINKING COMPETENCIES

Critical thinking competencies are the cognitive processes a nurse uses to make judgments about the clinical care of patients (Kataoka-Yahiro and Saylor, 1994). These include general critical thinking, specific critical thinking in clinical situations, and specific critical thinking in nursing. General critical thinking processes are not unique to nursing. They include the scientific method, problem solving, and decision making. Specific critical thinking competencies include diagnostic reasoning, clinical inference, and clinical decision making. The specific critical thinking competency in nursing is the nursing process, which involves each of the other three specific critical thinking competencies.

General Critical Thinking

Scientific Method.   The scientific method is a methodical way to solve problems using reasoning. It is a systematic, ordered approach to gathering data and solving problems used by a variety of health care professionals. This approach looks for the truth or verifies that a set of facts agrees with reality. Nurse researchers use the **scientific method** when testing research questions (see Chapter 5). The scientific method has five steps:

1. Identify the problem.
2. Collect data.
3. Formulate a question or hypothesis.
4. Test the question or hypothesis.
5. Evaluate results of the test or study.

Box 15-2 offers an example of a nursing practice issue solved by applying the scientific method in a research study.

Problem Solving.   Patients routinely present problems in nursing practice. For example, a home care nurse learns that a patient has difficulty taking her medications regularly. The patient is unable to describe which medications she has taken for the last 3 days. The medication bottles are labeled and filled. The nurse has to solve the problem of why the patient is not adhering to or following her medication schedule. The nurse knows that, when the patient was discharged from the hospital, she had five medications ordered. The patient tells the nurse that she also takes two over-the-counter medications regularly. When the nurse asks her to show the medications that she takes in the morning, the nurse notices that the patient has difficulty seeing the medication labels. The patient is able to describe the medications that she is to take but is uncertain about the times of administration.

BOX 15-2 Using the Scientific Method to Solve Nursing Practice Questions

Clinical Problem: Heart failure commonly results in 30-day hospital readmissions among hospitalized older adults. The Affordable Care Act, which includes two separate pieces of legislation—the Patient Protection and Affordable Care Act (P.L. 111-148) and the Health Care and Education Reconciliation Act of 2010 (P.L. 111-152), contains provisions that increase hospitals' financial accountability for preventable readmissions. If patients are inappropriately readmitted, hospitals receive less financial reimbursement. Are preventable readmissions in some way related to the level of care patients receive?

Identify the Problem: Are nurse staffing levels and nurse education associated with 30-day readmissions among Medicare patients with heart failure?

Collect Data: The researcher reviews the literature about heart failure readmissions and previous studies examining the effects that baccalaureate-prepared nurses have on discharge planning.

The researcher also reviews information about how a nursing work environment affects care delivery.

Form a Research Question to Study the Problem: What is the relationship between hospital nursing factors (defined as nurse work environment, nurse staffing levels, and nurse education) and 30-day readmissions among Medicare patients with heart failure?

Answer the Question: Analysis of data from three states in the United States included hospital nursing (i.e., work environment, patient-to-nurse ratios, and proportion of nurses holding a BSN degree), patient discharge data, and the American Hospital Association Annual Survey data.

Evaluate the Results of the Study. Is the Research Question Answered? Statistical methods estimated the relationship between nursing factors and 30-day readmission. Nearly 1 quarter of patients admitted to the hospital with heart failure (23.3% [n=39,954]) were readmitted within 30 days. Each additional patient assigned per nurse in the average nurse's workload was associated with 7% higher risk for readmission for heart failure. Care in a hospital with a good-versus-poor work environment was associated with odds of readmission that were 7% lower for heart failure (McHugh and Ma, 2013).

The nurse recommends having the patient's pharmacy relabel the medications in larger lettering. In addition, the nurse shows the patient examples of pill organizers that will help her sort her medications by time of day for a period of 7 days.

Effective **problem solving** involves evaluating a situation over time, identifying possible solutions, and trying a solution over time to make sure that it is effective. It becomes necessary to try different options if a problem recurs. From the previous example, during a follow-up visit the nurse finds that the patient has organized her medications correctly and is able to read the labels without difficulty. The nurse obtained information that correctly clarified the cause of the patient's problem and tested a solution that proved successful. Having solved a problem in one situation adds to a nurse's experience in practice, which allows the nurse to apply that knowledge in future patient situations.

Decision Making. When you face a problem or situation and need to choose a course of action from several options, you are making a decision. **Decision making** is a product of critical thinking that focuses on problem resolution. Following a set of criteria helps you make a thorough and thoughtful decision. The criteria may be personal; based on an organizational policy; or, in the case of nursing, a professional standard. For example, decision making occurs when a person decides on the choice of a health care provider. To make

a decision, an individual has to recognize and define the problem or situation (need for a certain type of health care provider to provide medical care) and assess all options (consider recommended health care providers or choose one whose office is close to home). The person has to weigh each option against a set of personal criteria (experience, friendliness, and reputation), test possible options (talk directly with the different health care providers), consider the consequences of the decision (examine pros and cons of selecting one health care provider over another), and make a final decision. Although the set of criteria follows a sequence of steps, decision making involves moving back and forth when considering all criteria. It leads to informed conclusions that are supported by evidence and reason. Examples of decision making in the clinical area include determining which patient care priority requires the first response, choosing a type of dressing for a patient with a surgical wound, or selecting the best teaching approach for a family caregiver who will assist a patient who is returning home after a stroke.

Specific Critical Thinking

Diagnostic Reasoning and Inference. Once you gather information about a patient, as Tonya did in collecting information about Mr. Lawson's discomfort, **diagnostic reasoning** begins. It is the analytical process for determining a patient's health problems (Harjai and Tiwari, 2009). Accurate recognition of a patient's problems is necessary before you decide on solutions and implement action. It requires you to assign meaning to the behaviors and physical signs and symptoms presented by a patient. For example, what does Mr. Lawson's restlessness, shortness of breath, and developing chest pain indicate? Diagnostic reasoning begins when you interact with a patient or make physical or behavioral observations. An expert nurse sees the context of a patient situation (e.g., Mr. Lawson just had major surgery; has been inactive; and is at risk for blood pooling in the lower extremities, which can cause clots to form in the circulation), observes patterns and themes (e.g., symptoms that include shortness of breath, sharp chest pain, and irregular heart rate), and makes decisions quickly (e.g., a clot may have dislodged and traveled to the patient's lung, requiring a quick medical response). The information that a nurse collects and analyzes leads to a diagnosis of a patient's condition. Nurses do not make medical diagnoses, but they do assess and monitor each patient closely and compare a patient's signs and symptoms with those that are common to a medical diagnosis (e.g., in the case of Mr. Lawson, a pulmonary embolus). Diagnostic reasoning helps health care providers pinpoint the nature of a problem more quickly and select proper therapies.

Part of diagnostic reasoning is clinical **inference**, the process of drawing conclusions from related pieces of evidence and previous experience with the evidence. When making an inference, you form patterns of information from data before making a diagnosis. *In the initial scenario Tonya noted that Mr. Lawson was lying in a position to splint movement of his incision, had a tense facial expression, and experienced tenderness when his wound was palpated. Tonya infers that Mr. Lawson has a level of discomfort.* She demonstrates diagnostic reasoning by identifying the nursing diagnosis *Acute Pain* (see Chapter 17).

In diagnostic reasoning Tonya used patient data that she gathered and analyzed logically to recognize a problem. As a student, confirm any judgments such as when you make nursing diagnoses or believe that a medical problem is developing with experienced nurses. At times you may be wrong, but consulting with nurse experts gives you feedback to build on future clinical situations.

Often you cannot make a precise diagnosis during your first meeting with a patient. Sometimes you sense that a problem exists but do not have enough data to make a specific diagnosis. Some patients' physical conditions limit their ability to tell you about symptoms. Some choose

to not share sensitive and important information during your initial assessment. Some patients' behaviors and physical responses become observable only under conditions not present during your initial assessment. When uncertain of a diagnosis, continue data collection. You have to critically analyze changing clinical situations until you are able to determine a patient's unique situation. Any diagnostic conclusions that you make will help health care providers identify the nature of a problem more quickly and select appropriate medical therapies.

Clinical Decision Making. As in the case of general decision making, clinical decision making is a problem-solving activity. It goes beyond diagnostic reasoning when you focus on defining a problem or diagnosis and selecting appropriate nursing interventions. When you approach a clinical problem such as a patient who is less mobile and develops an area of redness over the hip, you make a decision that identifies the problem (impaired skin integrity in the form of a pressure ulcer) and choose the best nursing interventions (skin care, special bed surface, and a turning schedule). Nurses make clinical decisions all the time to improve a patient's health or maintain wellness. This means reducing the severity of the problem or resolving the problem completely. **Clinical decision making** requires careful reasoning (i.e., choosing the options for the best patient outcomes on the basis of a patient's condition and the priority of the problem).

Skilled clinical decision making occurs through **knowing the patient** (Zolnierek, 2014). Knowing the patient is an in-depth knowledge of a patient's patterns of responses within a clinical situation and knowing the patient as a person (Tanner et al., 1993). It has two components: a nurse's understanding of a specific patient and his or her subsequent selection of interventions. Knowing the patient relates to a nurse's experience with caring for patients, time spent in a specific clinical area, and having a sense of closeness with patients (Radwin, 1996). For example, an expert nurse who has worked on a general surgery unit for many years has been caring for a patient the last 2 days. The nurse is familiar with how the patient is progressing physically and mentally. When the patient begins to experience a change (e.g., a slight fall in blood pressure, becoming less responsive), the nurse knows that something is wrong, suspects the patient may be bleeding internally, and takes action. Because of her clinical experience and knowing the patient, the expert nurse can make a clinical decision and act more quickly than a new nurse can be expected to act.

Knowing the patient is central to individualizing nursing care so a patient feels cared for and cared about (Zolnierek, 2014). Knowing offers a nurse "the big picture" and "knowing the whole person" so he or she can make suitable decisions to protect patients from harm. Henneman et al. (2010) found that knowing the patient enabled nurses to identify problems and potential errors and thus rescue their patients from potential adverse events. A critical aspect to knowing patients and thus being able to make timely and appropriate decisions is spending time establishing relationships with them (Zolnierek, 2014). A study found that work relationships with patients, families, and colleagues are most strongly associated with nurses' expertise (Roche et al., 2009).

Build your ability to make clinical decisions by fostering knowing your patients. Follow these tips:

- Spend more time during initial patient assessments to observe patient behavior and measure physical findings as a way to improve knowledge of your patients. Determine what is important to them and make an emotional connection. Patients perceive meaningful time as that involving personal rather than task-oriented conversation.
- When talking with patients, listen to their accounts of their experiences with illness, watch them, and come to understand how they typically respond (Tanner, 2006).

- Consistently check on patients to assess and monitor problems to help you identify how clinical changes develop over time.
- Ask to have the same patient assigned to you over consecutive days. Researchers have noted that a nurse-patient relationship develops from getting to know a patient and building a foundation for connecting on the first day of care, to deepening understanding of the patient and sustaining a connection by the second day, to being comfortable with the patient by the third day (Lotzkar and Bottorff, 2010).
- Social conversation and continuity are important for developing knowing and nurse-patient relationships (Zolnierek, 2014).

Always keep a patient as your center of focus as you try to solve clinical problems. Making accurate clinical decisions allows you to set priorities for the interventions to implement first (see Chapter 18). Do not assume that certain health situations produce automatic priorities. For example, a patient who has surgery is anticipated to experience a certain level of postoperative pain, which often becomes a priority for care. However, if a patient is experiencing severe anxiety that increases pain perception, you need to focus on ways to relieve the anxiety before pain-relief measures will be effective.

Critical thinking and clinical decision making are complicated because nurses care for multiple patients in fast-paced and unpredictable environments. When you work in a busy setting, use criteria that includes the clinical condition of the patient, Maslow's hierarchy of needs (see Chapter 6), the risks involved in treatment delays, environmental factors (staff resources available), and patients' expectations of care to determine which patients have the greatest priorities for care. For example, a patient who is having a sudden drop in blood pressure along with a change in consciousness requires your attention immediately as opposed to a patient who needs you to collect a urine specimen or one who needs your help to walk down the hallway. Critical thinking in decision making allows you to attend to a patient whose condition is changing quickly and delegate the specimen collection and ambulation to nursing assistive personnel. For you to manage the wide variety of problems associated with groups of patients, skillful, prioritized clinical decision making is critical (Box 15-3).

BOX 15-3   Clinical Decision Making for Groups of Patients

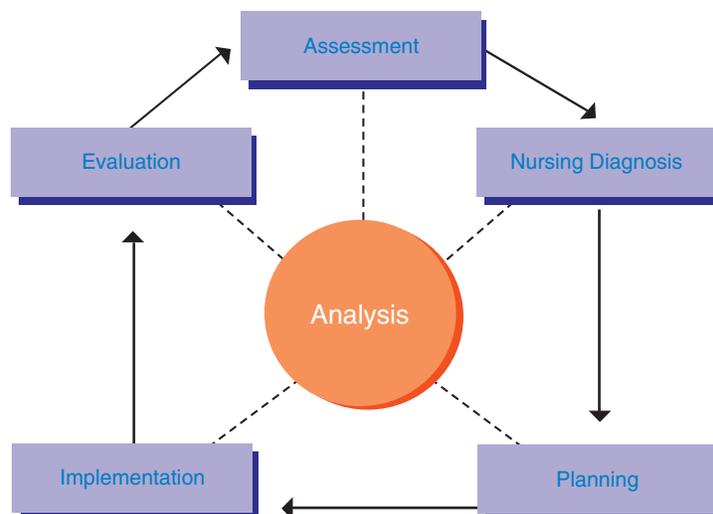
- Identify the nursing diagnoses and collaborative problems of each patient (see Chapter 17).
- Analyze the diagnoses/problems and decide which are most urgent on the basis of basic needs, the patients' changing or unstable status, and problem complexity (see Chapter 18).
- Consider the time it will take to care for patients whose problems are of high priority (e.g., do you have the time to restart a critical intravenous [IV] line when medication is due for a different patient?).
- Consider resources you have to manage each problem, nursing assistive personnel assigned with you, other health care providers, and patients' family members.
- Involve patients and/or their family as decision makers and participants in care.
- Decide how to combine activities to resolve more than one patient problem at a time.
- Decide which, if any, nursing care procedures to delegate to assistive personnel so you are able to spend your time on activities requiring professional nursing knowledge.
- Discuss complex cases with other members of the health care team to ensure a smooth transition in care requirements.


FIGURE 15-2 Five-step nursing process model.

Nursing Process as a Competency

Nurses apply the **nursing process** as a competency when delivering patient care (Kataoka-Yahiro and Saylor, 1994). The American Nurses Association (ANA) (2010) developed standards that set forth the framework necessary for critical thinking in the application of the five-step nursing process: assessment, diagnosis, planning, implementation, and evaluation. The purpose of the nursing process is to diagnose and treat human responses (e.g., patient symptoms, need for knowledge) to actual or potential health problems (ANA, 2010). Use of the process allows nurses to help patients meet agreed-on outcomes for better health (Figure 15-2). The nursing process requires a nurse to use the general and specific critical thinking competencies described earlier to focus on a particular patient's unique needs. The format for the nursing process is unique to the discipline of nursing and provides a common language and process for nurses to "think through" patients' clinical problems (Kataoka-Yahiro and Saylor, 1994). Unit III describes the nursing process.

A CRITICAL THINKING MODEL FOR CLINICAL DECISION MAKING

Thinking critically is at the core of professional nursing competence. The ability to think critically, improve clinical practice, and decrease errors in clinical judgments is an aim of nursing practice. This text offers a model to help you develop critical thinking. Models help to explain concepts. Because critical thinking in nursing is complex, a model explains what is involved as you make clinical decisions and judgments about your patients. Kataoka-Yahiro and Saylor (1994) developed a model of critical thinking for nursing judgment based in part on previous work by a number of nurse scholars and researchers (Miller and Malcolm, 1990; Paul, 1993) (see Figure 15-1). The model defines the outcome of critical thinking: nursing judgment that is relevant to nursing problems in a variety of settings. According to this model, there are five components of critical thinking: knowledge base, experience, critical thinking competencies (with emphasis on the nursing process), attitudes, and standards. The elements of the model combine to explain how nurses make clinical judgments that are necessary for safe, effective nursing care (see Box 15-3). Throughout this text the model shows you how to apply critical thinking as part of the nursing process. Graphic illustration of the critical thinking model in our clinical chapters shows you how to apply elements of critical thinking in assessing patients, planning the interventions you provide, and evaluating the results. Consistently applying each element of this model in the way you think about patients will help you become a more confident and effective professional.

Specific Knowledge Base

The first component of the critical thinking model is a nurse's specific knowledge base. Knowledge prepares you to better anticipate and identify patients' problems by understanding their origin and nature. Nurses' knowledge varies according to educational experience and includes basic nursing education, continuing education courses, and additional college degrees. In addition, it includes the initiative you show in reading the nursing literature to remain current in nursing science. A nurse's knowledge base is continually changing as science progresses (Swinny, 2010). As a nurse your knowledge base includes information and theory from the basic sciences, humanities, behavioral sciences, and nursing. Nurses use their knowledge base in a different way than other health care disciplines because they think holistically about patient problems. For example, a nurse's broad knowledge base offers a physical, psychological, social, moral, ethical, and cultural view of patients and their health care needs. The depth and extent of knowledge influence your ability to think critically about nursing problems.

> *Tonya previously earned a bachelor's degree in education and taught high school for 1 year. She is now in her second year as a nurse. She is taking prerequisites to further her education, including courses in health ethics and population health. Her experience as a staff nurse has allowed her to develop knowledge about a variety of surgical procedures, the effects of different medications,*

and responses patients typically show to their treatment. Although she is still new to nursing, her experiences as a teacher and her preparation and knowledge base in nursing help her know how to interact and form relationships with patients that help her make clinical decisions about patients' health promotion practices.

Experience

Nursing is a practice discipline. Clinical learning experiences are necessary to acquire clinical decision-making skills. Swinny (2010) explains that knowledge itself is not necessarily related to the development of critical thinking. Instead knowledge combined with clinical expertise from experience defines critical thinking. In clinical situations you learn from observing, sensing, talking with patients and families, and reflecting actively on all experiences. Clinical experience is the laboratory for developing and testing approaches that you safely adapt or revise to fit the setting, a patient's unique qualities, and the experiences you have from caring for previous patients. With experience you begin to understand clinical situations, anticipate and recognize cues of patients' health patterns, and interpret the cues as relevant or irrelevant. Perhaps the best lesson a new nursing student can learn is to value all patient experiences, which become stepping-stones for building new knowledge and inspiring innovative thinking.

When Tonya was finishing her last year in nursing school, she worked as a nurse assistant in a nursing home. This experience provided valuable time for interacting with older-adult patients and giving basic nursing care. Each patient provided her with valuable learning experiences that she applies with other patients. Specifically she developed good interviewing skills, understands the importance of the family in an individual's health, and learned to become a patient advocate. She also learned that older adults need more time to perform activities such as eating, bathing, and grooming; therefore she has adapted these skill techniques. Finally Tonya's previous experience as a teacher helps her apply educational principles in her nursing role.

Your practice improves from what you learn personally. The opportunities you have to experience different emotions, crises, and successes in your lives and relationships with others build your experience as a nurse.

The Nursing Process Competency

The nursing process competency is the third component of the critical thinking model. In your practice you will apply critical thinking components during each step of the nursing process. Chapters 16 through 20 describe each step of the nursing process.

Attitudes for Critical Thinking

The fourth component of the critical thinking model is attitudes. Eleven attitudes define the central features of a critical thinker and how a successful critical thinker approaches a problem (Paul, 1993) (Box 15-4). For example, when a patient complains of anxiety before a diagnostic procedure, a curious nurse seeks an explanation and information by asking several questions to learn what the patient does not know and the nature of the patient's concerns (Kaddoura, 2013). The nurse shows discipline in forming questions and collecting a thorough assessment to find the source of the patient's anxiety. Attitudes of inquiry involve an ability to recognize that problems exist and that there is a need for evidence to support the truth in what you think is true. Critical thinking attitudes are guidelines for how to approach a problem or decision-making situation. Important parts of critical thinking are interpreting, evaluating, and making judgments about the

---

BOX 15-4   Components of Critical Thinking in Nursing

I.   Specific knowledge base in nursing
II. Experience
III. Critical thinking competencies
   A. General critical thinking
   B. Specific critical thinking
   C. Specific critical thinking in nursing: nursing process
IV. Attitudes for critical thinking
   Confidence, independence, fairness, responsibility, risk taking, discipline, perseverance, creativity, curiosity, integrity, humility
V. Standards for critical thinking
   A. Intellectual standards
      Clear—Plain and understandable (e.g., clarity in how one communicates).
      Precise—Exact and specific (e.g., focusing on one problem and possible solution).
      Specific—To mention, describe, or define in detail
      Accurate—True and free from error; getting to the facts (objective and subjective)
      Relevant—Essential and crucial to a situation (e.g., a patient's changing clinical status)
      Plausible—Reasonable or probable
      Consistent—Expressing consistent beliefs or values
      Logical—Engaging in correct reasoning from what one believes in a given instance to the conclusions that follow
      Deep—Containing complexities and multiple relationships
      Broad—Covering multiple viewpoints (e.g., patient and family)
      Complete—Thoroughly thinking and evaluating
      Significant—Focusing on what is important and not trivial
      Adequate (for purpose)—Satisfactory in quality or amount
      Fair—Being open-minded and impartial
   B. Professional standards
      1. Ethical criteria for nursing judgment
      2. Criteria for evaluation
      3. Professional responsibility

Modified from Kataoka-Yahiro M, Saylor C: A critical thinking model for nursing judgment, *J Nurs Educ* 33(8):351, 1994. Data from Paul RW: The art of redesigning instruction. In Willsen J, Blinker AJA, editors: *Critical thinking: how to prepare students for a rapidly changing world,* Santa Rosa, Calif, 1993, Foundation for Critical Thinking.

---

adequacy of various arguments and available data. Knowing when you need more information, knowing when information is misleading, and recognizing your own knowledge limits are examples of how critical thinking attitudes guide decision making. Table 15-3 summarizes the use of critical thinking attitudes in nursing practice.

Confidence.   Confidence is the belief in oneself, one's judgment and psychomotor skills, and one's possession of the knowledge and the ability to think critically and draw appropriate conclusions (Etheridge, 2007). When you are confident, you feel certain about accomplishing a task or goal such as performing a procedure or making a diagnosis. Confidence grows with experience in recognizing your strengths and limitations. You shift your focus from your own needs (e.g., remembering what assessment data means or how to perform a procedure) to a patient's needs. When you are not confident in knowing if a patient is clinically changing or in performing a nursing skill, you become

TABLE 15-3 **Critical Thinking Attitudes and Applications in Nursing Practice**	
Critical Thinking Attitude	**Application in Practice**
Confidence	Learn how to introduce yourself to a patient; speak with conviction when you begin a treatment or procedure. Do not lead a patient to think that you are unable to perform care safely. Always be well prepared before performing a nursing activity. Encourage a patient to ask questions.
Thinking independently	Read the nursing literature, especially when there are different views on the same subject. Talk with other nurses and share ideas about nursing interventions.
Fairness	Listen to both sides in any discussion. If a patient or family member complains about a co-worker, listen to the story and speak with the co-worker as well. If a staff member labels a patient uncooperative, assume the care of that patient with openness and a desire to meet the patient's needs.
Responsibility and authority	Ask for help if you are uncertain about how to perform a nursing skill. Refer to a policy and procedure manual to review steps of a skill. Report any problems immediately. Follow standards of practice in your care.
Risk taking	If your knowledge causes you to question a health care provider's order, do so. Be willing to recommend alternative approaches to nursing care when colleagues are having little success with patients.
Discipline	Be thorough in whatever you do. Use known scientific and practice-based criteria for activities such as assessment and evaluation. Take time to be thorough and manage your time effectively.
Perseverance	Be cautious of an easy answer. If co-workers give you information about a patient and some fact seems to be missing, clarify the information or talk to the patient directly. If problems of the same type continue to occur on a nursing division, bring co-workers together, look for a pattern, and find a solution.
Creativity	Look for different approaches if interventions are not working for a patient. For example, a patient in pain may need a different positioning or distraction technique. When appropriate, involve the patient's family in adapting your approaches to care methods used at home.
Curiosity	Always ask why. A clinical sign or symptom often indicates a variety of problems. Explore and learn more about a patient so as to make appropriate clinical judgments.
Integrity	Recognize when your opinions conflict with those of a patient; review your position and decide how best to proceed to reach outcomes that will satisfy everyone. Do not compromise nursing standards or honesty in delivering nursing care.
Humility	Recognize when you need more information to make a decision. When you are new to a clinical division, ask for an orientation to the area. Ask registered nurses (RNs) regularly assigned to the area for assistance with approaches to care.

anxious about not knowing what to do. This prevents you from giving attention to the patient. Always be aware of what you know and what you don't know. If you question the meaning of a clinical situation and you don't know if the information you have is important, discuss it with your nursing instructor first. Never perform a procedure unless you have the knowledge base and feel confident. Patient safety is of the upmost importance. When you show confidence, your patients recognize it by how you communicate and the way you perform nursing care. Confidence builds trust between you and your patients.

Thinking Independently. As you gain new knowledge, you learn to consider a wide range of ideas and concepts before forming an opinion or making a judgment. This does not mean that you ignore other people's ideas. Instead you learn to consider all sides of a situation. A critical thinker does not accept another person's ideas without question. When thinking independently, you challenge the ways that others think and look for rational and logical answers to problems. You begin to raise important questions about your practice. For example, why is one type of surgical dressing ordered over another, why do patients on your nursing unit fall, and what can you do to help patients with literacy problems learn about their medications? When nurses ask questions and look for the evidence behind clinical problems, they are thinking independently; this is an important step in evidence-based practice (see Chapter 5). Independent thinking and reasoning are essential to the improvement and expansion of nursing practice.

Fairness. A critical thinker deals with situations justly. This means that bias or prejudice does not enter into a decision. For example, regardless of how you feel about obesity, you do not allow personal attitudes to influence the way you care for a patient who is overweight. Look at a situation objectively and consider all viewpoints to understand the situation completely before making a decision. Having a sense of imagination helps you develop an attitude of fairness. Imagining what it is like to be in your patient's situation helps you see it with new eyes and appreciate its complexity.

Responsibility and Accountability. Responsibility is the knowledge that you are accountable for your decisions, actions, and critical thinking (Etheridge, 2007). When caring for patients, you are responsible for correctly performing nursing care activities on the basis of standards of practice. Standards of practice are the minimum level of performance accepted to ensure high-quality care. For example, you do not take shortcuts (e.g., failing to identify a patient, preparing medication doses for multiple patients at the same time) when administering medications. A professional nurse is responsible for competently performing nursing therapies and making clinical decisions about patients. As a nurse you are answerable or accountable for your decisions and the outcomes of your actions. This means that you are accountable for recognizing when nursing care is ineffective and you know the limits and scope of your practice.

Risk Taking. People often associate taking risks with danger. Driving 30 miles an hour over the speed limit is a risk that sometimes results in injury to the driver and an unlucky pedestrian. But risk taking does not always have negative outcomes. Risk taking is desirable, particularly when the result is a positive outcome. A critical thinker is willing to take risks when trying different ways to solve problems. The willingness to take risks comes from experience with similar problems. Risk taking often leads to advances in patient care. In the past nurses have taken risks when trying different approaches to skin and wound care and pain management, to name a few. When taking a risk, consider all options; follow safety guidelines; analyze any potential dangers to a patient; and act in a well-reasoned, logical, and thoughtful manner.

Discipline. A disciplined thinker misses few details and is orderly or systematic when collecting information, making decisions, or taking action. For example, you have a patient who is in pain. Instead of only asking the patient, "How severe is your pain on a scale of 0 to 10?", you also ask more specific questions about the character of pain. For example, "What makes the pain worse? Where does it hurt? How long have you noticed it?" Being disciplined helps you identify problems more accurately and select the most appropriate interventions.

Perseverance. A critical thinker is determined to find effective solutions to patient care problems. This is especially important when problems remain unresolved or recur. Learn as much as possible about a problem and try various approaches to care. Persevering means to keep looking for more resources until you find a successful approach. For example, a patient who is unable to speak following throat surgery poses challenges for the nurse to be able to communicate effectively. Perseverance leads the nurse to try different communication approaches (e.g., message boards or alarm bells) until he or she finds a method that the patient is able to use. A critical thinker who perseveres is not satisfied with minimal effort but works to achieve the highest level of quality care.

Creativity. Creativity involves original thinking. This means that you find solutions outside of the standard routines of care while still following standards of practice. Creativity motivates you to think of options and unique approaches. A patient's clinical problems, social support systems, and living environment are just a few examples of factors that make the simplest nursing procedure more complicated. For example, a home care nurse has to find a way to help an older patient with arthritis have greater mobility in the home. The patient has difficulty lowering and raising herself in a chair because of pain and limited range of motion in her knees. The nurse uses wooden blocks to elevate the chair legs so the patient is able to sit and stand with little discomfort while making sure that the chair is safe to use.

Curiosity. A critical thinker's favorite question is "Why?" In any clinical situation you learn a great deal of information about a patient. As you analyze patient information, data patterns appear that are not always clear. Having a sense of curiosity (asking yourself, "What if?") motivates you to inquire further (e.g., question family or physician, review the scientific literature) and investigate a clinical situation so you get all the information you need to make a decision.

Integrity. Critical thinkers question and test their own knowledge and beliefs. Your personal integrity as a nurse builds trust from your co-workers. Nurses face many dilemmas or problems in everyday clinical practice, and everyone makes mistakes at times. A person of integrity is honest and willing to admit to mistakes or inconsistencies in his or her own behavior, ideas, and beliefs. A professional nurse always tries to follow the highest standards of practice.

Humility. It is important for you to admit to any limitations in your knowledge and skill. Critical thinkers admit what they do not know and try to find the knowledge needed to make proper decisions. It is common for a nurse to be an expert in one area of clinical practice but a novice in another because the knowledge in all areas of nursing is unlimited. A patient's safety and welfare are at risk if you do not admit your inability to deal with a practice problem. You have to rethink a situation; learn more; and use the new information to form opinions, draw conclusions, and take action.

Mr. Lawson continues to have chest pain and shortness of breath. As Tonya waits for the medical team to arrive, she knows that she is responsible for his welfare until treatment can be initiated. Tonya acts independently by keeping Mr. Lawson comfortable in the chair, not moving him (to avoid worsening of his condition), and gathering additional assessment data. She displays discipline in further assessing Mr. Lawson's condition: rechecking vital signs, observing his abdominal wound and incision, and talking with him to notice if there is a change in consciousness. Tonya knows that she cannot diagnose medically. When the physician arrives, she objectively reports what happened with Mr. Lawson once he sat up in the chair, the symptoms he displayed, and how those symptoms have changed.

Standards for Critical Thinking

The fifth component of the critical thinking model includes intellectual and professional standards (Kataoka-Yahiro and Saylor, 1994).

Intellectual Standards. Paul (1993) identified 14 intellectual standards (see Box 15-4) universal for critical thinking. An intellectual standard is a principle for rational thought. You apply these standards during all steps of the nursing process. For example, when you consider a patient problem, apply the intellectual standards of preciseness, accuracy, and consistency to make sure that you have all the data you need to make sound clinical decisions. During planning, apply standards such as being logical and significant so that the plan of care is meaningful and relevant to a patient's needs. A thorough use of intellectual standards in clinical practice prevents you from performing critical thinking haphazardly.

The physician orders a lung scan, chest x-ray and places Mr. Lawson on bed rest. Blood tests are also ordered in anticipation of placing the patient on anticoagulation (to prevent further clot formation). Tonya asks the physician if there are risks to be considered regarding Mr. Lawson's wound should the patient receive an anticoagulant (relevant question). She also asks if she can give additional pain medication at this time to manage the patient's surgical incision pain during the x-ray procedures (logical decision). By applying intellectual standards, Tonya is a competent partner in managing the patient's care, showing her ability to anticipate possible clinical problems.

Professional Standards. Professional standards for critical thinking refer to ethical criteria for nursing judgments, evidence-based criteria used for evaluation, and criteria for professional responsibility (Paul, 1993). Application of professional standards requires you to use critical thinking for the good of individuals or groups (Kataoka-Yahiro

and Saylor, 1994). Professional standards promote the highest level of quality nursing care.

Excellent nursing practice is a reflection of ethical standards (see Chapter 22). Patient care requires more than just the application of scientific knowledge. Being able to focus on a patient's values and beliefs helps you make clinical decisions that are just, faithful to a patient's choices, and beneficial to a patient's well-being. Critical thinkers maintain a sense of self-awareness through conscious awareness of their beliefs, values, and feelings and the multiple perspectives that patients, family members, and peers present in clinical situations. Critical thinking also requires the use of evidence-based criteria for making clinical judgments. These criteria are sometimes scientifically based on research findings (see Chapter 5) or practice based on standards developed by clinical experts and performance improvement initiatives of an institution. Examples are the clinical practice guidelines developed by individual clinical agencies and national organizations such as the Agency for Healthcare Research and Quality (AHRQ). A clinical practice guideline includes standards for the treatment of select clinical conditions such as stroke, deep vein thrombosis, and pressure ulcers. Another example is clinical criteria used to categorize clinical conditions such as the criteria for staging pressure ulcers (see Chapter 48) and rating phlebitis (see Chapter 42). Evidence-based evaluation criteria set the minimum requirements necessary to ensure appropriate and high-quality care.

Nurses routinely use evidence-based criteria to assess patients' conditions and determine the efficacy of nursing interventions. For example, accurate assessment of symptoms such as pain includes use of assessment criteria, including the duration, severity, location, aggravating or relieving factors, and effects on daily lifestyle (see Chapter 44). In this case assessment criteria allow you to accurately determine the nature of a patient's symptoms, select appropriate therapies, and evaluate if the therapies are effective. The standards of professional responsibility that a nurse tries to achieve are the standards cited in Nurse Practice Acts, institutional practice guidelines, and professional organizations' standards of practice (e.g., The ANA Standards of Professional Performance (see Chapter 1). These standards "raise the bar" for the responsibilities and accountabilities that a nurse assumes in guaranteeing quality health care to the public.

CRITICAL THINKING SYNTHESIS

Critical thinking is a reasoning process by which you reflect on and analyze your thoughts, action, and knowledge. As a beginning nurse it is important to learn the steps of the nursing process and incorporate the elements of critical thinking (Figure 15-3). The two processes go hand in hand in making quality decisions about patient care. This text provides a model to show you how important critical thinking is in the practice of the nursing process.

DEVELOPING CRITICAL THINKING SKILLS

To develop critical thinking skills you learn how to connect knowledge and theory with day-to-day practices. The ability to make sense of what you learn in the classroom, from reading, or from having dialogue with other students and then to apply it during patient care is challenging.

Reflective Journaling

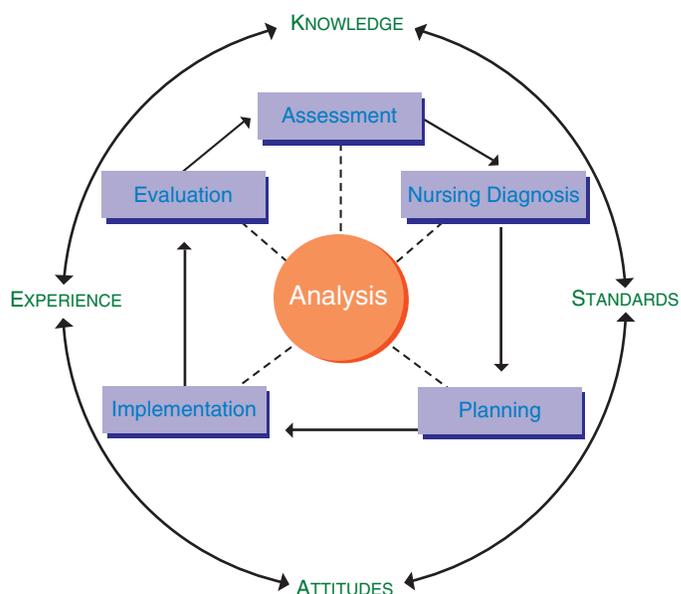
Reflective journal writing is a tool for developing critical thought and reflection by clarifying concepts. These concepts are embedded in the day-to-day clinical situations and problems you face. Reflective writing gives you the chance to define and express clinical experiences in your


FIGURE 15-3 Synthesis of critical thinking with the nursing process competency.

own words. Always begin by recording notes after a clinical experience. The use of a journal improves your observation and descriptive skills and ultimately your clinical decision making. Use these tips for reflecting on a clinical experience to explore its meaning:

1. Which experience, situation, or information in your clinical experience is confusing, difficult, or interesting?
2. What is the meaning of the experience? What feelings did you have? What feelings did your patient or family have? What influenced the experience?
3. Do the feelings, guesses, or questions remind you of any experiences from the past or something that you think is a desirable future experience? How does it relate?
4. What are the connections between what is being described and what you have learned about nursing science and theory?

Meeting with Colleagues

Nurses depend on others to help them think like nurses (Etheridge, 2007). A way to develop critical thinking skills is regularly meeting with colleagues such as faculty members or preceptors to discuss and examine work experiences and validate decisions. Connecting with others will help you learn that you do not need to know everything because support is available from other colleagues. When nurses have a formal means to discuss their experiences such as a staff meeting or unit practice council, the dialogue allows for questions, differing viewpoints, and sharing experiences. When they are able to discuss their practices, the process validates good practice and also offers challenges and constructive criticism. Much can be learned by drawing from others' experiences and perspectives to promote reflective critical thinking.

Concept Mapping

As a nurse you will care for patients who have multiple nursing diagnoses or collaborative problems. A **concept map** is a visual representation of patient problems and interventions that shows their relationships to one another. It is a nonlinear picture of a patient to be used for comprehensive care planning. The primary purpose of concept mapping is to better synthesize relevant data about a patient, including assessment data, nursing diagnoses, health needs, nursing

---

BOX 15-5   EVIDENCE-BASED PRACTICE

Impact of Stressful Work Environments on Thinking and Decision Making

PICO Question: What are the effects on thinking and decision making among acute care nurses who work in stressful work environments versus nonstressful environments?

Evidence Summary

Regions of the cortex, amygdala, and brainstem of the brain interact between mental and physiological states (Critchley et al., 2013). Thus cognitive and emotional processes are affected by autonomic mechanisms during the stress response. Stress is a common condition in the health care workplace, resulting from workload, leadership/management style, professional conflict, and the emotional cost of caring for patients. Understanding the relationship between the stress of caregiving and cognitive and decision-making processes and empathy is important for nursing practice (Critchley et al., 2013). Stress alters the ability to problem solve accurately, speak fluently and clearly, remember, and manage emotions. Negative mood and stress often affects what and how nurses communicate to one another (Pfaff, 2012). During stress there is greater

likelihood for cynicism and frustration and inaccurate information being conveyed.

Application to Nursing Practice

- Learn to recognize when you are feeling stressed: your muscles will tense, you become reactive when others communicate with you, you have trouble concentrating, and you feel very tired.
- Take a time out. Try to find a way to relax by doing a quick relaxation exercise or finding a place where colleagues are not bombarding you with questions.
- Discuss the difficult and stressful patient care experiences that you are having with your colleagues with someone you trust. Realizing that your concerns are shared by others relieves stress.
- Participate in opportunities to make decisions about practice activities.
- Attend a stress-management class at work.

---

interventions, and evaluation measures. Through drawing a concept map, you learn to organize or connect information in a unique way so the diverse information that you have about a patient begins to form meaningful patterns and concepts. You begin to see a more holistic view of a patient. When you see the relationship between the various patient diagnoses and the data that support them, you better understand a patient's clinical situation. Concept maps can be found in the clinical chapters of this text (see Units V and VI).

MANAGING STRESS

The connection between stress in a health care setting and its effects on a nurse's mental and physiological state is receiving more attention. Autonomic control of decision making, error detection, speech, memory, and emotions during stressful situations are disrupted because of continued sympathetic nervous system stimulation. Research has shown that the stress of working 12-hour shifts, for example, impairs medical judgment, in part because of the way stress affects attention (McClelland et al., 2013). The work of professional nursing is difficult as you see patients endure suffering from disease and painful therapies and as you try to manage care responsibilities in busy, fast-paced work settings. Stress over a prolonged period or when extreme can lead to poor work productivity, impaired decision making and communication, and reduced ability to cope with clinical situations (Donovan et al., 2013). Box 15-5 offers perspectives on ways to better manage stress so you can make clear, thoughtful decisions and communicate effectively with health care colleagues (see Chapter 38).

KEY POINTS

- Clinical decision making involves judgment that includes critical and reflective thinking and action and application of scientific and practical logic.
- Nurses who apply critical thinking in their work focus on options for solving problems and making decisions rather than rapidly and carelessly forming quick, single solutions.
- Reflection involves purposeful thinking back or recalling a situation to discover its purpose or meaning.
- Following a procedure step by step without adjusting to a patient's unique needs is an example of basic critical thinking.

- In complex critical thinking a nurse learns that alternative and perhaps conflicting solutions exist.
- In diagnostic reasoning you collect patient data and analyze them to determine the patient's problems.
- The critical thinking model combines a nurse's knowledge base, experience, competence in the nursing process, attitudes, and standards to explain how nurses make clinical judgments that are necessary for safe, effective nursing care.
- Clinical learning experiences are necessary for you to acquire clinical decision-making skills.
- Critical thinking attitudes help you know when more information is necessary and when it is misleading and to recognize your own knowledge limits.
- The use of intellectual standards during assessment ensures that you obtain a complete database of information.
- Professional standards for critical thinking refer to ethical criteria for nursing judgments, evidence-based criteria for evaluation, and criteria for professional responsibility.
- Meeting regularly with colleagues allows you to discuss anticipated and unanticipated outcomes in any clinical situation to continually learn and develop your expertise.
- Stress over a prolonged period or when extreme can cause distress, leading to poor work productivity and impaired decision making and communication.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Medical treatment stabilized Mr. Lawson's condition. He had a pulmonary embolus, but he is now on anticoagulants, medications that will reduce likelihood of more clot formation. Knowing that Mr. Lawson is on anticoagulants and has had recent surgery and the processes of normal wound healing (see Chapter 48), Tonya believes that the patient is at risk for bleeding from his surgical wound. She acts by increasing assessments of the wound and teaching Mr. Lawson how to avoid placing stress on the wound

1. Describe the critical thinking skill that Tonya is demonstrating.

      After Tonya assesses the wound, she enters a note in the medical record. She describes the appearance of the incision in detail,

reports on the length of the incision, and notes that one suture is loose but there is no drainage.

2. Identify the three intellectual standards that Tonya uses in making a note in the record.

3. Mr. Lawson complains of more discomfort after lying on his right side for 30 minutes. Tonya asks him to describe the pain; it is focused more on his right shoulder and ribs. Tonya sees that the drainage tubing exiting the surgical wound is caught underneath the patient. She moves it, questions the patient further to find out that he has a history of arthritis in the shoulder, and then repositions and aligns him. This is an example of which critical thinking competencies?

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

▉ REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. Two patient deaths have occurred on a medical unit in the last month. The staff notices that everyone feels pressured and team members are getting into more arguments. As a nurse on the unit, what will best help you manage this stress?
   1. Keep a journal
   2. Participate in a unit meeting to discuss feelings about the patient deaths
   3. Ask the nurse manager to assign you to less difficult patients
   4. Review the policy and procedure manual on proper care of patients after death

2. A nurse has seen many cancer patients struggle with pain management because they are afraid of becoming addicted to the medicine. Pain control is a priority for cancer care. By helping patients focus on their values and beliefs about pain control, a nurse can best make clinical decisions. This is an example of:
   1. Creativity.
   2. Fairness.
   3. Clinical reasoning.
   4. Applying ethical criteria.

3. A nurse prepares to insert a Foley catheter. The procedure manual calls for the patient to lie in the dorsal recumbent position. The patient complains of having back pain when lying on her back. Despite this, the nurse positions the patient supine with knees flexed as the manual recommends and begins to insert the catheter. This is an example of:
   1. Accuracy.
   2. Reflection.
   3. Risk taking.
   4. Basic critical thinking.

4. A nurse is preparing medications for a patient. The nurse checks the name of the medication on the label with the name of the medication on the doctor's order. At the bedside the nurse checks the patient's name against the medication order as well. The nurse is following which critical thinking attitude:
   1. Responsible
   2. Complete
   3. Accurate
   4. Broad

5. A nurse on a busy medicine unit is assigned to four patients. It is 10 AM. Two patients have medications due and one of those has a specimen of urine to be collected. One patient is having complications from surgery and is being prepared to return to the operating room. The fourth patient requires instructions about activity restrictions before going home this afternoon. Which of the following should the nurse use in making clinical decisions appropriate for the patient group? (Select all that apply.)
   1. Consider availability of assistive personnel to obtain the specimen
   2. Combine activities to resolve more than one patient problem
   3. Analyze the diagnoses/problems and decide which are most urgent based on patients' needs
   4. Plan a family conference for tomorrow to make decisions about resources the patient will need to go home
   5. Identify the nursing diagnoses for the patient going home

6. By using known criteria in conducting an assessment such as reviewing with a patient the typical characteristics of pain, a nurse is demonstrating which critical thinking attitude?
   1. Curiosity
   2. Adequacy
   3. Discipline
   4. Thinking independently

7. A nurse just started working at a well-baby clinic. One of her recent experiences was to help a mother learn the steps of breast-feeding. During the first clinic visit the mother had difficulty positioning the baby during feeding. After the visit the nurse considers what affected the inability of the mother to breastfeed, including the mother's obesity and inexperience. The nurse's review of the situation is called:
   1. Reflection.
   2. Perseverance.
   3. Intuition.
   4. Problem solving.

8. Place the steps of the scientific method in their correct order with number 1 being the first step of the process.
   1. Formulate a question or hypothesis.
   2. Evaluate results of the study.
   3. Collect data.
   4. Identify the problem.
   5. Test the question or hypothesis.

9. A nurse changed a patient's surgical wound dressing the day before and now prepares for another dressing change. The nurse had difficulty removing the gauze from the wound bed yesterday, causing the patient discomfort. Today he gives the patient an analgesic 30 minutes before the dressing change. Then he adds some sterile saline to loosen the gauze for a few minutes before removing it. The patient reports that the procedure was much more comfortable. Which of the following describes the nurse's approach to the dressing change? (Select all that apply.)
   1. Clinical inference
   2. Basic critical thinking
   3. Complex critical thinking
   4. Experience
   5. Reflection

10. Which of the following describes a nurse's application of a specific knowledge base during critical thinking? (Select all that apply.)
   1. Initiative in reading current evidence from the literature
   2. Application of nursing theory
   3. Reviewing policy and procedure manual
   4. Considering holistic view of patient needs
   5. Previous time caring for a specific group of patients

11. **Fill in the Blank.** When a nurse tries to understand a patient's and family caregiver's perspective of why a patient is falling at home, the nurse applies the intellectual standard of _____ to understand all viewpoints.

12. An aspect of clinical decision making is knowing the patient. Which of the following is the most critical aspect of developing the ability to know the patient?
1. Working in multiple health care settings
2. Learning good communication skills
3. Spending time establishing relationships with patients
4. Relying on evidence in practice

13. In which of the following examples is a nurse applying critical thinking skills in practice? (Select all that apply.)
1. The nurse thinks back about a personal experience before administering a medication subcutaneously.
2. The nurse uses a pain-rating scale to measure a patient's pain.
3. The nurse explains a procedure step by step for giving an enema to a patient care technician.
4. The nurse gathers data on a patient with a mobility limitation to identify a nursing diagnosis.
5. A nurse offers support to a colleague who has witnessed a stressful event.

14. A nurse enters a 72-year-old patient's home and begins to observe her behaviors and examine her physical condition. The nurse learns that the patient lives alone and notices bruising on the patient's leg. When watching the patient walk, the nurse notes that she has an unsteady gait and leans to one side. The patient admits to having fallen in the past. The nurse identifies the patient as having the nursing diagnosis of Risk for Falls. This scenario is an example of:
1. Inference.
2. Basic critical thinking.
3. Evaluation.
4. Diagnostic reasoning.

15. Match the concepts for a critical thinker on the right with the application of the term on the left.

Term Application	Concepts for Critical Thinkers
a. Anticipate how a patient might respond to a treatment.	___ 1. Truth seeking
b. Organize assessment on the basis of patient priorities.	___ 2. Open-mindedness
c. Be objective in asking questions of a patient.	___ 3. Analyticity
d. Be tolerant of the patient's views and beliefs.	___ 4. Systematicity

Nursing Assessment

ⓔ MEDIA RESOURCES

The **nursing process** is a critical thinking five-step process (Figure 16-1) that professional nurses use to apply the best available evidence to caregiving and promoting human functions and responses to health and illness (ANA, 2010). It is the fundamental blueprint for how to care for patients. A patient-centered care approach is holistic and essential when applying the nursing process. Such an approach enhances patient assessment and education, family centeredness, patient adherence to interventions, and patient outcomes (Bertakis and Azari, 2011). The Quality and Safety Education for Nurses (QSEN) institute (2014) defines patient-centered care as "recognizing a patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for a patient's preferences, values, and needs." Thus assessment is an important first step for learning as much as you can about each patient's health condition and health problems by partnering together in a therapeutic relationship. Consider the following scenario that was also described in Chapter 15.

Mr. Lawson is a 62-year-old patient who had abdominal surgery for a colon resection and removal of a tumor 2 days ago. His nurse, Tonya, implemented pain-control strategies in an effort to help him become more mobile so recovery could proceed. Up until now he was getting out of bed and rating his pain at a level of 4 on a scale of 0 to 10. The patient still tends to guard his incision by placing his hand over the wound when moving.

Mr. Lawson weighs 109 kg (240 lbs) and is 5 ft 11 inches tall. He has tried to cough more during his postoperative deep-breathing exercises. Tonya is caring for him for the third day in a row and begins the morning shift by inspecting his surgical wound. The wound is approximately 15 cm (6 inches) in length and closed with steel sutures. Tonya notices separation of the wound between two sutures at the bottom of the incision. There is a small amount of serous drainage. The area is inflamed, and she asks the patient if the incision is tender when she gently palpates around the area. Mr. Lawson states, "Ow, that feels sore there. I think I pulled it when I coughed last night." He also rates pain at this time as being at a level of 5. Tonya checks Mr. Lawson's vital signs and notes that his temperature is 37.5° C (99.6° F), slightly above his average temperature of 37.2° C (99.0° F). Tonya also inspects the intravenous (IV) access device in the patient's left forearm. It is intact, and there are no signs of phlebitis at the IV site.

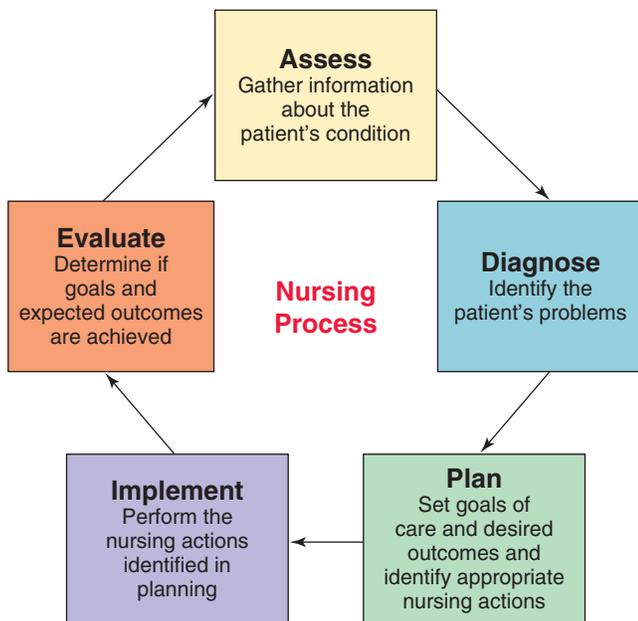
Each time you meet a patient, you apply the nursing process, as Tonya does while caring for Mr. Lawson. The first step of the nursing process, assessment, involves the gathering and analysis of information about a patient's health status. *In the case example Tonya gathers information*


FIGURE 16-1 Five-step nursing process.

by looking at the patient's wound (inspection) to note its character (length, presence of sutures) and condition (slight separation with drainage and inflammation at site). She also checks the patient's vital signs and compares data with temperature measurements previously obtained. Inspection of the IV site involves further assessment.

As a nurse you learn to make clinical judgments from assessment data to identify a patient's level of wellness and desire for health promotion or to identify existing health problems. An individual's undesirable responses to a health condition or his or her desire to increase well-being is identified in the form of either nursing diagnoses or collaborative problems (see Chapter 17) (Herdman and Kamitsuru, 2014). Assessment must be complete, relevant to a patient's condition, and accurate for you to correctly identify a person's desire to improve his or her health or identify any health problem. A comprehensive assessment leads to making accurate nursing diagnoses, allowing you to then create an appropriate plan of care for a patient. The next step, implementation, involves performing the planned interventions or collaboration. After implementation you evaluate the patient's responses and whether the interventions were effective. The nursing process is central to your ability to provide timely and appropriate care to your patients.

The nursing process is a form of scientific reasoning. Initially you will learn how to apply the process step by step. However, as you gain more clinical experience and care for more patients, you learn to move back and forth through the steps of the process, critically making judgments about your patients' clinical situations and individualizing your approaches to care (O'Neill et al., 2011). Practicing the five steps of the nursing process allows you to organize and conduct your practice in a systematic way. You learn to make inferences about the meaning of a patient's responses to a health problem or generalize about his or her functional state of health. The data collected during assessment forms patterns that help lead to diagnostic conclusions. *For example, the condition of Mr. Lawson's incision leads Tonya to infer that wound healing is possibly impaired. Tonya gathers more information (e.g., checking temperature, noting Mr. Lawson's reaction to wound palpation) until she makes an accurate classification of the patient's problem.*

Clearly defining your patient's problems on the basis of assessment ensures that you can plan care, implement appropriate nursing interventions, and evaluate the outcomes of care.

A CRITICAL THINKING APPROACH TO ASSESSMENT

Assessment is the deliberate and systematic collection of information about a patient to determine the patient's current and past health and functional status and his or her present and past coping patterns (Carpenito-Moyet, 2013). Nursing **assessment** includes two steps:

1. Collection of information from a primary source (a patient) and secondary sources (e.g., family or friends, health professionals, and the medical record)
2. The interpretation and validation of data to ensure a complete database

In the case study Tonya collected information from the patient through observation and asking questions. She saw the inflammation in the incisional area and validated its presence by asking the patient if it was tender. She interpreted her data: an open area of an incision, draining fluid, and the resultant tenderness around the site indicating a pattern of altered wound healing. She also measured the body temperature to see if an early sign of a more serious systemic infection was present.

When a plumber comes to your home to repair a problem that you describe as a "leaking faucet," the plumber checks the faucet, its attachments to the water line, and the water pressure in the system to determine the real problem. When a patient presents an initial health problem, you conduct an assessment that will allow you to identify the problem correctly. However, patients are different from leaky faucets in that their clinical situation changes over time, sometimes quickly. *For example, Mr. Lawson presents with signs of altered wound healing. Tonya reports these findings to the patient's surgeon, who orders antibiotics intravenously for 24 hours but also plans for the patient's discharge tomorrow. Mr. Lawson's clinical condition has changed from immediate recovery from surgery to planning for discharge home. Tonya wants to continue to try to control the patient's pain but now has to conduct further assessment of the patient's knowledge, observe his behaviors, ask questions about his ability to care for his wound when he goes home, observe the nonverbal cues he provides, and determine if there are problems that will affect discharge planning.*

Once a plumber knows the source of the leaking faucet, he is able to repair it. Once you know the nature and source of a patient's specific health needs or problems (such as Mr. Lawson's *Risk for Infection* and his need to be prepared for discharge), you are able to provide interventions that will restore, maintain, or improve the patient's health.

Critical thinking is a vital part of assessment (see Chapter 15). While gathering data about a patient, you synthesize relevant knowledge, recall prior clinical experiences, apply critical thinking standards and attitudes, and use professional standards of practice to direct your assessment in a meaningful and purposeful way (Figure 16-2). Your knowledge from the physical, biological, and social sciences allows you to ask relevant questions and collect relevant history and physical assessment data related to a patient's presenting health care needs. *For example, Tonya knows that Mr. Lawson had part of his colon removed to remove a cancerous tumor. She reviewed her medical-surgical textbook and learned how a colectomy alters gastrointestinal function and poses risks for blood clots in the legs after surgery. This knowledge leads her to assess Mr. Lawson's bowel sounds, ask him if he is passing flatus, and assess the status of circulation in his legs. Tonya has learned from previous experience caring for patients with abdominal surgery that they will be given activity restrictions after surgery to reduce strain on the incision. Mr. Lawson's incision has a small separation; thus Tonya knows that she needs to assess what he has learned so far about the activity restrictions. Using good communication skills through interviewing and applying critical thinking intellectual standards (such as relevance [which activities the patient performs at home]), and broad (including patient's wife in*

Developing the Nurse-Patient Relationship for Data Collection

An assessment is necessary for you to gather information to make accurate judgments about a patient's current condition. Your information comes from:

- The patient through interview, observations, and physical examination.
- Family members or significant others' reports and response to interviews.
- Other members of the health care team.
- Medical record information (e.g., patient history, laboratory work, x-ray film results, multidisciplinary consultations).
- Scientific and medical literature (evidence about disease conditions, assessment techniques, and standards).

Typically there is a lot of information to consider about a patient. Where should you begin? Start by taking quality time to be with a patient, even if it is for a few minutes. Establishing a nurse-patient therapeutic relationship allows you to know a patient as a person. This occurs during admission of a patient to your unit, during rounds when you begin a shift of care, or in any encounter with a patient. Chapter 24 explains details of how you develop a therapeutic relationship. In this chapter patient assessment is explained as part of the working phase of a nurse-patient relationship. Patricia Benner (1984) described in her early research the importance of a healing relationship established between nurse and patient. This relational process mobilizes hope for a patient and nurse; allows for an acceptable

interpretation and understanding of a patient's illness, pain, fear, and anxiety; and helps a patient use support from health care providers (Benner, 1984).

Connecting with a patient by showing interest in his or her problems and concerns helps you collect a relevant database. Research shows that hearing accounts of patients' health and illness experiences, watching them, and coming to understand how they typically respond develops a type of knowing that fosters good clinical judgments (Tanner, 2006). Visiting a hospitalized patient at set intervals (called *rounding*) allows you to address essential care needs and patient experiences and helps organize your workload on your work unit (Ministry of Health, 2013). Rounding is a vital opportunity to build trust with patients, increasing the likelihood that you will gain more information that will help you identify and communicate their health care problems more accurately and effectively.

Types of Assessments

Remember that assessment is all about accurate and thorough data collection. You will learn to conduct different types of assessments: the patient-centered interview during a nursing health history, a physical examination, and the periodic assessments you make during rounding or administering care. For example, when you bathe a patient or change a dressing, you are always using your skills of observation and physical examination (see Chapter 31) to gather data about him or her.

When you begin assessment, think critically about what to assess for that specific patient in that specific situation. As you are forming your relationship and connecting with a patient, the patient will begin to share information. Determine which questions or measurements are appropriate on the basis of what you initially learn from a patient about his or her health concerns and history, your clinical knowledge,

| Male patient in bed looks uncomfortable | Patient presents with discomfort in surgical area |

Cues
• Lies still with arms along sides; tense
• States has not turned for some time
• Reports pain a 7 on a scale of 0 to 10

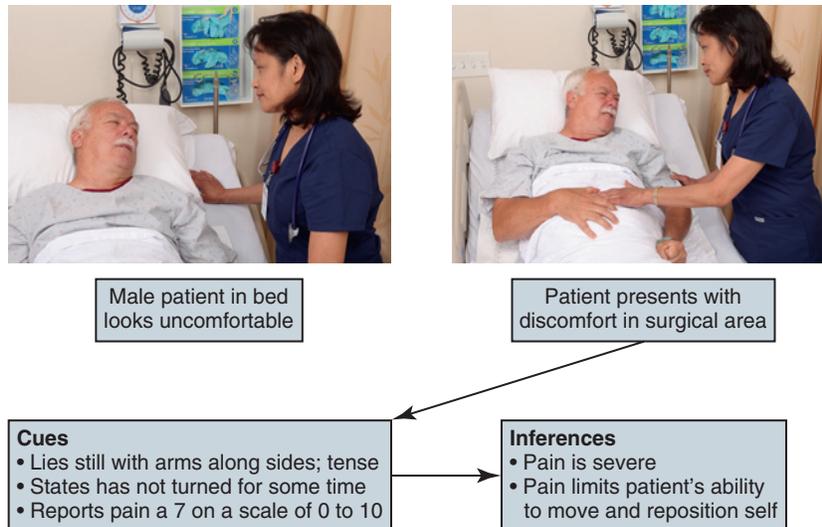
Inferences
• Pain is severe
• Pain limits patient's ability to move and reposition self


FIGURE 16-3 Observational overview using cues and forming inferences.

and your experience with other patients. In most cases a patient will reveal information that directs you to conduct a quick screening. This is common when you make rounds on a patient. For example, an emergency department nurse uses the ABC (airway-breathing-circulation) approach when a patient develops respiratory distress; and a medical-surgical nurse focuses on a patient's symptoms after returning from surgery, the expected healing response, and signs of potential complications. *For Mr. Lawson, Tonya focuses on the condition of the patient's surgical wound, looking for signs of healing. She later expands her assessment to determine how Mr. Lawson is adjusting emotionally to his surgery and whether he is prepared for discharge.*

You learn to differentiate important data from the total data you collect. A **cue** is information that you obtain through use of the senses. An **inference** is your judgment or interpretation of these cues (Figure 16-3). For example, a patient crying is a cue that possibly implies fear, pain, or sadness. You ask the patient about any concerns and make known any nonverbal expressions that you notice in an effort to direct the patient to share his or her feelings. It is possible to miss important cues during an initial overview. However, always try to interpret cues from the patient to know how in depth to make your assessment. Remember, thinking is human and imperfect. You will acquire appropriate thinking processes the more you conduct assessments, but sometimes you will make mistakes and miss important cues. Assessment is dynamic and allows you to freely explore relevant patient problems as you discover them.

When you conduct a more comprehensive patient history (i.e., a detailed assessment of a patient's physical, psychological, social, cultural, and spiritual needs), there are two approaches to this assessment. One involves use of a structured database format on the basis of an accepted theoretical framework or practice standard. Watson and Foster's model of "The Attending Caring Nurse" (2003), Nola Pender's "Health Promotion Model" (2011), and Gordon's model of 11 **functional health patterns** (1994) are examples. A theory or practice standard provides categories of information for you to assess. Pender's model is outlined in Chapter 6. Watson's model supports a comprehensive assessment of caring needs and concerns from a patient's frame of reference. It uses caring theory as a guide for identifying caring needs and assessing the meaning of both subjective and objective concerns (Watson and Foster, 2003). Gordon's functional health patterns model offers a holistic framework for assessment of any health problem

BOX 16-1   Typology of 11 Functional Health Patterns

• **Health perception–health management pattern:** Describes patient's self-report of health and well-being, how patient manages health (e.g., frequency of health care provider visits, adherence to therapies at home), knowledge of preventive health practices
• **Nutritional-metabolic pattern:** Describes patient's daily/weekly pattern of food and fluid intake (e.g., food preferences or restrictions, special diet, appetite), actual weight, weight loss or gain
• **Elimination pattern:** Describes patterns of excretory function (bowel, bladder, and skin)
• **Activity-exercise pattern:** Describes patterns of exercise, activity, leisure, and recreation; ability to perform activities of daily living
• **Sleep-rest pattern:** Describes patterns of sleep, rest, and relaxation
• **Cognitive-perceptual pattern:** Describes sensory-perceptual patterns: language adequacy, memory, decision-making ability
• **Self-perception–self-concept pattern:** Describes patient's self-concept pattern and perceptions of self (e.g., self-concept/worth, emotional patterns, body image)
• **Role-relationship pattern:** Describes patient's patterns of role engagements and relationships
• **Sexuality-reproductive pattern:** Describes patient's patterns of satisfaction and dissatisfaction with sexuality pattern, patient's reproductive patterns, premenopausal and postmenopausal problems
• **Coping–stress tolerance pattern:** Describes patient's ability to manage stress, previous coping responses, sources of support, effectiveness of coping patterns in terms of stress tolerance
• **Value-belief pattern:** Describes patterns of values, beliefs (including spiritual practices), and goals that guide patient's choices or decisions

Data from Gordon M: *Nursing diagnosis: process and application,* ed 3, St Louis, 1994, Mosby; and Carpenito-Moyet LJ: *Nursing diagnosis: application to clinical practice,* ed 13, Philadelphia, 2009, Lippincott Williams & Wilkins.

(Box 16-1). *For example, Tonya plans to direct further assessment of Mr. Lawson to the cognitive-perceptual pattern to learn more about what the patient knows about recovering from surgery, any restrictions recommended by the surgeon, and how Mr. Lawson prefers to learn and make decisions about his care.* A theoretical or standard-based assessment

provides for a comprehensive review of a patient's health care problems.

A comprehensive assessment moves from the general to the specific. For example, start by assessing a patient using all of Gordon's 11 functional health patterns and then determine if patterns or problems appear in your data. Typically certain aspects of a situation stand out as most important. You then ask more focused questions on the basis of a patient's responses and physical signs. The data lead you to clarify which problems exist. You begin to see patterns of behavior and physiological responses that relate to a functional health category. You cannot understand one health pattern without knowledge of the other patterns (Gordon, 1994). Ultimately your assessment identifies functional (patient strengths) and dysfunctional (nursing diagnoses) patterns that help you develop the nursing care plan (see Chapter 18).

The second approach for conducting a comprehensive assessment is problem oriented. You focus on a patient's presenting situation and begin with problematic areas such as incisional pain or limited understanding of postoperative recovery. You ask the patient follow-up questions to clarify and expand your assessment so you can understand the full nature of the problem. Later your physical examination focuses on the same problem areas to further confirm your observations. Table 16-1 offers an example of a problem-focused assessment.

Whatever approach you use to collect data, you cluster cues, make inferences, and identify emerging patterns and potential problem areas. To do this well you critically anticipate, which means that you continuously think about what the data tell you and decide if more data are needed. Remember to always have supporting cues before you make an inference. Your inferences direct you to further questions. Once you ask a patient a question or make an observation, patterns form, and the information branches to an additional series of questions or observations (Figure 16-4). Knowing how to probe and frame questions is a skill that grows with experience. You learn to decide which questions are relevant to a situation and attend to accurate data interpretation on the basis of inferences and experience.

Types of Data

There are two primary sources of data: subjective and objective. **Subjective data** are your patients' verbal descriptions of their health problems. For example, Mr. Lawson's self-report of pain at the area where his incision slightly separated is an example of subjective data. Subjective data include patients' feelings, perceptions, and self-report of symptoms. Only patients provide subjective data relevant to their health condition. The data often reflect physiological changes, which you further explore through objective review of body systems.

TABLE 16-1 Example of Problem-Focused Patient Assessment: Pain

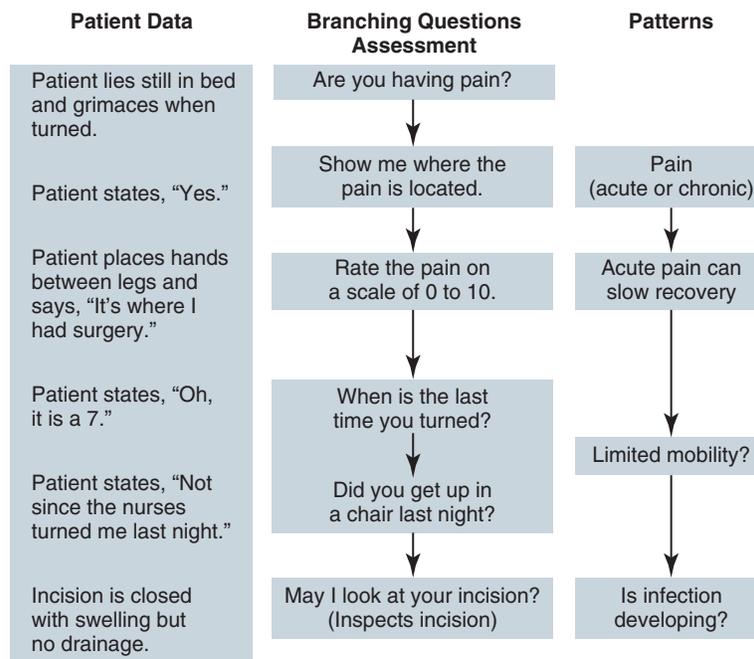
Problem and Associated Factors	Questions	Physical Assessment
Nature of pain	Describe your pain. Place your hand over the area that hurts or is uncomfortable.	Observe nonverbal cues. Observe where patient points to pain; note if it radiates or is localized.
Precipitating factors	Do you notice if pain worsens during any activities or specific time of day? Is pain associated with movement?	Observe if patient demonstrates nonverbal signs of pain during movement, positioning, swallowing.
Severity	Rate your pain on a scale of 0 to 10.	Inspect area of discomfort; palpate for tenderness.


FIGURE 16-4 Example of branching logic for selecting assessment questions.

Objective data are observations or measurements of a patient's health status. Inspecting the condition of a surgical incision or wound, describing an observed behavior, and measuring blood pressure are examples of objective data. Objective data is measured on the basis of an accepted standard such as the Fahrenheit or Celsius measure on a thermometer, inches or centimeters on a measuring tape, or a rating scale (e.g., pain). When you collect objective data, apply critical thinking intellectual standards (e.g., clear, precise, and consistent) so you can correctly interpret your findings.

Sources of Data

A variety of sources provide information about a patient's current level of wellness and functional status, anticipated prognosis, risk factors for any health problems, health practices and goals, cultural background, responses to previous treatment, and patterns of health and illness.

Patient. A patient is usually your best source of information. Patients who are conscious, alert, and able to answer questions without cognitive impairment provide the most accurate information. You learn through the eyes of patients their health care needs, cultural and lifestyle patterns, present and past illnesses, perception of symptoms, responses to treatment, and changes in activities of daily living. Always consider the setting for your assessment and your patient's condition. A patient having acute symptoms in an emergency department will not offer as much information as one who comes to an outpatient clinic for a routine checkup. Also know your patient's health literacy level. A patient with limited literacy has difficulty obtaining, processing, and understanding basic health information (AHRQ, 2014). This means that patients do not always understand some of the questions you use to assess their conditions, especially if you use more clinically focused words or terms or do not speak their language. You will not gather accurate information if a patient does not understand your assessment questions (Box 16-2).

An older adult may require more time for assessment than someone younger if hearing or cognitive deficits exist. Use short (but not leading) questions, keep your language uncomplicated, and listen to a patient's perspective carefully (Ball et al., 2015) (Box 16-3). Always be attentive, engaged, and show a caring presence with patients (see Chapter 7). Patients are less likely to fully reveal the nature of health care problems when you show little interest or are easily distracted by activities around them such as entering an assessment into a computer.

Family and Significant Others. Family members and significant others are primary sources of information for infants or children, critically ill adults, and patients who are mentally handicapped or have cognitive impairment. In cases of severe illness or emergency situations, families are often the only sources of information for health care providers. The family and significant others are also important secondary sources of information. They confirm findings or identify patterns that a patient provides (e.g., whether he takes medications regularly at home or how well he sleeps or eats). Include the family when appropriate. Patients do not always want you to question or involve their family; thus some facilities require oral or written permission to do so. A spouse or close friend who sits in during an assessment can provide his or her view of the patient's health problems or needs. Not only do they supply information about a patient's current health status, but they are also able to tell when changes in the patient's status occurred. Family members are often very well informed because of their experiences living with a patient and observing how health problems affect daily living activities. Family and friends make important observations

---

BOX 16-2 EVIDENCE-BASED PRACTICE

Health Literacy Assessment

PICO Question: In adults does the use of literacy screening tools versus an assessment of patients' educational or occupational level assess level of health literacy?

Evidence Summary

Several assessment tools are available for assessing health literacy in adults, including the Rapid Estimate of Adult Literacy in Medicine—Short form (REALM-S); the Shortened Test of Functional Health Literacy in Adults (S-TOFHLA); and the Newest Vital Sign (NVS), a tool that consists of a nutrition label and only six questions (Mottus et al., 2014; Weiss et al., 2005). A thorough assessment of a patient's health literacy is not measured consistently by health care providers because of the time it takes to complete existing literacy assessment tools. The NVS has been tested among adults and geriatric patients (Johnson and Weiss, 2008; Patel et al., 2011). It takes on average 3 minutes for adults to complete the NVS but a longer period of time (11 minutes) for African-American older adults (Johnson and Weiss, 2008; Patel et al., 2011). A study by Mottus et al. (2014) tested the associations between health literacy (using the REALM, S-TOFLHA, and NVS tools) and three objective health outcomes in older people (physical fitness, body mass index (BMI), and count of natural teeth). The study found that cognitive ability in old age and childhood and educational and occupational levels accounted for the majority of the outcome associations (as much as health literacy scores).

Application to Nursing Practice

Knowing the level of patient's health literacy may help physicians and nurses deliver health information in a way that patients can understand (Patel et al., 2011).

When literacy assessment tools are not available, you need to include a review of general cognitive ability and educational and/or occupational levels in your nursing assessment.

Lower health literacy is associated with poorer health outcomes. Measure literacy levels to help patients obtain information, apply the information in real-life situations, and understand the information and services needed to make health decisions.

Asking the single question "How confident are you in filling out medical forms by yourself?" is often successful in detecting limited health literacy (Wallace et al., 2006).

---

about patients' needs that can affect the way care is delivered (e.g., how a patient eats a meal or how he or she makes choices).

Health Care Team. You frequently communicate with other health care team members to assess patients. In the acute care setting the change-of-shift report, bedside rounds, and patient hand-off are ways that nurses from one shift communicate information to nurses on the next shift (see Chapter 26). A hand-off is an interactive process of passing patient-specific information from one caregiver to another for ensuring patient-centered care and patient safety (Chaboyer et al., 2010). During a hand-off you have the chance to collect the first set of information about patients assigned to your care. Ideally during bedside rounds the nurse who is completing care for a shift, the patient, and the nurse who is assuming care for the next shift share information about the patient's condition, status of problems, and treatment plan. In many settings rounds are multidisciplinary. Nurses, physicians, physical therapists, social workers, or other staff collaborate and consult on a patient's condition and share information about how he or she is reacting to treatments, the result of diagnostic procedures or

therapies, and the future plan of care. Every member of the team is a source of information for identifying and verifying essential information about a patient.

Medical Records. The medical record is a source for a patient's medical history, laboratory and diagnostic test results, current physical findings, and the primary health care provider's treatment plan. The record is a valuable tool for checking the consistency and similarities of data with your personal observations. Data in the records offer a baseline and ongoing information about a patient's response to illness and progress to date. The Health Insurance Portability and Accountability Act (HIPAA) of 1996, made effective in 2003, has the privacy rule to set standards for the protection of health information (USDHHS, 2014). Information in a patient's record is confidential. Each health care agency has policies governing how a patient's health information can be shared among health care providers (see Chapter 26). Only individuals involved in a patient's care can access medical records (see agency policies).

Other Records and the Scientific Literature. Educational, military, and employment records often contain significant health care information (e.g., immunizations). If a patient received services at a community clinic or a different hospital, you need written permission from the patient or guardian to access the record. The HIPAA regulations protect access to patients' health information. The privacy rule allows health care providers to share protected information as long as they use reasonable safeguards. Consult agency policies and participate in annual HIPAA training as required.

Reviewing recent nursing, medical, and pharmacological literature about a patient's illness completes a patient's assessment database. This review increases your knowledge about a patient's diagnosed problems, expected symptoms, treatment, prognosis, and established standards of therapeutic practice. The scientific literature offers evidence (see Chapter 5) to direct you on how and why to conduct assessments for

particular patient conditions. A knowledgeable nurse obtains relevant, accurate, and complete information for a patient's assessment.

Nurse's Experience. Your experiences in caring for patients are a source of data. Through clinical experience you observe other patients' behaviors and physical signs and symptoms; track trends and recognize clinical changes; and learn the types of questions to ask, choosing the questions that will give the most useful information. This experience builds your ability to know patients (i.e., knowing the patient's pattern of responses and knowing the patient as a person) (Tanner, 2006). A nurse's expertise develops after testing and refining questions with patients who have similar conditions or problems. W*hile caring for Mr. Lawson, Tonya has learned what a colectomy incision looks like and how a patient responds to the associated discomfort. She also is gaining knowledge about what an incision looks like when separation begins. During future care of patients Tonya will more quickly recognize behaviors of patients in acute pain and the signs of impaired wound healing.*

Practical experience and the opportunity to make clinical decisions strengthen your critical thinking.

THE PATIENT-CENTERED INTERVIEW

When a patient is admitted to a health care agency or when it is necessary to gather detailed information about a patient, you will collect an assessment using interview and observational skills. A patient-centered interview is relationship based and is an organized conversation focused on learning about the well and the sick as they seek care (Ball et al., 2015). A primary objective during an initial history taking is to discover details about a patient's concerns, explore expectations for the encounter you are having, and display genuine interest and partnership. A patient-centered interview becomes the basis for forming trust and effective long-term therapeutic relationships with patients (see Chapter 24).

One type of patient-centered interview is motivational interviewing. It is a technique used often in counseling that allows you to become a helper in the change process (see Chapter 38). Motivational interviewing is a process that addresses a patient's ambivalence to medically indicated behavior change and supports patients in making health care decisions in cases in which there is more than one reasonable option (Elwyn et al., 2014).

Effective communication with patients during an assessment interview requires the following communication skills (Ball et al., 2015):

- *Courtesy:* Greet patients by the name by which they prefer to be addressed. Ask, "Would you prefer I call you by Mrs. Silver or your first name?" Introduce yourself and explain your role (if it is the first time you have met) such as gathering an admission history or exploring a recent symptom or problem. Meet and acknowledge any visitors in a patient's room and learn their names. Remember to ask the patient's permission to conduct the interview in visitors' presence. Assure the patient that the information will be kept confidential among his or her health care providers (Ball et al., 2015). HIPAA regulations require patients to sign an authorization before you collect personal health data (USDHHS, 2014) (see agency policy).
- *Comfort:* If a patient is having symptoms such as pain, nausea or fatigue, it is difficult for you to gather a thorough and accurate history. In a hospital setting perform any necessary comfort measures before beginning the interview. Maintain privacy by closing room curtains or doors. Be sure the room temperature is comfortable and ensure good lighting. In the home choose a location that is quiet and free of interruptions. Timing is

important in avoiding interruptions. If possible, set aside a 10- to 15-minute period when no other activities are planned but realize that this is difficult to plan when you have multiple patients. Avoid overtiring a patient; you can always return for another visit to gather more information (Ball et al., 2015).

- *Connection:* It is so important to make a good first impression. If you begin collecting a history by staring at a computer screen to fill in required data fields or talking on a cell phone, patients will perceive you as uncaring or uninterested in hearing their stories. Patients know if you care. Establish eye contact and sit at eye level if possible during an interview. Do not dominate a discussion or assume that you know the nature of a patient's problems. Start with open-ended questions: "How have you been feeling?" or "What questions would you like to discuss?" Listen and be attentive. Use your observational skills—what is the patient's tone of voice, posture, level of energy when talking? Respect silence and be flexible; let the patient's needs, concerns, or questions guide your follow-up questions. Health problems can have multiple causes; do not leap to one cause too quickly (Ball et al., 2015).
- *Confirmation:* At the end of an interview, ask the patient to summarize the discussion so there are no uncertainties. Be open to further clarification or discussion; ask the patient "Is there anything else you would like to share"? If there are questions you cannot answer, say so and promise that you will return with a follow-up if possible (Ball et al., 2015).

Interview Preparation

Before you begin an interview, be prepared. Review a patient's medical record when information is available. If your interview is performed at patient admission, there may be little information in the medical record except for an admitting diagnosis. In other cases review the previous medical or nurse's note entry. Were problems identified that perhaps need clarification or follow-up? Does a patient's admitting diagnosis or other diagnoses suggest lines of questions for you to ask? The information you share with another nurse during hand-off at the beginning of a shift helps frame a clinical problem about which you want to learn more.

Phases of an Interview

An interview is an approach for gathering subjective and objective data from a patient through an organized conversation. An initial interview involves collecting a nursing health history and gathering information about a patient's condition (Ball et al., 2015). Later interviews have a different focus; you assess more about a patient's presenting situation and discuss specific problem areas. All patient-centered interviews follow three phases.

Orientation and Setting an Agenda. Begin an interview by introducing yourself and your position and explaining the purpose of the interview. Explain why you are collecting data and assure patients that all of the information will be confidential. Your aim is to set an agenda for how you will gather information about a patient's current chief concerns or problems. Remember, the best clinical interview focuses on a patient's goals, preferences, and concerns and not on your agenda. Explain your purpose (such as collecting a brief assessment or a nursing history) and ask a patient for his or her list of concerns or problems. This is the time that allows a patient to feel comfortable speaking with you and become an active partner in decisions about care. The professionalism and competence that you show when interviewing patients strengthens the nurse-patient relationship.

Tonya is doing a follow-up interview to learn more about Mr. Lawson's home situation. She explains, "Mr. Lawson, it looks like your doctor wants to send you home tomorrow. It's important for us to know more about how you care for yourself at home. Will your wife be able to help you when necessary? Are you comfortable and can I take a few minutes to talk about your discharge?" Mr. Lawson replies, "I feel a bit better, and yes, I've been thinking about some questions I want to ask." Tonya replies, "Good, we'll start there."

Working Phase—Collecting Assessment or Nursing Health History. Start an assessment or a nursing health history with open-ended questions that allow patients to describe more clearly their concerns and problems. For example, begin by having a patient explain symptoms or physical concerns and describe what he or she knows about the health problem or ask him or her to describe health care expectations. Use attentive listening and other therapeutic communication techniques (see Chapter 24) that encourage a patient to tell his or her story. The verbal cues that a patient expresses will help you stay focused so you can direct the assessment appropriately. Do not rush a patient. An initial interview (e.g., the one you collect to complete a nursing history) is more extensive. You gather information about a patient's concerns and then complete all relevant sections of the nursing history. Ongoing interviews, which occur each time you interact with your patient, do not need to be as extensive. An ongoing interview allows you to update a patient's status and concerns, focus on changes previously identified, and review new problems. In the case study Tonya gathers information to plan postoperative teaching and discharge planning for Mr. Lawson.

Tonya: "Mr. Lawson, you said you had some questions. Can you tell me what they are?"

Mr. Lawson: "Well, the doctor told me that I would not be able to lift anything heavy for a while, and I'm not sure if I understand. The way my incision looks, will I need to do something to it?"

Tonya: Let's start with your question about lifting. First of all, what types of things do you lift regularly at home (for example, children, a pet, groceries)?

Mr. Lawson: "Well, when our grandchildren visit, they do like to be picked up. We have a pet schnauzer, but he just jumps up on the chair with me. My wife does the grocery shopping, but I come out to unload the car."

Tonya: "Ok, and about your incision, yes you will need to care for it. Do you know the signs of infection?"

Mr. Lawson: "Not sure I do, but I guess it would hurt more. Is infection common?"

Tonya: "No, but you need to know the signs so, if something happens once you return home, you can call your doctor quickly. Has your doctor talked about ways to care for your incision?"

Mr. Lawson: "No, he hasn't mentioned anything about that yet."

Tonya: "Ok, I'll explain everything you need to know. Do you learn best by reading information or listening to explanations?"

Mr. Lawson: "I think I do okay with both."

Tonya's assessment focuses on the patient's questions and how they pertain to the information he will need to learn to go home and assume self-care.

Terminating an Interview. Termination of an interview requires skill. You summarize your discussion with a patient and check for accuracy of the information collected. Give your patient a clue that the interview is coming to an end. For example, say, "I have just two more questions. We'll be finished in a few more minutes." This helps

a patient maintain direct attention without being distracted by wondering when the interview will end. This approach also gives him or her an opportunity to ask additional questions. End the interview in a friendly manner, telling the patient when you will return to provide care.

> *Tonya: "You've given me a good idea of which topics we need to cover to prepare you for going home. And we'll include your wife in these discussions. I'll return after checking on two other patients,"*
> *Mr. Lawson: "You've been helpful already."*

A skillful interviewer adapts interview strategies on the basis of a patient's responses. You successfully gather relevant health data when you are prepared for an interview and able to carry out each interview phase with minimal interruption.

Interview Techniques

How you conduct an interview is just as important as the questions you ask. During an interview you are responsible for directing the flow of the discussion so patients have the opportunity to freely contribute stories about their health problems to enable you to get as much detailed information as possible. Remember, some interviews are focused; others are comprehensive. Listen and consider the information shared because this helps you direct a patient to provide more detail or discuss a topic that might reveal a possible problem. Because a patient's report includes subjective information, validate data from the interview later with objective data. For example, if a patient reports difficulty breathing, this will lead you to further assess respiratory rate and lung sounds during the physical examination.

Observation. Observation is powerful. Observe a patient's nonverbal communication such as use of eye contact, body language, or tone of voice. While observing nonverbal behavior, appearance, and interaction with the environment, you determine whether the data you obtained are consistent with what the patient states verbally. Your observations lead you to pursue further objective information to form accurate conclusions. Patients also obtain information during interviews. If you establish a trusting nurse-patient relationship, the patient feels comfortable asking you questions about the health care environment, planned treatments, diagnostic testing, and available resources. A patient needs this information to partner in making decisions and planning the goals of care.

Open-Ended Questions. In a patient-centered interview you try to find out, in the patient's own words, his or her health goals and any concerns or problems that exist and their probable cause. Patients are the best resources for talking about their symptoms or relating their health history. Begin by asking a patient an *open-ended question* to elicit his or her story. An open-ended question gives a patient discretion about the extent of his or her answer (Ball et al., 2015). For example, "So, tell me more about ….." or "What are your concerns about this?" or "Tell me how you're feeling." An open-ended question does not presuppose a specific answer. The use of **open-ended questions** prompts patients to describe a situation in more than one or two words. This technique leads to a discussion in which patients actively describe their health status and strengthens your relationship with them. Open-ended questions show that you want to hear a patient's thoughts and feelings. Remember to encourage and let your patient tell the entire story.

Leading Question. These questions are the most risky because of possibly limiting the information provided to what a patient thinks you want to know (Ball et al., 2015). Examples include, "It seems to me this is bothering you quite a bit. Is that true?" or "Now, that wasn't very hard to do, was it?"

Back Channeling. Reinforce your interest in what a patient has to say through the use of good eye contact and listening skills. Also use **back channeling**, which includes active listening prompts such as "all right," "go on," or "uh-huh." These indicate that you have heard what a patient says, are interested in hearing the full story, and are encouraging the patient to give more details.

Probing. As a patient tells his or her story, encourage a full description without trying to control the direction the story takes. This requires you to probe with further open-ended statements such as "Is there anything else you can tell me?" or "What else is bothering you?" Each time a patient offers more detail, probe again until the patient has nothing else to say and has told the full story. Always stay observant. If a patient becomes fatigued or uncomfortable, know that it is time to postpone an interview.

Direct Closed-Ended Questions. As you learn information from a patient, you will ask direct questions to seek specific information. This problem-seeking technique gives details to identify a patient's problems accurately. This approach takes the information provided in a patient's story and more fully describes and identifies specific problem areas. For example, a patient reports experiencing indigestion over the course of several days and acknowledges having some diarrhea and loss of appetite. The patient's explanation for the cause relates to a recent series of trips that changed his eating habits. The nurse focuses on the symptoms the patient identifies and the general indigestion problem by asking **closed-ended questions** that limit answers to one or two words such as "yes" or "no" or a number or frequency of a symptom. For example, ask, "How often does the diarrhea occur?" or "Do you have pain or cramping?" Closed-ended questions require short answers and clarify previous information or provide additional information. The questions do not encourage the patient to volunteer more information than you request. The technique allows you to acquire specific information about health problems such as symptoms, precipitating factors, or relief measures.

A good interviewer leaves with a complete story that contains enough details for understanding a patient's perceptions of his or her health status and the information needed to help identify nursing diagnoses and/or collaborative health problems (see Chapter 17). Always clarify or validate any information about which you are unclear. Make no assumptions.

NURSING HEALTH HISTORY

You gather a **nursing health history** during an initial or early contact with a patient. The history is a key component of a comprehensive assessment. Most health history forms (manual and electronic) are structured. However, on the basis of information you gain as you conduct the patient-centered interview, you learn which components of the history to explore fully and which require less detail. A good assessor learns to refine and broaden questions as needed to correctly assess a patient's unique needs. Time and patient priorities determine how complete a history will be. A comprehensive history covers all health dimensions (Figure 16-5), allowing you to develop a complete plan of care.

Cultural Considerations

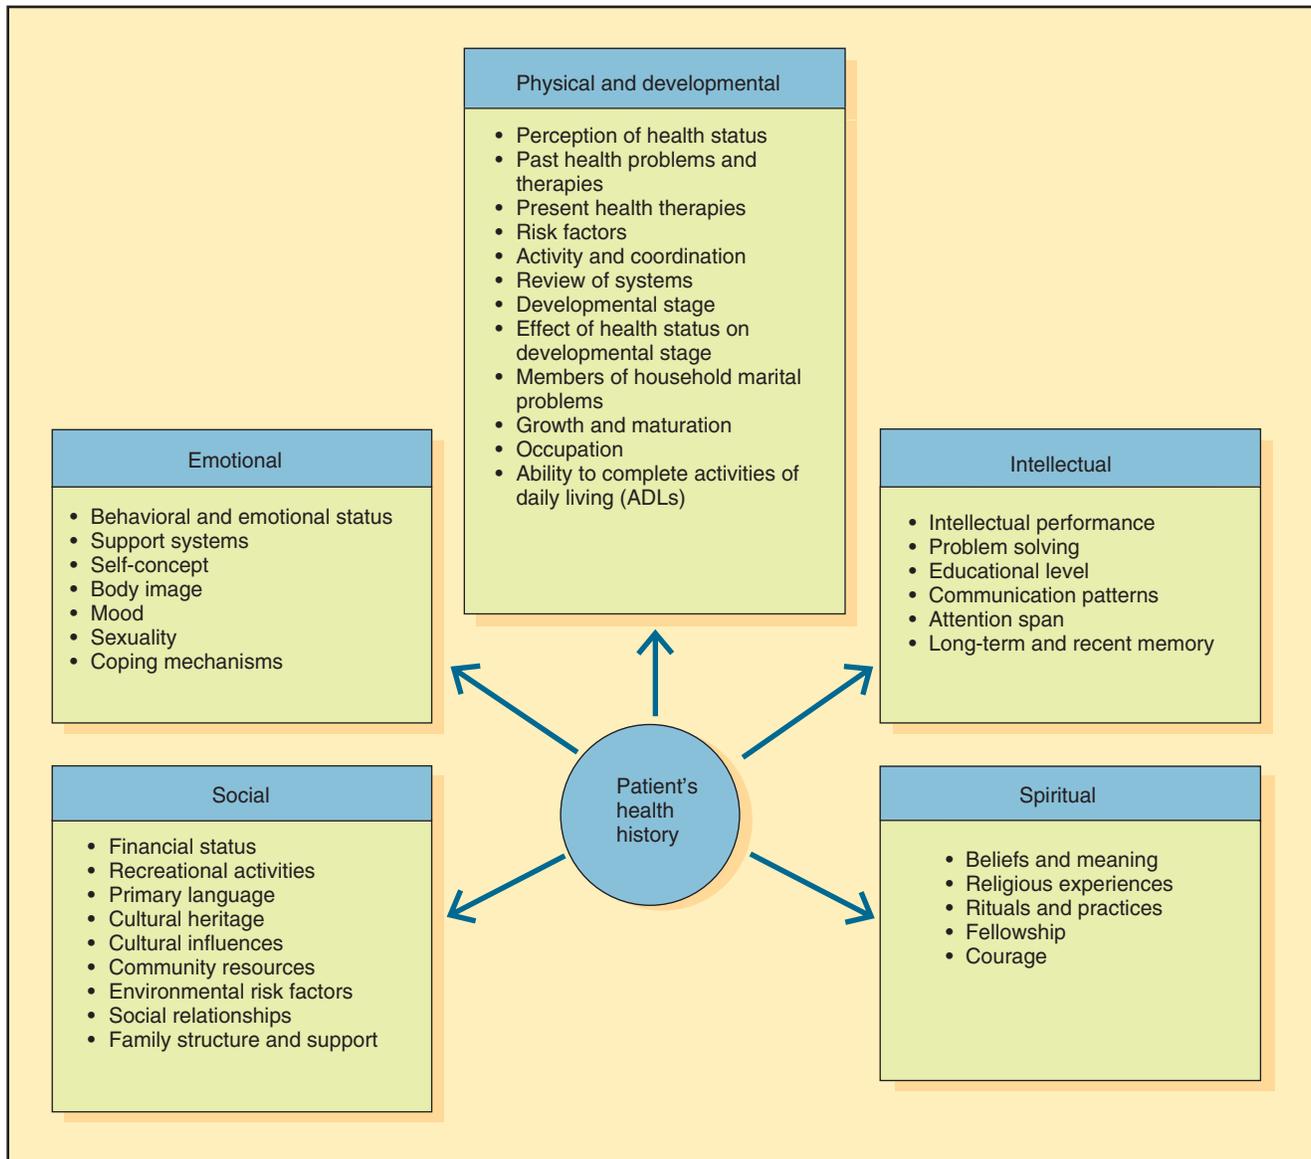
Obtaining a nursing health history requires cultural competence. This involves self-awareness, reflective practice, and knowledge of a patient's


FIGURE 16-5 Dimensions for gathering data for a health history.

core cultural issues (Ball et al., 2015). Adapt each assessment to the unique needs of patients of backgrounds and cultures different from your own. Be respectful; understand these differences; and do not impose your own attitudes, biases, and beliefs (e.g., attitudes towards aging, obesity, or lifestyle). Having a genuine curiosity about a patient's beliefs and values lays a foundation for a trusting patient-nurse relationship (Ball et al., 2015). To conduct an accurate and complete assessment, consider a patient's cultural background. For clarity, explain the intent of any questions you have. Avoid making stereotypes; the assumptions tied to stereotypes (e.g., obese patients do not exercise regularly) can lead you to collect inaccurate information. Draw on knowledge from your assessment and ask questions in a constructive and probing way to allow you to truly know who a patient is (Box 16-4). Be sure to grasp exactly what a patient means and gain feedback to know if what a patient thinks you mean is accurate. If you are unsure about what a patient is saying, clarify to prevent making the wrong diagnostic conclusion. Do not form stereotypes and do not assume that you know a patient's cultural beliefs and behaviors without validation from the patient.

Components of the Nursing Health History

Most health histories contain the same components. Do not let a history form shape your assessment entirely. Decide what information you need on the basis of your patient's needs, responses to your questions, and changing status during the interview.

Biographical Information. Biographical information is factual demographic data that include a patient's age, address, occupation, and working status; marital status; source of health care; and types of insurance. The staff in an admitting office usually collects this information.

Chief Concern or Reason for Seeking Health Care. This is the information you gather when you initially set an agenda during a patient-centered interview. You learn a patient's chief concerns or problems. Compare what you learn from the patient with the "chief complaint," which is often typed on the patient's admission sheet. Often you learn much more. Ask a patient why he or she is seeking

BOX 16-4 CULTURAL ASPECTS OF CARE

Developing a Patient-Centered Approach

To successfully explore a patient's illness or health care problems, use a patient-centered approach. Elicit patient values, preferences, and expressed needs as part of your clinical interview (QSEN Institute, 2014). Ensure the interview is inclusive. Remove barriers to having families present on the basis of patient preferences.

Implications for Patient-Centered Care
- When talking about a patient's illness, try to understand it "through the patient's eyes."
  - What do you think is wrong with you?
  - What worries you most about your illness?
- When talking about treatments, value a patient's expertise with own health and symptoms.
  - What should we do to eliminate your problem?
  - Which types of treatment do you use?
  - What benefit do you expect from the treatment?
- If there is a cross-cultural difference between you and your patient, ask yourself these questions (Suhonen et al., 2011).
  - What is unique to your patient's culture and its impact on the treatment plan?
  - What potential is there to have a cultural misunderstanding? If one exists, try to correct it.
  - Which types of treatments or health practices do you use?

health care (e.g., "Tell me, Mr. Lynn, what brought you to the clinic today"). You record the patient's response in quotations to indicate the subjective response. As you explore a patient's reason for seeking health care, you will learn the chronological and sequential history of his or her health problems (Ball et al., 2015). A patient's statement is not diagnostic; instead it is his or her perception of reasons for seeking health care. Clarification of a patient's perception identifies potential needs for symptom management, education, counseling, or referral to community resources.

Patient Expectations. It is important to assess a patient's expectations of health care providers (e.g., being diagnosed correctly, receiving comfort measures, or being treated successfully for a disease). Patient satisfaction, a standard measure of quality for all hospitals throughout the country, can be perceived by patients as poor if their expectations are unmet (see Chapter 2). Patients typically have expectations of receiving information about their treatments and prognosis and a plan of care for returning home. In addition, they expect relief of pain and other symptoms and caring expressed by health care providers. During the initial interview a patient expresses expectations when entering the health care setting. Later, as a patient interacts with health care providers, assess whether these expectations have changed or been met.

Present Illness or Health Concerns. If a patient presents with an illness, collect essential and relevant data about the symptoms and their effects on the patient's health. Apply critical thinking intellectual standards (see Box 15-4) and use the acronym (PQRST) to guide an assessment:

- **P—Provokes** (e.g., precipitating and relieving factors): What causes symptom? What makes it better or worse? Are there activities (e.g., exercise) that affect it?
- **Q—Quality:** What does the symptom feel like? If patient cannot describe, offer probes such as "Is it sharp? Dull? Burning?"

- **R—Radiate:** Where is the symptom located? Is it in one place? Does it go anywhere else? Have patient be as precise as possible.
- **S—Severity:** Ask a patient to rate the severity of a symptom on a scale of 0 to 10. This gives you a baseline with which to compare in follow-up assessments.
- **T—Time:** Assesses onset and duration of symptom. When did it start? Does it come and go? If so, how often and for how long? What time of day or day of the week?

Also assess if the patient has **concomitant symptoms**. Does he or she experience other symptoms along with the primary symptom? For example, does nausea accompany pain?

Health History. A health history provides a holistic view of a patient's health care experiences and current health habits (see Figure 16-5). Assess whether a patient has ever been hospitalized or injured or has had surgery. Include a complete medication history (including herbal and over-the-counter [OTC] drugs). Also essential are descriptions of allergies, including allergic reactions to food, latex, drugs, or contact agents (e.g., soap). Asking patients if they have had problems with medications or food helps to clarify the type and amount of agent, the specific reaction, and whether a patient has required treatment. If the patient has an allergy, note the specific reaction and treatment on the assessment form and special armband provided.

The history also includes a description of a patient's habits and lifestyle patterns. Assessing for the use of alcohol, tobacco, caffeine, or recreational drugs (e.g., methamphetamine or cocaine) determines a patient's risk for diseases involving the liver, lungs, heart, or nervous system. It is essential to gather information about the type of habit and the frequency and duration of use. Assessing patterns of sleep (see Chapter 43), exercise (see Chapter 39), and nutrition (see Chapter 45) are also important when planning nursing care. Ultimately your aim is to match a patient's lifestyle patterns with approaches in the plan of care as much as possible.

Family History. The family history includes data about immediate and blood relatives. Your objective is to determine whether a patient is at risk for illnesses of a genetic or familial nature and to identify areas of health promotion and illness prevention (see Chapter 6). The family history also reveals information about family structure, interaction, support, and function that often is useful in planning care (see Chapter 10). *For example, Tonya assesses the level of support that Mrs. Lawson is willing to provide. Mrs. Lawson tells Tonya that the two have been married 32 years and states, "I feel I can do whatever is needed for him." Tonya's assessment shows a pattern that Mrs. Lawson is supportive and able to help her husband adjust to any initial limitations in activity when he returns home. Her assessment ultimately allows her to incorporate Mrs. Lawson into the patient teaching portion of the patient's plan of care* (see Chapter 18). If a patient's family is not supportive, it is better not to involve the family in care. Stressful family relationships are sometimes a significant barrier when you try to help patients with problems involving loss, self-concept, spiritual health, and personal relationships.

> **QSEN** **QSEN: BUILDING COMPETENCY IN PATIENT-CENTERED CARE** Describe how to approach an interview with Mrs. Lawson using a patient-centered approach. Describe how you would interview Mrs. Lawson about her husband's pending wound care treatment at home.
>
> ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

Psychosocial History. A psychosocial history provides information about a patient's support system, which often includes a spouse

or partner, children, other family members, and close friends. The history also includes information about ways that a patient and family typically cope with stress (see Chapter 38). Behaviors that patients use at home to cope with stress such as walking, reading, or talking with a friend can also be used as nursing interventions if the patient experiences stress while receiving health care. In addition, you need to learn if the patient has experienced any recent losses that create a sense of grief (see Chapter 37).

Spiritual Health.   Life experiences and events shape a person's spirituality. The spiritual dimension represents the totality of one's being and is difficult to assess quickly (see Chapter 36). Review with patients their beliefs about life, their source for guidance in acting on beliefs, and the relationship they have with family in exercising their faith. Also assess rituals and religious practices that patients use to express their spirituality. Patients may request availability of these practices while in a health care setting.

Review of Systems.   The **review of systems (ROS)** is a systematic approach for collecting subjective information from patients about the presence or absence of health-related issues in each body system (Ball et al., 2015). For example, the review of the skin, hair, and nails includes assessment of whether a patient has noticed any rash or skin lesions or has itching or abnormal nail or hair growth. When using an admission form, you probably will not cover all of the questions for each body system every time you collect a history. You include questions about each system to explore any unexpected signs or symptoms that a patient mentions. In this case explore the system more in depth. The systems you assess thoroughly depend on a patient's condition and the urgency in starting care. During the ROS ask the patient about the normal functioning of each body system and any noted changes. Such changes are subjective data because they are described as perceived by the patient.

Along with the ROS, a nurse conducts a physical examination (see Chapter 31) to further explore and confirm patient information. The examination involves use of the techniques of inspection, palpation, percussion, auscultation, and smell.

Observation of Patient Behavior

Throughout a patient-centered interview and physical examination it is important to closely observe a patient's verbal and nonverbal behaviors. The information adds depth to your objective database. You learn to determine if data obtained by observation matches what a patient communicates verbally. For example, a patient expresses no concern about an upcoming diagnostic test but shows poor eye contact, shakiness, and restlessness, all suggesting anxiety and verbal and nonverbal data conflict. Observations direct you to gather additional objective information to form accurate conclusions about the patient's condition.

An important aspect of observation includes a patient's level of function: the physical, developmental, psychological, and social aspects of everyday living. Observation of level of function differs from observations you make during an interview. You assess level of function by watching what a patient does when eating or making a decision about preparing a medication rather than what the patient tells you that he or she can do. Observation of function often occurs in the home or in a health care setting during a return demonstration.

Diagnostic and Laboratory Data

The results of diagnostic and laboratory tests provide further explanation of alterations or problems identified during the health history and physical examination. For example, during the history a patient reports having a bad cold for 6 days and at present has a productive cough with brown sputum and mild shortness of breath. On physical examination you notice an elevated temperature, increased respirations, and decreased breath sounds in the right lower lobe. You review the results of a complete blood count and note that the white blood cell count is elevated (indicating an infection). You report your results to the patient's health care provider, who orders a chest x-ray film. When the results of the x-ray film show the presence of a right lower lobe infiltrate, the health care provider makes the medical diagnosis of pneumonia. Your assessment leads to the associated nursing diagnosis of *Impaired Gas Exchange.*

Some patients collect and monitor laboratory data in the home. For example, patients with diabetes mellitus often measure blood glucose daily. Ask patients about their routine results to determine their response to illness and information about the effects of treatment measures. Compare laboratory data with the established norms for a particular test, age-group, and gender.

Interpreting and Validating Assessment Data

Assessment involves the continuous interpretation of information. This is a critical thinking aspect of assessment. The successful ongoing interpretation and validation of assessment data ensures that you have collected a complete database. Ultimately this leads you to the second step of the nursing process, in which you make clinical decisions in your patient's care. These decisions are either in the form of nursing diagnoses or collaborative problems that require treatment from all collaborative disciplines (Carpenito-Moyet, 2013) (see Chapter 17).

Interpretation.   When critically interpreting assessment information, you determine the presence of abnormal findings, recognize that further observations are needed to clarify information, and begin to identify a patient's health problems. This is clinical reasoning. You begin to see patterns of data that direct you to collect more information and clarify what you have. The patterns of data reveal meaningful and usable clusters. A data cluster is a set of signs or symptoms that you group together in a logical way (Box 16-5). The clusters begin to clearly identify a patient's health problems.

Data Validation.   Before you complete data interpretation, validate the information you have collected to avoid making incorrect inferences. **Validation** of assessment data is the comparison of data with another source to determine data accuracy. For example, you observe a patient crying and logically infer that it is related to hospitalization or a medical diagnosis. Making such an initial inference is not wrong, but problems result if you do not validate the inference with the patient. Instead ask, "I notice that you have been crying. Can you tell me about it?" By validating you discover the real reason for the patient's crying behavior. Ask patients to validate unclear information obtained during an interview and history. Validate findings from the physical examination and observation of patient behavior by comparing data in the medical record and consulting with other nurses or health care team members. Often family or friends validate your assessment information.

Validation opens the door for gathering more assessment data because it involves clarifying vague or unclear data. Occasionally you need to reassess previously covered areas of the nursing history or gather further physical examination data. Continually analyze to make concise, accurate, and meaningful interpretations. Critical thinking applied to assessment enables you to fully understand a patient's problems, judge the extent of the problems carefully, and discover possible relationships between the problems.

BOX 16-5   Recognizing Data Clusters

Interpret how data form patterns or trends.
- Patient uncomfortable: remains still in bed
  - Limits turning
  - Grimaces when moving
- Mobility limited: limits turning
  - Only out of bed once after surgery
- Knowledge about postoperative care: asks questions about restrictions and expresses concerns about incision
  - Unsure about dressing care
  - Asks about risk of infection
- Appears anxious or uneasy: poor eye contact at times
  - Restless
  - Asks numerous questions

Tonya has gathered assessment data to better understand Mr. Lawson's health care needs. The focus of her assessment switched from pain to that of physical characteristics of the surgical incision because the patient's condition changed. Her findings suggest a problem that the patient is at risk for infection. She also assessed the patient's knowledge and learning needs so she can adequately formulate a plan of care to prepare him for discharge. She applied critical thinking in her assessment as she considered the need to include Mr. Lawson's wife in the assessment. In addition, she reflected on her knowledge base concerning surgical colectomies and anticipated what she needed to assess to eventually plan Mr. Lawson's instruction. When Tonya saw the need for more information, she directed her assessment to learn more about Mr. Lawson's concerns about the success of his surgery and what to expect during recovery.

Data Documentation

Record the results of the nursing health history and physical examination in a clear, concise manner using appropriate terminology. This information becomes the baseline to identify patient health problems, plan and implement care, and evaluate a patient's response to interventions. Standardized forms, especially electronic forms, make it easy to enter assessment data as a patient responds to questions. A timely, clear, concise record is necessary for use by other health care professionals (see Chapter 26). If you do not record an assessment finding or problem interpretation, it is lost and unavailable to anyone else caring for the patient. If information is not specific, the reader is left with only general impressions. Observing and recording patient status are legal and professional responsibilities. The Nurse Practice Acts in all states and the American Nurses Association Nursing's Social Policy Statement (ANA, 2010) require accurate data collection and recording as independent functions essential to the role of the professional nurse.

Being factual is easy after it becomes a habit. The basic rule is to record all observations succinctly. When recording data, pay attention to facts and be as descriptive as possible. You need to report anything you hear, see, feel, or smell precisely. Record objective information in accurate terminology (e.g., weighs 77.2 kg (170 lbs), abdomen is soft and nontender to palpation). Record any subjective information by using quotation marks. Do not generalize or form judgments through written communication when entering data. Conclusions about such data become nursing diagnoses and thus must be factual and accurate. As you gain experience and become familiar with clusters and patterns of signs and symptoms, you will correctly

conclude the existence of a health problem. Review Chapter 26 for details on documentation.

Concept Mapping

Most patients for whom you care will present with more than one health problem. A concept map is a visual representation that allows you to graphically show the connections among a patient's many health problems. The concept map is a strategy that develops critical thinking skills by helping a learner understand the relationships that exist among patient problems (Bittencourt et al., 2013). Concept maps foster reflection and help students evaluate critical thinking patterns and see the reasons for nursing care. Your first step in concept mapping is to organize the assessment data you collect. Placing all of the cues together into the clusters that form patterns leads you to the next step of the nursing process, nursing diagnosis (see Chapter 17). Through concept mapping you obtain a holistic perspective of your patient's health care needs, which ultimately leads you to making better clinical decisions. Figure 16-6 shows the first step in a concept map that Tonya develops for Mr. Lawson as a result of her nursing assessment. *Tonya begins to identify patterns reflecting Mr. Lawson's problems. As a result of the assessment she has continuing discomfort over the incision, the risk for infection developing, and need for instruction about surgical postoperative care.* The next step (see Chapter 17) is to identify specific nursing diagnoses so you can plan appropriate nursing interventions.

▌ KEY POINTS

- The nursing process is a variation of scientific reasoning that involves five steps: assessment, nursing diagnosis, planning, implementation, and evaluation.
- Assessment is an important first step of the nursing process for learning as much as you can about each patient by partnering together in a therapeutic relationship.
- Assessment involves collecting information from a patient and secondary sources (e.g., health care providers, family members) along with interpreting and validating the information to form a complete database.
- Establishing a nurse-patient therapeutic relationship allows you to know a patient as a person.
- There are two approaches to gathering a comprehensive assessment: use of a structured database format and use of a problem-focused approach.
- Effectively communicating with patients during an assessment interview requires communication skills built on courtesy, comfort, connection, and confirmation.
- Once a patient provides subjective data, explore the findings further by collecting objective data.
- During assessment critically anticipate and use an appropriate branching set of questions or observations to collect data and cluster cues of assessment information to identify emerging patterns and problems.
- In a patient-centered interview an organized conversation with a patient allows the patient to set the initial focus and initiate discussion about his or her health problems.
- An initial patient-centered interview involves: (1) setting the stage, (2) gathering information about the patient's problems and setting an agenda, (3) collecting the assessment or a nursing health history, and (4) terminating the interview.
- When literacy assessment tools are not available, a review of general cognitive ability and educational and/or occupational levels needs to be part of nursing assessment.

CONCEPT MAP

Potential pattern: Comfort problem
- Wound tender when palpated
- Pain severity has ranged from 8 to 4
- At times patient moves more slowly

Potential pattern: Requests information about postoperative care
- Unclear about activity restrictions
- Asks if he will need to "do something to" his incision
- Lifts various objects at home
- Does not know signs of infection

Primary health problem: Colectomy
Priority assessments: Condition of incision, gastrointestinal function, comfort level, knowledge of home care requirements and ability to learn, resources for discharge.

Potential pattern: Altered wound healing
- Has a small separation of wound edges
- Patient is obese
- Drainage from wound
- Incision tender and inflamed near area of separation

FIGURE 16-6 Concept map for Mr. Lawson: Assessment.

- An assessment needs to adapt to the unique needs of patients of backgrounds and cultures different from your own.
- When collecting a complete nursing history, let the patient's story guide you in fully exploring the components related to his or her problems.
- Successful interpretation and validation of assessment data ensure that you have collected a complete database.

▮ CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Tonya is planning to return to Mr. Lawson's room and spend more time discussing his concerns about going home and what to expect. She knows that Mrs. Lawson usually comes to visit around 11 AM, just before lunchtime. Tonya believes that Mrs. Lawson will be an important source of support in providing Mr. Lawson's ongoing home care. The surgeon has ordered directions for wound care and standard activity restrictions.

1. Tonya goes to Mr. Lawson's room and asks the patient, "What concerns do you and your wife have about cleaning the wound?" Which type of assessment question is this and why has Tonya asked it?

2. Tonya and Mr. Lawson have the following interaction:
   Tonya: Mr. Lawson, What do you understand about the reason for the activity restrictions your doctor ordered?
   Mr. Lawson: I think it will prevent me from not hurting myself.
   Tonya: Uh huh … go on.
   Mr. Lawson: I think the doctor said I could pull my stitches.
   Tonya's phrase "uh huh … go on" is an example of which interviewing technique? Explain why it is useful.

3. Tonya returns to Mr. Lawson's room to discuss his discharge instructions, but she notes as she enters the room that the patient is grimacing. She asks him, "Tell me where the pain is." Mr. Lawson is asked to rate the pain on a scale of 0 to 10 and rates it a 6. Tonya looks at the patient's surgical wound and notes that the area of separation is still inflamed. Match the assessment technique on the left with the type of measurement on the right.

1. Patient rates pain 6 on a 0 to 10 scale.	___ **A.**	Determining location of a symptom
2. Tell me where the pain is.	___ **B.**	Observation
3. Patient is seen grimacing.	___ **C.**	Inspection
4. Nurse looks at condition of wound.	___ **D.**	Determining severity of a symptom

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. Which of the following examples are steps of nursing assessment? (Select all that apply.)
   1. Collection of information from patient's family members
   2. Recognition that further observations are needed to clarify information
   3. Comparison of data with another source to determine data accuracy
   4. Complete documentation of observational information
   5. Determining which medications to administer based on a patient's assessment data

2. A nurse assesses a patient who comes to the pulmonary clinic. "I see that it's been over 6 months since you've been here, but your appointment was for every 2 months. Tell me about that. Also I see from your last visit that the doctor recommended routine exercise. Can you tell me how successful you've been in following his plan?" The nurse's assessment covers which of Gordon's functional health patterns?
   1. Value-belief pattern
   2. Cognitive-perceptual pattern
   3. Coping–stress-tolerance pattern
   4. Health perception–health management pattern

3. When a nurse conducts an assessment, data about a patient often comes from which of the following sources? (Select all that apply.)
   1. An observation of how a patient turns and moves in bed
   2. The unit policy and procedure manual
   3. The care recommendations of a physical therapist
   4. The results of a diagnostic x-ray film
   5. Your experiences in caring for other patients with similar problems

4. The nurse observes a patient walking down the hall with a shuffling gait. When the patient returns to bed, the nurse checks the strength in both of the patient's legs. The nurse applies the information gained to suspect that the patient has a mobility problem. This conclusion is an example of:
   1. Cue.
   2. Reflection.
   3. Clinical inference.
   4. Probing.

5. A 72-year-old male patient comes to the health clinic for an annual follow-up. The nurse enters the patient's room and notices him to be diaphoretic, holding his chest and breathing with difficulty. The nurse immediately checks the patient's heart rate and blood pressure and asks him, "Tell me where your pain is." Which of the following assessment approaches does this scenario describe?
   1. Review of systems approach
   2. Use of a structured database format
   3. Back channeling
   4. A problem-oriented approach

6. The nurse asks a patient, "Describe for me a typical night's sleep. What do you do to fall asleep? Do you have difficulty falling or staying asleep? This series of questions would likely occur during which phase of a patient-centered interview?
   1. Orientation
   2. Working phase
   3. Data validation
   4. Termination

7. A nurse is assigned to a 42-year-old mother of 4 who weighs 136.2 kg (300 lbs), has diabetes, and works part time in the kitchen of a restaurant. The patient is facing surgery for gallbladder disease. Which of the following approaches demonstrates the nurse's cultural competence in assessing the patient's health care problems?
   1. "I can tell that your eating habits have led to your diabetes. Is that right?"
   2. "It's been difficult for people to find jobs. Is that why you work part time?"
   3. "You have four children; do you have any concerns about going home and caring for them?"
   4. "I wish patients understood how overeating affects their health."

8. Which type of interview question does the nurse first use when assessing the reason for a patient seeking health care?
   1. Probing
   2. Open-ended
   3. Problem-oriented
   4. Confirmation

9. A nurse gathers the following assessment data. Which of the following cues together form(s) a pattern suggesting a problem? (Select all that apply.)
   1. The skin around the wound is tender to touch.
   2. Fluid intake for 8 hours is 800 mL.
   3. Patient has a heart rate of 78 beats/min and regular.
   4. Patient has drainage from surgical wound.
   5. Body temperature is 38.3° C (101° F).
   6. Patient states, "I'm worried that I won't be able to return to work when I planned."

10. A nurse is checking a patient's intravenous line and, while doing so, notices how the patient bathes himself and then sits on the side of the bed independently to put on a new gown. This observation is an example of assessing:
    1. Patient's level of function.
    2. Patient's willingness to perform self-care.
    3. Patient's level of consciousness.
    4. Patient's health management values.

11. A nurse makes the following statement during a change-of-shift report to another nurse. "I assessed Mr. Diaz, my 61-year-old patient from Chile. He fell at home and hurt his back 3 days ago. He has some difficulty turning in bed, and he says that he has pain that radiates down his leg. He rates his pain at a 6, and he moves slowly as he transfers to a chair." What can the nurse who is beginning a shift do to validate the previous nurse's assessment findings when she conducts rounds on the patient? (Select all that apply.)
    1. The nurse asks the patient to rate his pain on a scale of 0 to 10.
    2. The nurse asks the patient what caused his fall.
    3. The nurse asks the patient if he has had pain in his back in the past.
    4. The nurse assesses the patient's lower-limb strength.
    5. The nurse asks the patient what pain medication is most effective in managing his pain.

12. A patient who visits the surgery clinic 4 weeks after a traumatic amputation of his right leg tells the nurse practitioner that he is worried about his ability to continue to support his family. He tells the nurse he feels that he has let his family down after having an auto accident that led to the loss of his left leg. The nurse listens and then asks the patient, "How do you see yourself now?" On the basis of Gordon's functional health patterns, which pattern does the nurse assess?
    1. Health perception–health management pattern
    2. Value-belief pattern
    3. Cognitive-perceptual pattern
    4. Self-perception–self-concept pattern

13. A nurse is conducting a patient-centered interview. Place the statements from the interview in the correct order, beginning with the first statement a nurse would ask.

 1. "You say you've lost weight. Tell me how much weight you've lost in the last month."

 2. "My name is Todd. I'll be the nurse taking care of you today. I'm going to ask you a series of questions to gather your health history."

 3. "I have no further questions. Thank you for your patience."

 4. "Tell me what brought you to the hospital."

 5. "So, to summarize, you've lost about 6 lbs in the last month, and your appetite has been poor—correct?"

14. During a visit to the clinic, a patient tells the nurse that he has been having headaches on and off for a week. The headaches sometimes make him feel nauseated. Which of the following responses by the nurse is an example of probing?

 1. So you've had headaches periodically in the last week and sometimes they cause you to feel nauseated—correct?

 2. Have you taken anything for your headaches?

 3. Tell me what makes your headaches begin.

 4. Uh huh, tell me more.

15. The nurse enters the room of an 82-year-old patient for whom she has not cared previously. The nurse notices that the patient wears a hearing aid. The patient looks up as the nurse approaches the bedside. Which of the following approaches are likely to be effective with an older adult? (Select all that apply.)

 1. Listen attentively to the patient's story.

 2. Use gestures that reinforce your questions or comments.

 3. Stand back away from the bedside.

 4. Maintain direct eye contact.

 5. Ask questions quickly to reduce the patient's fatigue.

Answers: 1. 1, 2, 3; **2.** 4; **3.** 1, 3, 4; **5.** 4; **6.** 2; **7.** 3; **8.** 2; **9.** 1, 4, 5; **10.** 1; **11.** 1, 4; **12.** 4; **13.** 2, 4, 1, 5, 3; **14.** 3; **15.** 1, 2, 4.

Nursing Diagnosis

OBJECTIVES

- Discuss how a nursing diagnosis guides nursing practice.
- Differentiate among a nursing diagnosis, medical diagnosis, and collaborative problem.
- Discuss the relationship of critical thinking to the nursing diagnostic process.
- Describe the steps of the nursing diagnostic process.
- Explain how defining characteristics and the etiological factor individualize a nursing diagnosis.
- Describe the differences among health promotion, problem-focused, and risk nursing diagnoses.
- Describe sources of diagnostic errors.
- Identify nursing diagnoses from a nursing assessment.

During the nursing assessment process (see Chapter 16) you gather information about a patient from a variety of sources. As you collect and analyze the data you begin to recognize cues that form patterns of data that indicate either a patient's level of wellness and desire for health promotion or his or her existing health problems. When you identify patterns accurately, they form diagnostic conclusions. A diagnosis is a clinical judgment made on the basis of information. Diagnostic conclusions include problems treated primarily by nurses (nursing diagnoses) and those treated by several disciplines (collaborative problems). Together nursing diagnoses and collaborative problems represent the range of patient conditions that require nursing care (Carpenito-Moyet, 2013).

When physicians and certified advanced practice nurses identify common medical diagnoses such as diabetes mellitus or osteoarthritis, they all know the meaning of the diagnoses and the standard approaches for treatment. A **medical diagnosis** is the identification of a disease condition based on a specific evaluation of physical signs and symptoms, a patient's medical history, and the results of diagnostic tests and procedures. A medical diagnosis stays constant as a condition remains. Physicians are licensed to treat diseases and conditions described in medical diagnostic statements. An advanced practice nurse can also treat medical diagnoses but does not perform surgery.

Nursing has a similar diagnostic language. Nursing diagnosis, the second step of the nursing process (Figure 17-1), classifies health problems within the domain of nursing (i.e., the problems that nurses can treat and manage). A **nursing diagnosis** is a clinical judgment concerning a human response to health conditions/life processes, or vulnerability for that response by an individual, family, or community that a nurse is licensed and competent to treat (Herdman and Kamitsuru, 2014). For example, acute pain is a response to an injury such as a surgical procedure or chemical burn. Nurses are licensed to treat acute pain. A nursing diagnosis can be problem focused or a state of health promotion or potential risk (Herdman and Kamitsuru, 2014). What makes the nursing diagnostic process unique is having patients actively involved, when possible, in the process. Nursing diagnoses are ever changing on the basis of a patient's needs.

A **collaborative problem** is an actual or potential physiological complication that nurses monitor to detect the onset of changes in a patient's health status (Carpenito-Moyet, 2013). When collaborative problems develop, nurses intervene in collaboration with personnel from other health care disciplines. The Canadian Interprofessional Health Collaborative (2010) defines interprofessional collaboration as a partnership between a team of health care providers (such as nurses, therapists, dietitians, and physicians) and a patient in a participatory collaborative and coordinated approach for shared decision making around health issues. Nurses manage collaborative problems such as hemorrhage, infection, and paralysis using medical, nursing, and allied health (e.g., physical therapy) interventions. For example, a patient with a surgical wound is at risk for developing an infection; thus a physician or advanced practice nurse prescribes antibiotics. The nurse monitors the patient for fever and other signs of infection and implements appropriate wound care measures. A dietitian recommends a therapeutic diet high in protein and nutrients to promote wound healing. The patient collaborates in learning hand

hygiene, the signs of infection, and wound care to perform wound care at home.

Selecting the correct nursing diagnosis on the basis of an assessment involves diagnostic expertise (i.e., being able to make quick and accurate conclusions from patient data) (Cho et al., 2010). This is essential because accurate diagnosis of actual or potential patient responses to health conditions or life processes ensures that you select more effective and efficient nursing interventions. Diagnostic expertise improves with clinical experience. Consider the case study involving Mr. Lawson and his nurse, Tonya.

During her assessment Tonya gathered information suggesting that Mr. Lawson possibly has a number of health problems. The data about Mr. Lawson are cues that form patterns in three areas: comfort, requesting information about postoperative care for impending discharge, and the potential for infection at his wound site. Selecting specific diagnostic labels for these problem areas will allow Tonya to develop a relevant and appropriate plan of care. For example, with respect to Mr. Lawson's request for information, there are two accepted nursing diagnostic labels for problems related to knowledge: **Deficient Knowledge** *and* **Readiness for Enhanced Knowledge.** *Knowing the difference between these two diagnoses and identifying which one applies to Mr. Lawson is essential to allow Tonya to select the right type of interventions for his problem. Knowing the difference between diagnoses is critical for health care providers who need to rule out diagnoses such as rheumatoid arthritis versus osteoarthritis to be sure that patients receive the right form of medical treatment. Tonya needs to use a critical thinking approach to identify the correct diagnosis that applies to Mr. Lawson's condition.*

HISTORY OF NURSING DIAGNOSIS

Nursing diagnosis was first introduced in the nursing literature in 1950 (McFarland and McFarlane, 1989). Fry (1953) proposed the formulation of nursing diagnoses and an individualized nursing care plan to better define nursing practice and science. This emphasized a nurse's independent practice (e.g., patient education and symptom relief) compared with the dependent practice driven by physicians' orders (e.g., medication administration and intravenous fluids). Initially professional nursing did not support nursing diagnoses. The *Model Nurse Practice Act* of the American Nurses Association (ANA) (1955) excluded diagnosis. As a result, few nurses used nursing diagnoses in their practice.

When Yura and Walsh (1967) developed the theory of the nursing process, it included four parts: assessment, planning, implementation, and evaluation. However, nurse educators soon recognized that assessment data needed to be analyzed and clustered into patterns and interpreted before nurses could complete the remaining steps of the process (NANDA-I, 2012). Soon diagnosis became part of the five-step nursing process. You cannot plan and intervene correctly for patients if you do not know the problems with which you are dealing. The same holds true when a physician or advanced practice nurse does not know a patient's medical diagnosis. In 1973 the first national conference on nursing diagnosis was held. Nurse leaders identified and defined 80 nursing diagnoses at that conference (Gebbie, 1998). Today the list contains several hundred diagnoses and continues to grow on the basis of nursing research and the work of members of the **North American Nursing Diagnosis Association International (NANDA-I)** (Herdman and Kamitsuru, 2014).

Nurses make diagnostic conclusions using nursing diagnosis to form clinical decisions necessary for safe and effective nursing practice.

Nursing Diagnosis—Validation and Reliability

PICO Question: Is the use of nursing diagnosis being researched to determine if the diagnoses apply to adult patients with different medical conditions?

Evidence Summary

For nursing diagnosis to be useful in nursing practice it must be diagnostically efficient and relevant, meaning that the defining characteristics are clinical indicators that apply to problems experienced by diverse patient groups. Various researchers are testing components of specific nursing diagnoses to determine if they apply to patients with specific medical conditions. Guedes et al. (2013) studied patients with hypertension and found that some clinical indicators (defining characteristics) have been identified for the nursing diagnosis *Sedentary Lifestyle*, whereas others have been added on the basis of their work. Escalada et al. (2013) reviewed studies involving nursing work in mental health and found that the most prevalent diagnosis was *Impaired Social Interaction*. Both studies encourage more research in application of nursing diagnosis.

Application to Nursing Practice

- Use of nursing diagnosis offers an approach to ensure more comprehensive nursing assessment and identification of patient health problems.
- Use of nursing diagnosis can improve selection of nursing interventions by nurses in all practice settings.
- Contributions from research will build on the evidence for use of defining characteristics and nursing diagnoses in identification of patients' health care problems.

The ANA's paper *Scope of Nursing Practice* (1987) defined nursing as the diagnosis and treatment of human responses to health and illness, strengthening the definition of nursing diagnosis. In 1980 and 1995 the ANA included diagnosis as a separate activity in its publication *Nursing: A Social Policy Statement* (ANA, 2003). It continues today in the ANA's most recent policy statement (ANA, 2010). Today most state Nurse Practice Acts includes nursing diagnosis as part of the domain of nursing practice.

There is one exception in reference to use of the term *nursing diagnosis* as part of the nursing process. The National Council of State Boards of Nursing (NCSBN, 2013), which administers the NCLEX examination, defines the nursing process as a scientific, clinical reasoning approach to patient care that includes assessment, *analysis*, planning, implementation, and evaluation. The use of the term *analysis* instead of diagnosis places emphasis on the analytical work needed to form correct nursing diagnoses.

Research in the field of nursing diagnosis continues to grow (Box 17-1). As a result, NANDA-I continually develops and adds new diagnostic labels to the list (Box 17-2). The use of standard formal nursing diagnostic statements serves several purposes in nursing practice:

- Provides a precise definition of a patient's responses to health problems that gives nurses and other members of the health care team a common language for understanding a patient's needs
- Allows nurses to communicate (e.g., written and electronic) what they do among themselves with other health care professionals and the public
- Distinguishes the nurse's role from that of other health care providers
- Helps nurses focus on the scope of nursing practice

- Fosters the development of nursing knowledge
- Promotes creation of practice guidelines that reflect the essence and science of nursing

TYPES OF NURSING DIAGNOSES

NANDA-I nursing diagnoses include three types: problem-focused, risk, and health promotion (Herdman and Kamitsuru, 2014). A **problem-focused nursing diagnosis** describes a clinical judgment concerning an undesirable human response to a health condition/life process that exists in an individual, family, or community. There are **defining characteristics** (observable assessment cues such as patient behavior, physical signs) that support each problem-focused diagnostic judgment (Herdman and Kamitsuru, 2014). The selection of a problem-focused nursing diagnosis indicates that there are sufficient assessment data from the defining characteristics to establish the nursing diagnosis. In addition, a problem-focused nursing diagnosis includes a related factor. A **related factor** is an etiological or causative factor for the diagnosis (i.e., the data that appear to show some type of patterned relationship with a nursing diagnosis) (Herdman and Kamitsuru, 2014). A related factor allows you to individualize a problem-focused nursing diagnosis for a specific patient need. *Tonya assessed Mr. Lawson initially in Chapter 15 as having discomfort from the colectomy incision. He rated pain at 7 on a 10-point rating scale and was grimacing. He guarded the incisional area that was tender. Mr. Lawson was also hesitant to move actively in bed. Tonya selected* **Acute Pain** *as a problem-focused nursing diagnosis on the basis of the patient's self-report of pain intensity, guarding behavior, and the expression of grimacing.* **Acute Pain** *related to trauma of surgical incision adds the related factor of trauma of surgical incision, allowing nurses who care for Mr. Lawson to focus interventions at measures to relieve incisional pain.* Examples of other problem-focused diagnoses include *Impaired Bed Mobility, Nausea, Sexual Dysfunction,* and *Impaired Skin Integrity*.

A **risk nursing diagnosis** is a clinical judgment concerning the vulnerability of an individual, family, group, or community for developing an undesirable human response to health conditions/life processes (Herdman and Kamitsuru, 2014). These diagnoses do not have defining characteristics or related factors because they have not yet occurred. Instead a risk diagnosis has risk factors. Risk factors are the environmental, physiological, psychological, genetic, or chemical elements that place a person at risk for a health problem. *For example, in Mr. Lawson's case the presence of his incision, the separation of an area between the stitches, and being hospitalized and exposed to sources of infection pose risks for a hospital-acquired wound infection.* The key assessment for a risk diagnosis is the presence of risk factors (e.g., an incision and the hospital environment) that support a patient's vulnerability. The risk factors are the diagnostic-related factors that help in planning preventive health care measures. In Mr. Lawson' case *Risk for Infection* is appropriate for his condition. Other examples of risk nursing diagnoses include *Risk for Loneliness* and *Risk for Ineffective Peripheral Tissue Perfusion*.

A **health promotion nursing diagnosis** is a clinical judgment concerning a patient's motivation and desire to increase well-being and actualize human health potential (Herdman and Kamitsuru, 2014). You make this type of diagnosis when patients in any health state express a readiness to enhance specific health behaviors. Health promotion diagnoses may apply to an individual, family, group, or community. The diagnoses have only defining characteristics, although you may use a related factor to improve understanding of the diagnosis (Herdman and Kamitsuru, 2014). *Tonya analyzes her information about Mr. Lawson and identifies that he has limited knowledge about infection or experience with postoperative wound care and freely asks questions*

with the desire to enhance his learning. His desire to ask questions is a critical defining characteristic that leads Tonya to select **Readiness for Enhanced Knowledge,** a health promotion diagnosis. Examples of other health promotion nursing diagnoses include:

- *Readiness for Enhanced Family Coping*
- *Readiness for Enhanced Nutrition*

CRITICAL THINKING AND THE NURSING DIAGNOSTIC PROCESS

The diagnostic process requires you to use critical thinking (see Chapter 15). You will learn to apply your knowledge, experience, critical thinking attitudes and intellectual standards when you collect and analyze assessment data to identify nursing diagnoses. Routinely applying critical thinking will make you more competent in making nursing diagnoses (Lunney, 2010).

In the practice of nursing it is important for you to know the nursing diagnostic labels, their definitions, the defining characteristics or risk factors for making diagnoses, related factors pertinent to the diagnoses, and the interventions suited for treating the diagnoses (Herdman and Kamitsuru, 2014). This means that you need to know how to access this information easily within the agency in which you work because the information is too extensive for you to memorize. Sources of information about nursing diagnoses include faculty, advanced practice nurses, documentation systems, and practice guidelines. Experience is essential in being competent at forming nursing diagnoses. Learn from your patients because this helps you think more carefully about your assessment information and what it means. Critical thinking helps you to be thorough, comprehensive, and accurate when identifying nursing diagnoses that apply to your patients.

The diagnostic reasoning process involves using the assessment data you gather about a patient to logically explain a clinical judgment, in this case a nursing diagnosis. The diagnostic process flows from the assessment process and includes decision-making steps (Figure 17-2). These steps include data clustering, identifying patient health problems, and formulating the diagnosis.

Data Clustering

Analysis and interpretation of assessment data begin by organizing all of a patient's data into meaningful and usable **data clusters**. A data cluster is a set of cues, the signs or symptoms gathered during assessment. Each cue is an objective or subjective sign, symptom, or risk factor that, when analyzed with other cues, begins to lead to diagnostic conclusions. A nurse collects cues intentionally or unintentionally (Herdman and Kamitsuru, 2014). Intentional assessment is the deliberate collection of data through physical examination or interviewing. Unintentional assessment is noticing cues that are important without planning to do so (Herdman and Kamitsuru, 2014). For example, an unintentional cue is noticing a patient grimace as you help him out of bed or hearing a patient's tone of voice while speaking with a visitor. You recognize the existence of cues and then cluster or group them together in a logical way to reveal how a patient is responding to a health condition or life process. During clustering of cues, your analysis makes you alert to thinking less about individual data points and instead to begin to see a pattern form. *For example, as Mr. Lawson begins to recover from surgery, he has questions. His knowledge of activity restrictions and signs of infection is unclear. Tonya clusters the cues she has learned from the patient, analyzes the cues, and recognizes the pattern of a knowledge problem.*

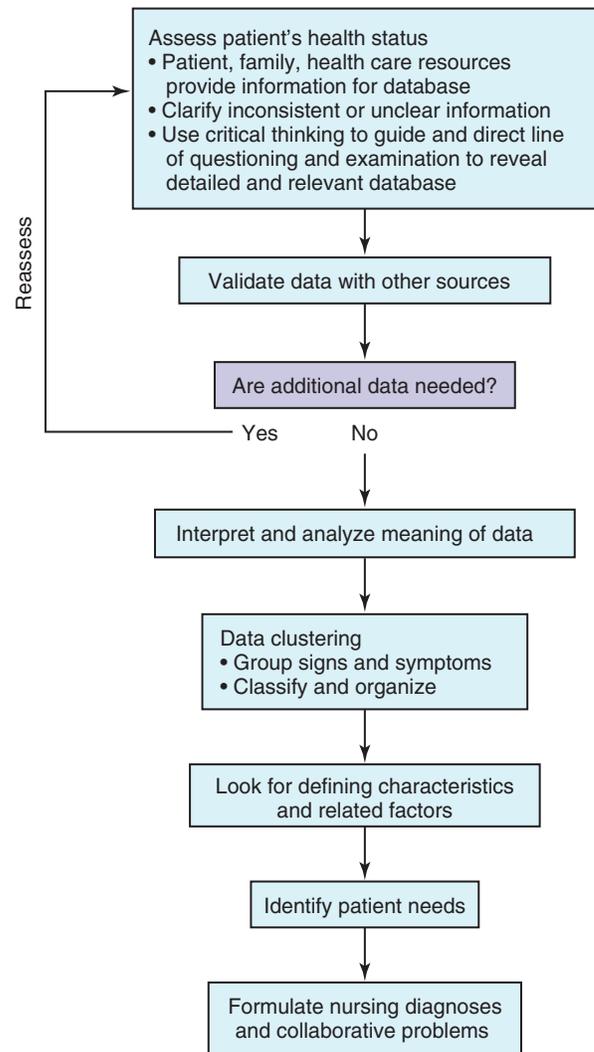
Data analysis and interpretation involve recognizing patterns in the clustered data, comparing them with standards, and coming to a


FIGURE 17-2 Nursing diagnostic process.

reasoned conclusion about a patient's response to a health problem. The NANDA-I classification of nursing diagnoses provides the standards for the patterns of data for each nursing diagnosis (Herdman and Kamitsuru, 2014). These standards are the defining characteristics or risk factors described earlier. Defining characteristics are the observable assessment cues that cluster as manifestations of a problem-focused or health promotion nursing diagnosis. The cues have been found through research to support a specific NANDA-I approved nursing diagnosis. Each NANDA-I–approved health promotion or problem-focused nursing diagnosis has an identified set of defining characteristics that support identification of the nursing diagnosis (Herdman and Kamitsuru, 2014). Your recognition of a cue or defining characteristic as a cue with special meaning depends on your knowledge and experience. You learn to recognize patterns of defining characteristics, comparing current data with expected data for a nursing diagnosis, and then select the correct diagnosis.

Working with similar patients over a period of time helps you recognize clusters of defining characteristics; but remember that each patient is unique and requires an individualized diagnostic approach. Box 17-3 shows two examples of nursing diagnoses and their associated defining characteristics. The first diagnosis, *Deficient Knowledge,* is a problem-focused diagnosis. The second, *Readiness for Enhanced Knowledge,* is a health promotion diagnosis. The defining

BOX 17-3   Examples of NANDA International–Approved Nursing Diagnoses with Defining Characteristics

Diagnosis: Deficient Knowledge	Diagnosis: Readiness for Enhanced Knowledge
Defining Characteristics	*Defining Characteristics*
• Inaccurate follow-through of instruction • Inaccurate performance on a test • Inappropriate behavior (e.g., hysterical, hostile, agitated, apathetic) • Insufficient knowledge	• Expresses a desire to increase or enhance learning

From Herdman TH, Kamitsuru S (Editors): *NANDA International nursing diagnoses: definitions & classification 2015-2017,* Oxford, 2014, Wiley Blackwell.

characteristics in both have similarities such as patient behaviors and self-reported information. However, *Deficient Knowledge* results from the absence or deficiency of information about a topic. The second diagnosis of *Readiness for Enhanced Knowledge* applies when a patient wants to learn more about a topic. As you gather cues and see clusters of data forming patterns, confirm your data with your source of information on NANDA-I diagnoses.

When assessment cues reveal risk factors (i.e., the factors that increase an individual's vulnerability to an unhealthy event), you will recognize patterns, compare the patterns with expected data for a risk diagnosis, and then select the correct risk nursing diagnosis.

Data Interpretation

While analyzing clusters of defining characteristics or risk factors, you consider a patient's responses to health conditions. Your interpretation of the information allows you to select among various diagnoses that may apply to your patient. Often there are numerous possible diagnoses or explanations to consider (Herdman and Kamitsuru, 2014). You compare defining characteristics or risk factors in your database with the different diagnoses in NANDA-I. To be more accurate, review all characteristics or risk factors, eliminate irrelevant ones, and confirm the relevant ones.

It is critical to select the correct diagnostic label for a patient's need. Usually from assessment to diagnosis you move from general information to specific. The patterns of assessment cues point you toward identifying a general health care problem, and the formulation of the nursing diagnosis becomes the specific health problem. *For example, after analyzing Mr. Lawson's problem with knowledge, Tonya began to identify data needed for a specific nursing diagnosis,* **Readiness for Enhanced Knowledge.**

Often a patient has defining characteristics or risk factors that apply to more than one diagnosis. There is no rule for the number necessary to form a diagnosis. It will depend on the diagnosis. *In Chapter 16 Mr. Lawson reported the following,* "*Well, the doctor did tell me that I wouldn't be able to lift anything heavy for a while; not sure if I understand. But with my incision looking the way it is, will I need to do something to it?*" This information might be interpreted as the patient reporting a problem, but the patient also expresses an interest in learning by asking a question. Just on the basis of this information, Tonya might choose *Deficient Knowledge* or *Readiness for Enhanced Knowledge* as nursing diagnoses, but she reviews her other findings. *Tonya assessed Mr. Lawson's knowledge of his problem,* "*Do you know what the signs of infection are? And the patient's response was,* "*Not sure I do, but I guess it*

would hurt more. Is infection common?*" The assessment revealed Mr. Lawson's ability to explain knowledge of the topic of wound infection.* When interpreting data to form a diagnosis, remember that the absence of certain defining characteristics suggests that you reject a diagnosis under consideration. *In the same example Tonya's assessment fails to reveal inappropriate behavior on the part of Mr. Lawson, and there are no exaggerated behaviors; thus it is more likely that Mr. Lawson has* **Readiness for Enhanced Knowledge,** *the correct diagnosis.*

While focusing on patterns of defining characteristics, compare a patient's pattern of data with information that is consistent with normal, healthy patterns. Use accepted norms as the basis for comparison and judgment such as laboratory and diagnostic test values, professional standards, and normal anatomical or physiological limits already established. When comparing patterns, judge whether the grouped signs and symptoms are expected for a patient (e.g., consider current condition, history) and whether they are within the range of healthy responses. Isolate any defining characteristics not within healthy norms to allow you to identify a specific problem.

Nursing diagnoses provide the basis for selection of nursing interventions to achieve outcomes for which you, as a nurse, are accountable (Herdman and Kamitsuru, 2014). A nursing diagnosis focuses on a patient's actual or potential response to a health condition rather than on the physiological event, complication, or disease. A nurse cannot independently treat a medical diagnosis such as a tumor of the prostate. *However, Tonya manages Mr. Lawson's postoperative care, monitoring his postoperative progress and wound care, intravenous fluid administration, and medication therapy to prevent collaborative problems from developing.* Collaborative problems occur or probably will occur in association with a specific disease process, trauma, or treatment (Carpenito-Moyet, 2013). *For example, Tonya monitors Mr. Lawson in an effort to prevent him from developing infection.* You need nursing knowledge to assess a patient's specific risk for these problems, identify the problems early, and take preventive action (Figure 17-3). Critical thinking is necessary in identifying nursing diagnoses and collaborative problems so you appropriately individualize care for your patients.

Formulating a Nursing Diagnostic Statement

After clustering assessment data and interpreting the meaning, your aim is to select the correct nursing diagnostic statement. If you make an incorrect nursing diagnosis, a patient is likely to receive inappropriate or unnecessary care. For example, your approach to *Acute Pain* related to a surgical incision will be very different from *Acute Pain* related to a traumatic injury. An accurate nursing diagnostic statement requires you to identify the correct diagnostic label with associated defining characteristics or risk factors and a related factor (when applicable).

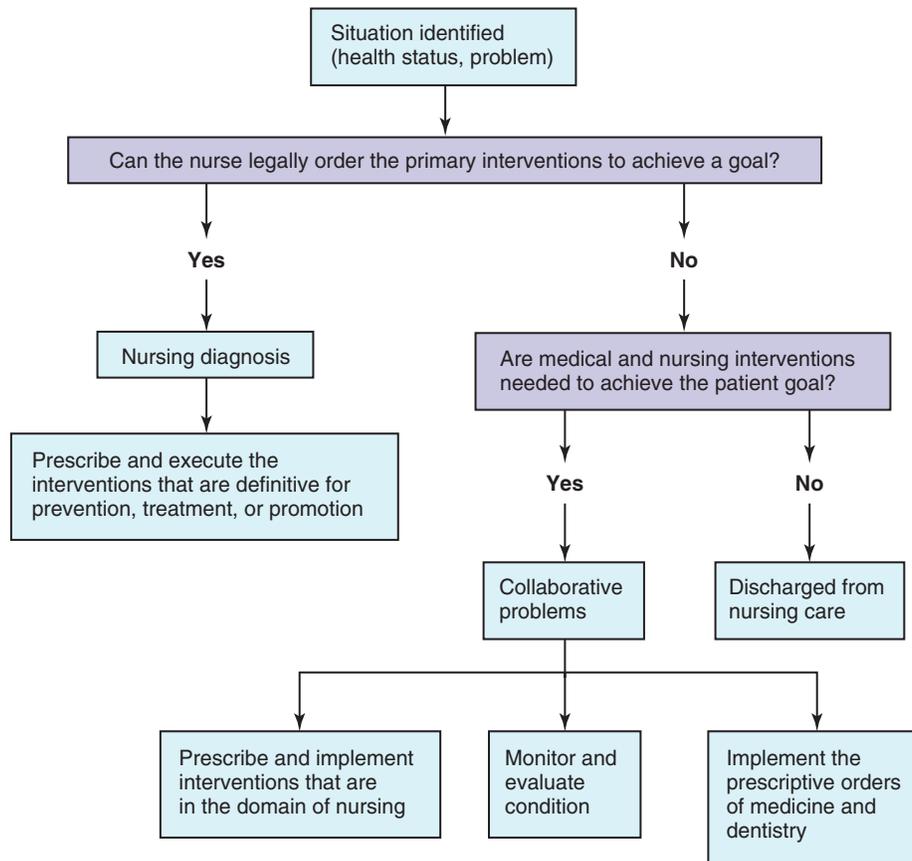
The **diagnostic label** is the name of the nursing diagnosis as approved by NANDA-I (see Box 17-2). It describes the essence of a patient's response to health conditions in as few words as possible. All NANDA-I approved diagnoses have a definition. The definition describes the characteristics of the human response identified and helps to select the correct diagnosis. *For example, Mr. Lawson just had surgery, is scheduled for discharge, and has ongoing self-care needs (wound care, activity restrictions) once he returns home. He shows interest in learning, and his wife is willing and able to help him at home.* The definition for *Readiness for Enhanced Knowledge* is "A pattern of cognitive information related to a specific topic, or its acquisition, which can be strengthened" (Herdman and Kamitsuru, 2014, p. 258). The definition helps to provide a context for understanding the assessment information gathered about Mr. Lawson's knowledge, and it is used in making a final diagnosis. Placing a diagnosis into the context of a


FIGURE 17-3 Differentiating nursing diagnoses from collaborative problems. (©1990, 1988, 1985 Lynda Juall Carpenito. Redrawn from Carpenito LJ: *Nursing diagnosis: application to clinical practice,* ed 6, Philadelphia, 1995, Lippincott.)

TABLE 17-1	Comparison of Interventions for Nursing Diagnoses with Different Related Factors	
Nursing Diagnoses	**Related Factor**	**Interventions**
Patient A		
Anxiety	Uncertainty over surgery	Provide detailed instructions about the surgical procedure, recovery process, and postoperative care activities. Plan formal time for patient to ask questions.
Impaired Physical Mobility	Acute pain	Administer analgesics 30 minutes before planned exercise. Instruct patient how to splint painful site during activity.
Patient B		
Anxiety	Loss of job	Consult with social worker to arrange for job counseling. Encourage patient to continue health promotion activities (e.g., exercise, routine social activities).
Impaired Physical Mobility	Musculoskeletal injury	Have patient perform active range-of-motion exercises to affected extremity every 2 hours. Instruct patient on use of three-point crutch gait.

patient's situation clarifies the nature of a patient's health problem. *Tonya considers the nature of Mr. Lawson's situation and identifies his diagnosis as **Readiness for Enhanced Knowledge.***

A complete diagnostic statement will also include a related factor (appropriate for problem-based and some health promotion diagnoses). You identify the related factor from the patient's assessment data. The related factor is associated with a patient's actual or potential response to a health problem and can change by using specific nursing interventions (Table 17-1). Related factors for NANDA-I diagnoses include four categories: pathophysiological (biological or psychological), treatment-related, situational (environmental or personal), and maturational (Carpenito-Moyet, 2013). The "related to" phrase is not a cause-and-effect statement. It indicates that the etiology contributes to or is associated with the patient's diagnosis (Figure 17-4). *Tonya selects the related factor impending discharge with self-care needs because it explains Mr. Lawson's response to a knowledge problem.* In this case, adding the related factor to the health promotion diagnosis provides an etiology that can be targeted through instruction. *When Tonya is ready to form her plan of care and select nursing interventions, the concise nursing diagnosis with related factor allows her to select*

therapies for actively involving the patient and his wife in postoperative instruction.

When communicating a nursing diagnosis, through either discussions with health care colleagues or documentation of your care, use the language adopted within an agency. Most settings use a two-part format in labeling health promotion and problem-focused nursing diagnoses: the NANDA-I diagnostic label followed by a statement of a related factor (Table 17-2). The two-part format provides a diagnosis meaning and relevance for a particular patient (Table 17-3).

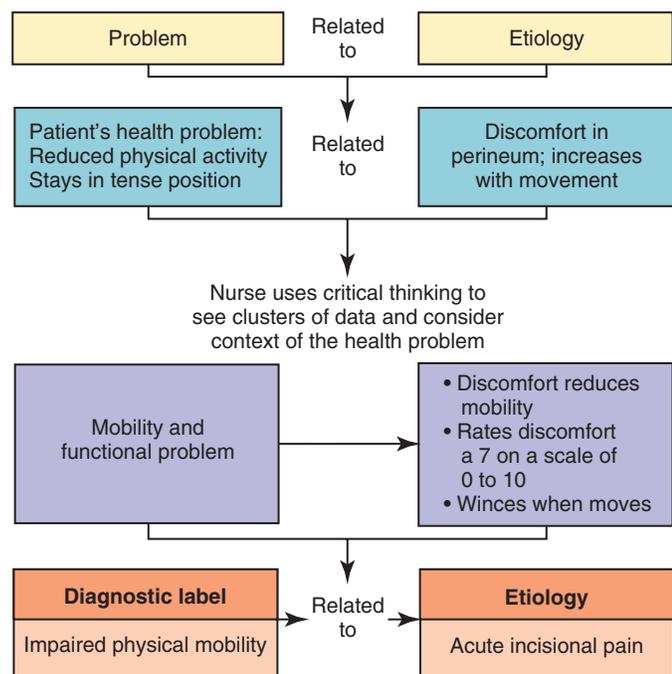
However, some agencies prefer a three-part nursing diagnostic label. In this case the diagnostic label consists of the NANDA-I label, the related factor, and the defining characteristics (Ackley and Ladwig, 2011). NANDA-I believes that a problem-focused nursing diagnosis, including a diagnosis label and the related factor as exhibited by defining characteristics, to be best practice (Herdman and Kamitsuru, 2014). This structure makes a diagnosis even more patient specific. Throughout this text you will more commonly find the two-part diagnostic statement to include the diagnosis label and related factor.


FIGURE 17-4 Relationship between a diagnostic label and related factor (etiology).

To write a three-part nursing diagnosis, the acronym PES, which stands for *p*roblem, *e*tiology, and *s*ymptoms, is helpful.
- **P** (problem)—NANDA-I label—Example: *Impaired Physical Mobility*
- **E** (etiology or related factor)—Example: incisional pain
- **S** (symptoms or defining characteristics)—Briefly lists defining characteristic(s) that show evidence of the health problem. Example: evidenced by restricted turning and positioning

Full three-part diagnostic statement: *Impaired Physical Mobility* related to incisional pain as evidenced by restricted turning and positioning.

Cultural Relevance of Nursing Diagnoses

When you select nursing diagnoses, consider your patients' cultural diversity, including values, beliefs, health practices, ethnicity, and gender (see Chapter 9). This also includes knowing the cultural differences that affect how patients define health and illness and their requests or choices for treatment. For example, Lai et al. (2013) explored how NANDA-I nursing diagnoses affect the quality of professional nursing from the perspective of Taiwanese nurses. Their work found that certain diagnoses were difficult for nurses to apply considering the cultural beliefs of a traditional Chinese health care setting, which emphasizes holistic harmony and balance. Nursing diagnoses are internationally accepted as a part of systematic and individualized nursing care (Herdman and Kamitsuru, 2014; ANA, 2010). However,

TABLE 17-2 NANDA International Two-Part Nursing Diagnosis Format	
Diagnostic Label	**Examples of Related Factors**
Acute Pain	Biological (e.g., limited blood flow to an organ), chemical (skin burn), physical (traumatic injury, trauma of surgical incision), or psychological injury (primary traumatic stress) agents. Example: *Acute Pain* related to trauma of surgical incision.
Impaired Physical Mobility	Activity intolerance, decrease in muscle strength, joint stiffness, cultural belief regarding appropriate activity, malnutrition, pain. Example: *Impaired Physical Mobility* related to incisional pain.
Impaired Memory	Alteration in fluid volume, anemia, decrease in cardiac output, neurological impairment. Example: *Impaired Memory* related to dehydration

TABLE 17-3 Developing a Two-Part Nursing Diagnosis Label			
Assessment Activities	**Defining Characteristics (Clustering Cues)**	**Etiologies ("Related To")**	**Nursing Diagnosis**
Ask patient to rate severity of pain on a scale from 0 to 10.	Verbal report of pain at a level of 7	Physical; swelling from incisional trauma	**Acute Pain** related to trauma of incision
Observe patient's positioning in bed.	Lies flat, avoids turning		
Ask patient to describe what he knows about surgery.	Has no knowledge about postoperative wound care	Inexperience; first time to have surgery	**Readiness for Enhanced Knowledge**
Observe his interactions.	Asks questions about activity restrictions; shows interest in learning what to expect		
Question wife's role in postoperative care and her level of knowledge.	Wife to provide support within the home; no knowledge of how to manage wound		

it is important to consider your patient's culture and your own cultural competence to accurately identify a patient's health care problems.

Consider the example of the nursing diagnosis *Sedentary Lifestyle*. The definition for the diagnosis is a patient reporting a habit of life that is characterized by a low physical activity level (Herdman and Kamitsuru, 2014). It would be easy to apply cultural bias in selecting this diagnosis for a patient, depending on your own exercise habits and the values that you hold regarding healthy behavior. However, the definition for the diagnosis stresses "patient report." The inappropriate selection of this diagnosis on the basis of your values or beliefs potentially results in the implementation of interventions that a patient likely will not accept. Consider asking these questions to make culturally competent nursing diagnoses:

- How has this health problem affected you and your family?
- What do you believe will help or fix the problem?
- What worries you the most about this problem?
- What do you expect from us, your nurses, to help maintain some of your values or practices for staying healthy?
- Which cultural practices do you observe to keep yourself and your family well?

When you ask questions such as these, you use a patient-centered approach that allows you to see a patient's health situation through his or her eyes. This is necessary to identify relevant cues pertaining to a patient's health problem. When making a nursing diagnosis, consider how culture influences the related factor for the diagnostic statement. For example, *Noncompliance* related to patient value system reflects a diagnostic conclusion that considers a patient's unique cultural needs.

CONCEPT MAPPING NURSING DIAGNOSES

In Chapter 16 you learned how concept mapping offers a graphic look at the connections among patient's multiple health problems. Once you enter practice as a graduate nurse, you will care for multiple patients. Then it becomes especially challenging to prioritize and focus on all patients' diagnoses. A concept map helps you critically think about a patient's diagnoses and how they relate to one another (Chabeli, 2010; Pilcher, 2011). Concept mapping helps you organize and link data about a patient's multiple diagnoses in a logical way. It graphically represents the connections among concepts (e.g., nursing diagnoses and the interventions later selected) that relate to a central subject (e.g., the patient's primary health problem).

In Figure 17-5, the concept map for Mr. Lawson, Tonya uses data gathered from her assessment of Mr. Lawson and now replaces patterns of problems with nursing diagnoses. *Tonya's assessment included Mr. Lawson's perspective of his health problems and the objective and subjective data she collected through observation and examination. She validated findings and added to the database as she learned new information. As Tonya begins to see patterns of defining characteristics, she places labels to identify three nursing diagnoses that apply to Mr. Lawson. She is also able to see the relation among the diagnoses and connects them on the concept map. If Mr. Lawson does not receive pain relief, Tonya knows from her experience in caring for patients with **Acute Pain** that he will not be attentive or receptive in her efforts to educate him about home care. Tonya wants to provide instruction about postoperative care, an intervention that will be planned later for **Readiness for Enhanced Knowledge**. The patient's **Risk for Infection** requires Tonya to address infection prevention strategies along with wound care and activity restrictions when she instructs Mr. and Mrs. Lawson.*

Concept mapping organizes and links information to allow you to see a dynamic holism and complexity of individualized patient care. The advantage of a concept map is its central focus on a patient rather than on a disease or health alteration. This encourages nursing

students to concentrate on patients' specific health problems and nursing diagnoses. The focus also promotes patient participation with the eventual plan of care.

SOURCES OF DIAGNOSTIC ERRORS

Errors occur in the nursing diagnostic process during data collection, clustering, and interpretation and in making a nursing diagnostic statement (Box 17-4). Accuracy in the selection of nursing diagnoses requires methodical critical thinking.

Errors in Data Collection

During assessment (see Chapter 16) be knowledgeable, thorough, and skillful. Avoid inaccurate or missing data and collect data in an organized way (see Chapter 31). For example, if a patient describes a problem swallowing, gather data about the types of food the patient can or cannot eat; whether there is pain in the mouth or throat; a thorough description of the pain; and what, if anything, improves swallowing. Be exhaustive in collecting data applicable to the problem. Application of intellectual standards for critical thinking will help you gather the comprehensive information you need.

Errors in Interpretation and Analysis of Data

Following data collection, review your database to decide if it is accurate and complete. Validate that measurable, objective physical findings support subjective data. For example, when a patient reports "difficulty breathing," you also listen to lung sounds, assess respiratory rate, and measure the patient's chest excursion (see Chapter 31). When you are unable to validate data, it signals an inaccurate match between clinical cues and the nursing diagnosis. Begin interpretation by identifying and organizing relevant assessment patterns to support the presence of patient problems. Be careful to consider conflicting cues or decide if there are insufficient cues to form a diagnosis. It is important to consider a patient's cultural background or developmental stage when interpreting the meaning of cues. For example, a male patient may express pain differently than a female patient. Thus misinterpreting how a male patient expresses pain could easily lead to an inaccurate diagnosis.

Errors in Data Clustering

Errors occur when you cluster data prematurely, incorrectly, or not at all. Premature clustering occurs when you make a nursing diagnosis

---

BOX 17-4   Sources of Diagnostic Error

Collecting
- Lack of knowledge or skill
- Inaccurate data
- Missing data
- Disorganization
- Failure to validate

Interpreting
- Inaccurate interpretation of cues
- Failure to consider conflicting cues
- Using an insufficient number of cues
- Using unreliable or invalid cues
- Failure to consider cultural influences or developmental stage

Clustering
- Insufficient cluster of cues
- Premature or early closure
- Incorrect clustering

Labeling
- Wrong diagnostic label selected
- Evidence that another diagnosis is more likely
- Condition is a collaborative problem
- Failure to validate nursing diagnosis with patient
- Failure to seek guidance

CONCEPT MAP

Nursing diagnosis: Acute pain related to incisional trauma
- Wound tender when palpated
- Pain severity has ranged from 8 to 4
- Patient guards incision by placing hand over wound when moving
- Patient states, "Ow! That is sore."

Interventions (to be developed during planning, Chapter 18)

Nursing diagnosis: Readiness for enhanced knowledge related to impending discharge with self-care needs
- Unclear about activity restrictions
- Asks if he will need to "do something to" his incision.
- Lifts various objects at home
- Does not know signs of infection

Interventions (to be developed during planning, Chapter 18)

Primary health problem: Colectomy
Priority assessments: Condition of incision, gastrointestinal function, comfort level, knowledge of home care requirements and ability to learn, resources for discharge

Nursing diagnosis: Risk for infection
- Has a small separation of wound edges
- Patient is obese
- Drainage from wound
- Incision tender and inflamed near area of separation
- In a health care environment

Interventions (to be developed during planning, Chapter 18)

——— Link between medical diagnosis and nursing diagnosis   - - - - Link between nursing diagnoses

FIGURE 17-5 Concept map for Mr. Lawson: Nursing Diagnoses.

before grouping all data. For example, a patient has urinary incontinence and states that he has dysuria. You cluster the available data and identify *Impaired Urinary Elimination* as a probable nursing diagnosis. Incorrect clustering occurs when you try to make a diagnosis fit the signs and symptoms that you obtain. In this example further assessment reveals that the patient also has bladder distention and dribbling; thus the correct diagnosis is *Urinary Retention*. Always identify a nursing diagnosis from the data, not the reverse. An incorrect nursing diagnosis affects quality of patient care.

Errors in the Diagnostic Statement

Clinical reasoning leads to a higher-quality level of nursing diagnosis, which eventually leads to etiology-specific interventions and enhanced patient outcomes (Muller-Staub et al., 2008). The correct selection of a diagnostic statement is more likely to result in the appropriate selection of interventions and outcomes (Herdman and Kamitsuru, 2014)

during planning and implementation (see Chapters 18 and 19). Reduce errors by selecting appropriate, concise, and precise language using NANDA-I terminology. Be sure that the etiology portion of the diagnostic statement is within the scope of nursing to diagnose and treat. Additional guidelines to reduce errors in the diagnostic statement follow.

1. Identify a patient's response, not the medical diagnosis (Carpenito-Moyet, 2013). Because a medical diagnosis requires medical interventions, it is legally inadvisable to include it in the nursing diagnosis. Change the diagnosis *Acute Pain* related to colectomy to *Acute Pain* related to trauma of a surgical incision.
2. Identify a NANDA-I diagnostic statement rather than the symptom. Identify nursing diagnoses from a cluster of defining characteristics and not just a single symptom. One defining characteristic is insufficient for problem identification. For

example, dyspnea alone does not definitively lead you to a diagnosis. However, the pattern of dyspnea, reduced chest excursion, and rapid respiratory rate are defining characteristics that lead you to the diagnosis of *Ineffective Breathing Pattern*. If a patient has severe chest pain resulting from a rib fracture, the final diagnosis will be *Ineffective Breathing Pattern* related to chest pain.

3. Identify a treatable related factor or risk factor rather than a clinical sign or chronic problem that is not treatable through nursing intervention. An accurate related factor allows you to select nursing interventions directed toward correcting the etiology of the problem or minimizing a patient's risk. A diagnostic test or a chronic dysfunction is not an etiology or a condition that a nursing intervention is able to treat. A patient with fractured ribs likely has pain when inhaling; impaired chest excursion; and slower, shallow respirations. An x-ray film may show atelectasis (collapse of alveolar air sacs) in the area affected. The nursing diagnosis of *Ineffective Breathing Pattern* related to shallow respirations is an incorrect diagnostic statement. *Ineffective Breathing Pattern* related to chest pain from rib fracture is more accurate.

4. Identify a problem caused by the treatment or diagnostic study rather than the treatment or study itself. Patients experience many responses to diagnostic tests and medical treatments. These responses are the area of nursing concern. The patient who has angina and is scheduled for a cardiac catheterization possibly has a nursing diagnosis of *Anxiety* related to lack of knowledge about cardiac testing. An incorrect diagnosis is *Anxiety* related to cardiac catheterization.

5. Identify a patient response to the equipment rather than the equipment itself. Patients are often unfamiliar with medical technology and its use. The diagnosis of *Deficient Knowledge* regarding the need for cardiac monitoring is accurate compared with the statement *Anxiety* related to cardiac monitor.

6. Identify a patient's problems rather than your problems with nursing care. Nursing diagnoses are always patient centered and form the basis for goal-directed care. Consider a patient with a peripheral intravenous line. *Potential Intravenous Complications* related to poor vascular access indicates a nursing problem in initiating and maintaining intravenous therapy. The diagnosis *Risk for Infection* properly centers attention on the patient's potential needs.

7. Identify a patient problem rather than a nursing intervention. You plan nursing interventions after identifying a nursing diagnosis. The intervention, "offer bedpan frequently because of altered elimination patterns," is not a diagnostic statement. Instead, with the proper assessment data the correct diagnostic statement would be *Diarrhea* related to food intolerance. This corrects the misstatement and allows proper implementation of the nursing process. More appropriate interventions are selected rather than a single intervention that alone will not solve the problem.

8. Identify a patient problem rather than the goal of care. You establish goals during the planning step of the nursing process (see Chapter 18). Goals based on accurate identification of a patient's problems serve as a basis to determine problem resolution. Change the goal-phrased statement, "Patient needs high-protein diet related to potential alteration in nutrition," to *Imbalanced Nutrition: Less Than Body Requirements* related to inadequate protein intake.

9. Make professional rather than prejudicial judgments. Base nursing diagnoses on subjective and objective patient data and do not include your personal beliefs and values. Remove your judgment from *Impaired Skin Integrity* related to poor hygiene habits by changing the nursing diagnosis to read *Impaired Skin Integrity* related to inadequate knowledge about perineal care.

10. Avoid legally inadvisable statements (Carpenito-Moyet, 2013). Statements that imply blame, negligence, or malpractice have the potential to result in a lawsuit. The statement, "*Acute Pain* related to insufficient medication," implies an inadequate prescription by a health care provider. Correct problem identification is *Acute Pain* related to poor adherence to analgesic schedule.

11. Identify the problem and etiology to avoid a circular statement. Circular statements are vague and give no direction to nursing care. Change the statement, "*Impaired Breathing Pattern* related to shallow breathing," to identify the real patient problem and cause, *Ineffective Breathing Pattern* related to incisional pain.

12. Identify only one patient problem in the diagnostic statement. Every problem has different specific expected outcomes (see Chapter 18). Confusion during the planning step occurs when you include multiple problems in a nursing diagnosis. For example, *Pain and Anxiety* related to difficulty in ambulating are two nursing diagnoses combined in one diagnostic statement. A more accurate statement would be two separate diagnoses: *Impaired Physical Mobility* related to pain in right knee and *Anxiety* related to difficulty in ambulating. It is permissible to include multiple etiologies contributing to one patient problem, as in *Complicated Grieving* related to diagnosed terminal illness and change in family role.

DOCUMENTATION AND INFORMATICS

Once you identify a patient's nursing diagnoses, enter them either on the written plan of care or in the electronic health information record (EHR) of the agency. State-of-the-art EHRs contain nursing diagnoses with NANDA-I approved diagnoses, interventions and outcomes, related or risk factors, and defining characteristics (Herdman and Kamitsuru, 2014). A nurse enters assessment data into the EHR, and the computer helps by organizing the data into clusters that enhance the ability to select accurate diagnoses. Once diagnoses are selected, the computer system will direct the nurse to outcome and intervention options to select for a patient. This makes building a care plan more theoretically based.

There are agencies with EHRs that do not use NANDA-I terminology. This makes entry of NANDA-I diagnoses more tedious. However it is important to know why to use NANDA-I terminology in a medical record entry (Herdman and Kamitsuru, 2014):

- NANDA-I diagnoses have a broad literature base, with many diagnoses being evidence based. Patient safety requires accurate documentation of health problems.
- NANDA-I classifications are the most comprehensive.
- NANDA-I diagnoses are under continual refinement and development by professional nurses.

In an agency, list nursing diagnoses chronologically as you identify them. When initiating an original care plan, place the highest-priority nursing diagnosis first. This will depend on a patient's condition and the nature of the nursing diagnosis. Thereafter add nursing diagnoses to the list. Date a nursing diagnosis at the time of initiation. When caring for a patient, review the list and identify nursing diagnoses with the greatest priority, regardless of chronological order.

NURSING DIAGNOSES: APPLICATION TO CARE PLANNING

Nursing diagnosis is a universal means for communication among professional nurses and across other health care disciplines. Diagnoses direct the planning process and the selection of nursing interventions to achieve desired outcomes for patients. Just as a medical diagnosis of diabetes leads a health care provider to prescribe a low-carbohydrate diet and medication for blood glucose control, the nursing diagnosis of *Impaired Skin Integrity* directs a nurse to apply a support surface to a patient's bed and initiate a turning schedule. In Chapter 18 you will learn how unifying the languages of NANDA-I with the Nursing Interventions Classification (NIC) and Nursing Outcomes Classification (NOC) facilitates the process of matching nursing diagnoses with accurate and appropriate interventions and outcomes. The care plan (see Chapter 18) is a map for nursing care and demonstrates your accountability for patient care. By making accurate nursing diagnoses, your subsequent care plan communicates a patient's health care problems to other professionals and ensures that you select relevant and appropriate nursing interventions.

KEY POINTS

- The diagnostic process is a clinical judgment that involves reviewing assessment information, recognizing cues, clustering cues into patterns of data, and identifying a patient's specific health care problems.
- Diagnostic conclusions include problems treated primarily by nurses (nursing diagnoses) and those requiring treatment by several disciplines (collaborative problems).
- Nurses manage collaborative problems by using medical, nursing, and allied health interventions.
- The use of standard formal nursing diagnostic statements provides a precise definition of a patient's problem that gives nurses and other members of the health care team a common language for understanding a patient's needs.
- Data analysis and interpretation involve recognizing patterns in clustered data, comparing them with standards such as the NANDA-I classification of nursing diagnoses and defining characteristics, and coming to a reasoned conclusion about a patient's response to a health problem.
- Accurate diagnosis of patient problems ensures the selection of more effective and efficient nursing interventions.
- Defining characteristics are the subjective and objective clinical cues that a nurse gathers intentionally and unintentionally, clusters, and uses to form a diagnostic conclusion.
- When an assessment reveals defining characteristics that apply to more than one nursing diagnosis, gather more information to clarify your interpretation.
- Absence of defining characteristics suggests that you reject a proposed diagnosis.

- A problem-focused nursing diagnosis is usually written in a two-part format, including a diagnostic label and an etiological or related factor.
- A three-part diagnostic statement includes defining characteristics that apply to a patient's condition.
- Assessing the cultural differences that affect how patients define health and illness and want or choose to be treated will assist in making correct diagnostic conclusions.
- The "related to" factor of a diagnostic statement helps you to individualize problem-focused and health promotion nursing diagnoses and provides direction for your selection of appropriate interventions.
- Risk factors serve as cues to indicate that a risk nursing diagnosis applies to a patient's condition.
- A concept map is a visual representation of a patient's nursing diagnoses and their relationship with one another.
- Nursing diagnostic errors occur by errors in data collection, interpretation and analysis of data, clustering of data, or the diagnostic statement.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Tonya begins to discuss Mr. and Mrs. Lawson's questions about caring for a wound at home. The patient lives in his own home. Mrs. Lawson has no restrictions to her activity and believes that she can help the patient with any physical limits. As they talk, Mr. Lawson shares with Tonya, "I'm worried about being able to return to work on time." When instructing the patient an hour ago, Tonya noticed that he was having trouble concentrating on what she had to say. He seemed more concerned about how his incision felt. Mrs. Lawson tells Tonya, "His office has been laying off workers; that's why he's concerned."

1. Consider Mr. Lawson's behaviors and statements in this case study and identify three pieces of assessment data that cluster together to form defining characteristics.
2. Tonya clusters the defining characteristics to select the diagnostic label of *Anxiety*. What would you identify as the related factor for this diagnosis?
3. If Tonya identified the patient's diagnosis as *Anxiety* related to need to perform wound care, would this be an accurate nursing diagnosis? Explain.

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse identified that a patient has difficulty turning in bed, moves slowly when assisted into a chair, and expresses having breathlessness after walking to the bathroom and back. The patient has been in the hospital for over 4 days. Write a three-part nursing diagnostic statement using the PES format.
2. Review the following problem-focused nursing diagnoses and identify the diagnoses that are stated correctly. (Select all that apply.)
   1. *Impaired Skin Integrity* related to physical immobility
   2. *Fatigue* related to heart disease
   3. *Nausea* related to gastric distention
   4. Need for improved *Oral Mucosa Integrity* related to inflamed mucosa
   5. *Risk for Infection* related to surgery

3. A nurse reviews data gathered regarding a patient's ability to cope with loss. The nurse compares the defining characteristics for *Ineffective Coping* with those for *Readiness for Enhanced Coping* and selects *Ineffective Coping* as the correct diagnosis. This is an example of the nurse avoiding an error in: (Select all that apply.)
   1. Data collection.
   2. Data clustering.
   3. Data interpretation.
   4. Making a diagnostic statement.
   5. Goal setting.

4. The nursing diagnosis *Impaired Parenting* related to mother's developmental delay is an example of a(n):
   1. Risk nursing diagnosis.
   2. Problem-focused nursing diagnosis.
   3. Health promotion nursing diagnosis.
   4. Wellness nursing diagnosis.

5. A nurse interviewed and conducted a physical examination of a patient. Among the assessment data the nurse gathered were an increased respiratory rate, the patient reporting difficulty breathing while lying flat, and pursed-lip breathing. This data set is an example of:
   1. Collaborative data set.
   2. Diagnostic label.
   3. Related factors.
   4. Data cluster.

6. In which of the following examples are nurses making diagnostic errors? (Select all that apply.)
   1. The nurse who observes a patient wincing and holding his left side and gathers no additional assessment data
   2. The nurse who measures joint range of motion after the patient reports pain in the left elbow
   3. The nurse who considers conflicting cues in deciding which diagnostic label to choose
   4. The nurse who identifies a diagnosis on the basis of a patient reporting difficulty sleeping
   5. The nurse who makes a diagnosis of *Ineffective Airway Clearance* related to pneumonia.

7. A nurse is reviewing a patient's list of nursing diagnoses in the medical record. The most recent nursing diagnosis is *Diarrhea* related to intestinal colitis. For which of the following reasons is this an incorrectly stated diagnostic statement?
   1. Identifying the clinical sign instead of an etiology
   2. Identifying a diagnosis on the basis of prejudicial judgment
   3. Identifying the diagnostic study rather than a problem caused by the diagnostic study
   4. Identifying the medical diagnosis instead of the patient's response to the diagnosis.

8. A nurse is assigned to a new patient admitted to the nursing unit following admission through the emergency department. The nurse collects a nursing history and interviews the patient. Place the following steps for making a nursing diagnosis in the correct order, beginning with the first step.
   1. Considers context of patient's health problem and selects a related factor
   2. Reviews assessment data, noting objective and subjective clinical information
   3. Clusters clinical cues that form a pattern
   4. Chooses diagnostic label

9. A nursing student reports to a lead charge nurse that his assigned patient seems to be less alert and his blood pressure is lower, dropping from 140/80 to 110/60. The nursing student states, "I believe this is a nursing diagnosis of *Deficient Fluid Volume*." The lead charge nurse immediately goes to the patient's room with the student to assess the patient's orientation, heart rate, skin turgor, and urine output for last 8 hours. The lead charge nurse suspects that the student has made which type of diagnostic error?
   1. Insufficient cluster of cues
   2. Disorganization
   3. Insufficient number of cues
   4. Evidence that another diagnosis is more likely

10. A nurse in a mother-baby clinic learns that a 16-year-old has given birth to her first child and has not been to a well-baby class yet. The nurse's assessment reveals that the infant cries when breast-feeding and has difficulty latching on to the nipple. The infant has not gained weight over the last 2 weeks. The nurse identifies the patient's nursing diagnosis as *Ineffective Breastfeeding*. Which of the following is the best "related to" factor?
    1. Infant crying at breast
    2. Infant unable to latch on to breast correctly
    3. Mother's deficient knowledge
    4. Lack of infant weight gain

11. A nurse is getting ready to assess a patient in a neighborhood community clinic. He was newly diagnosed with diabetes just a month ago. He has other health problems and a history of not being able to manage his health. Which of the following questions reflects the nurse's cultural competence in making an accurate diagnosis? (Select all that apply.)
    1. How is your diabetic diet affecting you and your family?
    2. You seem to not want to follow health guidelines. Can you explain why?
    3. What worries you the most about having diabetes?
    4. What do you expect from us when you do not take your insulin as instructed?
    5. What do you believe will help you control your blood sugar?

12. A nurse assesses a young woman who works part time but also cares for her mother at home. The nurse reviews clusters of data that include the patient's report of frequent awakenings at night, reduced ability to think clearly at work, and a sense of not feeling well rested. Which of the following diagnoses is in the correct PES format?
    1. *Disturbed Sleep Pattern* evidenced by frequent awakening
    2. *Disturbed Sleep Pattern* related to family caregiving responsibilities
    3. *Disturbed Sleep Pattern* related to need to improve sleep habits
    4. *Disturbed Sleep Pattern* related to caregiving responsibilities as evidenced by frequent awakening and not feeling rested

13. A nursing student is working with a faculty member to identify a nursing diagnosis for an assigned patient. The student has assessed that the patient is undergoing radiation treatment and has had liquid stool and the skin is clean and intact; therefore she selects the nursing diagnosis *Impaired Skin Integrity*. The faculty member explains that the student has made a diagnostic error for which of the following reasons?
    1. Incorrect clustering
    2. Wrong diagnostic label
    3. Condition is a collaborative problem.
    4. Premature closure of clusters

14. The use of standard formal nursing diagnostic statements serves several purposes in nursing practice, including which of the following? (Select all that apply.)
    1. Defines a patient's problem, giving members of the health care team a common language for understanding the patient's needs
    2. Allows physicians and allied health staff to communicate with nurses how they provide care among themselves

18

Planning Nursing Care

ⓔ MEDIA RESOURCES

Tonya conducted a thorough assessment of Mr. Lawson's health status and identified three nursing diagnoses: Acute Pain related to trauma of surgical incision, Readiness for Enhanced Knowledge related to impending discharge, and Risk for Infection. Tonya is responsible for the initial planning of Mr. Lawson's nursing care after identifying relevant nursing diagnoses. The care that she plans will continue throughout the course of Mr. Lawson's hospital stay by the other nurses involved in Mr. Lawson's' care. If Tonya plans well, the individualized interventions that she selects will prepare the patient for a smooth transition home. Collaboration with the patient and his wife will be critical for a plan of care to be successful. Using input from Mr. Lawson, Tonya identifies the goals and expected outcomes for each of his nursing diagnoses. The goals and outcomes direct Tonya in selecting appropriate therapeutic nursing interventions. Tonya knows that Mrs. Lawson must be involved in her husband's care because of the ongoing support that she provides and because she will be a key care provider once Mr. Lawson returns home. Consultation with other health care providers such as home health ensures that the right resources will be used in planning care. In addition, Tonya poses a PICOT question about Mr. Lawson: Does the use of visual aids compared with standard discharge literature affect adult patients' ability to learn

infection control principles? Tonya will use results of her literature search to build interventions for Mr. Lawson's care. Careful planning involves seeing the relationships among a patient's problems, recognizing that certain problems take precedence over others, identifying the most appropriate interventions, and proceeding with planning a safe and efficient approach to care.

After making a medical diagnosis, a health care provider will choose interventions and communicate the plan to the health care team. For example, after making a diagnosis of diabetes mellitus, a health care provider will prescribe a treatment plan that includes an insulin regimen, specific caloric diet, blood glucose monitoring, and an exercise plan. The health care provider establishes the plan with the goal of achieving blood glucose control. Outcomes for determining if the goal is met include blood glucose levels and hemoglobin A1c test measures.

After identifying a patient's nursing diagnoses and collaborative problems, the nurse prioritizes the diagnoses, sets patient-centered goals and expected outcomes, and chooses nursing interventions appropriate for each diagnosis. This is the third step of the nursing process, **planning**. The nurse collaborates with a patient and family (as appropriate) and the rest of the health care team to determine the

urgency of the identified problems and prioritizes patient needs (Ackley and Ladwig, 2014). Planning requires critical thinking applied through deliberate decision making and problem solving. Perhaps the most important principle to learn about planning is the need to individualize a plan of care for a patient's unique needs. This requires communicating closely with patients, their families, and the health care team and ongoing consultation with team members. The nursing diagnoses that you identify direct your selection of individualized nursing interventions and the goals and outcomes you hope to achieve (Suhonen et al., 2011). Know that a plan of care is dynamic and changes as a patient's needs change.

ESTABLISHING PRIORITIES

A single patient often has multiple nursing diagnoses and collaborative problems. When you enter nursing practice, you will care for multiple patients. You must be able to set priorities for these patients carefully and wisely to ensure safe, timely, and effective care. **Priority setting** is the ordering of nursing diagnoses or patient problems using notions of urgency and importance to establish a preferential order for nursing interventions. Priority setting is not the ordering of a list of care tasks, but an organization of a vision of desired outcomes for a patient.

Symptom pattern recognition from your assessment database and certain knowledge triggers help you understand which diagnoses require intervention and the associated time frame to intervene effectively (Ackley and Ladwig, 2014). An example is a patient who suddenly spikes a fever. Coupling this symptom with other symptoms of purulent drainage from a surgical wound and an inflamed incision tells the nurse that an infection has developed, and the nurse recognizes the symptoms as an immediate cause for action.

As you care for a patient or multiple patients, you must deal with certain aspects of care before others. By ranking a patient's nursing diagnoses in order of importance and always monitoring changing signs and symptoms (defining characteristics) of patient problems, you attend to each patient's most important needs and better organize ongoing care activities. Priorities help you to anticipate and sequence nursing interventions when a patient has multiple nursing diagnoses and collaborative problems. You also set priorities by selecting mutually agreed-on priorities with a patient on the basis of the urgency of the problems, the patient's safety and desires, the nature of the treatment indicated, and the relationship among the diagnoses. Priority setting is not a matter of numbering the nursing diagnoses on the basis of severity or physiological importance. Such a numbering system does not always reflect actual clinical changes in patients. You must establish priorities in relation to their ongoing clinical importance.

Classify patients' priorities as high, intermediate, or low importance. Nursing diagnoses that, if untreated, result in harm to a patient or others (e.g., those related to airway status, circulation, safety, and pain) have the highest priorities. One way to consider nursing diagnoses of high priority is to consider Maslow's hierarchy of needs (see Chapter 6). For example, *Risk for Other-Directed Violence, Impaired Gas Exchange,* and *Decreased Cardiac Output* are examples of high-priority nursing diagnoses that drive the priorities of safety, adequate oxygenation, and adequate circulation. However, it is always important to consider each patient's unique situation. Avoid classifying only physiological nursing diagnoses as high priority. *Consider Mr. Lawson's case. Among his nursing diagnoses,* **Acute Pain** *was an initial priority because Tonya knew that she needed to relieve Mr. Lawson's acute pain for him to be responsive to discharge education. Now that his pain has been controlled reasonably well,* **Readiness for Enhanced Knowledge** *has become a priority because of the patient's expressed desire to learn and the urgency of preparing him adequately for pending discharge.*

Intermediate-priority nursing diagnoses involve nonemergent, nonlife-threatening needs of patients. In Mr. Lawson's case, *Risk for Infection* is an intermediate diagnosis. The nursing staff will continue to monitor his wound healing, and it is important for Mr. and Mrs. Lawson to learn the signs of infection and understand what to observe once the patient returns home. In this case focused and individualized instruction from all members of the health care team about infection prevention is necessary throughout the patient's hospitalization.

Low-priority nursing diagnoses are not always directly related to a specific illness or prognosis but affect a patient's future well-being. Many low-priority diagnoses focus on a patient's long-term health care needs. You learned in Chapter 17 that Mr. Lawson shares a concern with Tonya, "I'm worried about being able to return to work on time." When instructing the patient, Tonya noticed that he was having trouble attending to what she had to say. Tonya has not yet identified a nursing diagnosis related to Mr. Lawson's concern about returning to work. She will need to assess more fully, but a nursing diagnosis such as *Anxiety* may be of low priority compared to others. However, if the patient's anxiety is left unaddressed, it could become a higher priority if it interferes with his ability to learn discharge information.

The order of priorities changes as a patient's condition and needs change, sometimes within a matter of minutes. Each time you begin a sequence of care such as at the beginning of a hospital shift or during a clinic visit, it is important to reorder priorities. For example, when Tonya first met Mr. Lawson, his *Acute Pain* was rated at a 7, and it was apparent that administering an analgesic and repositioning the patient were greater priorities than trying to prepare him for instruction. Later, after receiving the analgesic, Mr. Lawson's pain lessened to a level of 4; and Tonya was able to gather more assessment information and begin to focus on his problem of *Readiness for Enhanced Knowledge.* Ongoing patient assessment is critical to determine the status of your patient's nursing diagnoses. The appropriate ordering of priorities ensures that you meet a patient's needs in a safe, timely, and effective way.

Priority setting begins when you identify and prioritize a patient's main diagnoses or problems. The next step is to prioritize the specific nursing interventions that you plan to use to help a patient achieve desired goals and outcomes. For example, as Tonya considers the high-priority diagnosis of *Acute Pain* for Mr. Lawson, she includes in her plan of care these options: administering an analgesic, repositioning, and teaching relaxation exercises. With each clinical encounter, Tonya applies critical thinking to prioritize which intervention to use. Tonya knows that a certain degree of pain relief is necessary before a patient can participate in relaxation exercises. When she is in the patient's room, she might decide to turn and reposition Mr. Lawson first and then prepare the analgesic. However, if Mr. Lawson expresses that pain is a high level and he is too uncomfortable to turn, Tonya chooses obtaining and administering the analgesic as her first priority. Later, with Mr. Lawson's pain more under control, she considers whether relaxation is appropriate.

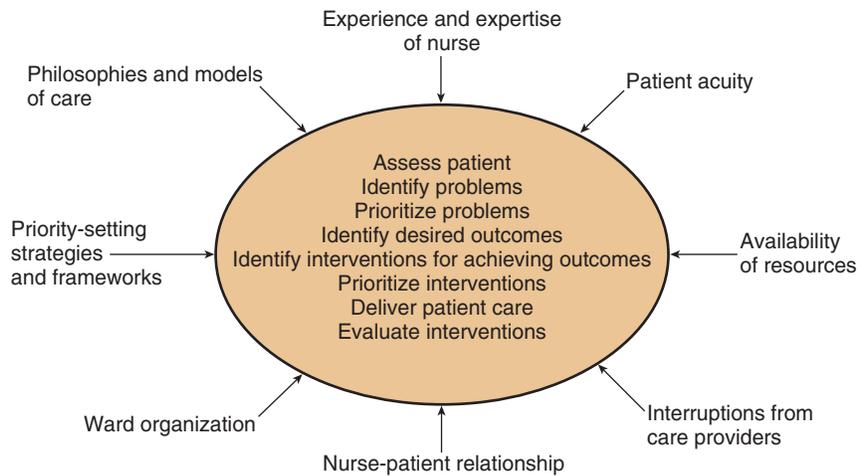
Involve patients in priority setting whenever possible. Patient-centered care requires you to know a patient's preferences, values, and expressed needs. In some situations a patient assigns priorities differently from those you select. Resolve any conflicting values concerning health care needs and treatments with open communication, informing the patient of all options and consequences. Consulting with and knowing a patient's concerns do not relieve you of the responsibility to act in a patient's best interests. Always assign priorities on the basis of good nursing judgment. Ethical care is a part of priority setting (see Chapter 22). Nurses decide about priorities on the basis of their fundamental disposition of what is good and right (Benner et al., 1996). Often these values remain unspoken and perhaps unrecognized, but nevertheless they profoundly influence what nurses attend to in a


FIGURE 18-1 A model for priority setting. (Modified from Hendry C, Walker A: Priority setting in clinical nursing practice, *J Adv Nurs* 47(4):427, 2004.)

particular clinical situation and the options they consider in making decisions and taking action (Tanner, 2006). When ethical issues make priorities less clear, it is important to have an open discussion with a patient, the family, and other health care providers. For example, when caring for patients with cancer and other disabling illnesses, discuss the situation with them and understand their expectations, understand your professional responsibility in protecting the patients from harm, know their health care provider's therapeutic or palliative goals, and then form appropriate plans of care.

Priorities in Practice

Many factors within the health care environment affect your ability to set priorities (Figure 18-1). For example, in a hospital setting the model for delivering care (see Chapter 21), the workflow routine of the nursing unit, staffing levels, and interruptions from other care providers affect the minute-by-minute determination of patient care priorities. In the home health setting the number of visits scheduled for a day and the availability of family caregivers and resources within a patient's home affect them. Available resources (e.g., nurse specialists and dietitians), policies and procedures, and supply access also affect priorities. Patients' conditions are always changing; thus priority setting is always changing.

Successful priority setting also involves working well with the health care team. When you work with nursing assistive personnel (NAP), discuss the purpose of each patient's hospitalization, the picture of how the patient should look at the end of the shift, the plan for achieving desired outcomes, and the part you and the NAP will play. You agree on priorities at the beginning of a shift, but they are usually reshuffled several times before the next shift. Patients' needs change, some patients are discharged, and new patients are admitted (Nelson et al., 2006).

The same factors that influence your minute-by-minute ability to prioritize nursing actions affect the ability to prioritize nursing diagnoses and plan care for groups of patients. The nature of nursing work challenges your ability to cognitively attend to a given patient's priorities when you care for more than one patient. The nursing care process is nonlinear (Potter et al., 2005). Often you complete an assessment and identify nursing diagnoses for one patient, leave the room to perform an intervention for a second patient, and move on to consult on a third patient. Nurses exercise "cognitive shifts" (i.e., shifts in attention from one patient to another during the conduct of the nursing process). This shifting of attention occurs in response to changing patient needs, new procedures being ordered, or environmental

processes interacting (Potter et al., 2005). Because of these cognitive shifts, it becomes important to stay organized and know your patients' priorities. Work from your plan of care and use patients' priorities to organize the order for delivering interventions and organizing documentation of care.

CRITICAL THINKING IN SETTING GOALS AND EXPECTED OUTCOMES

When you start nursing school, your goal is to graduate. Success in meeting that goal is measured by grades and the outcomes of your class work. A baseball team strives to achieve the goal of winning the World Series. The team achieves that goal through the outcome of winning more games than other teams. The use of goals and outcomes in patient care is designed to help focus the efforts of all health care team members to a common purpose: helping a patient achieve or maintain a desired level of health. In the case of Mr. Lawson, Tonya sets the goal of the patient being "infection free." The expected outcomes for achieving that goal include the patient remaining afebrile, without wound drainage, and with wound edges healing. Expected outcomes are time limited, measurable ways of determining if a goal is met (Table 18-1).

After identifying a patients' nursing diagnoses and collaborative problems, ask yourself, "What do I plan to achieve?" and "How will I know when I have achieved what I want?" During planning you select goals and expected outcomes for each nursing diagnosis or problem to provide clear direction for the type of interventions needed to care for your patient and to then evaluate the effectiveness of these interventions. A **goal** is a broad statement that describes a desired change in a patient's condition, perceptions, or behavior. Mr. Lawson has the diagnosis of *Readiness for Enhanced Knowledge.* A goal of care for this diagnosis includes, "Patient will understand postoperative risks." The goal requires making Mr. Lawson aware of the risks associated with his type of surgery. It gives Tonya a clear focus on the topics to include in her instruction. For Tonya to know if Mr. Lawson does understand postoperative risks, the patient must meet expected outcomes. An **expected outcome** is the measurable change (patient behavior, physical state, or perception) that must be achieved to reach a goal. In Mr. Lawson's case, after Tonya provides an educational intervention, the expected outcome would be, "Patient identifies signs and symptoms of wound infection before discharge." Tonya might measure along a continuum of no correct answers versus three correct to determine if Mr. Lawson identifies signs and symptoms correctly. Sometimes several

TABLE 18-1 **Examples of Goal Setting with Expected Outcomes for Mr. Lawson**

Nursing Diagnoses	Goals	Expected Outcomes
Acute Pain related to trauma of surgical incision	Mr. Lawson will achieve pain relief by day of discharge.	Mr. Lawson reports pain at a level of 3 or below by discharge. Mr. Lawson transfers from bed to chair with no increase in pain in 48 hours. Mr. Lawson's incisional area shows signs of wound healing by discharge.
Readiness for Enhanced Knowledge related to impending discharge with self-care needs	Mr. Lawson will express understanding of postoperative risks in 24 hours.	Mr. Lawson describes activity restrictions to follow by discharge. Mr. Lawson demonstrates how to cleanse surgical wound by discharge. Mr. Lawson describes three risks for infection in 24 hours.
Risk for Infection	Mr. Lawson will remain infection free by discharge.	Mr. Lawson remains afebrile by discharge. Mr. Lawson's wound shows no purulent drainage by discharge. Mr. Lawson's wound closes at site of incision separation by discharge

FIGURE 18-2 Critical thinking and the process of planning care.

expected outcomes must be met for a single goal. In all cases the goal and expected outcomes align with the patient's nursing diagnoses.

In health care today the terms *goals* and *outcomes* are sometimes interchanged, and this can be confusing. Significant importance is placed on outcome measurement within health care institutions; however, even the way electronic health records (EHRs) label the categories that nurses use to complete plans of care can be unclear. But again, think of a goal as an ultimate outcome and expected outcomes as the measurable changes that must be achieved to reach a goal.

Planning nursing care requires you to critically evaluate the identified nursing diagnoses, the urgency or priority of the problems, and the resources of the patient and the health care delivery system (Figure 18-2). Apply knowledge from the medical, sociobehavioral, and nursing sciences to plan patient care. When Tonya selected her PICOT question about approaches for teaching infection control, she applied the knowledge she gained in selecting a specific teaching approach. The selection of goals, expected outcomes, and interventions requires consideration of your previous experience with similar patient

problems and any established standards for clinical problem management. The goals and outcomes need to meet established intellectual standards by being relevant to patient needs, specific, singular, observable, measurable, and time limited. You also use critical thinking attitudes in selecting interventions with the greatest likelihood of success.

Role of the Patient in Goal/Outcome Setting

Always partner with patients when setting their individualized goals. Mutual goal setting includes a patient and family (when appropriate) in prioritizing the goals of care and developing a plan of action. For patients to participate in goal setting, they need to be alert and have some degree of independence in completing activities of daily living, problem solving, and decision making. They also need to understand the priority problems and have a willingness/motivation to resolve those problems. Unless goals are mutually set and there is a clear plan of action, patients may not fully participate in the plan of care, leading to suboptimal outcomes. Patients need to understand and see the value of nursing therapies, even though they are often totally dependent on you as the nurse. When setting goals, act as an advocate or support for the patient to select nursing interventions that promote his or her return to health or prevent further deterioration when possible.

*Tonya has a discussion with Mr. Lawson and his wife together about setting the plan for the diagnosis of **Readiness for Enhanced Knowledge.** Tonya explains the topics that they need to discuss so the couple understands Mr. Lawson's postoperative risks. In addition, she talks about the use of a DVD program on infection control that the couple can watch in their room. Tonya applied knowledge learned from her PICOT question literature search and chose the visual aid strategy. They plan for the couple to view the DVD when Mrs. Lawson visits. Mr. Lawson asks Tonya to also provide specific instruction about the activities he can and cannot do once he returns home. Tonya agrees and consults with the surgeon to be sure that her information is accurate and realistic.*

Selecting Goals and Expected Outcomes

A **patient-centered goal** reflects a patient's highest possible level of wellness and independence in function. It is realistic and based on patient needs, abilities, and resources. A patient-centered goal or outcome reflects a patient's specific behavior, not your own goals or interventions.

- A correct goal statement: "Patient will ambulate independently in 3 days."
- A correct outcome statement: "Patient ambulates in the hall 3 times a day by 4/22."
- A common error is to write an intervention: "Ambulate patient in the hall 3 times a day."

A patient-centered goal represents a predicted resolution of a diagnosis or problem, progress toward improved health status, or continued maintenance of good health or function (Carpenito-Moyet, 2013). Nurses monitor and manage patient conditions and diagnose problems that are amenable to nursing intervention. The clinical reasoning and decision making of nurses is a key part of quality health care (Moorhead et al., 2013). Thus it becomes important to select and measure patient outcomes that are influenced by nursing care. A **nursing-sensitive patient outcome** is a measurable patient, family, or community state, behavior, or perception largely influenced by and sensitive to nursing interventions (Moorhead et al., 2013). Examples of nursing-sensitive outcomes include reduction in pain frequency and severity, incidence of pressure ulcers, and incidence of falls. In comparison, medical outcomes are largely influenced by medical interventions. Examples include patient mortality, surgical wound infection,

and hospital readmissions. For the nursing profession to become a full participant in clinical evaluation research, policy development, and interdisciplinary work, nurses need to identify and measure patient outcomes influenced by nursing interventions.

The Iowa Intervention Project has shown the link between nursing diagnoses and outcomes. It publishes the **Nursing Outcomes Classification** (NOC), which link outcomes to NANDA International (NANDA-I) nursing diagnoses (Moorhead et al., 2013). This resource is an option that you can use in selecting goals and outcomes for your patients. For each NANDA-I nursing diagnosis there are multiple NOC suggested outcomes. The outcomes have labels for describing the focus of nursing care and include indicators (expected outcomes) to use in evaluating the success with nursing interventions. The indicators for each NOC outcome allow measurement of the outcomes at any point on a five-point Likert scale from most negative to most positive (Moorhead et al., 2013). Such a rating system adds objectivity to judging a patient's progress. Many health care institutions use NOC as part of the infrastructure of their documentation system. Using standardized nursing terminologies such as NOC makes it more possible to measure aspects of nursing care on a national and international level (Park, 2013). For example, when researchers compare databases that have used the standard terminologies from NOC, they can determine which common nursing interventions favorably impact outcomes.

What NOC describes as an outcome such as anxiety level, appetite, or physical comfort is a very abstract term, which in real clinical practice comes closer to a goal statement. For example, in NOC terminology the outcome for the nursing diagnosis of *Acute Pain* is described as "pain control" or pain relief, the goal set for Mr. Lawson. The NOC outcome indicators are the same for what most clinicians set as expected outcomes. In the example of pain control, the expected outcomes include symptom severity measured on a pain scale or mobility level. Table 18-2 offers more examples of how to use NOC terminology for describing the focus or goals of nursing care and outcome indicators as they relate to nursing diagnoses.

Writing Goals and Expected Outcomes

Goals and expected outcomes direct your nursing care. Once you set a patient-centered goal for a nursing diagnosis, the expected

TABLE 18-2   Examples of NANDA International Nursing Diagnoses and Suggested NOC Linkages

Nursing Diagnosis	Examples of NOC Outcomes (Consider as Goal Statements)	Outcome Indicators (Examples)
Impaired Oral Mucous Membrane	Oral Health	Knowledge of infection management
		Self-care oral hygiene
	Tissue Integrity	Hydration
		Infection severity
Activity Intolerance	Activity Tolerance	Oxygen saturation with activity
		Pulse rate with activity
		Respiratory rate with activity
	Self-Care Status	Bathes self
		Dresses self
		Prepares food and fluid for eating

NOC, Nursing Outcomes Classification.

outcomes provide the desired physiological, psychological, social, developmental, or spiritual responses that indicate resolution of the patient's health problems. Usually you develop several expected outcomes for each nursing diagnosis and goal. For a patient to resolve a goal, several measurable outcomes are needed to ensure that the goal is met. In the case of Mr. Lawson's diagnosis of *Risk for Infection,* Tonya knows that more than one outcome is needed to ensure that the patient is infection free.

The SMART acronym (*S*pecific, *M*easurable, *A*ttainable, *R*ealistic, *T*imed) is a useful approach for writing goals and outcome statements more effectively (Ackley and Ladwig, 2013).

Specific or Singular Goal or Outcome. You need to be precise when you evaluate a patient's response to a nursing intervention during the evaluation phase of the nursing process (see Chapter 20). Each goal and outcome addresses only one behavior, perception, or physiological response. The example, "Patient will administer a self-injection and demonstrate infection control measures," is incorrect because the statement includes two different behaviors, administer and demonstrate. Instead word each goal separately as follows, "Patient will administer a self-injection by discharge," and "Patient will demonstrate infection control measures at home."

Expected outcomes must also be singular. For example, consider the expected outcome, "Patient's lungs are clear to auscultation, and respiratory rate is 20 breaths/min by 8/22." It will be difficult to measure if the patient has achieved the goal of "Improved respiratory status" by using a combined outcome statement. When you evaluate that the lungs are clear but the respiratory rate is 28 breaths/min, the patient did not achieve the expected outcome because only one of the desired physical changes was achieved. By splitting the statement into two parts, "Lungs will be clear to auscultation by 8/22," and "Respiratory rate will be 20 breaths/min by 8/22," you are able to determine if and when the patient achieves each outcome. Specificity allows you to decide if there is a need to modify the plan of care.

Measurable. Goals and expected outcomes are the standards against which to measure or observe a patient's response to nursing care. You need to be able to measure or observe if change takes place in a patient's status. Changes occur in physiological findings and in a patient's knowledge, perceptions, and behavior. Examples such as, "Body temperature will remain 98.6° F (37° C)," and "Apical pulse will remain between 60 and 100 beats/min" allow you to objectively measure physical changes in a patient's status. The outcome statement, "Patient's pain is less than 4 on a scale of 0 to 10 in 48 hours" allows you to objectively measure patient perception using a pain-rating scale. Do not use vague qualifiers such as "normal," "acceptable," or "stable" in an expected outcome statement. Vague terms result in guesswork in determining a patient's response to care. Terms describing quality, quantity, frequency, length, or weight allow you to evaluate outcomes precisely.

Attainable. For a patient's health to improve, he or she must be able to attain the outcomes of care that are set. A goal and an outcome likely are attainable when mutually set with the patient. This ensures that a patient and nurse agree on the direction and time limits of care. Mutually set attainable goals and outcomes (e.g., distance to walk, topics to learn about medications) increase a patient's motivation and cooperation. As a patient advocate, apply standards of practice, evidence-based knowledge, safety principles, and basic human needs when helping patients set goals. Your knowledge background helps to select goals and outcomes that your patients should meet on the basis of typical responses to clinical interventions. Always consider patients'

desires to recover and their physical and psychological condition to set goals and outcomes to which they can agree.

Realistic. Set goals and expected outcomes that a patient is able to realistically reach. Your assessment of a patient will reveal a patient's condition and willingness and ability to be a care participant. For example, a patient who just experienced a stroke and has left-sided weakness in the arm has the goal of "assuming self-care with bathing." The patient will be limited by what he or she can do independently during the first several days and weeks ahead. You set realistic time-specific goals and outcomes within the patient's limitations and abilities. For example, an initial goal is, "Patient will wash hands and face in 72 hours." Your assessment and collaboration with occupational therapy will determine if the goal is realistic for the level of the patient's weakness.

Setting realistic goals and outcomes often requires you to communicate these goals and outcomes to caregivers in other settings who will assume responsibility for patient care (e.g., home health, rehabilitation). Realistic goals give patients a sense of hope. To establish realistic goals, assess the resources of a patient, health care facility, and family. Be aware of the patient's physiological, emotional, cognitive, and socio-cultural potential and the economic cost and resources available to reach expected outcomes in a timely manner.

Timed. Each goal and outcome is time limited so the health care team has a common time frame for problem resolution. For example, the goal of "patient will achieve pain relief" for Mr. Lawson is complete by adding the time frame "by day of discharge." With this goal in place, all members of the nursing team will aim to manage and reduce the patient's pain while he is hospitalized. At the time of discharge, evaluation of expected outcomes (e.g., pain-rating score, signs of grimacing, level of movement) show if the goal was met. The time frame depends on the nature of the problem, etiology, overall condition of the patient, and treatment setting. A **short-term goal** is an objective behavior or response that you expect a patient to achieve in a short time, usually less than a week. In an acute care setting you often set goals for over a course of just a few hours. A **long-term goal** is an objective behavior or response that you expect a patient to achieve over a longer period, usually over several days, weeks, or months (e.g., "Patient will be tobacco free within 60 days"). Always collaborate with patients to set realistic and reasonable time frames. Time frames help you and a patient determine if the patient is making progress at a reasonable rate. If not, you must revise the plan of care. Time frames also promote accountability in delivering and managing nursing care.

CRITICAL THINKING IN PLANNING NURSING CARE

Part of the planning process is selecting nursing interventions for meeting a patient's goals and outcomes. Once you identify nursing diagnoses and select goals and outcomes, you choose interventions individualized for a patient's situation. Nursing interventions are any treatments or actions based on clinical judgment and knowledge that nurses perform to enhance patient outcomes (Bulechek et al., 2013). During planning you select interventions designed to help a patient move from the present level of health to the level described in the goal and measured by the expected outcomes. The actual implementation of these interventions occurs during the implementation phase of the nursing process (see Chapter 19). Choosing suitable nursing interventions involves applying the best evidence for a patient's health problems and using good clinical judgment.

Tonya identified a PICOT question to help her select instructional interventions for enhancing Mr. and Mrs. Lawson's knowledge about infection control. She also chooses interventions on the basis of what she has learned about the etiologies behind his learning needs. Mr. Lawson has not experienced postoperative care, he is facing restrictions with which he is unfamiliar, and the condition of his incision requires wound care at home. Tonya will plan instructional topics to address postoperative risks in a way that will be relevant to Mr. Lawson and his usual routines at home. The instruction will include Mrs. Lawson since she is a reliable resource for Mr. Lawson.

Types of Interventions

There are three categories of nursing interventions: nurse-initiated, health care provider-initiated, and collaborative interventions. Some patients require all three categories, whereas others need only nurse- and health care provider-initiated interventions.

Nurse-initiated interventions are the **independent nursing interventions** or actions that a nurse initiates without supervision or direction from others. Examples include positioning patients to prevent pressure ulcer formation, instructing patients in side effects of medications, or providing skin care to an ostomy site. Independent nursing interventions do not require an order from another health care provider. Nurse-initiated interventions are autonomous actions based on scientific rationale. Such interventions benefit a patient in a predicted way related to nursing diagnoses and patient goals (Bulechek et al., 2013). Each state within the United States has Nurse Practice Acts that define the legal scope of nursing practice (see Chapter 23). According to the Nurse Practice Acts in a majority of states, independent nursing interventions pertain to activities of daily living, health education and promotion, and counseling. *For Mr. Lawson Tonya selects the following nursing interventions to resolve his acute pain: positioning, relaxation therapy, and exercise promotion.*

Health care provider–initiated interventions are **dependent nursing interventions**, or actions that require an order from a health care provider. The interventions are based on the health care provider's response to treating or managing a medical diagnosis. Advanced practice nurses who work under collaborative agreements with physicians or who are licensed independently by state practice acts are also able to write dependent interventions. As a nurse you intervene by carrying out the health care provider's written and/or verbal orders. Administering a medication, implementing an invasive procedure (e.g., inserting a Foley catheter, starting an intravenous [IV] infusion) and preparing a patient for diagnostic tests are examples of health care provider-initiated interventions.

Each health care provider-initiated intervention requires specific nursing responsibilities and technical nursing knowledge. You are often the one performing the intervention, and you must know the types of observations and precautions to take for the intervention to be delivered safely and correctly. For example, when administering a medication you are responsible for not only giving the medicine correctly, but also knowing the classification of the drug; its physiological action, normal dosage, and side effects; and nursing interventions related to its action or side effects (see Chapter 32). You are responsible for knowing when an invasive procedure is necessary, the clinical skills necessary to complete it, and its expected outcome and possible side effects. You are also responsible for adequate preparation of a patient and proper communication of the results. You perform dependent nursing interventions, like all nursing actions, with appropriate knowledge, clinical reasoning, and good clinical judgment.

Collaborative interventions, or interdependent interventions, are therapies that require the combined knowledge, skill, and expertise of multiple health care providers. Typically when you plan care for a patient, you review the necessary interventions and determine if the collaboration of other health care disciplines is necessary. A patient care conference with an interdisciplinary health care team results in selection of interdependent interventions.

In the case study involving Mr. Lawson, Tonya plans independent interventions to help relieve Mr. Lawson's pain and begin teaching him about postoperative care activities. Among the dependent interventions Tonya plans to implement are the administration of an analgesic and ordered wound care. Tonya's collaborative intervention involves consulting with the unit discharge coordinator, who will help Mr. and Mrs. Lawson plan for their return home, and the home health department to ensure that the Lawsons have home health visits.

When preparing for health care provider-initiated or collaborative interventions, do not automatically implement the therapies but determine whether they are appropriate for each patient. Every nurse faces an inappropriate or incorrect order at some time. The nurse with a strong knowledge base and clinical experience recognizes an error and seeks to correct it. The ability to recognize incorrect therapies is particularly important when administering medications or procedures. Errors occur in writing orders or transcribing them to a documentation form or computer screen. Clarifying an order is competent nursing practice, and it protects a patient and members of the health care team. When you carry out an incorrect or inappropriate intervention, it is as much your error as the person who wrote or transcribed the original order. You are legally responsible for any complications resulting from an error (see Chapter 23).

Selection of Interventions

During planning do not select interventions randomly. For example, patients with the diagnosis of *Anxiety* do not always need care in the same way with the same interventions. You treat *Anxiety related to the uncertainty of surgical recovery* very differently than *Anxiety related to a threat to loss of job*. When choosing interventions, consider six important factors: (1) desired patient outcomes, (2) characteristics of the nursing diagnosis, (3) research base knowledge for the intervention, (4) feasibility for doing the intervention, (5) acceptability to the patient, and (6) your own competency (Bulechek et al., 2013) (Box 18-1).

When developing a plan of care, review resources such as the scientific literature, standard protocols or guidelines, the Nursing Outcomes Classification (NOC) and **Nursing Interventions Classification (NIC)**, policy or procedure manuals, or textbooks. Collaboration with other health professionals is also useful. As you select interventions, review your patient's needs, priorities, and previous experiences to select the interventions that have the best potential for achieving the expected outcomes.

Nursing Interventions Classification. Just as with the standardized NOC, the Iowa Intervention Project has developed a set of nursing interventions that provides a level of standardization to enhance communication of nursing care across all health care settings and compare outcomes (Bulechek et al., 2013). The NIC model includes three levels: domains, classes, and interventions for ease of use. The seven domains are the highest level (level 1) of the model, using broad terms (e.g., safety and basic physiological) to organize the more specific classes and interventions (Table 18-3). The second level of the model includes 30 classes, which offer useful clinical categories to reference when selecting interventions. The third level of the model includes the 554 interventions, defined as any treatment based on

BOX 18-1 Choosing Nursing Interventions

Desired Patient Outcomes
- Outcome serves as the criteria against which to judge efficacy of intervention.
- Nursing Outcomes Classification (NOC) outcomes are linked to Nursing Interventions Classification (NIC) interventions. NIC is designed to show the link to NOC (Moorhead et al., 2013). Use these resources to develop care plans.

Characteristics of the Nursing Diagnosis
- Choose interventions to alter the etiological (related to) factor or causes of the diagnosis. **Example:** Acute Pain related to trauma of surgical incision—choose interventions for Mr. Lawson that relieve swelling and strain on incision site (positioning and turning measures) and lower pain reception (analgesic).
- When an etiological factor cannot change, direct the interventions toward treating the signs and symptoms (e.g., defining characteristics for a diagnosis). **Example:** Readiness for Enhanced Knowledge related to impending discharge with self-care needs—choose interventions that provide information that answers Mr. and Mrs. Lawson's questions about recovery procedures, wound care, and what to observe.
- For risk diagnoses, direct interventions at altering or eliminating the risk factors for the diagnosis. **Example:** Risk for Infection requires interventions for keeping Mr. Lawson's incisional area clean, free from further trauma, and for maintaining good nutrition.

Research Base
- Be familiar with the research evidence for an intervention and use it for the appropriate patient group and/or setting (see Chapter 5).

- Research evidence in support of a nursing intervention will indicate the effectiveness of using the intervention with certain types of patients.
- When research is not available, use scientific principles (e.g., infection control, learning) or consult a clinical expert about your patient.

Feasibility
- A specific intervention has the potential to interact with other interventions provided by the nurse and other health professionals.
- Know and be involved in a patient's total plan of care.
- Consider cost of an intervention and the amount of time required for implementation. **Example:** If you plan to get a patient up into a chair 3 times a day, will there be staff to assist with the transfer?

Acceptability to the Patient
- When possible, offer a patient a choice of interventions to assist in reaching outcomes.
- Promote informed choice; give patients information about each intervention and how they are expected to participate.
- Consider a patient's values, beliefs, and culture for a patient-centered approach to selecting interventions.

Capability of the Nurse
- Have knowledge of the scientific rationale for the intervention.
- Have the necessary psychosocial and psychomotor skills to complete the intervention.
- Be able to function within the specific setting to effectively use health care resources.

Modified from Bulechek GM, et al: *Nursing interventions classification (NIC),* ed 6, St Louis, 2013, Mosby.

BOX 18-2 Example of Interventions for Physical Comfort Promotion

Class: Physical Comfort Promotion (Level 2)
Interventions to promote comfort using physical techniques

Interventions (Examples)
Aromatherapy
Cutaneous Stimulation
Environmental Management
Heat/Cold Application
Nausea Management
Pain Management
Progressive Muscle Relaxation

Examples of Linked Nursing Diagnoses
Acute Pain
Chronic Pain

BOX 18-3 Example of an Intervention and Associated Nursing Activities

Intervention—Environmental Management: Comfort
Examples of Activities
- Create a calm and supportive environment.
- Provide a single room if it is the patient's preference to offer quiet and rest.
- Adjust room temperature to that most comfortable for the individual.
- Provide a safe and clean environment.
- Determine sources of discomfort: damp dressing, positioning on tubing, wrinkled linen.
- Provide hygiene measures for comfort (e.g., skin creams, oral care).
- Provide prompt attention to call lights, which should always be within reach.

From Bulechek GM, et al: *Nursing interventions classification (NIC),* ed 6, St Louis, 2013, Mosby.

clinical judgment and knowledge that a nurse performs to enhance patient outcomes (Bulechek et al., 2013) (Box 18-2). Each intervention then includes a variety of nursing activities from which to choose (Box 18-3) and which a nurse commonly uses in a plan of care. NIC interventions are also linked with NANDA-I nursing diagnoses for ease of use (NANDA-I, 2012). For example, if a patient has a nursing diagnosis of *Acute Pain,* there are 20 recommended interventions, including pain

management, cutaneous stimulation, and anxiety reduction. Each of the recommended interventions has a variety of activities for nursing care. For example, cutaneous stimulation activities include selection of massage, cold or heat. NIC is a valuable resource for selecting appropriate interventions and activities for your patient. It is evolving and practice oriented. The classification is comprehensive, including independent and collaborative interventions. It remains your decision to determine which interventions and activities best suit your patient's individualized needs and situation.

TABLE 18-3 **Nursing Interventions Classification (NIC) Taxonomy**		
Domain 1	**Domain 2**	**Domain 3**
Level 1 Domains		
1. Physiological: Basic	**2. Physiological: Complex**	**3. Behavioral**
Care that supports physical functioning	Care that supports homeostatic regulation	Care that supports psychosocial functioning and facilitates lifestyle changes
Level 2 Classes		
A *Activity and Exercise Management:* Interventions to organize or assist with physical activity and energy conservation and expenditure	G *Electrolyte and Acid-Base Management:* Interventions to regulate electrolyte/acid-base balance and prevent complications	O *Behavior Therapy:* Interventions to reinforce or promote desirable behaviors or alter undesirable behaviors
B *Elimination Management:* Interventions to establish and maintain regular bowel and urinary elimination patterns and manage complications caused by altered patterns	H *Drug Management:* Interventions to facilitate desired effects of pharmacological agents	P *Cognitive Therapy:* Interventions to reinforce or promote desirable cognitive functioning or alter undesirable cognitive functioning
C *Immobility Management:* Interventions to manage restricted body movement and the sequelae	I *Neurological Management:* Interventions to optimize neurological functions	Q *Communication Enhancement:* Interventions to facilitate delivering and receiving verbal and nonverbal messages
D *Nutrition Support:* Interventions to modify or maintain nutritional status	J *Perioperative Care:* Interventions to provide care before, during, and immediately after surgery	R *Coping Assistance:* Interventions to assist another to build on own strengths, adapt to a change in function, or achieve a higher level of function
E *Physical Comfort Promotion:* Interventions to promote comfort using physical techniques	K *Respiratory Management:* Interventions to promote airway patency and gas exchange	S *Patient Education:* Interventions to facilitate learning
F *Self-Care Facilitation:* Interventions to provide or assist with routine activities of daily living	L *Skin/Wound Management:* Interventions to maintain or restore tissue integrity	T *Psychological Comfort Promotion:* Interventions to promote comfort using psychological techniques
	M *Thermoregulation:* Interventions to maintain body temperature within a normal range	
	N *Tissue Perfusion Management:* Interventions to optimize circulation of blood and fluids to the tissue

SYSTEMS FOR PLANNING NURSING CARE

In any health care setting a nurse is responsible for providing a nursing plan of care for all patients. The plan of care can take several forms (e.g., nursing Kardex, computerized plans, and standardized care plans). With the growth of EHRs within health care institutions, documentation systems typically include software programs for nursing care plans. Many of these software programs use the NANDA, NOC, and NIC taxonomies, enabling nurses to clearly identify a plan of care using appropriate nursing diagnoses, outcomes, and interventions. There is value in using standardized nursing terminologies in EHRs (Lundberg et al., 2008). Patients benefit from continuity of care being facilitated through the use of standardized terminologies that offer improved and clear communication between clinicians. Health care organizations benefit by measuring nursing care and its effects on patient care through queries of patient records instead of costly manual chart audits. The use of standardized nursing terminologies allows health care institutions to determine the impact of nursing and thus validate the contribution of nursing to health care and patient safety (Lundberg et al., 2008).

A **nursing care plan** includes nursing diagnoses, goals and/or expected outcomes, specific nursing interventions, and a section for evaluation findings so any nurse is able to quickly identify a patient's clinical needs and situation. Nurses revise a plan when a patient's status changes. Preprinted standardized care plans and EHR care plans follow a standardized format, but you can individualize each plan to a patient's unique needs (see Chapter 26). The plan gives all nurses a central document that outlines a patient's diagnoses/problems, the plan of care for each diagnosis/problem, and the outcomes for monitoring and evaluating patient progress.

In hospitals and community-based settings, patients receive care from more than one nurse, health care provider, or allied health professional. Thus more institutions are developing **interdisciplinary care plans**, which include contributions from all disciplines involved in patient care. The interdisciplinary plan focuses on patient priorities and improves the coordination of all patient therapies and communication among all disciplines.

A well-planned, comprehensive nursing care plan reduces the risk for incomplete, incorrect, or inaccurate care. As a patient's problems and status change, so does the plan. A nursing care plan is a guideline for coordinating nursing care, promoting continuity of care, and listing outcome criteria to be used later in evaluation (see Chapter 20). The plan of care communicates nursing care priorities to nurses and other health care providers. It also identifies and coordinates resources for delivering nursing care. For example, in a care plan you list specific supplies necessary to use in a dressing change or names of clinical nurse specialists who are consulting for a patient.

The nursing care plan enhances the continuity of nursing care by listing specific nursing interventions needed to achieve the goals of care. All nurses who care for a given patient carry out these nursing interventions (e.g., throughout each day during a patient's length of stay [in a hospital] or during weekly visits to the home [home health nursing]). A correctly formulated nursing care plan makes it easy to continue care from one nurse to another. The Nursing Care Plan is an example of a care plan for Mr. Lawson, using the format found throughout this text.

A care plan includes a patient's short- and long-term goals and outcomes, making it an important part of discharge planning. Thus you need to involve the family in planning care if the patient is agreeable. The family is often a resource to help a patient meet health care goals.

Domain 4	Domain 5	Domain 6	Domain 7
4. Safety Care that supports protection against harm	**5. Family** Care that supports the family	**6. Health System** Care that supports effective use of the health care delivery system	**7. Community** Care that supports the health of the community
U *Crisis Management:* Interventions to provide immediate short-term help in both psychological and physiological crises V *Risk Management:* Interventions to initiate risk-reduction activities and continue monitoring risks over time	W *Childbearing Care:* Interventions to assist in understanding and coping with the psychological and physiological changes during the childbearing period Z *Childrearing Care:* Interventions to assist in rearing children X *Life Span Care:* Interventions to facilitate family unit functioning and promote the health and welfare of family members throughout the life span	Y *Health System Mediation:* Interventions to facilitate the interface between patient/family and the health care system a *Health System Management:* Interventions to provide and enhance support services for the delivery of care b *Information Management:* Interventions to facilitate communication among health care providers	c *Community Health Promotion:* Interventions that promote the health of the whole community d *Community Risk Management:* Interventions that assist in detecting or preventing health risks to the whole community

In addition, meeting some of the family's needs can improve a patient's level of wellness. Discharge planning is especially important for a patient with a disability or injury that was not present before hospitalization. As a result, the patient must undergo long-term rehabilitation in the community and often will require home health care. Same-day surgeries and earlier discharges from hospitals require you to begin planning discharge from the moment the patient enters the health care agency. The complete care plan is the blueprint for nursing action.

Hand-off Reporting

Part of planning is transferring essential information (along with responsibility and authority) from one nurse to the next during transitions in care (e.g., end of shift, during a patient transfer to a new care unit, discharge to another setting). Hand-off reporting offers the opportunity to ask questions, clarify, and confirm important details about a patient's progress and continuing care needs. A hand-off report is the standard practice used by a nurse to communicate information about a patient's plan of care to oncoming patient care personnel. During a hand-off report always provide accurate, up-to-date, and pertinent information to the next nurse assuming patient care. The hand-off is a critical time for ensuring continuity of care for a patient and preventing errors or delays in providing nursing interventions. Recent research identifies approaches to use for effective hand-offs and barriers to their effectiveness (Riesenberg, 2012; Riesenberg et al., 2010) (Box 18-4). Written care plans organize information exchanged by nurses in hand-off reports (see Chapter 26). You learn to focus your reports on the nursing care and treatments completed, patient responses, and expected outcomes documented in the care plans.

Student Care Plans

Student care plans help you learn problem-solving techniques, the nursing process, skills of written communication, and organizational skills for nursing care. Most important, a student care plan helps you apply scientific knowledge gained from the scientific literature and the classroom to a practice situation. Students typically write a care plan for each nursing diagnosis. The student care plan is more elaborate than a care plan used in a hospital or community agency because its purpose is to teach the process of planning care. Each school uses a different format for student care plans. Often the format used is similar to the one used by the health care agency that provides students from that school their clinical experiences.

One example of a form of care plan developed by students is the five-column format. Starting from left to right, the five columns include: (1) assessment data relevant to corresponding diagnosis, (2) goals/outcomes identified for the patient, (3) implementation (selected interventions) for the plan of care, (4) a **scientific rationale** (the reason that you chose a specific nursing action, based on supporting evidence), and (5) a section to evaluate your care. The following questions help you design a plan:

- *What* is the intervention, and is it evidence based?
- *When* should each intervention be implemented?
- *How* should the intervention be performed for this specific patient?
- *Who* should be involved in each aspect of intervention?

Each scientific rationale that you use to support a nursing intervention needs to include a reference, whenever possible, to document the source from the scientific literature. This reinforces the importance of evidence-based nursing practice. It is also important that each intervention be specific and unique to a patient's situation. Nonspecific nursing interventions result in incomplete or inaccurate nursing care, lack of continuity among caregivers, and poor use of resources. Common omissions that nurses make in writing nursing interventions include action, frequency, quantity, method, or person to perform them. These errors occur when nurses are unfamiliar with the

◎ **NURSING CARE PLAN**

Anxiety

ASSESSMENT

Mr. Lawson is a 62-year-old patient who had abdominal surgery for a colon resection and removal of a tumor 3 days ago. The patient has a 7.5 to 8.75 cm (3- to 3½-inch) surgical incision in the left abdominal quadrant. Previous assessment revealed a separation in the wound edges between two sutures at the bottom of the incision. Mr. Lawson knows that he will have activity restrictions. His wife will be a resource to him once he returns home. His discharge has been planned tentatively. His family still depends on his income. Now he begins to share concerns with Tonya about being able to return to work after surgery. Tonya senses that a new diagnosis might be applicable to Mr. Lawson and knows that she needs to gather additional information.

Assessment Activities*	Findings/Defining Characteristics
Ask patient to clarify concerns he has about surgery.	Patient **reports concern** about his wound not healing and keeping him from being able to return to work on time. He is to return to work in 6 weeks.
Assess patient's cognitive function.	Patient **does not attend** to Tonya's explanation of risk factors for infection and shows **poor eye contact** when discussing condition.
Observe patient's emotions.	Patient is **irritable** with technicians who enter room for a blood sample.

*****Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Anxiety related to uncertainty over ability to return to work

PLANNING

Goals	Expected Outcomes (NOC)[†]
	Anxiety Level
Mr. Lawson will explain types of activity restrictions in context of resuming self-care at home by day of discharge.	Patient maintains attention during instruction about activity restrictions within 24 hours.
	Patient shows eye contact during scheduled instructional sessions within 24 hours.
	Patient shows less facial tension during discussions in 24 hours.
	Information Processing
Mr. Lawson will demonstrate proper wound care approach (see plan for knowledge enhancement) by day of discharge.	Patient describes reason for activity restriction by day of discharge.
	Patient describes steps of wound care 24 hours before discharge.
	Coping
Mr. Lawson will verbalize acceptance of need to gain full recovery before returning to work by day of discharge.	Patient shares concerns about work with wife by day of discharge.

[†]Outcomes classification labels from Moorhead S, et al: *Nursing outcomes classification (NOC)*, ed 5, St Louis, 2013, Mosby.

INTERVENTIONS (NIC)[‡]	RATIONALE
Anxiety Reduction	
Use a calm, reassuring approach during discussions and instruction.	For patient to be able to express concerns and ask questions, he must see nurse as being nonthreatening, reliable, and understanding (Vacarolis and Halter, 2014).
Encourage Mrs. Lawson to stay with her husband as much as possible; include her in discussions.	A support system benefits a patient experiencing stress. Strong families tend to have good problem-solving skills and a commitment to one another (Schumacher et al., 2006).
Collaborate with health care provider to provide factual information concerning activity restrictions, progress of wound healing, and expectations for ability to return to work.	Facts provide patient with a more objective view of feasibility of returning to work as anticipated.
Confirm with patient that following postoperative care guidelines will improve likelihood of recovery and ability to return to work.	When comparing people with similar degrees of functional impairment, people with optimistic expectations recover more quickly by using coping strategies and have a higher quality of life (Conversano et al., 2010).

[‡]Intervention classification labels from Bulechek GM, et al: *Nursing interventions classification (NIC)*, ed 6, St Louis, 2013, Mosby.

EVALUATION

Nursing Actions	Patient Response/Finding	Achievement of Outcome
Ask Mr. Lawson to explain the types of activity restrictions he will have when going home.	Mr. Lawson reports that his surgeon has told him that he must limit lifting objects greater than 30 lbs for 6 weeks to reduce stress on the suture line.	Outcome achieved.
Have Mr. Lawson explain his thoughts about needing to recover fully before returning to work. Observe his behavior during discussion.	Mr. Lawson is able to attend to discussion about his recovery and shows good eye contact. He has some worries about whether he will be able to perform normally at his job.	Patient's level of anxiety is declining. Continue discussion about what he will be able to do at 6 weeks.

BOX 18-4   EVIDENCE-BASED PRACTICE

Nursing Hand-off Reports

PICO Question: Does the use of bedside hand-off communication compared with traditional end-of shift report between nurses in acute care settings reduce errors?

Evidence Summary

A nursing hand-off during change of shift involves a nurse-to-nurse verbal exchange of information about patients. The Agency for Healthcare Research and Quality (AHRQ, 2011) surveyed 1032 hospitals, with over 50% of staff respondents agreeing that important patient care information is often lost during shift changes. Athwal et al. (2009) found that a combination of a written update along with a bedside hand-off report reduced the total time expended for shift report, reduced nurse overtime hours, and led to fewer times patients used call lights. A systematic review of scientific articles discussing nursing hand-offs identified strategies for and barriers to effective hand-offs (Riesenberg et al., 2010). Research suggests that there is no evidence pointing to the best nursing hand-off practices and whether errors are reduced. However, hand-offs have multiple purposes, including information transfer, shared decision making, review of treatment options, and shared planning (Riesenberg, 2012). Carefully consider the following strategies and decide if they are useful and if they fit your own institutional setting and resources.

Application to Nursing Practice
Strategies for Effective Nursing Hand-offs
- Do prework; manage your time so you are prepared to give report and be concise.
- Keep report patient centered; ask questions and clarify.
- Standardize the process using tools, forms, and checklists and be sure that essential information is consistently included.
- During walking rounds include patient and family in discussion of goals.
- Limit interruptions and distraction.
- Acknowledge information received and transfer of responsibility (Riesenberg, 2012)

Barriers to Effective Nursing Hand-offs
- Communication barriers, including omissions (missing or incomplete information), errors (incorrect, extraneous, duplicate), disorganized report or one that is routine and not individualized
- Social problems, including a culture of blame on unit that inhibits questioning
- Complexity of cases and high patient care load—increased volume of patient information and inadequate time to report

TABLE 18-4   Frequent Errors in Writing Nursing Interventions

Type of Error	Incorrectly Stated Nursing Intervention	Correctly Stated Nursing Intervention
Failure to precisely or completely indicate nursing actions	Perform exercises on left lower extremity.	Perform ROM for flexion and extension of right knee; plantar flexion and dorsiflexion of right ankle 3 times a day.
Failure to indicate frequency	Perform blood glucose measurements.	Measure blood glucose before each meal: 0700—1100—1700.
Failure to indicate quantity	Irrigate wound once a shift: 0600—1400—2000.	Irrigate wound with 100 mL normal saline until clear: 0600—1400—2000.
Failure to indicate method	Change patient's dressing daily.	Apply a transparent dressing to skin tear site daily.

ROM, Range of motion.

planning process. Table 18-4 illustrates these types of errors by showing incorrect and correct statements of nursing interventions. The fifth column of the care plan includes a section for you to evaluate the plan of care: was each goal/outcome fully or only partially met? Use the evaluation column to document whether the plan requires revision or when outcomes are met, thus indicating when a particular nursing diagnosis is no longer relevant to a patient's plan of care (see Chapter 20).

Care Plans for Community-Based Settings. Planning care for patients in community-based settings (e.g., clinics, community centers, or patients' homes) applies the same principles of nursing practice. However, in these settings you need to complete a more comprehensive community, home, and family assessment. Ultimately a patient/family unit must be able to provide the majority of health care independently. You design a plan to (1) educate the patient/family about the necessary care techniques and precautions, (2) teach a patient/family how to integrate care within family activities, and (3) guide the patient/family on how to assume a greater percentage of care over time. Finally the plan includes nurses' and the patient's/family's evaluation of expected outcomes.

Concept Maps

Chapter 16 first described concept maps and their use in the nursing process. Because you care for patients who have multiple health problems and related nursing diagnoses, it is often not realistic to have a written columnar plan developed for each nursing diagnosis. In addition, the columnar plans do not contain a means to show the association between different nursing diagnoses and different nursing interventions. A concept map is a visual representation of all of a patient's nursing diagnoses and allows you to diagram interventions for each. Research shows that use of concept maps help nursing students make better clinical decisions and develop better clinical judgment skills (Gerdeman et al., 2013). A map shows you the relationship within the nursing process (i.e., how nursing interventions often apply to more than one nursing diagnosis). Concept maps group and categorize nursing concepts to give you a holistic view of your patient's health care needs.

In Chapter 17 you learned how to add nursing diagnostic labels to a concept map. When planning care for each nursing diagnosis, analyze the relationships among the diagnoses. Draw dotted lines between nursing diagnoses to indicate their relationship to one another (Figure 18-3). It is important for you to make meaningful associations between

CONCEPT MAP

Nursing diagnosis: Acute pain related to incisional trauma
- Wound tender when palpated
- Pain severity has ranged from 8 to 4
- Patient guards incision by placing hand over wound when moving

Interventions
- Administer analgesic around-the-clock per orders
- Reposition patient on left side; side of comfort
- Teach relaxation exercises to be used when pain in control

Nursing diagnosis: Readiness for enhanced knowledge related to impending discharge with self-care needs
- Unclear about activity restrictions
- Asks if he will need to "do something" to his incision
- Lifts various objects at home
- Does not know signs of infection

Interventions
- Provide a pamphlet outlining postoperative risks
- Demonstrate method for cleansing incision
- Discuss activities not to perform at home because of activity restrictions

Primary health problem: Colectomy
Priority assessments: Condition of incision, gastrointestinal function, comfort level, knowledge of home care requirements and ability to learn, resources for discharge

Nursing diagnosis: Risk for infection
- Has a small separation of wound edges
- Patient is obese
- Drainage from wound
- Incision tender and inflamed near area of separation
- In a health care environment

Interventions
- Instruct patient and wife on signs/symptoms of infection
- Instruct patient and wife on hand hygiene in the home

Nursing diagnosis: Anxiety
- Worried about returning to work on time
- Does not consistently attend to nurse during instruction
- Poor eye contact

Interventions
- Use a calm, reassuring approach during discussions and instruction
- Include Mrs. Lawson in instruction
- Confirm with patient that following postoperative care guidelines will improve likelihood of recovery and ability to return to work

——— Link between medical diagnosis and nursing diagnosis   - - - - Link between nursing diagnoses

FIGURE 18-3 Concept map for Mr. Lawson: Planning.

one concept and another. The links need to be accurate, meaningful, and complete so you can explain why nursing diagnoses are related. Mr. Lawson's concept map has a new, fourth nursing diagnosis, *Anxiety*. Mr. Lawson's *Anxiety* and *Acute Pain* are interrelated; in addition, *Acute Pain* has an influence on his *Readiness for Enhanced Learning*.

Finally, on a separate sheet of paper or on the map itself, list nursing interventions to attain the measurable outcomes for each nursing diagnosis. This step corresponds to the planning phase of the nursing process. While caring for a patient, use the map to write his or her responses to each nursing activity. Also write your clinical impressions and inferences regarding the patient's progress toward expected outcomes and the effectiveness of interventions. Keep the concept map with you throughout the clinical day. As you revise the plan, take notes and add or delete nursing interventions. Use the information recorded on the map to document patient care. Critical thinkers learn by organizing and relating cognitive concepts. Concept maps help you learn the interrelationships among nursing diagnoses to create a unique meaning and organization of information collected.

CONSULTING WITH OTHER HEALTH CARE PROFESSIONALS

Planning involves consultation with members of the health care team when you face problems in providing nursing or collaborative care. Consultation occurs at any step in the nursing process, but you consult most often during planning and implementation. During these times you are more likely to identify a problem requiring additional

knowledge, skills, or resources. One way to consult is using the SBAR approach, a mechanism for framing conversations, especially critical ones, requiring a clinician's immediate attention and action (see Chapter 26). SBAR is an acronym for *Situation*, *Background*, *Assessment*, and *Recommendation*.

Consultation requires you to be aware of your strengths and limitations as a team member. During a **consultation** you seek the expertise of a specialist such as your nursing instructor, a health care provider, or a clinical nurse educator to identify ways to handle problems in patient management or the planning and implementation of therapies. The consultation process is important so all health care providers are focused on common patient goals and outcomes. Be prepared before you make a consultation. Consultation is based on the problem-solving approach, and the consultant is the stimulus for change.

An experienced nurse is a valuable consultant when you face an unfamiliar patient care situation such as a new procedure or a patient presenting a set of symptoms that you cannot identify. In clinical nursing consultation helps to solve problems in the delivery of nursing care. For example, a nursing student consults a clinical specialist for wound care techniques or an educator for useful teaching resources. Nurses are consulted for their clinical expertise, patient education skills, or staff education skills. Nurses also consult with other members of the health care team such as physical therapists, nutritionists, and social workers.

> **QSEN: BUILDING COMPETENCY IN TEAMWORK AND COLLABORATION** Mr. Lawson's concept map includes the nursing diagnosis of *Anxiety related to uncertainty over ability to return to work*. How would you apply principles of teamwork and collaboration in planning interventions for this diagnosis?
>
> ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

When to Consult

Consultation occurs when you identify a problem that you are unable to solve using personal knowledge, skills, and resources. The process requires good interprofessional collaboration. Consultation with other care providers increases your knowledge about a patient's problems and helps you learn skills and obtain resources. A good time to consult with another health care provider is when the exact problem remains unclear. An objective consultant enters a clinical situation and more clearly assesses and identifies the nature of a problem, whether it is patient, personnel, or equipment oriented. Most often you consult with health care providers who are working in your clinical area. However, sometimes you consult over the telephone (Box 18-5).

How to Consult

Begin with your own understanding of a patient's clinical problems. The first step in making a consultation is to assess the situation and identify the general problem area. Second, direct the consultation to the right professional such as another nurse or social worker. Third, provide a consultant with relevant information about the problem area and seek a solution. Include a brief summary of the problem, methods used to resolve the problem so far, and outcomes of these methods. Also share information from the patient's medical record, conversations with other nurses, and the patient's family. Fourth, do not prejudice or influence consultants. Consultants are in the clinical setting to help identify and resolve a nursing problem, and biasing or prejudicing them blocks problem resolution. Avoid bias by not overloading consultants with subjective and emotional conclusions about the patient and the problem.

Fifth, be available to discuss a consultant's findings and recommendations. Provide a private, comfortable atmosphere for the consultant and patient to meet. However, this does not mean that you leave the environment. A common mistake is turning the whole problem over to the consultant. The consultant is not there to take over the problem but to help you resolve it. When possible, request the consultation for a time when both you and the consultant are able to discuss the patient's situation with minimal interruptions or distractions. Finally, incorporate the consultant's recommendations into the care plan. The success of the advice depends on the implementation of the problem-solving techniques. Always give the consultant feedback regarding the outcome of the recommendations.

KEY POINTS

- After identifying a patient's nursing diagnoses and collaborative problems, establish a plan of care that prioritizes the diagnoses and establishes nursing interventions, patient-centered goals, and expected outcomes.
- Planning involves individualizing a plan of care for a patient's unique needs.
- Priority setting is the ordering of nursing diagnoses or patient problems using notions of urgency and importance to establish a preferential order for nursing actions.
- Priorities help you anticipate and sequence nursing interventions when a patient has multiple nursing diagnoses and collaborative problems.
- A patient-centered goal or outcome reflects a patient's specific behavior, not your own goals or interventions.
- The use of goals and outcomes in patient care is designed to focus the efforts of all health care team members on a common purpose.
- Outcomes provide the desired physiological, psychological, social, developmental, or spiritual responses that indicate resolution of a patient's health problems.
- When writing goals and outcomes, use the SMART acronym: *S*pecific, *M*easurable, *A*ttainable, *R*ealistic, and *T*imed.

- During planning select interventions designed to help a patient move from the present level of health to the level described in the goal and measured by the expected outcomes.
- Independent nursing interventions are actions that a nurse initiates without supervision or direction from others, are autonomous based on scientific rationale, and do not require an order from another health care provider.
- Health care provider-initiated interventions require specific nursing responsibilities and technical nursing knowledge.
- Care plans increase communication among nurses and facilitate the continuity of care from one nurse to another and from one health care setting to another.
- A nurse hand-off transfers essential information (along with responsibility and authority) from one nurse to the next during transitions in care and allows you to ask questions, clarify, and confirm important details.
- A concept map is a visual representation of a patient's nursing diagnoses with links to nursing interventions, helping you learn to make better clinical decisions.
- The NIC taxonomy provides a standardization to help nurses select suitable interventions for patients' problems.
- Correctly written nursing interventions include actions, frequency, quantity, method, and the person to perform them.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Tonya formally plans Mr. Lawson's care. For the nursing diagnosis of *Acute Pain related to trauma of surgical incision,* Tonya identifies the goal of "Patient will use relaxation technique after ambulation"; and the outcome she lists is, "Patient reports pain below level of 4 and does not splint incision when moving within 48 hours." The interventions she selects for her plan include administering the ordered analgesic, progressive relaxation, and splinting the incision when the patient gets out of bed.

1. Critique the goal and outcomes that Tonya set and explain if they were written correctly. If they are incorrect, how could you reword them so they are correctly stated?
2. Among the interventions that Tonya selected, which ones are independent, dependent, and collaborative?
3. If Tonya were to write on the patient's care plan, "use progressive relaxation," would that be an accurate way of writing an intervention? If not, which error(s) has been made?

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse enters the room of a 32-year-old patient newly diagnosed with cancer at the beginning of the 0700 evening/night shift. The nurse noted in the patient's nursing history that this is her first hospitalization. She is scheduled for surgery in the morning to remove a tumor and has questions about what to expect after surgery. She is observed talking with her mother and is crying. The patient says, "This is so unfair." An order has been written for an enema to be given this evening in preparation for the surgery. The nurse establishes priorities for which of the following situations first?
   1. Giving the enema on time
   2. Talking with the patient about her past experiences with illness
   3. Talking with the patient about her concerns and acknowledging her sense of unfairness
   4. Beginning instruction on postoperative procedures
2. A 62-year-old patient had a portion of the large colon removed and a colostomy created for drainage of stool. The nurse has had repeated problems with the patient's colostomy bag not adhering to the skin and thus leaking. The nurse wants to consult with the wound care nurse specialist. Which of the following should the nurse do? (Select all that apply.)
   1. Assess condition of skin before making the call
   2. Rely on the nurse specialist to know the type of surgery the patient likely had
   3. Explain the patient's response emotionally to the repeated leaking of stool
   4. Describe the type of bag being used and how long it lasts before leaking
   5. Order extra colostomy bags currently being used
3. It is time for a nurse hand-off between the night nurse and nurse starting the day shift. The night nurse checks the most recent laboratory results for the patient and then begins to discuss the patient's plan of care to the day nurse using the standard checklist for reporting essential information. The patient has been seriously ill, and his wife is at the bedside. The nurse asks the wife to leave the room for just a few minutes. The night nurse completes the summary of care before the day nurse is able to ask a question. Which of the following activities are strategies for an effective hand-off? (Select all that apply.)
   1. Using a standardized checklist for essential information
   2. Asking the wife to briefly leave the room
   3. Completing the hand-off without inviting questions
   4. Doing prework such as checking laboratory results before giving a report
   5. Including the wife in the hand-off discussion
4. A nurse assesses a 78-year-old patient who weighs 108.9 kg (240 lbs) and is partially immobilized because of a stroke. The nurse turns the patient and finds that the skin over the sacrum is very red and the patient does not feel sensation in the area. The patient has had fecal incontinence on and off for the last 2 days. The nurse identifies the nursing diagnosis of *Risk for Impaired Skin Integrity*. Which of the following outcomes is appropriate for the patient?
   1. Patient will be turned every 2 hours within 24 hours.
   2. Patient will have normal bowel function within 72 hours.
   3. Patient's skin integrity will remain intact through discharge.
   4. Erythema of skin will be mild to none within 48 hours.
5. Which of the following factors does a nurse consider in setting priorities for a patient's nursing diagnoses? (Select all that apply.)
   1. Numbered order of diagnosis on the basis of severity
   2. Notion of urgency for nursing action
   3. Symptom pattern recognition suggesting a problem
   4. Mutually agreed on priorities set with patient
   5. Time when a specific diagnosis was identified
6. A home health nurse visits a 42-year-old woman with diabetes who has a recurrent foot ulcer. The ulcer has prevented the woman from working for over 2 weeks. The patient has had diabetes for 10 years. The ulcer has not been healing; it has drainage with a foul-smelling odor. As the nurse examines the patient, she learns that the patient is not following the ordered diabetic diet. Which of the following is considered a low-priority goal for this patient?
   1. Achieving wound healing of the foot ulcer
   2. Enhancing patient knowledge about the effects of diabetes

3. Providing a dietitian consultation for diet retraining
4. Improving patient adherence to diabetic diet

7. The nurse writes an expected outcome statement in measurable terms. An example is:
    1. Patient will have normal stool evacuation.
    2. Patient will have fewer bowel movements.
    3. Patient will take stool softener every 4 hours.
    4. Patient will report stool soft and formed with each defecation.

8. A patient has the nursing diagnosis of *Nausea*. The nurse develops a care plan with the following interventions. Which are examples of collaborative interventions? (Select all that apply.)
    1. Providing mouth care every 4 hours
    2. Maintaining intravenous (IV) infusion at 100 mL/hr
    3. Administering prochlorperazine (Compazine) via rectal suppository
    4. Consulting with dietitian on initial foods to offer patient
    5. Controlling aversive odors or unpleasant visual stimulation that triggers nausea

9. An 82-year-old patient who resides in a nursing home has the following three nursing diagnoses: *Risk for Fall, Impaired Physical Mobility related to pain,* and *Imbalanced Nutrition: Less Than Body Requirements related to reduced ability to feed self*. The nursing staff identified several goals of care. Match the goals on the left with the appropriate outcome statements on the right.

Goals	Outcomes
1. _____ Patient will ambulate independently in 3 days.	a. Patient expresses fewer nonverbal signs of discomfort within 24 hrs.
2. _____ Patient will be injury free for 1 month.	b. Patient increases calorie intake to 2500 daily.
3. _____ Patient will achieve 5-lb weight gain in 1 month.	c. Patient walks 20 feet using a walker in 24 hrs.
4. _____ Patient will achieve pain relief by discharge.	d. Patient identifies barriers to remove in the home within 1 week.

10. Which of the following factors does a nurse consider for a patient with the nursing diagnosis of *Disturbed Sleep Pattern related to noisy home environment* in choosing an intervention for enhancing the patient's sleep? (Select all that apply.)
    1. The intervention should be directed at reducing noise.
    2. The intervention should be one shown to be effective in promoting sleep on the basis of research.
    3. The intervention should be one commonly used by the patient's sleep partner.
    4. The intervention should be one acceptable to the patient.
    5. The intervention should be one you used with other patients in the past.

11. A nurse begins the night shift being assigned to five patients. She learns that the floor will be a registered nurse (RN) short as a result of a call in. A patient care technician from another area is coming to the nursing unit to assist. The nurse is required to do hourly rounds on all patients, so she begins rounds on the patient who has recently asked for a pain medication. As the nurse begins to approach the patient's room, a nurse stops her in the hallway to ask about another patient. Which factors in this nurse's unit environment will affect her ability to set priorities? (Select all that apply.)
    1. Policy for conducting hourly rounds
    2. Staffing level

3. Interruption by staff nurse colleague
4. RN's years of experience
5. Competency of patient care technician

12. A nursing student is reporting during hand-off to the registered nurse (RN) assuming her patient's care. The student states, "Mr. Roarke had a good day, his intravenous (IV) fluid is infusing at 124 mL/hr with $D_5\frac{1}{2}NS$ infusing in right forearm. The IV site is intact, and no complaints of tenderness. I ambulated him twice during the shift; he tolerated well walking to end of hall and back with no shortness of breath. He still uses his cane without difficulty. Mr. Roarke said he slept better last night after I closed his door and gave him a chance to be uninterrupted. If the nurse's goal for Mr. Roarke was to improve activity tolerance, which expected outcomes were shared in the hand-off? (Select all that apply.)
    1. IV site not tender
    2. Uses cane to walk
    3. Walked to end of hall
    4. No shortness of breath
    5. Slept better during night

13. A nursing student is reporting during hand-off to the RN assuming her patient's care. She explains, "I ambulated him twice during the shift; he tolerated well walking to end of hall and back with no shortness of breath. Mr. Roarke said he slept better last night after I closed his door and gave him a chance to be uninterrupted. I changed the dressing over his intravenous (IV) site and started a new bag of $D_5\frac{1}{2}NS$. Which intervention is a dependent intervention?
    1. Reporting hand-off at change of shift
    2. Ambulating patient down hallway
    3. Sleep hygiene
    4. IV fluid administration

14. A nursing student knows that all patients should be ambulated regularly. The patient to which she is assigned has had reduced activity tolerance. She followed orders to ambulate the patient twice during the shift of care. In what way can the nursing student make the goal of improving the patient's activity tolerance a patient-centered effort?
    1. Engage the patient in setting mutual outcomes for distance he is able to walk
    2. Confirm with the patient's health care provider about ambulation goals
    3. Have physical therapy assist with ambulation
    4. Refer to medical record regarding nature of patient's physical problem

15. A patient signals the nurse by turning on the call light. The nurse enters the room and finds the patient's drainage tube disconnected, 100 mL of fluid remaining in the intravenous (IV) line, and the patient asking questions about whether his doctor is coming. Which of the following does the nurse perform first?
    1. Reconnect the drainage tubing
    2. Inspect the condition of the IV dressing
    3. Obtain the next IV fluid bag from the medication room
    4. Explain when the health care provider is likely to visit

Answers: 1. 3; **2.** 1, 3, 4; **3.** 1, 4, 5; **4.** 4, 5; **5.** 2, 3, 4; **6.** 2; **7.** 4; **8.** 2, 4; **9.** 1c, 2d, 3b, 4a; **10.** 1, 2, 4; **11.** 1, 2, 3; **12.** 3, 4; **13.** 4; **14.** 1; **15.** 1.

Implementing Nursing Care

OBJECTIVES

- Explain the relationship of implementation to the nursing diagnostic process.
- Describe the association between critical thinking and selecting nursing interventions.
- Discuss the differences between protocols and standing orders.
- Discuss the influence of organizational culture on interdisciplinary collaboration.

- Discuss the value of the Nursing Interventions Classification system in documenting nursing care.
- Discuss the steps for revising a plan of care before performing implementation.
- Define the three implementation skills.
- Describe and compare direct and indirect nursing interventions.
- Select appropriate interventions for a patient.

You first met Tonya and Mr. Lawson in Chapter 15. Mr. Lawson is a 68-year-old patient who had abdominal surgery for a colon resection and is preparing to be discharged soon from the hospital. His nurse Tonya developed a plan of care to address four different nursing diagnoses: Acute Pain, Anxiety, Readiness for Enhanced Knowledge, and Risk for Infection. Mr. Lawson is interested in learning about his postoperative activity restrictions and being able to care for his incision, which had a small separation. He also shared with Tonya that he is worried about being able to return to work after surgery. Tonya and the other nursing staff have consistently applied the nursing process. Tonya identified the diagnosis of Anxiety while planning for Mr. and Mrs. Lawson's education. During implementation Tonya will provide planned interventions, along with her health care colleagues, to achieve the goals and expected outcomes identified in Mr. Lawson's plan of care. Critical thinking, which includes good clinical decision making, is important for the successful implementation of nursing interventions.

Implementation, the fourth step of the nursing process, formally begins after you develop a plan of care. With a care plan based on clear and relevant nursing diagnoses, you initiate interventions designed to help a patient achieve the goals and expected outcomes needed to support or improve the patient's health status. A **nursing intervention** is any treatment based on clinical judgment and knowledge that a nurse performs to enhance patient outcomes (Bulechek et al., 2013).

Ideally nursing interventions are evidence based (see Chapter 5), providing the most current, up-to-date, and effective approaches for delivering patient-centered care. Nursing interventions include direct and indirect care measures aimed at individuals, families, and/or the community.

Direct care interventions are treatments performed through interactions with patients (Bulechek et al., 2013). For example, a patient receives direct intervention in the form of medication administration, insertion of a urinary catheter, discharge instruction, or counseling during a time of grief. **Indirect care** interventions are treatments performed away from a patient but on behalf of the patient or group of patients (e.g., managing a patient's environment [e.g., safety and infection control]), documentation, and interdisciplinary collaboration (Bulechek et al., 2013). Both direct and indirect care measures fall under the intervention categories described in Chapter 18: nurse-initiated, health care provider–initiated, and collaborative. For example, the direct intervention of patient education is a nurse-initiated intervention. The indirect intervention of consultation is a collaborative intervention.

Dr. Patricia Benner (1984) defined the domains of nursing practice, which explain the nature and intent of the many ways nurses intervene for patients (Box 19-1). These domains are current today. However, the extent of organizational and work role competencies in health care has become more complex, making it a challenge to fulfill each domain of practice. Nurses are required to have effective organizational skills and maintain competencies in advanced nursing care.

In addition, nurses must be able to manage conflict and effectively advocate for patients in challenging interdisciplinary relationships. Thus it is important for implementation to be patient-centered. Nursing is an art and a science. It is not simply a task-based profession. You must learn to intervene for a patient within the context of his or her unique situation. Consider these factors during implementation: Who is the patient? How do a patient's attitudes, values, and cultural background affect how you provide care? What does an illness mean to a patient and his or her family? Which clinical situation requires you to intervene? How does a patient perceive the interventions that you will deliver? In what way do you best support or show caring as you intervene? The answers to these questions enable you to deliver care compassionately and effectively with the best outcomes for your patients.

STANDARD NURSING INTERVENTIONS

Health care settings offer various ways for nurses to create and individualize patients' care plans. It is critical for each patient to have his or her unique set of interventions. However, many health care systems have mechanisms for standardizing the more common types of interventions. Many patients have common health problems; thus standardized interventions make it quicker and easier for nurses to intervene. More important, if the standards are evidence-based, you are likely to deliver the most clinically effective care that will result in the best patient outcomes (see Chapter 5). As a nurse, you are accountable for individualizing standardized interventions as necessary.

Standardized interventions most often set a level of clinical excellence for practice. Nurse- and health care provider–initiated standardized interventions are available in the form of clinical guidelines or protocols, preprinted (standing) orders, and Nursing Interventions Classification (NIC) interventions. At a professional level the American Nurses Association (ANA) defines standards of professional nursing practice, which include standards for the implementation step of the nursing process. The Quality and Safety Education for Nurses (QSEN) defines skills competencies. These standards are authoritative statements of the duties that all registered nurses (RNs) are expected to perform competently, regardless of role, patient population they serve, or specialty (ANA, 2010) (see Chapter 1).

Clinical Practice Guidelines and Protocols

A **clinical practice guideline** or protocol is a systematically developed set of statements that helps nurses, physicians, and other health care providers make decisions about appropriate health care for specific clinical situations (Manchikanti et al., 2010). Evidence-based research provides the basis for sound clinical practice guidelines and associated recommendations that often improves quality of care (AHRQ, 2014a). A guideline establishes interventions for specific health care problems

or conditions. A nurse individualizes how to apply interventions for each unique patient. The National Guidelines Clearinghouse (NGC) is a public resource for evidence-based clinical practice guidelines (AHRQ, 2014b). The NGC guidelines are linked to a particular term derived from the U.S. National Library of Medicine (NLM) Medical Subject Headings (MeSH), a controlled vocabulary for disease/condition, treatment/intervention, and health services administration. You can access guidelines for patients with a wide variety of conditions and problems such as arthritis, wounds and injuries, and pain management. These guidelines are readily available to any clinician or health care institution.

Clinicians within a health care agency sometimes review the scientific literature and their own standard of practice to develop guidelines and protocols in an effort to improve the standard of care at their facility. For example, a hospital develops a rapid-assessment protocol to improve the identification and early treatment of patients suspected of having a stroke or sepsis. Many times clinicians will develop guidelines that incorporate standards unique to their organizational processes and guidelines from national health groups such as the National Institutes of Health (NIH) and the NGC. Another valuable source for nursing practice guidelines is the University of Iowa (n.d.) Hartford Center, which develops evidence-based practice (EBP) guidelines for geriatric nursing. The center has numerous clinical guidelines, including ones for acute confusion and delirium, acute pain management, and fall prevention for older adults.

Advanced practice nurses (APNs) who provide primary care for patients in a variety of settings frequently follow diagnostic and treatment protocols for their interventions. A collaborative agreement with a physician identifies protocols for the medical conditions that APNs are permitted to treat such as controlled hypertension and the types of treatment that they are permitted to administer such as antihypertensive medications. These state-derived protocols vary from state to state. APNs are also able to act independently, developing and applying clinical protocols that outline independent nursing interventions. For example, in the long-term setting scientifically based protocols for incontinence, pressure ulcers, depression, and aggressive behavior are common. Databases such as Up-to-Date and the Cochrane library provide valuable treatment guidelines supported by rigorous systematic reviews to provide evidence-based treatment guidelines.

Standing Orders

A **standing order** is a preprinted document containing orders for routine therapies, monitoring guidelines, and/or diagnostic procedures for specific patients with identified clinical problems. A standing order directs patient care in a specific clinical setting. Licensed prescribing health care providers in charge of care at the time of implementation approve and sign standing orders. These orders are common in critical care settings and other specialized acute care settings where patients' needs change rapidly and require immediate attention. An example of such a standing order is one specifying certain medications such as diltiazem (Cardizem) and amiodarone (Cordarone) for an irregular heart rhythm. A critical care nurse compares assessment data to the protocol criteria and implements the protocol without first notifying the physician. The physician's initial standing order covers the nurse's action. After completing a standing order, the nurse notifies the physician in case further treatment is needed. Standing orders are also common in community health settings, where nurses face situations that do not permit immediate contact with a health care provider. Standing orders give nurses legal protection to intervene appropriately in the best interests of patients with rapidly changing needs.

Nursing Interventions Classification Interventions

The NIC system developed by the University of Iowa differentiates nursing practice from that of other health care disciplines (Box 19-2) by offering a language that nurses can use to describe sets of actions in delivering nursing care. The NIC interventions offer a level of standardization to enhance communication of nursing care across settings and to compare outcomes. Many health care information systems have incorporated the NIC system. By using NIC you will learn the common interventions recommended for the various NANDA-International (NANDA-I) nursing diagnoses. Chapter 18 describes the NIC system in more detail.

Standards of Practice

Nurses use the ANA Standards of Professional Nursing Practice (ANA, 2010) as evidence of the standard of care provided to patients (see Chapter 1). The standards are formally reviewed on a regular basis. The newest standards include competencies for establishing professional and caring relationships, using evidence-based interventions and technologies, providing ethical holistic care across the life span to diverse groups, and using community resources and systems. In addition, the standards emphasize implementing a timely plan following patient safety goals (ANA, 2010).

Quality and Safety Education for Nurses (QSEN)

The QSEN Institute established standard competencies in knowledge, skills, and attitudes (KSAs) for the preparation of future nurses (QSEN, 2014). The goal of QSEN is to prepare nurses so they can continuously improve the quality and safety of the health care systems within which they work. Examples of QSEN skills include providing patient-centered care with sensitivity and respect for the diversity of the human experience, initiating effective treatments to relieve pain and suffering, and participating in building consensus or resolving conflict in the context of patient care (QSEN, 2014).

CRITICAL THINKING IN IMPLEMENTATION

Clinical judgment includes making appropriate interpretations or conclusions about the interventions used to address a patient's human response to health conditions or life processes. It requires a nurse to use or modify standard approaches and to sometimes improvise new ones (ideally based on evidence) to respond appropriately (Tanner,

2006). The critical thinking model discussed in Chapter 15 provides a framework for how to make decisions when implementing nursing care. You learn how to implement nursing care by applying appropriate knowledge, experience, attitudes, and standards of care (Figure 19-1). The delivery of nursing interventions is complex. It is based on the knowledge you have about a patient and the social context of the unit where you work. Interdisciplinary relationships, particularly those between nurses and health care providers, contribute to nursing judgments in the degree to which you pursue understanding a patient's problem and intervene effectively (Box 19-3). The context in which you deliver care to each patient and the many interventions required result in decision-making approaches for each clinical situation. Critical thinking allows you to consider the complexity of interventions, changing priorities, alternative approaches, and the amount of time available to act.

*Tonya identified four relevant nursing diagnoses for Mr. Lawson: **Acute Pain related to trauma of surgical incision, Readiness for Enhanced Knowledge related to impending discharge with self-care needs, Risk for Infection,** and **Anxiety related to uncertainty over ability to return to work.** The diagnoses are interrelated, and sometimes a planned intervention (e.g., promoting relaxation exercises) treats or modifies more than one of the patient's health problems (anxiety and acute pain). Tonya applies critical thinking and uses her time with Mr. Lawson wisely by anticipating his priorities, applying the knowledge she has about his problems and the interventions planned, and implementing care strategies skillfully.*

As you implement interventions, use critical thinking to confirm whether the interventions are correct and still appropriate. Be sure that

you understand a patient's clinical situation. Always be aware of a patient's changing condition and what you would expect after caring for patients with similar conditions. You will "reflect-in-action" (i.e., what Tanner [2006] describes as being able to read a patient and how he or she is responding to your interventions) and then adjust the interventions on the basis of ongoing assessment.

Critical thinking requires you to make correct judgments as you care for multiple patients with different needs and whose priorities can change quickly. You need to maintain critical thinking, organization, and time management skills to provide safe and effective care to patients (see Chapter 21).

Even though you plan a set of interventions for a patient, you have to exercise critical judgment and decision making while delivering each intervention. Always think before you act. Consider the resources you have and the scheduling of activities on a nursing unit, which often dictate when and how to complete an intervention. Many factors influence your decision on how and when to intervene. You are responsible for having the necessary knowledge and clinical competency to perform interventions for your patients safely and effectively. Follow these tips for making decisions during implementation:

- Review the set of all possible nursing interventions for a patient's problem (e.g., for Mr. Lawson's pain Tonya considered analgesic administration, positioning and splinting, progressive relaxation, and other nonpharmacological approaches).

- Review all possible consequences associated with each possible nursing action (e.g., Tonya considers that the analgesic will relieve pain; have little or insufficient effect; or cause an adverse reaction, including sedating the patient and increasing the risk of falling).
- Determine the probability of all possible consequences (e.g., if Mr. Lawson's pain continues to decrease with analgesia and positioning and there have been no side effects, it is unlikely that adverse reactions will occur, and the intervention will be successful; however, if the patient continues to remain highly anxious, his pain may not stay relieved, and Tonya needs to consider an alternative).
- Judge the value of the consequence to the patient (e.g., if the administration of an analgesic is effective, Mr. Lawson will likely become less anxious and more responsive to postoperative instruction and counseling about his anxiety).

Selecting nursing interventions for a patient is part of clinical decision making. It is important to know the purpose of an intervention, the steps in performing the intervention correctly, the current medical condition of the patient, and his or her expected response. Always prepare well before providing any intervention. With experience you become more proficient in anticipating what to expect in a given clinical situation and how to modify your approach. As you gain clinical experience, you are able to consider patterns of responses from similar patients and the interventions that did or did not work previously and why. It also helps to know the clinical standards of practice for your agency.

As you perform a nursing intervention, apply intellectual standards, which are the guidelines for rational thought and responsible action (see Chapter 15). *For example, before Tonya begins to teach Mr. Lawson, she considers how to make her instructions relevant, clear, logical, and complete to promote patient learning.* A critical thinker applies critical thinking attitudes when intervening. For example, show confidence in performing an intervention. When you are unsure of how to perform a procedure, be responsible. Seek assistance from others. Confidence in performing interventions builds trust with patients. Creativity and self-discipline are attitudes that guide you in reviewing, modifying, and implementing interventions. As a beginning nursing student, seek out supervision from instructors or experienced nurses or review agency policy and procedures to guide you in the decision-making process for implementation.

IMPLEMENTATION PROCESS

Preparation for implementation ensures efficient, safe, and effective nursing care. Five preparatory activities are reassessing the patient, reviewing and revising the existing nursing care plan, organizing resources and care delivery, anticipating and preventing complications, and implementing nursing interventions.

Tonya returns to Mr. Lawson's room to begin instruction. His wife is present, and Mr. Lawson reports that his incisional pain is currently a level of 3. Tonya helps the patient sit up in a chair. She gets the teaching DVD program identified in her review of evidence and the booklets she wants to use to prepare the patient and his wife for infection control, wound care, and activity restrictions in the home. She knows that Mr. Lawson still has concerns about returning to work and thus wants to incorporate discussion about wound care with expected postoperative recovery. Tonya sees the opportunity of using Mr. Lawson's desire to return to work to increase the likelihood of his adherence to postoperative restrictions. If Mrs. Lawson understands how she can help Mr. Lawson in recovery, positive outcomes should be achieved.

Reassessing a Patient

Assessment is a continuous process that occurs each time you interact with a patient. When you collect new data about a patient, you sometimes identify a new nursing diagnosis or determine the need to modify the care plan. Creating a concept map helps you better understand the relationship between different nursing diagnoses and interventions appropriate to a patient's care (Figure 19-2). During the initial phase of implementation reassess the patient to be sure that you have selected appropriate interventions. The reassessment often focuses on one primary nursing diagnosis, or one dimension of a patient such as level of comfort, or one system such as the cardiovascular system. The reassessment helps you decide if the proposed nursing actions are still appropriate for a patient's level of wellness. Reassessment is not the evaluation of care or determination of a patient's response to an intervention (see Chapter 20), but it is the gathering of additional information to ensure that the plan of care is still appropriate. *For example, Tonya begins to talk with Mr. and Mrs. Lawson about wound care and the patient's activity restrictions. Mrs. Lawson shares that Mr. Lawson's*

employer called to ask how he was doing. Tonya notices that Mr. Lawson begins to show more anxiety; as Tonya explains lifting restrictions, the patient is not able to teach back what he can and cannot do. Tonya decides to redirect the discussion. She says to Mr. Lawson, "Let's talk about going back to work. Tell me more about when they expect you to return and what your work actually involves." Tonya realizes that to be effective with instruction she needs an attentive learner. Gaining more detail about the patient's work will help him express his concerns while at the same time allow Tonya to explain how activity restrictions fit into daily routines.

Reviewing and Revising the Existing Nursing Care Plan

Reassessment allows you to validate a patient's nursing diagnoses, review the care plan, and determine whether the nursing interventions remain the most appropriate for a patient's needs. If a patient's status has changed and the nursing diagnosis and related nursing interventions are no longer appropriate, modify the nursing care plan. An out-of-date or incorrect care plan compromises the quality of nursing care. Review and modification enable you to provide timely nursing interventions to best meet a patient's needs. Modification of an existing written care plan includes four steps:

1. Revise data in the assessment column to reflect the patient's current status. Date any new data to inform other members of the health care team of the time that the change occurred.
2. Revise the nursing diagnoses. Delete nursing diagnoses that are no longer relevant and add and date any new diagnoses. Revise related factors and the patient's goals, outcomes, and priorities. Date any revisions.
3. Revise specific interventions that correspond to the new nursing diagnoses and goals. Be sure that revisions reflect the patient's present status.
4. Choose the method of evaluation for determining whether the patient achieved his or her outcomes.

As Tonya continues to prepare Mr. Lawson for discharge, she reassesses his pain status. His pain has been controlled well on around-the-clock analgesics. In consultation with the physician and in preparation for discharge, the physician decides to order an analgesic prn. Tonya also decides to include Mrs. Lawson as a coach to facilitate relaxation exercises for Mr. Lawson.

Preparing for Implementation

A nurse organizes time and resources in preparation for implementing nursing care. Always be sure that a patient is physically and psychologically ready for any interventions or procedures.

Time Management. Nurses practice within work environments that are part of the social-cultural context of health care organizations. As a result, they must assume dual roles: that of a patient care provider and an organizational employee (Jones, 2010). Your focus on providing individualized patient care can compete with the focus of standardization, efficiency, and cost control of the organization. Inadequate nursing time contributes to poor quality of patient care, and excess nursing time contributes to high costs of care (Aiken, 2008; Storfjell et al., 2008). Time devoted to nursing care has three components: physical (the physical amount of time consumed in the completion of nursing activities), psychological (what nursing care patients experience and how they experience it), and sociological (the sequential ordering of events within the daily routines of a practice setting) (Jones, 2010). All components of time occur within the context of an organization and the resources available. As a new nurse, understand that the decisions you make about how your time is allocated, prioritized, and sequenced are always interpreted by the patients you serve (Jones, 2010). Delayed and hurried responses convey disinterest,

CONCEPT MAP

Nursing diagnosis: Acute pain related to incisional trauma
- Wound tender when palpated
- Pain severity has ranged from 8 to 4
- Patient guards incision by placing hand over wound when moving

Interventions
- Administer analgesic prn as ordered
- Educate patient about managing prn medication
- Teach relaxation exercises to be used when pain in control; include wife as coach

Nursing diagnosis: Readiness for enhanced knowledge related to impending discharge with self-care needs
- Unclear about activity restrictions
- Asks if he will need to "do something" to his incision
- Lifts various objects at home
- Does not know signs of infection

Interventions
- Provide a pamphlet outlining postoperative risks
- Demonstrate method for cleansing incision
- Discuss activities not to perform at home because of activity restrictions

Primary health problem: Colectomy
Priority assessments: Condition of incision, gastrointestinal function, comfort level, knowledge of home care requirements and ability to learn, resources for discharge

Nursing diagnosis: Risk for infection
- Has small separation of wound edges
- Patient is obese
- Drainage from wound
- Incision tender and inflamed near area of separation
- In a health care environment

Interventions
- Have patient and wife view DVD on signs/symptoms of infection
- Instruct patient and wife on hand hygiene in the home

Nursing diagnosis: Anxiety related to uncertainty over ability to return to work
- Worried about returning to work on time
- Does not consistently attend to nurse during instruction
- Poor eye contact

Interventions
- Use a calm, reassuring approach during discussions and instruction
- Include Mrs. Lawson in instruction
- Confirm with patient that following postoperative care guidelines will improve likelihood of recovery and ability to return to work

——— Link between medical diagnosis and nursing diagnosis   - - - - - Link between nursing diagnoses

FIGURE 19-2 Concept map for Mr. Lawson: Implementation.

whereas timely interaction conveys care and concern. Be aware of factors affecting time with patients and apply time-management principles (see Chapter 21).

Equipment. Most nursing procedures require some equipment or supplies. Before performing an intervention, decide which supplies you need and determine their availability. Is the equipment in working order to ensure safe use, and do you know how to use it? Place supplies in a convenient location to provide easy access during a procedure. Keep extra supplies available in case of errors or mishaps, but do not open them unless you need them. This controls health care costs, allowing you to be a fiscally responsible member of the health care team. After a procedure return any unopened supplies to storage areas.

Personnel. Nursing care delivery models determine how nursing personnel deliver patient care (see Chapter 21). A nurse's role in a team nursing model differs from that in a primary nursing model. As a nurse you are responsible for deciding whether to perform an intervention, delegate it to an unlicensed member of the nursing team, or have an RN colleague assist you. Your ongoing assessments of your patients, the priorities of each, and not an intervention alone, direct your decision about delegation. You have a legal duty to follow delegation guidelines and only delegate interventions within the delegate's training and ability according to the state Nurse Practice Act.

Patient care staff work together as patients' needs demand it. If a patient makes a request such as use of a bedpan or assistance in feeding, help the patient if you have time rather than trying to find a nursing assistive personnel (NAP) who is in a different room. Nursing staff

respect colleagues who show initiative; collaborate together; and communicate with one another on an ongoing, reciprocal basis as patients' needs change (Potter et al., 2010). When interventions are complex or physically difficult, you will need assistance from colleagues. For example, you and the NAP more effectively change a dressing in a large gaping wound when you apply the dressing and the NAP assists with patient positioning and handing off of supplies.

Environment. A patient's care environment needs to be safe and conducive to implementing therapies. Patient safety is your first concern. If a patient has sensory deficits, physical disabilities, or an alteration in level of consciousness, arrange the environment to prevent injury. For example, provide a patient's assist devices (e.g., walker or eyeglasses), rearrange furniture and equipment when ambulating a patient, or make sure that the water temperature is not too warm before a bath. Patients benefit most from nursing interventions when surroundings are compatible with care activities. When you need to expose a patient's body parts, do so privately by closing room doors or curtains because the patient will then be more relaxed. Ask visitors to leave as you complete care. Reduce distractions during teaching to enhance a patient's learning opportunities. Make sure that lighting is adequate to perform procedures correctly.

Patient. Before you implement interventions, make sure that your patients are physically and psychologically comfortable. Control noise, temperature, and lighting for maximal comfort. Physical symptoms such as nausea, dizziness, fatigue, or pain often interfere with a patient's full concentration and ability to cooperate. Offer comfort measures before initiating interventions to help patients participate more fully. If you need a patient to be alert, administer a dose of pain medication strong enough to relieve discomfort but not to impair mental faculties (e.g., ability to follow instruction and communication). If a patient is fatigued, delay ambulation or transfer to a chair until after he or she has had a chance to rest. Also consider a patient's level of endurance and plan only the amount of activity that he or she is able to tolerate comfortably.

Awareness of a patient's psychosocial needs helps you create a favorable emotional climate. *Do not rush your care.* Some patients feel reassured by having a significant other present to lend encouragement and moral support. Other strategies include planning sufficient time or multiple opportunities for a patient to work through and ventilate feelings and anxieties. Adequate preparation allows a patient to obtain maximal benefit from each intervention.

Anticipating and Preventing Complications

As a nurse, always stay alert for the risks posed by a patient's illness and treatments. If a patient's condition changes, adapt your choice of interventions to the situation, evaluate the relative benefit of the treatment versus the risk, and take risk-prevention measures. Many conditions place patients at risk for complications. For example, a patient with preexisting left-sided paralysis following a stroke 2 years earlier is at risk for developing a pressure ulcer following orthopedic surgery that requires traction and bed rest. A patient with obesity and diabetes mellitus who has major abdominal surgery is at risk for poor wound healing. Nurses are often the first ones to detect and document changes in patients' conditions. Expert nurses learn to anticipate breakdown and deterioration of patients even before confirming diagnostic signs develop.

Your knowledge of pathophysiology and experience with previous patients help in identifying the risk of complications that can occur. A thorough assessment reveals the level of a patient's current risk. The evidence or scientific rationales for how interventions (e.g., pressure-relief devices, repositioning, or wound care) prevent or minimize complications help you select the most appropriate preventive measures. For example, if a patient who is obese has uncontrolled postoperative pain, the risk for pressure ulcer development increases because the patient is unwilling or unable to change position frequently. The nurse anticipates when a patient's pain will increase, administers ordered analgesics, and then positions the patient to remove pressure on the skin and underlying tissues. If a patient continues to have difficulty turning or repositioning, the nurse selects a pressure-relief device to place on the patient's bed.

Some nursing procedures pose risks. Be aware of potential complications and take precautions. For example, a patient who has a feeding tube is at risk for aspiration. Position the patient in high-Fowler's position, check for residual, and check tube position before administering a feeding.

Identifying Areas of Assistance. Certain patient care situations require you to obtain assistance by seeking additional personnel, knowledge, and/or nursing skills. Before beginning care, review the plan to determine the need for assistance and the type required. Sometimes you need assistance in performing a procedure, providing comfort measures, or preparing a patient for a diagnostic test. Do not take shortcuts if assistance is not immediately available since this increases risk of injury to you and the patient. For example, when you care for a patient who is overweight and immobilized, you require additional personnel and transfer equipment to turn and position the patient safely. Be sure to determine the number of additional personnel and if you need them in advance. Discuss your need for assistance with other nurses or the NAP.

You require additional knowledge and skills in situations in which you are less experienced. Because of the continual growth in health care technology, you may lack the skills to perform a procedure. When you are asked to administer a new medication, operate a new piece of equipment, or administer a procedure with which you are unfamiliar, follow these steps.

1. Seek the information you need to be informed about a procedure. Check the scientific literature for evidence-based information, review resource manuals and the procedure book of the agency, or consult with experts (e.g., pharmacists, clinical nurse specialists).
2. Collect all equipment necessary for the procedure.
3. Have another nurse (e.g., staff nurse, faculty, clinical nurse specialist) who has completed the procedure correctly and safely provide assistance and guidance. Requesting assistance occurs frequently in all types of nursing practice. It is a learning process that continues throughout educational experiences and into professional development. One tip is to verbalize with an instructor or staff nurse the steps you will take before actually performing the procedure to improve your confidence and ensure accuracy.

Implementation Skills

Nursing practice requires cognitive, interpersonal, and psychomotor (technical) skills to implement direct and indirect nursing interventions. You are responsible for knowing when one type of implementation skill is preferred over another and for having the necessary knowledge and skill to perform each.

Cognitive Skills. Cognitive skills include the critical thinking and decision-making skills described earlier. Always use good judgment and sound clinical decision making when performing any intervention. This ensures that no nursing action is automatic. Grasp each

clinical situation at hand, interpret the information you observe, and anticipate a patient's response so you individualize patient care appropriately. Know the rationale for therapeutic interventions and understand normal and abnormal physiological and psychological responses. Also know the evidence in nursing science to ensure that you deliver current and relevant nursing interventions.

Tonya knows the pathophysiology of colon cancer, the anatomy of the abdomen and surrounding structures, and the normal mechanisms for pain. She considers each of these as she observes Mr. Lawson, noting how the patient's movement and position either aggravate or lessen his incisional pain. Tonya focused initially on relieving Mr. Lawson's acute pain with an analgesic; but, now that pain has become well managed, she considers additional nonpharmacological approaches to keep him comfortable and also help lessen any anxiety.

Interpersonal Skills. Interpersonal communication is essential for effective nursing action. Develop a trusting relationship, express a level of caring, and communicate clearly with patients and their families (see Chapter 24). Good interpersonal communication keeps patients informed and engaged in decision making, provides individualized instruction, and supports patients who have challenging emotional needs. Proper use of interpersonal skills enables you to be perceptive of a patient's verbal and nonverbal communication. As a member of the health care team, communicate patient problems and needs clearly, intelligently, and in a timely way.

Psychomotor Skills. Psychomotor skills require the integration of cognitive and motor activities. For example, when giving an injection you need to understand anatomy and pharmacology (cognitive) and use good coordination and precision to administer the injection correctly (motor). With time and practice you learn to perform skills correctly, smoothly, and confidently. This is critical in establishing patient trust. You are responsible for acquiring necessary psychomotor skills through your experience in the nursing laboratory, the use of interactive instructional technology, or actual hands-on care of patients. When performing a new skill, assess your level of competency and obtain the necessary resources to ensure that your patient receive safe treatment.

DIRECT CARE

Nurses provide a wide variety of direct care measures through patient interactions. How a nurse interacts affects the success of any direct care activity. Remain sensitive to a patient's clinical condition, previous experiences, expectations, and cultural views. All direct care measures require competent safe practice. Show a caring approach each time you provide direct care.

Activities of Daily Living

Activities of daily living (ADLs) are usually performed in the course of a normal day; they include ambulation, eating, dressing, bathing, and grooming. A patient's need for assistance with ADLs is temporary, permanent, or rehabilitative. For example, a patient with impaired physical mobility because of bilateral arm casts temporarily needs assistance. After the casts are removed, the patient gradually regains the strength and range of motion needed to perform ADLs. In contrast, a patient with an irreversible cervical spinal cord injury is paralyzed and has a permanent need for assistance. It is unrealistic to plan rehabilitation with a goal of becoming independent with ADLs for this patient. Instead the patient learns new ways to perform ADLs

independently through rehabilitation. Occupational and physical therapists play a key role in rehabilitation to restore ADLs function.

When a patient is experiencing fatigue, a limitation in mobility, confusion, and/or pain, assistance with ADLs is likely. For example, a patient who experiences shortness of breath avoids eating because of associated fatigue. Help the patient by setting up meals and offering to cut up food and plan for more frequent, small meals to maintain his or her nutrition. Assistance with ADLs ranges from partial assistance to complete care. Remember to always respect a patient's wishes and determine his or her preferences. Patients from some cultures prefer receiving assistance with ADLs from family members. As long as a patient is stable and alert, it is appropriate to allow family to help with care. Most patients want to remain independent in meeting their basic needs. Allow a patient to participate to the level that he or she is able. Involving patients in planning the timing and types of interventions boosts their self-esteem and willingness to become more independent.

Instrumental Activities of Daily Living

Illness or disability sometimes alters a patient's ability to be independent in society. **Instrumental activities of daily living (IADLs)** include skills such as shopping, preparing meals, housecleaning, writing checks, and taking medications. Nurses within home care and community health settings frequently help patients adapt ways to perform IADLs. Occupational therapists are specially educated to adapt approaches for patients to use when performing IADLs. Often family and friends are excellent resources for helping patients. In acute care it is important to anticipate how patients' illnesses will affect their ability to perform IADLs so you can make appropriate referrals to be sure that they have resources they need at home.

Physical Care Techniques

You routinely perform a variety of physical care techniques when caring for patients. Physical care techniques involve the safe and competent administration of nursing procedures (e.g., turning and positioning, inserting a feeding tube, administering medications, and providing comfort measures). The specific knowledge and skills needed to perform these procedures are in subsequent clinical chapters of this text. All physical care techniques require you to protect yourself and patients from injury, use safe patient-handling techniques, use proper infection control practices, stay organized, and follow applicable practice guidelines.

To carry out a procedure you need to be knowledgeable about the procedure itself, the standard frequency, the associated risks, and the necessary assessments before, during, and after performing the skill. Always remain thoughtful of a patient's condition and how the patient has responded to the procedure in the past. Know how the procedure is going to affect the patient and which expected outcomes you desire. In a hospital you perform many procedures each day, often for the first time. Before performing a new procedure, assess the situation and your personal competencies to determine if you need assistance, new knowledge, or new skills. Performing any procedure correctly requires critical thinking and thoughtful decision making.

Lifesaving Measures

A **lifesaving measure** is a physical care technique that you use when a patient's physiological or psychological state is threatened (see Chapters 38 and 41). The purpose of lifesaving measures is to restore physiological or psychological homeostasis. Such measures include administering emergency medications, instituting cardiopulmonary resuscitation, intervening to protect a confused or violent patient, and obtaining immediate counseling from a crisis center for a severely anxious

patient. If an inexperienced nurse faces a situation requiring emergency measures, the proper nursing actions are to stay with the patient, maintain support, and have another staff member obtain an experienced professional.

Counseling

Counseling is a direct care method that helps patients use problem-solving processes to recognize and manage stress and facilitate interpersonal relationships. As a nurse you counsel patients to accept actual or impending changes resulting from stress (see Chapter 38). Examples include patients who are facing terminal illness or chronic disease. Counseling involves emotional, intellectual, spiritual, and psychological support. A patient and family who need nurse counseling have normal adjustment difficulties and are upset or frustrated, but they are not necessarily psychologically disabled. An example is the stress that a young woman faces when caring for her aging mother. Family caregivers need assistance in adjusting to the physical and emotional demands of caregiving. Sometimes they need respite (i.e., a break from providing care). The recipient of care also needs assistance in adjusting to his or her disability. Patients with psychiatric diagnoses require therapy from nurses specializing in psychiatric nursing or social workers, psychiatrists, or psychologists.

Many counseling techniques foster cognitive, behavioral, developmental, experiential, and emotional growth in patients. Counseling encourages individuals to examine available alternatives and decide which choices are useful and appropriate. When patients are able to examine alternatives, they develop a sense of control and are able to better manage stress.

Teaching

Patient education is key to patient-centered care (see Chapter 25). A teaching plan is essential, especially when patients are inexperienced and being asked to manage health problems they are facing for the first time. Counseling and teaching closely align. Both involve using good interpersonal skills to create a change in a patient's knowledge and behavior. Counseling results in changes in the development of new attitudes, behaviors, and feelings; whereas teaching focuses on intellectual growth or the acquisition of psychomotor skills.

When you educate patients, respect their expertise with their own health and symptoms, their daily routines, the diversity of their human experiences, their values and preferences as to how they learn, and the importance of shared decision making. As an educator you present health care principles, procedures, and techniques to inform patients about their health status in such a way that patients can adapt what they learn to their daily routines at home to achieve self-care. Emphasis has been placed on patient education in acute care recently because of the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS), a standardized survey used across the country by hospitals to measure patients' perspectives on hospital care (HCAHPS, 2014). The survey results currently are a standard for measuring and comparing quality of hospitals. Hospitals stress the importance of nurses addressing the topics covered by the survey, including patient education. Examples of questions on the HCAHPS include:

- How often did nurses explain things in a way you could understand?
- During this hospital stay did you get information in writing about which symptoms or health problems to look for after you left the hospital?
- Before giving you new medicine, how often did staff describe possible side effects in a way you could understand?

The HCAHPS initiative stresses the importance of patient education. But remember, teaching is an ongoing process of keeping patients

FIGURE 19-3 Nurse providing discharge instructions to patient and family.

informed. Patients want to know why you do what you do. When performing a procedure, engage your patient and explain the procedure, why it is being done and the expected outcomes, and any problems to look for afterwards. Encourage patients to ask questions. Here is an example of incorporating teaching in your daily work. When starting an intravenous (IV) infusion, explain what the IV fluid bag contains, how long the bag should last, sensations the patient will feel if the IV site becomes inflamed, the fact that a small flexible catheter is in the arm, and any potential side effects of medications in the bag.

Teaching takes place in all health care settings (Figure 19-3). As a nurse you are accountable for the quality of education you deliver. Know your patient; be aware of the cultural and social factors that influence a patient's willingness and ability to learn. It is also important to know your patient's health literacy level (see Chapter 25). Can he or she read directions or make calculations that often are necessary with self-care skills? Do not assume that patients understand their illness or disease. If they seem uneasy or refuse a treatment, simply ask what concerns them. This gives you the chance to provide further teaching and correct knowledge deficiencies.

Controlling for Adverse Reactions

An **adverse reaction** is a harmful or unintended effect of a medication, diagnostic test, or therapeutic intervention. Adverse reactions can result from any nursing intervention; thus learn to anticipate and know which adverse reactions to expect. Nursing actions that control for adverse reactions reduce or counteract a reaction. For example, when applying a moist heat compress, you know that burning the patient's skin is a possible adverse reaction unless you protect the skin. First assess the condition of the area where you plan to place the compress. Following application of the compress, inspect the area every 5 minutes for any adverse reaction such as excessive reddening of the skin from the heat or skin maceration from the moisture (see Chapter 48). Taking the right precautions can prevent adverse reactions.

When completing a health care provider–directed intervention such as medication administration, always know the potential side effects of the drug. After you administer a medication, evaluate the patient for adverse effects. Also be aware of drugs that counteract the side effects. For example, a patient has an unknown hypersensitivity to penicillin and develops hives after three doses. You record the reaction, stop further administration of the drug, and consult with the physician. You then administer an ordered dose of diphenhydramine (Benadryl), an antihistamine and antipruritic medication, to reduce the allergic response and relieve the itching.

BOX 19-4 Examples of Indirect Care Activities

- Documentation (electronic or written)
- Delegation of care activities to nursing assistive personnel (NAP)
- Medical order transcription
- Infection control (e.g., proper handling and storage of supplies, use of protective isolation)
- Environmental safety management (e.g., making patient rooms safe, strategically assigning patients in a geographical proximity to a single nurse)
- Telephone consultations with physicians and other health care providers
- Hand-off reports to other health care team members
- Collecting, labeling, and transporting specimens
- Transporting patients to procedural areas and other nursing units

From Bulechek GM, et al: *Nursing interventions classification (NIC)*, ed 6, St Louis, 2013, Mosby.

When caring for patients who undergo diagnostic tests, you need to understand the test and any potential adverse effects. For example, a patient has not had a bowel movement in 24 hours after a barium enema. Because bowel impaction is a potential side effect of a barium enema, you increase fluid intake and instruct the patient to let a nurse know when a bowel movement occurs. Although adverse effects are not common, they do occur. It is important that you recognize the signs and symptoms of an adverse reaction and intervene in a timely manner.

Preventive Measures

Preventive nursing actions promote health and prevent illness to avoid the need for acute or rehabilitative health care (see Chapter 2). Changes in the health care system are leading to greater emphasis on health promotion and illness prevention. Primary prevention aimed at health promotion includes health education programs, immunizations, and physical and nutritional fitness activities. Secondary prevention focuses on people who are experiencing health problems or illnesses and who are at risk for developing complications or worsening conditions. It includes screening techniques and treating early stages of disease. Tertiary prevention involves minimizing the effects of long-term illness or disability, including rehabilitation measures.

INDIRECT CARE

Indirect care measures are nursing actions that manage the patient care environment and interdisciplinary collaborative actions that support the effectiveness of direct care interventions (Bulechek et al., 2013). Many of the measures are managerial in nature such as emergency cart maintenance and environmental and supply management (Box 19-4). Nurses spend much time in indirect and unit management activities. Communication of information about patients (e.g., hand-off report, hourly rounding, and consultation) is critical, ensuring that direct care activities are planned, coordinated, and performed with the proper resources. Delegation of care to NAP is another indirect care activity (see Chapter 21). When performed correctly, delegation ensures that the right care provider performs the right tasks so the nurse and NAP work together most efficiently for a patient's benefit.

Communicating Nursing Interventions

Any intervention that you provide for a patient is communicated in an electronic, written, or oral format (see Chapter 26). Electronic health records (EHRs) or written charts have sections for individualized interventions that are part of the nursing care plan (see Chapter 18) and a patient's permanent medical record. The record entry usually includes a brief description of pertinent assessment findings, the specific intervention(s), and the patient's response. An EHR or written record validates that you performed a procedure and provides valuable information to subsequent caregivers about the approaches needed to provide successful care. Some institutions have **interdisciplinary care plans** (i.e., plans representing the contributions of all disciplines caring for a patient). You enter nursing interventions into the plan, documenting the treatment and patient's response (see Chapter 26).

Effective communication and good teamwork are ways to reduce medical errors and prevent adverse patient outcomes (ECRI, 2015). Miscommunication is often the root cause for most reported adverse or sentinel events that occur in health care organizations. Communication with other health care professionals needs to be timely, accurate, and relevant to a patient's clinical situation. Ineffective or incomplete communications result in caregivers being uninformed, interventions possibly duplicated needlessly, procedures possibly delayed, or tasks possibly left undone. Chapter 26 explains the approach for effective hand-off communication between two care providers. Always be clear, concise, and to the point when you communicate nursing interventions.

Delegating, Supervising, and Evaluating the Work of Other Staff Members

A nurse who develops a patient's care plan frequently does not perform all of the nursing interventions. Some activities you coordinate and delegate to other members of the health care team (see Chapter 21). Delegation requires clinical judgment and accountability for patient care (Weydt, 2010). The frequency and manner in which nursing care activities are delegated often depends on a nursing unit delivery of care model. Koloroutis et al. (2007) describe three approaches for delegation based on the way RN and NAP assignments are made.

- Unit-based scenario—NAP serves the unit. The NAP works off a task list usually found in the job description and has minimal direction from or interaction with RNs. Limited 1:1 delegation occurs. Lack of communication can cause conflicts.
- Pairing—One RN works with a licensed practical nurse (LPN) and/or a NAP for a shift. The RN and LPN and/or NAP are not intentionally scheduled to work the same shift each day. For a given shift they work together, or are paired, and care for the same group of patients. Delegation usually increases with pairing.
- Partnering—Involves one RN and one LPN and/or NAP who are consistently scheduled to work together. The partners commit to healthy interpersonal relationships, trust in one another, and advance each other's knowledge. It is recognized that the RN has the authority to make the delegation decisions.

Delegation allows you to use your time more wisely and to have NAP assist by performing noninvasive and frequently repetitive interventions such as skin care, ambulation, vital signs on stable patients, and hygiene measures. When you delegate tasks to NAP, you are responsible for ensuring that you assign each task appropriately and that the NAP completes each task according to the standard of care. You must be sure that any delegated action was completed correctly, documented, and evaluated. You only delegate direct care interventions to personnel who are competent.

ACHIEVING PATIENT GOALS

You implement interventions to achieve patient goals and expected outcomes. In most clinical situations multiple interventions are needed

to achieve select outcomes. In addition, patients' conditions often change minute by minute. Therefore it is important to apply principles of care coordination such as good time management, organizational skills, and appropriate use of resources to ensure that you deliver interventions effectively and meet desired outcomes (see Chapter 21). Priority setting is critical in successful implementation. Priorities help you to anticipate and sequence nursing interventions when a patient has multiple nursing diagnoses and collaborative problems (see Chapter 18).

Another way to help patients achieve their goals is to help them adhere to their treatment plan. **Patient adherence** means that patients and families invest time in carrying out required treatments. To ensure that patients have a smooth transition across different health care settings (e.g., hospital to home and clinic to home to assisted living), it is important to introduce interventions that patients are willing and able to follow. Adequate and timely discharge planning and education of a patient and family are the first steps in promoting a smooth transition from one health care setting to another or to the home. Effective discharge planning and education involve individualizing your care and taking into consideration the various factors that influence a patient's health beliefs (see Chapter 6). *For example, for Tonya to effectively help Mr. Lawson follow the activity limitations required after surgery, she needs to know if Mr. Lawson understands the risks to wound healing if limitations are not followed. His anxiety about being able to return to work on time will likely improve his motivation to adhere.* You are responsible for delivering interventions in a way that reflects your understanding of a patient's health beliefs, culture, lifestyle pattern, and patterns of wellness. In addition, reinforcing successes with the treatment plan encourages a patient to follow his or her care plan.

KEY POINTS

- Implementation, the fourth step of the nursing process, formally begins after a nurse develops a plan of care. The nurse then initiates interventions that are designed to achieve patient goals and expected outcomes.
- A direct care intervention is a treatment performed through interactions with a patient that include nurse-initiated, health care provider–initiated and collaborative approaches.
- Always think first and determine if an intervention is correct and appropriate and if you have the resources needed to implement it.
- Clinical guidelines or protocols are evidence-based documents that guide decisions and interventions for specific health care problems.
- Remaining competent and using good communication skills build your ability to participate in interdisciplinary practices.
- A clinical practice guideline establishes evidence-based interventions for specific health care problems or conditions.
- The implementation of nursing care often requires additional knowledge, nursing skills, and personnel resources.
- Before performing an intervention, make sure that a patient is as physically and psychologically comfortable as possible.
- Use good judgment during implementation to ensure that no nursing action is automatic.
- Know the purpose of each intervention, the associated preassessment and postassessment risks, steps in performing the intervention correctly, the current medical condition of a patient, and his or her expected response so you can anticipate what to expect in a given clinical situation and how to modify your approach.
- To anticipate and prevent complications, identify risks to a patient, adapt interventions to the situation, evaluate the relative benefit of a treatment versus the risk, and initiate risk-prevention measures.
- When you administer physical care techniques, protect yourself and the patient from injury, use proper infection control practices, stay organized, and follow applicable practice guidelines.
- When you delegate aspects of a patient's care, you are responsible for ensuring that each task is assigned appropriately and completed according to the standard of care.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Tonya responds to Mr. Lawson's call light and finds that he has questions about his medications before his discharge. She conducts further assessment and asks Mr. Lawson which questions he has regarding his home medication therapy. Tonya determines Mr. Lawson's knowledge of the medications and assesses his routines for eating meals and going to bed at home. Tonya positions the patient comfortably and checks his abdominal incision; she notices that the drainage has not increased. She explains the purpose, doses, and times for administration of the medicines. She asks Mr. Lawson to explain to her when he should take the medicines once he is at home. Tonya also reviews the signs and symptoms of wound infection.

1. Why does Tonya inspect the patient's incision when Mr. Lawson asked about his medications?
2. Why does Tonya assess Mr. Lawson's routines for eating meals and going to bed?
3. Tonya's explanation of the signs and symptoms of wound infection was an example of which aspect of organizing resources and care delivery?

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse working on a surgery floor is assigned five patients and has a patient care technician assisting her. Which of the following shows the nurse's understanding and ability to safely delegate to the patient care tech? (Select all that apply.)
   1. The nurse considers the time available to gather routine vital signs on one patient before checking on a second patient arriving from a diagnostic test.
   2. Determining what is the patient care technician's current workload.
   3. The nurse chooses to delegate the measurement of a stable patient's vital signs and not the assessment of the patient arriving from a diagnostic test.
   4. The nurse reviews with the NAP, newly hired to the floor, her experience in measuring a blood pressure.
   5. The nurse confers with another registered nurse about organizing priorities.
2. The nurse administers a tube feeding via a patient's nasogastric tube. This is an example of which of the following?
   1. Physical care technique
   2. Activity of daily living
   3. Indirect care measure
   4. Lifesaving measure
3. A nurse is caring for a complicated patient 3 days in a row. The nurse attends an interdisciplinary conference to discuss the

patient's plan of care. In which ways can the nurse develop trust with members of the conference team? (Select all that apply.)
1. Is willing to challenge other members' ideas because the nurse disagrees with their rationale
2. Shows competence in how to monitor patients' clinical status and inform the physician of critical changes
3. Asks a more experienced nurse to attend the conference
4. Listens to opinions of members of interdisciplinary team and expresses recommendations for care clearly
5. During the meeting focus on similar problems the nurse has had in delivering care to other patients.

4. Which principle is most important for a nurse to follow when using a clinical practice guideline for an assigned patient?
1. Knowing the source of the guideline
2. Reviewing the evidence used to develop the guideline
3. Individualizing how to apply the clinical guideline for a patient
4. Explaining to a patient the purpose of the guideline

5. A nurse is visiting a patient in the home and is assessing the patient's adherence to medications. While talking with the family caregiver, the nurse learns that the patient has been missing doses. The nurse wants to perform interventions to improve the patient's adherence. Which of the following will affect how this nurse will make clinical decisions about how to implement care for this patient? (Select all that apply.)
1. Reviewing the family caregiver's availability during medication administration times
2. Making a judgment of the value of improved adherence for the patient
3. Reviewing the number of medications and time each is to be taken
4. Determining all consequences associated with the patient missing specific medicines
5. Reviewing the therapeutic actions of the medications

6. The nurse enters a patient's room and finds that the patient was incontinent of liquid stool. Because the patient has recurrent redness in the perineal area, the nurse worries about the risk of the patient developing a pressure ulcer. The nurse cleanses the patient, inspects the skin, and applies a skin barrier ointment to the perineal area. The nurse consults the ostomy and wound care nurse specialist for recommended skin care measures. Which of the following correctly describe the nurse's actions? (Select all that apply.)
1. The application of the skin barrier is a dependent care measure.
2. The call to the ostomy and wound care specialist is an indirect care measure.
3. The cleansing of the skin is a direct care measure.
4. The application of the skin barrier is an instrumental activity of daily living.
5. Inspecting the skin is a direct care activity.

7. During the implementation step of the nursing process, a nurse reviews and revises a patient's plan of care. Place the following steps of review and revision in the correct order.
1. Modify care plan as needed.
2. Decide if the nursing interventions remain appropriate.
3. Reassess the patient.
4. Compare assessment findings to validate existing nursing diagnoses.

8. Before consulting with a physician about a female patient's need for urinary catheterization, the nurse considers the fact that the patient has urinary retention and has been unable to void on her

own. The nurse knows that evidence for alternative measures to promote voiding exists, but none has been effective, and that before surgery the patient was voiding normally. This scenario is an example of which implementation skill?
1. Cognitive
2. Interpersonal
3. Psychomotor
4. Consultative

9. Match the category of direct care on the left with the specific direct care activity on the right.
1. Counseling ___
2. Lifesaving measure ____
3. Physical care technique ___
4. Activity of daily living ____

a. Assisting patient with oral care
b. Discussing a patient's options in choosing palliative care
c. Protecting a violent patient from injury
d. Using safe patient handling during positioning of a patient

10. What is the importance of the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey?
1. Measures a nurse's competency in interdisciplinary care
2. Measures the number of adverse events in a hospital
3. Measures quality of care within hospitals
4. Measures referrals to a health care agency

11. **Fill in the Blank.** A nurse administered an antibiotic 30 minutes ago and returns to the patient's room to determine if the patient is having any unexpected symptoms. This is an example of assessing for a(n) _____.

12. Which measures does a nurse follow when being asked to perform an unfamiliar procedure? (Select all that apply.)
1. Checks scientific literature or policy and procedure
2. Reassesses the patient's condition
3. Collects all necessary equipment
4. Delegates the procedure to a more experienced nurse
5. Considers all possible consequences of the procedure

13. A nurse is conferring with another nurse about the care of a patient with a stage II pressure ulcer. The two decide to review the clinical practice guideline of the hospital for pressure ulcer management. The use of a standardized guideline achieves which of the following? (Select all that apply.)
1. Makes it quicker and easier for nurses to intervene
2. Sets a level of clinical excellence for practice
3. Eliminates need to create an individualized care plan for the patient
4. Delivers evidence-based interventions for stage II pressure ulcer
5. Summarizes the various approaches used for the practice concern or problem

14. A nurse reviews all possible consequences before helping a patient ambulate such as how the patient ambulated last time; how mobile the patient was before admission to the health care facility; or any current clinical factors affecting the patient's ability to stand, remain balanced, or walk. Which of the following is an example of a nurse's review of this situation?
1. Critical thinking
2. Managing an adverse event
3. Exercising self-discipline
4. Time management

15. A nurse collects equipment needed to administer an enema to a patient. Previously the nurse reviewed the procedure in the policy manual. The nurse raises the patient's bed and adjusts the room lighting to illuminate the work area. A patient care technician

comes into the room to assist. Which aspect of organizing resources and care delivery did the nurse omit?

1. Environment
2. Personnel
3. Equipment
4. Patient

Evaluation

Critical thinking in nursing practice influences a nurse's workplace performance and reflects his or her ability to resolve patients' health-related problems (Shu-Yuan et al., 2013). When you apply the nursing process to identify patient problems and select and deliver relevant interventions, the evaluation step determines if patient problems are resolved. The outcomes of nursing practice are the measurable conditions of patient, family, or community status; behavior; or perception. These outcomes are the criteria used to judge success in delivering nursing care.

When a repairman comes to a home to fix a leaking faucet, he turns the faucet on to determine the problem, changes or adjusts parts, and rechecks the faucet to determine if the leak is fixed. After a patient diagnosed with pneumonia completes a course of antibiotics, the health care provider often has him or her return to the office to have a chest x-ray film examination to determine if the pneumonia has resolved. When a nurse provides wound care, including application of a warm compress, several steps are involved. He or she assesses the appearance of the wound, determines its severity, applies the appropriate form of compress, and returns later to inspect the wound to determine if the condition has improved. These three scenarios depict what ultimately occurs during the process of evaluation. The repairman rechecks the faucet, the health care provider orders a chest x-ray film, and the nurse reinspects the patient's wound. Through the process of evaluation you determine if a patient has improved, resulting in a desired outcome.

The previous chapters on the nursing process describe how you apply critical thinking to gather patient data, form nursing diagnoses, develop a plan of care, and implement interventions. **Evaluation**, the final step of the nursing process, is crucial to determine whether, after application of the first four steps of the nursing process, a patient's condition or well-being improves. *You conduct evaluative measures to determine if your patients met expected outcomes, not if nursing interventions were completed.* The expected outcomes established during planning are the standards against which you judge whether goals have been met and if care is successful.

> In the continuing case study Mr. Lawson is going home in a couple of hours. Tonya organizes her care so she can take the time needed to evaluate the outcomes of her plan of care. Mr. Lawson took two doses of the prn analgesic ordered for his pain over the last 8 hours. Thirty minutes after the last dose he rated his pain a 3 on a scale of 0 to 10. He states, "I only really notice now when I move too quickly." Mrs. Lawson is in the room, so Tonya takes time to inspect and evaluate Mr. Lawson's wound, describes what she sees, and asks the Lawsons to explain the signs of infection and how to care for the wound at home. Tonya gives the Lawsons the discharge instruction sheet that is part of the standard of care of her nursing unit. She asks Mr. Lawson to explain the types of activity he needs to avoid for the first 2 weeks that he is home.

CRITICAL THINKING IN EVALUATION

Critical thinking is key to evaluation (Figure 20-1). In Chapter 15 you learned that clinical decision making is complex, requiring flexibility and the ability to know and recognize subtle changes or aspects of a patient's condition. In an extensive literature review of studies examining critical thinking indicators, Shu-Yuan et al. (2013) identified four indicators reflecting a nurse's ability to perform evaluation:
- Examine the results according to clinical data collected.
- Compare achieved effect with goals and expected outcomes.
- Recognize errors.
- Understand a patient situation, participate in self-reflection, and correct errors.

KNOWLEDGE
Characteristics of improved physiological,
psychological, spiritual, and sociocultural status
Expected outcomes of pharmacological, medical,
nutritional, and other therapies
Unexpected outcomes of pharmacological,
medical, nutritional, and other therapies
Characteristics of improved family and group
dynamics
Community resources

EXPERIENCE

FIGURE 20-1 Critical thinking and evaluation.

These indicators show that the evaluation process is comprehensive. It requires more than making a quick check of a patient to be sure that he or she is stable or without further problems. It is a methodical approach for determining if nursing implementation effectively influenced a patient's progress or condition favorably.

Examine Results

Evaluation is an ongoing process that occurs whenever you have contact with a patient. Once you deliver an intervention, you continuously examine results by gathering subjective and objective data from a patient, family, and health care team members. Tanner (2006) calls this *reflection-in-action* (i.e., a nurse is able to "read" a patient by reviewing assessment data and determine how the patient is responding). At the same time you review knowledge regarding a patient's current condition, the treatment, and the resources available for recovery. By reflecting on previous experiences caring for similar patients, you are in a better position to know how to evaluate your patient. You can anticipate what to evaluate.

The effective examination of results requires you to have an open mind, keen observation skills, and the ability to exhibit a neutral perspective (Shu-Yuan et al., 2013). Do not form a judgment about a patient's progress or response without gathering data pertinent to the health care problem. *For example, because Mr. Lawson is being discharged and there have been no delays, Tonya might assume that his pain is under control. However, until Tonya reassesses the patient's pain character and severity, evaluation is not complete.* Be thorough in gathering all clinical information needed to adequately evaluate a patient's condition.

FIGURE 20-2 Evaluative measures. Nurse evaluates patient's vital signs.

Evaluative Measures.   You examine the results of care by using **evaluative measures**, which are assessment skills and techniques (e.g., observations, physiological measurements, use of measurement scales, patient interview) (Figure 20-2). In fact, evaluative measures are the same as assessment measures, but you perform them at the point of care when you make decisions about a patient's status and progress (Table 20-1). The intent of assessment is to identify which, if any, problems exist. The intent of evaluation is to determine if the known problems have remained the same, improved, worsened, or otherwise changed.

TABLE 20-1	Evaluative Measures to Determine the Success of Goals and Expected Outcomes	
Goals	**Evaluative Measures**	**Expected Outcomes**
Patient's pressure ulcer will heal within 7 days.	Inspect color, condition, and location of pressure ulcer. Measure diameter of ulcer daily. Note odor and color of drainage from ulcer.	Erythema is reduced in 2 days. Diameter of ulcer decreases in 5 days. Ulcer has no drainage in 2 days. Skin overlying ulcer is closed in 7 days.
Patient will tolerate ambulation to end of hall by 11/20.	Palpate patient's radial pulse before exercise. Palpate patient's radial pulse 10 minutes after exercise. Assess respiratory rate during exercise. Observe patient for dyspnea or breathlessness during exercise.	Pulse remains below 110 beats/min during exercise. Pulse rate returns to resting baseline within 10 minutes after exercise. Respiratory rate remains within two breaths of patient's baseline rate. Patient denies feeling of breathlessness.

In many clinical situations it is important to collect evaluative measures over a period of time. You look for trends to determine if a pattern of improvement or change exists. A one-time observation of a pressure ulcer is insufficient to determine that the ulcer is healing. It is important to note a consistency in change. For example, over a period of 3 days is the pressure ulcer gradually decreasing in size, is the amount of drainage declining, and is the redness of inflammation resolving? Recognizing a pattern of improvement or deterioration allows you to reason and decide whether a patient's problems (expressed in nursing diagnoses) are resolved. This is very important in the home care or nursing home setting. It may take weeks or even months to determine if interventions led to a pattern of improvement. For example, when evaluating a patient's risk for falls over time, has the patient, family, or health care team successfully reduced fall risks in the home such as eliminating barriers in the home, removing factors impairing the person's vision, or providing direction for proper use of assistive devices?

It is important to use the right evaluative measure. For example, pain scales have been shown to be valid and reliable for assessing pain severity (see Chapter 44) and change over time. The European and National Pressure Ulcer Advisory Panels (EPUAP and NPUAP, 2009) have specific criteria for the accurate staging of a pressure ulcer (see Chapter 48) that allow you to identify if the condition of a treated ulcer has changed. By using the right measure you are more likely to accurately identify if there has been a change in a patient's condition.

Being able to evaluate behavioral change is more difficult. The information about behavior (e.g., taking medications correctly, following a diet) often relies on a patient's self-report. An example is any survey or interview that evaluates a patient's ability to perform self-care and achieve self-management. Self-report is a measure of a patient's own perceptions or beliefs and may not truly reflect if behavior has changed. Your willingness to use self-report as an outcome measure of behavior reflects trust in the patient. When using self-report, it is very important that the patient understands questions posed and why his or her response is important to gauge behavior change.

Much emphasis in health care today is on patients and their family caregivers to achieve self-management to improve the quality of their lives. The aim of self-management is to minimize the impact of chronic disease or sudden acute illness on physical health status and functioning and to enable people to cope with the psychological effects of an illness. *In Mr. Lawson's case, Tonya has planned and implemented educational interventions designed to improve his ability to adopt the behaviors needed for self-care, specifically to follow activity restrictions and perform correct wound care. Tonya evaluates the patient's ability by measuring what he is able to either explain or demonstrate.* There are relevant, objective, and appropriate evaluative indicators of

TABLE 20-2	Self-Management Evaluation
Evaluation Indicator	**Examples of Measures**
Self-Efficacy	General self-efficacy (GSE) scale, disease-specific self-efficacy scales (e.g., arthritis, cardiac); medication-adherence self-efficacy scale
Health Behavior	Adherence to medication schedule (e.g., pill count), demonstrated psychomotor skill (e.g., dressing change, self-injection), adherence to medical follow-up visits
Health Status	Clinical indicators (e.g., exercise tolerance, blood pressure control, blood glucose control (HgA1C)
Health Service Utilization	Readmission to hospital in 30 days Admission to Emergency Department
Quality of Life	Quality-of-life scales (e.g., for chronic illness, cancer, chronic pain)
Psychological Indicators	Perceived-stress scale, self-control (e.g., Impulsivity Teen Conflict survey),

self-management, including self-efficacy, health behavior or attitude, health status, health service use, quality of life, and psychological indicators (Du and Yuan, 2010) (Table 20-2).

During planning a valuable resource for selecting outcomes is the Nursing Outcomes Classification (NOC) (see Chapter 18). The classification offers a language for the evaluation step of the nursing process. The purposes of NOC are (1) to identify, label, validate, and classify **nurse-sensitive patient outcomes**; (2) to field test and validate the classification; and (3) to define and test measurement procedures for the outcomes and indicators using clinical data (Moorhead et al., 2013). Within the NOC taxonomy you can select outcomes specific for nursing interventions that relate to nursing diagnoses. The NOC classification offers nurse-sensitive outcomes for NANDA-International (NANDA-I) nursing diagnoses (Table 20-3). For each outcome there are specific recommended evaluative measures, called *evaluation indicators* (i.e., the patient's physical condition, behaviors, or perceptions that are measures of outcome achievement).

QSEN **QSEN: BUILDING COMPETENCY IN INFORMATICS**

Explain how the use of the NOC classification in an electronic health record could improve patient safety. How would such a system help you monitor patient outcomes?

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

Compare Achieved Effect with Goals and Outcomes. In Chapter 18 you learned that an expected outcome is a state, behavior, or perception that is measured along a continuum in response to a nursing intervention (Moorhead et al., 2013). During evaluation you perform evaluative measures that allow you to compare clinical data, patient behavior measures, and patient self-report measures collected before implementation with the evaluation findings gathered after administering nursing care. Next you evaluate whether the results of care match the expected outcomes and goals set for a patient. If outcomes are met, the overall goals for the patient also are met. Critical thinking directs you to analyze the findings from evaluation (Figure 20-3). Has the patient's condition improved? Is the patient able to improve, or are there physical factors preventing recovery? To what degree does this patient's motivation or willingness to pursue healthier behaviors influence responses to therapies?

TABLE 20-3 Linkages Between Nursing Outcomes Classification and Nursing Diagnoses

Nursing Diagnosis	Suggested Outcomes	Indicators (Examples)
Anxiety	Anxiety level	Ability to attend or concentrate Ability to learn Level of verbalized anxiety
Deficient Knowledge	Knowledge: treatment procedures Adherence behavior	Description of treatment procedures Description of prescribed activity Use of strategies to optimize health Performance of activities of daily living consistent with energy and tolerance

Adapted from Moorhead S, et al: *Nursing outcomes classification (NOC)*, ed 5, St Louis, 2013, Mosby.

Outcomes are statements of progressive, step-by-step physical, emotional, or behavioral responses that a patient needs to accomplish to achieve the goals of care. When your patients achieve outcomes, the related factors for a nursing diagnosis usually no longer exist. *In Mr. Lawson's case the nursing diagnosis of **Anxiety related to uncertainty over ability to return to work** has the goal of "Mr. Lawson will be able to assume activity restrictions at home." Tonya has planned and implemented nursing care to prepare Mr. Lawson for a smooth postoperative recovery. She implements interventions to minimize his anxiety and provides instruction about his activity restrictions so he will adhere to his treatment plan. The aim is to achieve adherence so return to work is a reasonable goal. Two of the expected outcomes for Mr. Lawson's goal include that the patient will maintain attention during instructional sessions and that patient will explain how activity restrictions aid recovery. Tonya uses evaluative measures, including observation of the patient's behavior during instruction and then patient self-report of what he understands about his activity restrictions. If Tonya's plan of care is successful, the related factor of "uncertainty over ability to return to work" was managed. Tonya will know that, because Mr. Lawson was able to attend during instruction and explain how adherence to activity restrictions will hasten his recovery, one source of anxiety has lessened.*

Interpreting and Summarizing Findings. A patient's clinical condition often changes during an acute illness. In contrast, chronic illness results in slow, subtle changes, although acute exacerbations can occur. When you evaluate the effect of interventions, you interpret or learn to recognize relevant evidence about a patient's condition, even evidence that sometimes does not match clinical expectations. By applying your clinical knowledge and experience, you recognize complications or adverse responses to illness and treatment in addition to expected outcomes.

Careful monitoring and early detection of problems are a nurse's first line of defense. Always make clinical judgments on the basis of your observations of what is occurring with a specific patient and not merely on what happens to patients in general. It is important to be detailed with your evaluation measures because change frequently

Gather objective and subjective data
Patient describes "tender or sore" as symptoms of wound infection.
Wife is able to describe symptoms of "redness, more swelling around stitches, and drainage."
Patient moves in chair by splinting incision.

Reflect on previous clinical experiences
Tonya has cared for patients who have been able to demonstrate learning following postoperative instruction and has cared for a patient who had difficulty learning until able to practice a skill.

Apply critical thinking attitudes
Tonya instructed the Lawsons with confidence and is being creative in letting Mrs. Lawson assist with the next dressing change.

Apply intellectual standards
Tonya wants the Lawsons' knowledge to be complete and asks Mr. Lawson about additional wound infection symptoms.

Review expected outcomes
Describe the signs and symptoms of wound infection.
Explain how activity affects wound healing.
Demonstrate a dressing change.

Were outcomes met?

Patient and wife described the signs and symptoms of wound infection and were able to explain effects of strain from lifting on incision line. Ability to change dressing will be evaluated further.

FIGURE 20-3 Critical thinking and the evaluation process.

TABLE 20-4	Examples of Objective Evaluation of Goal Achievement		
Goals	**Outcome Criteria**	**Patient Response**	**Evaluation Findings**
Patient will change surgical dressing correctly by 12/18.	Patient demonstrates correct hand hygiene by 12/16. Patient describes material to use in dressing change by 12/17. Patient demonstrates dressing change by 12/18.	Patient used antiseptic hand rub correctly to wash hands. Patient applied clean gauze correctly and taped securely in place over incision.	Patient shows progression toward outcomes and achieved desired behavior.
Patient's lungs will be free of secretions by 11/30.	Coughing is nonproductive by 11/29. Lungs are clear to auscultation by 11/30. Respirations are 20/min by 11/30.	Patient coughed frequently and productively on 11/29 following nebulization. Lungs were clear to auscultation on 11/30. Respirations were 18/min on 11/29.	Patient will require continued nebulizer therapy. Condition is improving.

is not obvious. Evaluations are patient specific, made on the basis of a close familiarity with each patient's behavior, physical status, and reaction to caregivers. Perceptive clinical judgment involves matching the results of evaluative measures with expected outcomes to determine whether or not a patient's status is improving. When interpreting findings, you compare a patient's behavioral responses, perceptions, and the physiological signs and symptoms you expect to see with those actually seen from your evaluation. Comparing expected and actual findings allows you to interpret and judge a patient's condition and whether predicted changes occurred (Table 20-4). Perform the following steps to objectively evaluate the degree of success in achieving outcomes of care:

1. Examine the outcome criteria to identify the exact desired patient behavior or response.
2. Evaluate a patient's actual behavior or response.
3. Compare the established outcome criteria with the actual behavior or response.
4. Judge the degree of agreement between outcome criteria and the actual behavior or response.
5. If there is no agreement (or only partial agreement) between the outcome criteria and the actual behavior or response, what is/are the barrier(s)? Why did they not agree?

Evaluation is easier to perform after you care for a patient over a long period. You are then able to make subtle comparisons of patient responses and behaviors. When you have not cared for a patient over an extended time, evaluation improves by referring to previous experiences or asking colleagues who are familiar with the patient to confirm evaluation findings. The accuracy of any evaluation improves when you are familiar with a patient's behavior and physiological status or have cared for more than one patient with a similar problem.

Remember to evaluate each expected outcome and its place in the sequence of care. If not, it is difficult to determine which outcome in the sequence was not met; therefore you cannot revise and redirect the plan of care at the most appropriate time.

Recognize Errors or Unmet Outcomes

During evaluation the recognition of errors or unmet outcomes requires you to have an open mind, to actively pursue truth, to be patient and confident, and to engage in self-reflection (Shu-Yuan et al., 2013). You cannot assume that your treatment approaches will be successful. You must apply your observational skills, critical thinking intellectual standards (see Chapter 15), and knowledge to recognize the actual results of your care. Reflection-in-action typically occurs when there is a trigger event (Tanner, 2006). The trigger often involves a breakdown or perceived breakdown in practice. For example, a nurse reviews results of evaluative measures and notes that an outcome has not been met. Or a nurse observes how a patient reacts to a treatment

---

BOX 20-1   EVIDENCE-BASED PRACTICE

Missed Care

PICO Question: In acute care settings which factors contribute to missed care involving adult patients?

Evidence Summary

Missed nursing care is any aspect of required patient care that is omitted or delayed (Kalisch et al., 2009). When nurses face the need to rethink priorities, manage the complexity of the nursing process for multiple patients, and deal with internal perceptions and values, the result is often delay in care, abbreviated care, or missed care. In a study by Kalisch and Lee (2010), teamwork alone accounted for about 11% of missed nursing care. In a study involving focus groups with staff nurses, nine themes of regularly missed nursing care included ambulation, turning, feedings, patient teaching, discharge planning, emotional support, hygiene, intake and output, documentation, and surveillance (evaluation) (Kalisch, 2006). These areas of omitted nursing care can influence patient outcomes negatively.

Application to Nursing Practice

- Work with team members and assign patients by acuity and geographical proximity rather than just by number.
- Learn to delegate effectively (see Chapter 21) and manage conflict when disagreements develop between colleagues.
- Teamwork requires accountability; responsibility; and a commitment to ongoing, clear communication.
- Review your plan of care routinely to minimize delays or omissions.

(e.g., exercise, positioning, or teaching) and realizes that the approach is ineffective. A final example is a nurse reviewing a patient's progress and identifying that planned interventions were not completed, often described in the literature as "missed care" (Box 20-1). Reflection-in-action involves a nurse's ability to recognize how a patient is responding and then adjust interventions as a result (Tanner, 2006). A nurse will change the frequency of an intervention, change how the intervention is delivered, or select a new intervention.

The nursing process is a systematic, problem-solving approach to individualized patient care, but many factors affect each patient with health care problems. Often you will discover patients who have unmet needs. Patients with the same health care problem are not treated the same way. As a result you sometimes make errors in judgment. The systematic use of evaluation provides a way for you to catch these errors. By consistently incorporating evaluation into practice, you minimize errors and ensure that a patient's plan of care is appropriate and relevant and changes according to met and unmet needs.

Self-Reflection and Correction of Errors

Reflection-in-action and subsequent clinical learning are also important parts of evaluation. What a nurse gains from caring for patients and carefully evaluating the outcomes of care later contributes to ongoing clinical knowledge development and capacity for making clinical judgments in the future (Tanner, 2006). Reflective reasoning improves the accuracy of making diagnostic conclusions (Mamede et al., 2012). This means that, when you gather evaluative measures about a patient, reflection on the findings and exploration about what the findings mean improve your ability to problem solve. Reflection lessens the likelihood that reasoning is based on assumptions or guesswork and increases the likelihood that it is based on objective critical thinking.

Care Plan Revision

As you evaluate patient care, your reflection-in-action helps you determine if the plan of care continues or if revisions are necessary. If your patient meets a goal successfully, discontinue that part of the care plan. Unmet and partially met goals require you to continue intervention. It also may be appropriate to modify or add nursing diagnoses for a new plan of care with appropriate goals, expected outcomes, and interventions. You must sometimes redefine priorities according to changes in patient condition, evaluation findings, or changes in the medical plan of care. An important step in critical thinking is knowing how a patient is progressing and how problems resolve, change, or worsen.

Tonya evaluates Mr. Lawson's understanding of how activity restrictions aid recovery. The patient explained the following, "My doctor doesn't want me to do any heavy lifting." As Tonya listens to Mr. and Mrs. Lawson discuss going home, Mrs. Lawson comments, "It will be great for my husband to see the grandkids soon. He's really close to them. He loves playing with the 3-year-old." Tonya uses the evaluative measure of patient self-report to determine what Mr. Lawson understands about his activity restrictions. She recognizes that playing with grandkids could involve picking up the children. *Tonya decides to modify her plan of care by reassessing the types of activities Mr. Lawson does at home (e.g., type of lifting, exercise, manual work) and adapting her instructions to be more comprehensive.*

Discontinuing a Care Plan. After you determine that your patient met expected outcomes and goals, confirm your evaluation with the patient when possible. If you and the patient agree, you discontinue that part of the care plan. Documentation of a discontinued plan ensures that other nurses will not unnecessarily continue interventions. Continuity of care assumes that care provided to patients is relevant and timely. You waste much time and energy when you do not communicate achieved goals with other nurses.

Modifying a Care Plan. When patients do not meet goals and outcomes, you identify the factors that interfere with their achievement. Usually a change in a patient's condition, needs, or abilities makes alteration of the care plan necessary. For example, when teaching self-administration of insulin, a nurse discovers that a patient has developed a new problem, a tremor associated with a side effect of a medication. The patient is unable to draw medication from a syringe or inject the needle safely. As a result, the original outcomes, "Patient correctly prepares insulin in a syringe," and "Patient administers insulin injection independently," are no longer appropriate because they cannot be met. The nurse introduces new interventions (instructing a family member in insulin preparation and administration) and revises outcomes, "Family caregiver correctly prepares insulin in

syringe," and "Family caregiver administers insulin injection correctly," to meet the goal of care.

At times a lack of goal achievement results from an error in nursing judgment or failure to follow each step of the nursing process. Patients often have multiple and complex problems. Always remember the possibility of overlooking or misjudging something. When a goal is not met, no matter what the reason, repeat the nursing process sequence for that nursing diagnosis. Reassess the patient; determine accuracy of the nursing diagnosis; and establish a plan with new goals, expected outcomes, and appropriate priority interventions.

Reassessment. If a nursing diagnosis is unresolved or if you determine that perhaps a new problem has developed, reassessment is necessary. A complete reassessment of patient factors relating to an existing nursing diagnosis and etiology is necessary when modifying a plan. Apply critical thinking while comparing new data about a patient's condition with previously assessed information. Knowledge from previous experiences helps you direct the reassessment process. Caring for patients and families who have had similar health problems gives you a strong background of knowledge to use for anticipating patient needs and knowing what to assess. Reassessment ensures that the database is accurate and current. It also reveals a missing link (i.e., a critical piece of new information that was overlooked and thus interfered with goal achievement). You sort, validate, and cluster all new data to analyze and interpret differences from the original database (see Chapter 16). You also document reassessment data to alert other nursing staff and collaborative health care providers to the patient's status.

Redefining Diagnoses. After reassessment determine which nursing diagnoses are accurate for the situation. Ask yourself whether you selected the correct diagnosis and if the etiological factor is accurate and current. Then revise the problem list to reflect the patient's changed status. Sometimes you form a new diagnosis, or the prioritizing of diagnoses change. You base your nursing care on an accurate list of nursing diagnoses. Accuracy is more important than the number of diagnoses selected. As a patient's condition changes, the diagnoses also change.

Goals and Expected Outcomes. When revising a care plan, review the goals and expected outcomes for necessary changes. For example, does the time frame for outcomes need to be revised? Have certain outcomes been met and others only partially met? Does your reassessment reveal a goal that is unrealistic? Examine the appropriateness of goals for any unchanged nursing diagnoses and remember that a change in one health care problem sometimes affects the goals for others. *In Mr. Lawson's case, if his anxiety were to worsen again, Tonya likely would not only have to revise the plan for managing the anxiety but also consider if her selection of teaching strategies also needs to be changed.* Determining that each goal and expected outcome is realistic for the problem, etiology, and time frame is particularly important. Unrealistic expected outcomes and time frames make goal achievement difficult.

Clearly document goals and expected outcomes for new or revised nursing diagnoses so all team members are aware of the revised care plan. When the goal is still appropriate but has not yet been met, try changing the evaluation criteria to allow more time. You may also decide at this time to change interventions that are more individualized to a patient need or status.

Interventions. The evaluation of interventions examines two factors: the appropriateness of the intervention selected and the correct application of the intervention. Appropriateness is based on the standard of care for a patient's health problem. A **standard of care** is the minimum level of care accepted to ensure high quality of patient care. Standards of care define the types of therapies typically administered to patients with defined problems or needs. For example, if a patient who is receiving chemotherapy for leukemia has the nursing diagnosis

Acute pain related to oral mucosa inflammation from mucositis, the standard of care established by the nursing department for this problem includes pain-control measures, mouth care guidelines, and diet therapy. Professional organizations such as the Oncology Nursing Society often have clinical guidelines as standards of care for select health problems. The nurse reviews the standard of care and decides which interventions have been chosen and whether additional ones are required to achieve expected outcomes.

Increasing or decreasing the frequency of interventions is another approach to ensure appropriate application of an intervention. You adjust interventions on the basis of a patient's actual response to therapy and your previous experience with similar patients. For example, if a patient continues to have congested lung sounds, you increase the frequency of coughing and deep-breathing exercises to remove secretions and add positioning to ensure airway clearance.

During evaluation you find that some planned interventions are designed for an inappropriate level of nursing care. If you need to change the level of care, substitute a different action verb such as *assist* in place of *provide* or *demonstrate* in place of *instruct.* For example, assisting a patient to walk requires a nurse to be at the patient's side during ambulation, whereas providing an assistive device (e.g., a cane or walker) suggests that the patient is more independent. In addition, demonstration requires you to show a patient how a skill is performed rather than simply telling the patient how to perform it. Sometimes the level of care is appropriate, but the interventions are unsuitable because of a change in the expected outcome. In this example discontinue the interventions and plan new ones.

Make any changes in the plan of care on the basis of the nature of a patient's unfavorable response. Consulting with other health care team members often yields suggestions for improving the care delivery approach. Experienced nurses are often excellent resources and can provide valuable insight. Simply changing a care plan is not enough. Implement the new plan and reevaluate the patient's response to the nursing actions. *Evaluation is continuous, occurring through each step of the nursing process.*

STANDARDS FOR EVALUATION

Nursing care helps patients resolve actual health problems, prevent the occurrence of potential problems, and maintain a healthy state. Evaluation is an integral step to that end. The American Nurses Association (ANA) defines standards of professional nursing practice (see Chapter 1), which include standards for the evaluation step of the nursing process. The standards are authoritative statements of the duties that all registered nurses, regardless of role, patient population they serve, or specialty, are expected to perform competently (ANA, 2010). The competencies for evaluation include being systematic and using criterion-based evaluation, collaborating with patients and health care professionals, using ongoing assessment data to revise a plan, and communicating results to patients and families. Always deliver interventions responsibly and appropriately to minimize unwarranted or unwanted treatment (ANA, 2010).

Collaborate and Evaluate Effectiveness of Interventions

An important aspect of evaluation is collaboration. Patient-centered care is only achieved when a patient and family are actively involved in the evaluation process. This requires you to consider what is important to your patients, including their values, preferences, and expressed needs. When you develop patient care goals and expected outcomes with patients, they are an important resource for being able to tell you if outcomes are being met. They are able to share their perspective of whether an intervention is successful. For example, a patient knows best if pain has lessened or if breathing is easier. The same holds true for the family, who often can recognize changes in patient behavior sooner than you can because of their familiarity with the patient.

It is essential for nurses to collaborate closely with all members of the health care team during evaluation. Successful collaboration involves interactions in which professionals work together cooperatively with shared responsibility and interdependence toward achieving patient outcomes. Members of the health care team who contribute to the patient's care also gather evaluative findings. Communicating openly and on a regular basis with the health care team improves the likelihood of staying informed about a patient's responses to care.

Proper evaluation determines the effectiveness of nursing interventions. It is also important to evaluate whether each patient reaches a level of wellness or recovery that the health care team and patient established in the goals of the care plan. In addition, have you met the patient's expectations of care? Ask patients about their perceptions of care such as, "Did you receive the type of pain relief you expected?" "Did you receive enough information to change your dressing when you return home?" This level of evaluation determines the patient's satisfaction with care and strengthens partnering between you and the patient.

Document Results

Documentation and reporting are important parts of evaluation because it is crucial to share information about a patient's progress and current status. Accurate information needs to be present in a patient's medical record and shared during hand-off communication so nurses and other health care team members know if a patient is progressing and to make ongoing clinical decisions. In settings in which the same nurse will not be providing care throughout a patient's stay, it becomes very important to have consistent, thorough documentation of a patient's progress toward expected outcomes. The use of nursing diagnostic language and the Nursing Interventions Classification (NIC) and NOC is becoming more common in electronic medical records, improving the quality, consistency, and accuracy of what is documented. In addition, electronic systems provide linkages to make it easier to interpret cues regarding whether interventions led to expected patient outcomes. When documenting a patient's response to your interventions, describe the interventions, the evaluative measures used, the outcomes achieved, and the continued plan of care. *Here is an example of Tonya's documentation of evaluation of care:*

> *1430: Instructed patient on importance of handwashing and need to observe surgical wound daily for signs of redness or drainage from incision. Discussed ways to reduce strain on suture line by avoiding lifting any object over 20 lbs. Asked patient to describe when it is necessary to call doctor about wound. Patient and wife were able to identify signs of infection and occurrence of pain as reasons to notify doctor. Wife was able to demonstrate proper handwashing technique. Patient was able to verbalize several examples of objects not to lift (grandchild, groceries, trash). Provided patient additional instruction in form of pamphlet with outline of wound care steps. Will recommend to home health need to observe patient and wife perform wound care at home.*

Your aim in documenting is to present a clear argument from the evaluative data as to whether a patient is progressing or not.

One of the ANA standards for evaluation is to share results of care with patients and their families according to federal and state regulations (ANA, 2010). Keep patients and families informed about the patients' progress. Be aware of guidelines of your agency for the type of clinical information (e.g., diagnostic findings, results of treatment) that you can communicate.

KEY POINTS

- Evaluation is a step of the nursing process that includes two components: an examination of a condition or situation and a judgment as to whether change has occurred.
- During evaluation apply critical thinking to make clinical decisions and redirect nursing care to best meet patient needs.
- Positive evaluations occur when your patient meets desired outcomes and goals.
- Criterion-based standards for evaluation are the physiological, emotional, and behavioral responses that are a patient's goals and expected outcomes.
- Evaluative measures are assessment skills or techniques that you use to collect data for determining if outcomes were met.
- It sometimes becomes necessary to collect evaluative measures over time to determine if a pattern of change exists.
- When interpreting findings, you compare a patient's behavioral responses and the physiological signs and symptoms that you expect to see with those actually seen from your evaluation and judge the degree of agreement.
- Documentation of evaluative findings allows all members of the health care team to know whether or not a patient is progressing.
- A patient's nursing diagnoses, priorities, and interventions sometimes change as a result of evaluation.
- Evaluation examines two factors: the appropriateness of the interventions selected and the correct application of the intervention.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Tonya organizes herself so she can take the time needed to evaluate the outcomes of her plan of care. Mr. Lawson has the nursing diagnosis of *Acute Pain related to incisional trauma.* The patient has taken two doses of the prn analgesic ordered for his pain over the last 8 hours. Thirty minutes after the last dose Mr. Lawson rated his pain a 3 on a scale of 0 to 10; he states, "I only really notice now when I move too quickly." An outcome for the patient's goal of achieving pain relief is for pain scores to be at 4 or less. Mrs. Lawson is in the room, so Tonya takes time to give the Lawsons the discharge instruction sheet that is part of standard of care of her nursing unit. She asks Mr. Lawson to explain the types of activity he must avoid for the first 2 weeks he is at home.

1. Describe the type of evaluation measure Tonya uses when asking Mr. Lawson to explain the types of activities he should avoid. What limitations are there in using this type of evaluation measure?
2. Explain how Tonya can determine if the patient's nursing diagnosis of *Acute Pain* has been resolved. Describe how this affects her other priorities.
3. Explain how Tonya's evaluation of the patient's ability to learn about activity restrictions can be patient centered.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. For the nursing diagnosis of *Deficient Knowledge* a nurse selects an outcome from the Nursing Outcome Classification (NOC) of patient knowledge of arthritis treatment. Which of the following are examples of an outcome indicator for this outcome? (Select all that apply.)
   1. Nurse provides four teaching sessions before discharge.
   2. Patient denies joint pain following heat application.
   3. Patient describes correct schedule for taking antiarthritic medications.
   4. Patient explains situations for using heat application on inflamed joints.
   5. Patient explains role family caregiver plays in applying heat to inflamed joint.
2. A nurse in a community health clinic has been caring for a young teenager with asthma for several months. The nurse's goal of care for this patient is to achieve self-management of asthma medications. Identify appropriate evaluative indicators for self-management for this patient. (Select all that apply.)
   1. Quality of life
   2. Patient satisfaction
   3. Use of clinic services
   4. Adherence to use of inhaler
   5. Description of side effects of medications
3. A nurse caring for a patient with heart failure instructs the patient on foods to eat for a low-sodium diet. The nurse will perform which of the following evaluation measures to determine success of her instruction?
   1. Patient weight
   2. Asking patient to identify three low-sodium foods to eat for lunch
   3. A calorie count of food
   4. Patient description of how food selections are made
4. From the following list of indicators, determine which indicators are goals (**G**) and which indicators are outcomes (**O**).
   1. _____ Will achieve pain relief
   2. _____ Ambulates 10 feet down hallway
   3. _____ Will remain free of infection
   4. _____ Will be afebrile
   5. _____ Reports pain severity reduced from 6 to a 4 on scale of 0 to 10
   6. _____ Will gain improved mobility
5. A nurse has been caring for a patient over 2 consecutive days. During that time the patient has had an intravenous (IV) catheter in the right forearm. At the end of shift on the second day the nurse inspects the catheter site, observes for redness, and asks if the patient feels tenderness when the site is palpated. This is an example of which indicator reflecting the nurse's ability to perform evaluation:
   1. Examining results of clinical data
   2. Comparing achieved effects with outcomes
   3. Recognizing error
   4. Self-reflection
6. A patient has been febrile and coughing thick secretions; adventitious lung sounds indicate rales in the left lower lobe of the lungs. The nurse decides to perform nasotracheal suction because the patient is not coughing. The nurse inspects the mucus that is suctioned, which is minimal. The nurse again auscultates for lung sounds. Auscultation and mucus inspection are examples of:
   1. Evaluative measures.
   2. Expected outcomes.
   3. Reassessments.
   4. Reflection.
7. After caring for a young man newly diagnosed with diabetes, a nurse is reviewing what was completed in his plan of care following discharge. She considers how she related to the patient and whether she selected interventions best suited to his educational level. It was the nurse's first time caring for a new patient with

diabetes. The nurse's behavior is an example of which of the following?
1. Reflection-in-action
2. Reassessment
3. Reprioritizing
4. Reflection-on-action

8. A nurse has been caring for a patient over the last 10 hours. The patient's plan of care includes the nursing diagnosis of *Nausea related to effects of postoperative anesthesia.* The nurse has been asking the patient to rate his nausea over the last several hours after administering antiemetics and using comfort measures such as oral hygiene. The nurse reviews the patient's responses over the past 10 hours and notes how the patient's self-report of nausea has changed. This review an example of:
1. Comparing outcome criteria with actual response.
2. Gathering outcome criteria.
3. Evaluating the patient's actual response.
4. Reprioritizing interventions.

9. A faculty member is reviewing a nursing student's plan of care, including the interventions the student provided for a patient with dementia. The student reviewed clinical guidelines on a professional website to identify interventions successful in reducing wandering in patients with dementia. The faculty member should evaluate which of the following? (Select all that apply.)
1. Number of interventions
2. Appropriateness of the intervention for the patient
3. The prior use of interventions by other nursing staff
4. Correct application of the intervention for the patient care setting
5. The time it takes to provide interventions

10. A nurse enters a patient's room and begins a conversation. During this time the nurse evaluates how a patient is tolerating a new diet plan. The nurse decides to also evaluate the patient's expectations of care. Which statement is appropriate for evaluating a patient's expectations of care?
1. On a scale of 0 to 10 rate your level of nausea.
2. The nurse weighs the patient.
3. The nurse asks, "Did you believe that you received the information you needed to follow your diet?"
4. The nurse states, "Tell me four different foods included in your diet."

11. A nurse checks an intravenous (IV) solution container for clarity of the solution, noting that it is infusing into the patient's left arm. The IV solution of 9% NS is infusing freely at 100 mL/hr as ordered. The nurse reviews the nurses' notes from the previous shift to determine if the dressing over the site was changed as scheduled per standard of care. While in the room the nurse inspects the condition of the dressing and notes the date on the dressing label. In which ways did the nurse evaluate the condition of the IV site? (Select all that apply.)
1. Checked the IV infusion rate
2. Checked the type of IV solution
3. Confirmed from nurses' notes the time of dressing change
4. Inspected the condition of the IV dressing at the site
5. Checked clarity of IV solution

12. A patient is being discharged after treatment for colitis (inflammation of the colon). The patient has had no episodes of diarrhea or abdominal pain for 24 hours. Following instruction, the patient identified correctly the need to follow a low-residue diet and the types of food to include if a bout of diarrhea develops at home. These behaviors are examples of:
1. Evaluative measures.
2. Expected outcomes.
3. Reassessments.
4. Standards of care.

13. Which of the following does a nurse perform when discontinuing a plan of care for a patient?
1. Confirms with the patient that expected outcomes and goals have been met
2. Talks with the patient about reprioritizing interventions in the plan of care
3. Changes the frequency of interventions provided
4. Reassesses how goals were met

14. Purposes of the Nursing Outcomes Classification (NOC) include which of the following? (Select all that apply.)
1. To identify and label nurse-sensitive patient outcomes
2. To test the classification in clinical settings
3. To establish health care reimbursement guidelines
4. To identify nursing interventions for linked nursing diagnoses
5. To define measurement procedures for outcomes

15. Which of the following statements correctly describes the evaluation process? (Select all that apply.)
1. Evaluation is an ongoing process.
2. Evaluation usually reveals obvious changes in patients.
3. Evaluation involves making clinical decisions.
4. Evaluation requires the use of assessment skills.
5. Evaluation is only done when a patient's condition changes.

Answers: 1. 3, 4; **2.** 1, 3, 4; **3.** 2; 4. 1-goal, 2-outcome, 3-goal, 4-goal, 5-outcome, 6-goal; **5.** 1; **6.** 1; **7.** 4; **8.** 1; **9.** 2, 4; **10.** 3; **11.** 1, 4; **12.** 2; **13.** 1; **14.** 1, 2, 5; **15.** 1, 3, 4.

Managing Patient Care

As a nursing student it is important for you to acquire the necessary knowledge and competencies that ultimately allow you to practice as an entry-level staff nurse. The National Council of State Boards of Nursing (NCSBN) identified competencies that registered nurses (RNs) and licensed practical nurses (LPNs)/licensed vocational nurses (LVNs) need on entry to practice (Kearney, 2009) (Box 21-1). Regardless of the type of setting in which you eventually choose to work as a staff nurse, you will be responsible for using organizational resources, participating in organizational routines while providing direct patient care, using time productively and setting priorities, collaborating with all members of the health care team, and using certain leadership skills to manage others on the nursing team. The delivery of nursing care within a health care system is a challenge because of the changes that influence health professionals, patients, and health care organizations (see Chapter 2). However, change offers opportunities. As you develop the knowledge and skills to become a staff nurse, you learn what it takes to effectively manage the patients for whom you care and to take the initiative in becoming a leader among your professional colleagues.

BUILDING A NURSING TEAM

Nurses want to work within an institutional and unit culture that promotes autonomy and quality (Kramer et al., 2011). Nurses are self-directed and, with proper leadership and motivation, are able to solve most complex problems. A nurse's education and commitment to practicing within established standards and guidelines ensures a rewarding professional career. As a nurse it is also important to work in an empowering environment as a member of a solid and strong nursing team. A strong nursing team works together to achieve the best outcomes for patients. Effective team development requires team building and training, trust, communication, and a workplace that facilitates collaboration (Huber, 2014). Patient care units where teamwork is stronger had fewer reports and incidents of missed nursing care, leading to improved quality and safety of nursing care for patients (Kalisch and Lee, 2010). Stronger levels of teamwork among staff members have been found to contribute to higher levels of job satisfaction among nurses (Kalisch et al., 2010).

Building an **empowered** nursing team begins with the nurse executive, who is often a vice president or director of nursing. The executive's position within an organization is critical in uniting the strategic direction of an organization with the philosophical values and goals of nursing. The nurse executive is a clinical and business leader who is concerned with maximizing quality of care and cost-effectiveness while maintaining relationships and professional satisfaction of the staff. Perhaps the most important responsibility of the nurse executive is to establish a philosophy for nursing that enables managers and staff to provide quality nursing care. Box 21-2 identifies the characteristics of an effective nurse leader.

The nurse manager is critical to developing a successful unit that works together as a healthy team (LeBlanc, 2014). The nurse manager who uses **transformational leadership** is focused on change and innovation through team development, motivates and empowers staff to function at a high level of performance, and serves as a role model for the nurses on the unit (Smith, 2011). The TEEAMS approach is an approach that the nurse manager may use. In this approach the nurse manager spends *time* on the unit with the staff sharing ideas, *empowers* the staff, is *enthusiastic* about seeking opportunities to enhance the

BOX 21-1   Entry-Level Nurse Competencies

- Possess a systems focus to see the big picture.
- Understand the environment of care.
- Manage the care of patients.
- Prioritize basic patient care needs.
- Be able to critically think as demonstrated by assessment of problem, identification of solution, implementation of solution, evaluation of care, and follow-up of care.
- Communicate effectively with physicians and health care team members.
- Demonstrate nursing knowledge and display confidence in knowledge base.
- Work as a team member collaborating with health care team members.
- Have a patient orientation and focus with actions focused on patient and patient needs.
- Respect the rights, beliefs, wishes, and values of patients.
- Be a patient advocate.
- Recognize own limitations and see support of validation of decisions as needed.
- Demonstrate knowledge of roles, responsibilities, and functions of a nurse.

Modified from Kearney MH: Report of the findings from the post-entry competence study, Chicago, 2009, National Council of State Boards of Nursing; National Council of State Boards of Nursing: 2009 Tuning analysis: a comparison of US and international nursing educational competencies, Chicago, 2010, National Councils State Boards of Nursing.

BOX 21-2   Characteristics of an Effective Leader

- Is an effective communicator
- Is consistent in managing conflict
- Is knowledgeable and competent in all aspects of delivery of care
- Is a role model for staff
- Uses participatory approach in decision making
- Shows appreciation for a job well done
- Delegates work appropriately
- Sets objectives and guides staff
- Displays caring, understanding, and empathy for others
- Motivates and empowers others
- Is proactive and flexible
- Focuses on team development

Modified from Dunham-Taylor J: Quantum leadership: love one another. In Dunham-Taylor J, Pinczak JZ: *Financial management for nurse managers*, ed 2, Boston, 2010, Jones & Bartlett Publishers; Huber DL: *Leadership & nursing care management,* ed 5, St Louis, 2014, Elsevier.

team, shows *appreciation* and recognizes team members for a job well done, *manages* the team and holds team members accountable, and provides *support* in the stressful health care environment (LeBlanc, 2014). Together a manager and the nursing staff have to share a philosophy of care for their work unit. A philosophy of care includes the professional nursing staff's values and concerns for the way they view and care for patients. For example, a philosophy addresses the purpose of the nursing unit, how staff works with patients and families, and the standards of care for the work unit. Selection of a nursing care delivery model and a management structure that supports professional nursing practice are essential to the philosophy of care.

The nurse manager's leadership style impacts the work environment and patient outcomes. Nursing units where nurse managers use

BOX 21-3   EVIDENCE-BASED PRACTICE

Nurses Work Engagement

PICO Question: In hospitals are nurses who are highly engaged in their work more likely to remain in nursing than nurses who have lower levels of work engagement?

Evidence Summary

Work engagement is "a positive, fulfilling state of mind about work that is characterized by vigor, dedication and absorption" (Bargagliotti, 2012, p. 1414). Nurses who trust in an organization, the nurse leader or manager, and colleagues and have a high degree of nursing autonomy contribute to the nurses' work engagement (Bargagliotti, 2012; Cowden et al., 2011). Nurses who are engaged in their work were less likely to consider leaving their current position (Carter and Tourangeau, 2012; Cowden et al., 2011). Nurse leaders who use meaningful recognition as a way to recognize the extraordinary contributions of their nursing staff help develop a healthy work culture where nurses are more engaged (Lefton, 2012). Work engagement of nurses has a positive impact on a nursing unit and health care organization. Research has shown that, when there is a highly engaged nursing workforce, nurses had higher levels of personal initiative, making work engagement contagious. This contagiousness and spread of work engagement often leads to a decrease in patient mortality and complications and an increase in financial profitability of the health care organization (Bargagliotti, 2012). Work engagement is an important factor in the delivery of safe patient care.

Application to Nursing Practice

- Build positive relationships with colleagues on the nursing unit (Fasoli, 2010).
- Work with nurse leaders on the unit to develop a meaningful recognition program for nurses' extraordinary work (Lefton, 2012).
- Nurse managers need to focus on meeting needs of nursing staff (Cowden et al., 2011).
- Participate in shared governance and decision making at the unit level (Cowden et al., 2011)
- Participate in professional development activities that stimulate personal growth (Carter and Tourangeau, 2012).

transformational leadership styles have a shared vision that leads the unit to work toward the unit goals together, and staff members have job clarity that improves productivity and staff motivation (Holly and Igwee, 2011). Research supports that, on nursing units where the nurse manager uses transactional leadership, there is an increased level of patient satisfaction, a lower patient mortality rate, and a lower rate of medication errors (Wong et al., 2013). Transformational leadership practices of the nurse manager also lead to increased staff satisfaction, decreased stress and burnout in staff nurses, increased overall staff feeling of well-being, and staff retention (Weberg, 2010). Nurse managers who use these relational leadership styles create a positive work environment by providing support, encouragement, and constructive feedback to staff through open communication (Wong et al., 2013). A positive work environment engages nurses in their practice, promotes good working relationships among colleagues and a high morale level, and prompts nurses to take responsibility for their career development morale level (Fasoli, 2010) (Box 21-3).

Magnet Recognition

One way of creating an empowering work environment is through the Magnet Recognition Program (see Chapter 2). The Magnet Recognition Program is based on five model components—transformational leadership; structural empowerment; exemplary professional practice, new

knowledge, innovation, and improvements; and empirical quality results. A hospital that is Magnet certified has a transformed culture with a practice environment that is dynamic, autonomous, collaborative, and positive for nurses. The culture focuses on concern for patients. Typically a Magnet hospital has clinical promotion systems and research and evidence-based practice programs. The nurses have professional autonomy over their practice and control over the practice environment (Kramer et al., 2010). A Magnet hospital empowers a nursing team to make changes and be innovative. Professional nurse councils at the organizational and unit level are one way to create an empowerment model. This culture and empowerment combine to produce a strong collaborative relationship among team members and improve patient quality outcomes (ANCC, 2014).

Nursing Care Delivery Models

Ideally the philosophy that nurses greatly contribute to the quality care of patients guides the selection of a care delivery model. However, too often a lack of nursing resources and the goals of the business plan of the hospital influence the final choice of a model. A care delivery model needs to help nurses achieve desirable outcomes for their patients in the way that work is organized, the roles that each care provider assumes, or the way a nurse's responsibilities are defined. Nursing care delivery models contain the common components of nurse-patient relationship, clinical decision making, patient assignments and work allocation, interprofessional communication, and management of the environment of care (Huber, 2014).

Two traditional models that sometimes are used today in some health care institutions are team nursing and primary nursing. Team nursing developed in response to the severe nursing shortage following World War II. By 2000 the interprofessional team was a more common model (Yoder-Wise, 2014). In team nursing the RN is the leader who leads a team of other RNs, practical nurses, and nursing assistive personnel (NAP) who provide direct patient care. The primary nursing model of care delivery was developed to place RNs at the bedside and improve the accountability of nursing for patient outcomes and the professional relationships among staff members (Yoder-Wise, 2014). The model became more popular in the 1970s and early 1980s as hospitals began to employ more RNs. Primary nursing supports a philosophy regarding nurse and patient relationships. It is typically not practiced today because of the high cost of an all RN staffing model.

More common models used today are patient-centered care, total patient care, and case management. **Patient- and family-centered care** is a model of nursing care in which mutual partnerships among the patient, family, and health care team are formed to plan, implement, and evaluate the nursing and health care delivered (IPFCC, 2010; Mastro et al., 2014). At the center of patient-centered care is the patient or family member as the source of control and full partner in providing care (QSEN Institute, 2014). The Institute for Patient-and Family-Centered Care identified four core concepts for patient-centered care (IPFCC, 2010; Mastro et al., 2014): (1) *respect and dignity,* ensuring that the care provided is given on the basis of a patient's and family's knowledge, values, beliefs, and cultural backgrounds; (2) *information sharing,* meaning that health care providers communicate and share information so patients and families receive timely, complete, and accurate information to effectively participate in care and decision making; (3) *participation,* whereby patients and families are encouraged and supported in participating in care and decision-making; and (4) *collaboration,* demonstrated by the health care leaders collaborating with patients and families in policy and program development, implementation, and evaluation and patients who are fully engaged in their health care. Nurses support and promote patient engagement and empowerment through the use of patient- and family-centered

communication, bedside shift report, and patient- and family-centered interprofessional rounds (Mastro et al., 2014).

Total patient care delivery was the original care delivery model developed during Florence Nightingale's time. In this model the RN is responsible for all aspects of care for one or more patients during a shift of care, working directly with patients, families, and health team members. There is a high degree of collaboration among health care team members. The model disappeared in the 1930s and became popular again during the 1970s and 1980s when the number of RNs increased; it is primarily found in critical care areas (Yoder-Wise, 2014).

Case management is a care-management approach designed to coordinate and link health care services across all levels of care for patients and their families while streamlining costs and maintaining quality (Yoder-Wise, 2014) (see Chapter 2). The case-management system is focused on achieving patient outcomes within effective time frames and with available resources (Huber, 2014). The Case Management Society of America (2012) defines case management as "a collaborative process of assessment, planning, facilitation, and advocacy for options and services to meet an individual's health needs through communication and available resources to promote quality cost-effective outcomes." Effective case management delivery is important; and there have been many initiatives to support case management because of hospitals' need to improve patient outcomes such as reduction of 30-day readmissions. Case management is unique because clinicians, either as individuals or as part of a collaborative group, oversee the management of patients with specific, complex health problems or are held accountable for some standard of cost management and quality.

For example, a case manager coordinates a patient's acute care in the hospital and follows up with the patient after discharge, either to home, rehabilitation, or a long-term care setting. Case managers do not provide direct care but instead work with and collaborate with direct-care providers about the care delivered by other staff and health care team members and actively coordinate patient discharge planning. Ongoing communication with team members facilitates a patient's transition to home. In this situation the case manager helps the patient identify health needs, determine the services and resources that are available, and make cost-efficient choices (Yoder-Wise, 2014). The case manager frequently oversees a caseload of patients with complex nursing and medical problems. Often he or she is an advanced practice nurse who, through specific interventions, helps to improve patient outcomes, optimize patient safety by facilitating care transitions, decrease length of stay, and lower health care costs.

Decision Making

With a philosophy for nursing established, it is the manager who directs and supports staff in the realization of that philosophy. The nurse executive supports managers by establishing a structure that helps to achieve organizational goals and provide appropriate support to care delivery staff. It takes a committed nurse executive, an excellent manager, and an empowered nursing staff to create an enriching work environment in which nursing practice thrives. Decision-making is a critical component of an effective leader and manager (Huber, 2014).

Decentralization is a component of the hierarchical level of decision making found in health care institutions (Huber, 2014). Higher degrees of decentralization take the decision making down to the lower levels of the health care institution and have less supervision of the decision-making process (Huber, 2014). More and more health care institutions have moved the decision making down to the level of staff. This type of decision-making structure has the advantage of creating an environment in which managers and staff become more actively

involved in shaping the identity and determining the success of a health care organization. Working in a decentralized structure has the potential for greater collaborative effort, increased competency of staff, increased staff motivation, and ultimately a greater sense of professional accomplishment and satisfaction.

Progressive organizations achieve more when employees at all levels are empowered and actively involved. As a result, the role of a nurse manager is critical in the management of effective nursing units or groups. Box 21-4 highlights the diverse responsibilities of nursing managers. To make shared decision making work, managers need to know how to move it down to the lowest level possible. On a nursing unit it is important for all nursing staff members (RNs, LPNs, and LVNs), nursing assistants, and unit secretaries to become engaged. They need to be kept well informed. They also need to be given the opportunity by managers to participate in problem-solving activities related to direct patient care and unit activities. This high level of employee engagement in shared governance is a key factor in promoting teamwork and collaboration on the nursing unit (LeBlanc, 2014; Smith, 2011). Important elements of the decision-making process are responsibility, autonomy, authority, and accountability (Yoder-Wise, 2014).

Responsibility refers to the duties and activities that an individual is employed to perform. A position description outlines a professional nurse's responsibilities. Nurses meet these responsibilities through participation as members of a nursing unit.

Responsibility reflects ownership. An individual who manages employees distributes responsibility, and the employees have to accept the manager's direction. Managers need to ensure that staff clearly understand their responsibilities, particularly in the face of change. For example, when hospitals participate in work redesign, patient care delivery models change significantly. A manager is responsible for clearly defining an RN's role within a new care delivery model. If decentralized decision making is in place, the professional nursing staff has a voice in identifying the new RN role. Each RN on the team is responsible for knowing his or her role and how to perform that role on the busy nursing unit. For example, nurses are responsible for completing a nursing assessment of all assigned patients and developing a plan of care that addresses each of the patient's nursing diagnoses (see Chapters 15 to 20). As the staff implements the plan of care, the nurse evaluates whether the plan is successful. This responsibility becomes a work ethic for the nurse in delivering excellent patient care.

Autonomy is freedom of choice and responsibility for the choices (Yoder-Wise, 2014). Autonomy consistent with the scope of professional nursing practice maximizes a nurse's effectiveness (Yoder-Wise, 2014). With clinical autonomy a professional nurse makes independent decisions about patient care (i.e., planning nursing care for a patient within the scope of professional nursing practice). The nurse implements independent nursing interventions (see Chapter 19). Another type of autonomy for nurses is work autonomy. In work autonomy a nurse makes independent decisions about the work of the unit such as scheduling or unit governance. Autonomy is not an absolute; it occurs in degrees. For example, a nurse has the autonomy to develop and implement a discharge teaching plan on the basis of specific patient needs for any hospitalized patient. He or she also provides nursing care that complements the prescribed medical therapy. Clear communication and organization of work to allow a nurse to act on nursing decisions using clinical judgment help to promote autonomy (Weston, 2010).

Authority refers to formal legitimate power to give commands and make final decisions specific to a given position (Huber, 2014). For example, a nurse managing the care of a patient discovers that one of the members of the health care team, the registered dietitian, did not follow through on a discharge teaching plan for an assigned patient. A nurse has the authority to consult a dietitian to learn why the recommendations on the plan of care were not implemented and to review the established plan with him or her to ensure that the recommended patient teaching is completed. The nurse is able to choose and recommend appropriate teaching strategies for the patient and for the other health care team members. The nurse has the final authority in selecting the best course of action for the patient's care.

Accountability refers to individuals being answerable for their actions. It means that as a nurse you take responsibility to provide excellent patient care by following standards of practice and institutional policies and procedures. You assume responsibility for the outcomes of the actions, judgments, and omissions in providing that care (Krautscheid, 2014). A nurse demonstrates accountability by doing his or her best each day. You are not accountable for the overall outcomes of patient care, but you are accountable for what you do (i.e., performing the nursing process, communicating effectively with health care team colleagues, and staying current on nursing practice issues).

A successful nursing unit supports the four elements of decision making: responsibility, autonomy, authority, and accountability. An effective nurse manager sets the same expectations for the staff in how decisions are made. The strong nurse manager is key in producing the environment that supports autonomy (Weston, 2010). Staff routinely meet to discuss and negotiate how to maintain an equality and balance in the elements. Staff members need to feel comfortable in expressing differences of opinion and challenging ways in which the team functions while recognizing their own responsibility, autonomy, authority, and accountability. Ultimately decentralized decision making helps create the philosophy of professional nursing care for the unit.

Staff Involvement. When transformational leadership and decentralized decision making exist on a nursing unit, all staff members actively participate in unit activities (Figure 21-1). Because the work environment promotes participation, all staff members benefit from the knowledge and skills of the entire work group. If the staff learns to value the pursuit of knowledge and the contributions of co-workers, better patient care is an outcome. Recognition of nurses' exceptional work with patients helps to reinforce these behaviors and create and maintain a healthy work environment (Lefton, 2012). Healthy work

FIGURE 21-1 Staff collaborating on practice issues. (From Yoder-Wise P: *Leading and managing in nursing,* ed 6, St Louis, 2015, Mosby.)

environments have nurses who are skilled in communication, true collaboration among health care team members in decision making, appropriate levels of staffing to meet patient needs, meaningful recognition of nurses, and a nurse leader engaged in authentic leadership (AACN, 2005). The use of transactional leadership practices positively impacts the work environment, resulting in greater nurse empowerment, improved culture and climate, increased nurses' research utilization, better teamwork between nurses and physicians, greater role clarity, and reduced conflict and ambiguity (Cummings et al., 2010). The nursing manager supports staff involvement through a variety of approaches:

1. **Establishing nursing practice through problem-solving committees or professional shared governance councils.** Chaired by senior clinical staff nurses, these groups establish and maintain care standards for nursing practice on their work unit. Shared governance is a dynamic process that promotes decision making, accountability, and empowerment in staff nurses and enables them to control their nursing practice (Huber, 2014; Kramer et al., 2010). Participation in shared governance empowers a nurse to make decisions and increases nurses' confidence in decision making and their autonomy (Huber, 2014; Newman, 2011). The committees review ongoing clinical care issues, identify problems, apply evidence-based practice in establishing standards of care, develop policy and procedures, resolve patient satisfaction issues, or develop new documentation tools. It is important for the committees to focus on patient outcomes rather than only work issues to ensure quality care on the unit. Quality of care is further improved when nurses control their own practice. The committee establishes methods to ensure that all staff have input or participation on practice issues. Managers do not always sit on a committee, but they receive regular reports of committee progress. The nature of work on the nursing unit determines committee membership. At times members of other disciplines (e.g., pharmacy, respiratory therapy, or clinical nutrition) participate in practice committees or shared governance councils.

2. **Interprofessional collaboration among nurses and health care providers.** Interprofessional collaboration among nurses and health care providers (e.g., medical doctors [MDs], physical therapists [PTs], respiratory therapists [RTs]) is critical to the delivery of quality, safe patient care and the creation of a positive work culture for practitioners (Andreatta, 2010; IECEP, 2011). Interprofessional collaboration involves bringing representatives of various disciplines together to work with patients and families to deliver quality care (see Figure 21-1) (IECEP, 2011). It involves more than having members of other disciplines present. Interprofessional collaboration involves all professions

bringing different points of view to the table to identify, clarify, and solve complex patient problems together, providing integrated and cohesive patient care (Legare et al., 2011). The nurse plays a unique role within the team and is often viewed as the team leader because it is the nurse who takes on the responsibilities of coordination of communication and patient care (Burzotta and Noble, 2011; Halabisky et al., 2010). Open communication, cooperation, trust, mutual respect, and understanding of team member roles and responsibilities are critical for successful interprofessional collaboration (Andreatta, 2010; Burzotta and Noble, 2011). A change in education and team training of health care practitioners is needed to build effective teams to improve interprofessional collaboration (Andreatta, 2010; Halabisky et al., 2010). The IECEP (2011) identified four competencies that health care practitioners need to bring to professional practice to be effective team members in interprofessional collaboration. The development of these competencies comes through interprofessional education. Competencies needed for effective interpersonal collaboration include:

- Work with individuals of other professions to maintain a climate of mutual respect and shared values.
- Use the knowledge of one's own role and those of other professions to appropriately assess and address the health care needs of patients and populations served.
- Communicate with patients, families, communities, and other health care professionals in a responsive and responsible manner that supports patient-centered care and a team approach to the maintenance of health and treatment of disease.

New graduate nurses often lack self-confidence and knowledge and experience fear when communicating with physicians and other members of the health care team (Plaff et al., 2014). Education, training, and role modeling are effective strategies that frequently help new graduates improve interprofessional collaboration (Robichaud et al., 2012). Apply relationship-building values and the principles of team dynamics to perform effectively in different team roles to plan and deliver patient- and population-centered care that is safe, timely, efficient, effective, and equitable.

3. **Interprofessional rounding.** Many institutions that are focused on patient- and family-centered care conduct interprofessional rounding to involve a patient and family in planning care and improving patient care coordination and communication among the health care team (Mastro et al., 2014). During rounding members of the team meet and share patient information, answer questions asked by other team members, discuss the patient's clinical progress and plans for discharge, and focus all team members on the same patient goals (Sharp, 2013). Interprofessional rounding helps decrease medical errors, decrease patient readmission rates, impact patient satisfaction, and improve quality of care (Begue et al, 2012; Townsend-Gervais et al., 2014). For interprofessional rounding to be successful, health care team members need to be flexible and open to ideas, questions, and suggestions offered by others.

4. **Staff communication.** A manager's greatest challenge, especially if a work group is large, is communication with staff. It is difficult to make sure that all staff members receive the same message (i.e., the correct message). In the present health care environment, staff quickly become uneasy and distrusting if they fail to hear about planned changes on their work unit. However, a manager cannot assume total responsibility for all communication. An effective manager uses a variety of

approaches to communicate quickly and accurately to all staff. For example, many managers distribute biweekly or monthly newsletters of ongoing unit or agency activities. Minutes of committee meetings are usually in an accessible location for all staff to read or are sent to individuals via email. When the team needs to discuss important issues regarding the operations of the unit, the manager conducts staff meetings. When the unit has practice- or quality-improvement committees, each committee member has the responsibility to communicate directly to a select number of staff members. Thus all staff members are contacted and given the opportunity for input.

5. **Staff education.** A professional nursing staff needs to always grow in knowledge. It is impossible to remain knowledgeable about current medical and nursing practice trends without ongoing education. A nurse manager is responsible for making learning opportunities available so staff members remain competent in their practice and empowered in their decision making (LeBlanc, 2014). This involves planning in-service programs, sending staff to continuing education classes and professional conferences, and having staff present case studies or evidence-based practice issues during staff meetings. Staff members are responsible for pursuing educational opportunities for relicensure/recertification and changing information regarding their patient population.

LEADERSHIP SKILLS FOR NURSING STUDENTS

It is important that as a nursing student you prepare yourself for leadership roles. This does not mean that you have to quickly learn how to lead a team of nursing staff. Instead first learn to become a dependable and competent provider of patient care. As a nursing student you are responsible and accountable for the care you give to your patients. Learn to become a leader by consulting with instructors and nursing staff to obtain feedback in making good clinical decisions, learning from mistakes and seeking guidance, working closely with professional nurses, and trying to improve your performance during each patient interaction. These skills require you to think critically and solve problems in the clinical setting. Thinking critically allows nurses to provide higher-quality care, meet the needs of patients while considering their preferences, consider alternatives to problems, understand the rationale for performing nursing interventions, and evaluate the effectiveness of interventions. Clinical experiences develop these critical thinking skills (Benner et al., 2010). Important leadership skills to learn include clinical care coordination, team communication, delegation, and knowledge building.

Clinical Care Coordination

You acquire necessary skills so you can deliver patient care in a timely and effective manner. In the beginning this often involves only one patient, but eventually it will involve groups of patients. Clinical care coordination includes clinical decision making, priority setting, use of organizational skills and resources, time management, and evaluation. The activities of clinical care coordination require use of critical reflection, critical reasoning, and clinical judgment (Benner et al., 2010). They are important first steps in developing a caring relationship with a patient. Use a critical thinking approach, applying previous knowledge and experience to the decision-making process (see Chapter 15).

Clinical Decisions. Your ability to make clinical decisions depends on application of the nursing process (see Chapters 16 to 20). When you begin a patient assignment, the first activity involves a focused but complete assessment of a patient's condition so you know the patient and make accurate clinical judgments about his or her nursing diagnoses and collaborative health problems (see Chapter 16) (Tanner, 2006). Knowing the patient involves more than gathering formal assessment data. It requires learning a patient's typical patterns of responses and his or her current situation and knowing the patient as an individual (Tanner, 2006). The initial contact with a patient is an important first step in developing a caring relationship. Encouraging patients to share their narrative of their health problems is very useful, such as "Tell me about how you are dealing with …", or "Can you share what has been your biggest problem since becoming ill?" After obtaining a thorough assessment and identifying a patient's diagnoses and problems, you develop a plan of care, implement nursing interventions, and evaluate patient outcomes. The process requires clinical decision making using a critical thinking approach (see Chapter 15).

If you do not make accurate clinical decisions about a patient, undesirable outcomes will probably occur. A patient's condition worsens or remains the same when you lose the potential for improvement. An important lesson in organizational skills is to be thorough. Learn to attend and listen to the patient, look for any cues (obvious or subtle) that point to a pattern of findings, and direct the assessment to explore the pattern further. Accurate clinical decision making keeps you focused on the proper course of action. Never hesitate to ask for assistance when a patient's condition changes.

Priority Setting. After forming a picture of a patient's total needs, you set priorities by deciding which patient needs or problems need attention first (see Chapter 18). Priority setting is not the ordering of a list of care tasks but an organization of a vision of desired outcomes for a patient. Symptom pattern recognition from your assessment database and certain knowledge triggers help you understand which diagnoses require intervention and the associated time frame to intervene effectively (Ackley and Ladwig, 2014). It is important to prioritize in all caregiving situations because it allows you to see relationships among patient problems and avoid delays in taking action that can lead to serious complications for a patient. If a patient is experiencing serious physiological or psychological problems, the priority becomes clear. You need to act immediately to stabilize his or her condition. Classify patient problems in three priority levels:

- High priority—An immediate threat to a patient's survival or safety such as a physiological episode of obstructed airway, loss of consciousness, or a psychological episode of an anxiety attack.
- Intermediate priority—Nonemergency, nonlife-threatening actual or potential needs that a patient and family members are experiencing. Anticipating teaching needs of patients related to a new drug and taking measures to decrease postoperative complications are examples of intermediate priorities.
- Low priority—Actual or potential problems that are not directly related to a patient's illness or disease. These problems are often related to developmental needs or long-term health care needs. An example of a low-priority problem is a patient at admission who will eventually be discharged and needs teaching for self-care in the home.

Many patients have all three types of priorities, requiring you to make careful judgments in choosing a course of action. Obviously high-priority needs demand immediate attention. When a patient has diverse priority needs, it helps to focus on his or her basic needs. For example, a patient who has just completed ambulation down the hall is short of breath. The dietary assistant arrives in the room to deliver a meal tray. Instead of immediately helping the patient with the meal, you position him comfortably in bed, offer basic hygiene measures,

and then evaluate his breathlessness. The patient likely becomes more interested in eating after he is more comfortable. He also is more receptive to any instruction you need to provide.

Eventually you will be required to meet the priority needs of a group of patients. This means that you need to know the priorities of each patient within the group, assessing each patient's needs as soon as possible while addressing high priorities first. To identify which patients require assessment first, rely on information from the change-of-shift report, your own most recent assessment of the patient, and information from the medical record. Over time you learn to spontaneously rank patients' needs by priority or urgency. Priorities do not remain stable but change as a patient's condition changes. It is important to think about the resources available, be flexible in recognizing that priority needs often change, and consider how to use time wisely.

You also make priorities on the basis of patient expectations. Sometimes you have established an excellent plan of care; however, if a patient is resistant to certain therapies or disagrees with the approach, you have very little success. Working closely with a patient and showing a caring attitude are important. Share the priorities you have defined with the patient to establish a level of agreement and cooperation.

Organizational Skills. Implementing a plan of care requires you to be effective and efficient. Effective use of time means doing the right things, whereas efficient use of time means doing things right. Learn to become efficient by combining various nursing activities (i.e., doing more than one thing at a time). For example, during medication administration or while obtaining a specimen, combine therapeutic communication, teaching interventions, and assessment and evaluation. Always establish and strengthen relationships with patients and use any patient contact as an opportunity to convey important information. Patient interaction gives you the chance to show caring and interest. Always attend to a patient's behaviors and responses to therapies to assess if new problems are developing and evaluate responses to interventions.

A well-organized nurse approaches any planned procedure by having all of the necessary equipment available and making sure that the patient is prepared. If the patient is comfortable and well informed, the likelihood that the procedure will go smoothly increases. Sometimes you require the assistance of colleagues to perform or complete a procedure. Keep the work area organized and complete preliminary steps before asking co-workers for assistance.

As you deliver care on the basis of established priorities, events sometimes occur within the health care setting that interfere with plans. For example, just as you begin to provide morning hygiene for a hospitalized patient, an x-ray film technician enters to take a chest x-ray film. Once the technician completes the x-ray film examination, a phlebotomist arrives to draw a blood sample. In this case your priorities conflict with the priorities of other health care personnel. It is important to always keep a patient's needs at the center of attention. If the patient experienced symptoms earlier that required a chest x-ray film and laboratory work, it is important to be sure that the diagnostic tests are completed. In another example a patient is waiting to visit family, and a chest x-ray film is a routine order from 2 days earlier. The patient's condition has stabilized, and the x-ray technician is willing to return later to shoot the film. In this case attending to the patient's hygiene and comfort so family members can visit is more of a priority.

Use of Resources. Appropriate use of resources is an important aspect of clinical care coordination. Resources in this case include

members of the health care team. In any setting the administration of patient care occurs more smoothly when staff members work together. Never hesitate to have staff help you, especially when there is an opportunity to make a procedure or activity more comfortable and safer for patients. For example, assistance in turning, positioning, and ambulating patients is frequently necessary when patients are unable to move. Having a staff member such as NAP assist with handling equipment and supplies during complicated procedures such as catheter insertion or dressing changes makes procedures more efficient. In addition, you need to recognize personal limitations and use professional resources for assistance. For example, you assess a patient and find relevant clinical signs and symptoms but are unfamiliar with the physical condition. Consulting with an experienced RN confirms findings and ensures that you take the proper course of action for the patient. A leader knows his or her limitations and seeks professional colleagues for guidance and support.

Time Management. Shorter hospital stays, early discharges, same-day surgeries, and increasing complexity of patients are examples that create stress for nurses as they work to meet patient needs. One way to manage this stress is through the use of time-management skills. These skills involve learning how, where, and when to use your time. Because you have a limited amount of time with patients, it is essential to remain goal oriented and use it wisely. You quickly learn the importance of using patient goals as a way to identify priorities. However, also learn how to establish personal goals and time frames. For example, you are caring for two patients on a busy surgical nursing unit. One had surgery the day before, and the other will be discharged the next day. Clearly the first patient's goals center on restoring physiological function impaired as a result of the stress of surgery. The second patient's goals center on adequate preparation to assume self-care at home. In reviewing the therapies required for both patients, you learn how to organize your time so the activities of care and patient goals are achieved. You need to anticipate when care will be interrupted for medication administration and diagnostic testing and when is the best time for planned therapies such as dressing changes, patient education, and patient ambulation. Delegation of tasks is another way to help improve time management.

One useful time-management skill involves making a priority to-do list (Thomack, 2012). When you begin working with a patient or patients, it helps to make a list that sequences the nursing activities you need to perform. The change-of-shift report helps to sequence activities on the basis of what you learn about a patient's condition and the care provided before you arrived on the unit. It is helpful to consider activities that have specific time limits in terms of addressing patient needs such as administering a pain medication before a scheduled procedure or instructing patients before their discharge home. You also analyze the items on the list that are scheduled by agency policies or routines (e.g., medications or intravenous [IV] tubing changes). Note which activities need to be done on time and which activities you can do at your discretion. You have to administer medication within a specific schedule, but you are also able to perform other activities while in the patient's room. Finally, estimate the amount of time needed to complete the various activities. Activities requiring the assistance of other staff members usually take longer because you have to plan around their schedules.

Good time management also involves setting goals to help you complete one task before starting another (Thomack, 2012). If possible, complete the activities started with one patient before moving on to the next. Care is less fragmented, and you are better able to focus on what you are doing for each patient. As a result, it is less likely that you will make errors. Time management requires you to anticipate the

BOX 21-5 Principles of Time Management

Goal setting: Review a patient's goals of care for the day and any goals you have for activities such as completing documentation, attending a patient care conference, giving a hand-off report, or preparing medications for administration.

Time analysis: Reflect on how you use your time. While working on a clinical area, keep track of how you use your time in different activities. This provides valuable information to reveal how well organized you really are.

Priority setting: Set the priorities that you have established for patients within set time frames. For example, determine when is the best time to have teaching sessions, plan ambulation, and provide rest periods on the basis of what you know about the patient's condition. For example, if a patient is nauseated or in pain, it is not a good time for a teaching session.

Interruption control: Everyone needs time to socialize or discuss issues with colleagues. However, do not let this interrupt important patient care activities such as medication administration (see Chapter 32), ordered treatments, or teaching sessions. Use time during report, mealtime, or team meetings to your advantage. In addition, plan time to help fellow colleagues so it complements your patient care schedule.

Evaluation: At the end of each day take time to think and reflect about how effectively you used your time. If you are having difficulties, discuss them with an instructor or a more experienced staff member.

---

activities of the day and combine activities when possible. When you practice good time management, you focus on organization and setting priorities. Other strategies include keeping your work area clean and clutter free and trying to decrease interruptions as you are completing tasks (Thomack, 2012). Box 21-5 summarizes principles of time management.

Evaluation. Evaluation is one of the most important aspects of clinical care coordination (see Chapter 20). It is a mistake to think that evaluation occurs at the end of an activity. It is ongoing, just like other steps of the nursing process. Once you assess a patient's needs and begin therapies directed at a specific problem area, immediately evaluate whether therapies are effective and the patient's response. The process of evaluation compares actual patient outcomes with expected outcomes. For example, a clinic nurse assesses a foot ulcer of a patient who has diabetes to determine if healing has progressed since the last clinic visit. When expected outcomes are not met, evaluation reveals the need to continue current therapies for a longer period, revise approaches to care, or introduce new therapies. As you care for a patient throughout the day, anticipate when to return to the bedside to evaluate care (e.g., 30 minutes after a medication was administered, 15 minutes after an IV line has begun infusing, or 60 minutes after discussing discharge instructions with the patient and family).

Keeping a focus on evaluation of a patient's progress lessens the chance of becoming distracted by the tasks of care. It is common to assume that staying focused on planned activities ensures that you will perform care appropriately. However, task orientation does not ensure positive patient outcomes. Learn that at the heart of good organizational skills is the constant inquiry into a patient's condition and progress toward an improved level of health.

Team Communication

Effective communication is critical to all teams (Haynes and Strickler, 2014). As a part of a nursing team, you are responsible for using open, professional communication. Regardless of the setting, an enriching professional environment is one in which staff members respect one another's ideas, share information, and keep one another informed.

On a busy nursing unit this means keeping colleagues informed about patients with emerging problems, physicians or other health care providers who have been called for consultation, and unique approaches that solved a complex nursing problem. Strategies to improve your communication with health care providers include addressing the colleague by name, having the patient and chart available when discussing patient issues, focusing on the patient problem, and being professional and assertive but not aggressive or confrontational. In a clinic setting it may mean sharing unusual diagnostic findings or conveying important information regarding a patient's source of family support. One way of fostering good team communication is by setting expectations of one another. A professional nurse treats colleagues with respect, listens to the ideas of other staff members without interruption, explores the way other staff members think, and is honest and direct while communicating. Part of good communication is clarifying what others are saying and building on the merits of co-workers' ideas (Yoder-Wise, 2014). An efficient team knows that it is able to count on all members when needs arise. Sharing expectations of what, when, and how to communicate is a step toward establishing a strong work team. Examples of communication tools that improve communication include briefings or short discussions among team members; group rounds on patients; callouts to share critical information such as vital signs with all team members at the same time; check backs to restate what a person has said to verify understanding of information; the two-challenge rule that allows concerns to be voiced twice, which allows all team members to voice concerns about safety; "CUS" words, which means "I'm **C**oncerned, I'm **U**ncomfortable, I don't feel this is **S**afe; and the use of Situation-Background-Assessment-Recommendation (SBAR) when sharing information (see Chapter 26) (Haynes and Strickler, 2014). When using electronic communication, it is important to communicate the appropriate information to the correct person, always maintaining patient privacy and confidentiality (NCSBN, 2011).

QSEN **QSEN: BUILDING COMPETENCY IN TEAMWORK AND COLLABORATION** The unit on which you are working just received the results of the Employee Opinion Survey that all staff members completed. The staff rated communication among team members as important, but satisfaction with communication was rated low. The unit nursing council has been charged with developing a plan to improve team communication. Which strategies does the council include in the plan?

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

Delegation

The art of effective delegation is a skill that you need to observe and practice to improve your own management skills. The American Nurses Association (ANA, 2012) defines **delegation** as transferring responsibility for the performance of an activity or task while retaining accountability for the outcome. The Nurse Practice Act of your state, along with principles of authority, accountability, and responsibility, is the basis for effective delegation (Plawecki and Amrhein, 2010; Weydt, 2010). Effective delegation results in achievement of quality, safe patient care; improved efficiency; increased productivity; empowered staff; and skill development of others (Mueller and Vogelsmeier, 2013). Asking a staff member to obtain an ordered specimen while you attend to a patient's pain medication request effectively prevents a delay in the patient gaining pain relief and accomplishes two tasks related to the patient. Delegation also provides job enrichment. You show trust in colleagues by delegating tasks to them and showing staff members that they are important players in the delivery of care.

Successful delegation is important to the quality of the RN-NAP relationship and their willingness to work together (Potter et al., 2010). Never delegate a task that you dislike doing or would not do yourself because this creates negative feelings and poor working relationships. For example, if you are in the room when a patient asks to be placed on a bedpan and there are no urgent care issues, you assist the patient rather than leave the room to find the nurse assistant. Remember that, even though the delegation of a task transfers the responsibility and authority to another person, you are accountable for the delegated task.

As a nurse you are responsible and accountable for providing care to patients and delegating care activities to the NAP. However, you do not delegate the steps of the nursing process of assessment, diagnosis, planning, and evaluation because these steps require nursing judgment (Duffy and McCoy, 2014). Patient teaching is also the responsibility of an RN and should not be delegated. Recognize that, when you delegate to the NAP, you delegate tasks, not patients. Do not give the NAP sole responsibility for the care of patients. Instead it is you as the professional nurse in charge of patient care who decides which activities the NAP performs independently and which the RN and NAP perform in partnership. One way to accomplish this is to have the RN and NAP conduct rounds together. You assess each patient as the NAP attends to basic patient needs. Care is delegated on the basis of assessment findings and priority setting. As an RN, you are always responsible for the assessment of a patient's ongoing status; but, if a patient is stable, you delegate vital sign monitoring to the NAP.

In most settings the RN is the one who decides when delegation is appropriate. The NCSBN (1995) provides some guidelines for delegation of tasks in accordance with an RN's legal scope of practice (Box 21-6). As the leader of the health care team, the RN gives clear

---

BOX 21-6   The Five Rights of Delegation

Right Task
The right tasks to delegate are ones that are repetitive, require little supervision, are relatively noninvasive, have results that are predictable, and have potential minimal risk (e.g., simple specimen collection, ambulating a stable patient, preparing a room for patient admission).

Right Circumstances
Consider the appropriate patient setting, available resources, and other relevant factors. In an acute care setting patients' conditions often change quickly. Use good clinical decision making to determine what to delegate.

Right Person
The right person is delegating the right tasks to the right person to be performed on the right person. A registered nurse (RN) knows which tasks to delegate to nursing assistive personnel (NAP) for each specific patient.

Right Direction/Communication
Give a clear, concise description of a task, including its objective, limits, and expectations. Communication needs to be ongoing between the RN and NAP during a shift of care.

Right Supervision/Evaluation
Provide appropriate monitoring, evaluation, intervention as needed, and feedback. NAP need to feel comfortable asking questions and seeking assistance.

Modified from The Council and American Nurses Association (ANA) and National Council of State Boards of Nursing (NCSBN): Joint statement on delegation, 2006, https://www.ncsbn.org/Delegation_joint_statement_NCSBN-ANA.pdf. Accessed March 28, 2015.

---

instructions, effectively prioritizes patient needs and therapies, and gives staff timely and meaningful feedback. NAPs respond positively when you include them as part of the nursing team.

Appropriate delegation begins with knowing which skills you are able to delegate. This requires you to be familiar with the Nurse Practice Act of your state, institutional policies and procedures, and the job description for NAPs provided by the institution (Duffy and McCoy, 2014). These standards help to define the necessary level of competency of the NAP and contain specific guidelines regarding which tasks or activities a nurse is able to delegate. The job description identifies any required education and the types of tasks the NAP can perform, either independently or with RN direct supervision. Institutional policy defines the amount of training required for the NAP. Procedures detail who is qualified to perform a given nursing procedure, whether supervision is necessary, and the type of reporting required. You need to have a means to easily access policies or have supervisory staff who inform you about the NAP's job duties.

As a professional nurse you cannot simply assign the NAP tasks without considering the implications. Assess the patient and determine a plan of care before identifying which tasks someone else is able to perform. When directing the NAP, determine how much supervision is necessary. Is it the first time the NAP performed the task? Does the patient present a complicating factor that makes the RN's assistance necessary? Does the NAP have prior experience with a particular type of patient in addition to having received training on the skill? The final responsibility is to evaluate whether the NAP performed the task properly and whether the desired outcomes were met.

Efficient delegation requires constant communication (i.e., sending clear messages and listening so all participants understand expectations regarding patient care) (Mueller and Vogelsmeier, 2013). Provide clear instructions and desired outcomes when delegating tasks. These instructions initially focus on the procedure itself, what will be accomplished, when it should be completed, and the unique needs of the patient. The RN also communicates when and which information to report such as expected observations and specific patient concerns (NCSBN, 2005). Communication is a two-way process in delegation; thus the NAP needs to have the chance to ask questions and have your expectations made clear (ANA and NCSBN, 2005; NCSBN, 2005). Conflict, which often impacts quality and patient safety, occurs between RNs and NAPs when there is little or poor communication (Kalisch, 2011; Potter et al., 2010). Hand-off disconnects from team member to team member, lack of knowledge about the workload of team members, and difficulties dealing with conflict are examples of communication failures that often result in delegation ineffectiveness and omissions of nursing care (Gravlin and Bittner, 2010). As you become more familiar with a staff member's competency, trust builds, and the staff member needs fewer instructions; but clarification of patients' specific needs is always necessary.

Important steps in delegation are evaluation of a staff member's performance, achievement of the patient's outcomes, the communication process used, and any problems or concerns that occurred (NCSBN, 2005). When a NAP performs a task correctly and does a good job, it is important to provide praise and recognition. If a staff member's performance is not satisfactory, give constructive and appropriate feedback. As a nurse, always give specific feedback regarding any mistakes that staff members make, explaining how to avoid the mistake or a better way to handle the situation. Giving feedback in private is the professional way and preserves the staff member's dignity. When giving feedback, make sure to focus on things that can be changed, choose only one issue at a time, and give specific details. Frequently when a NAP's performance does not meet expectations, it is the result of inadequate training or assignment of too many tasks. You may

discover the need to review a procedure with staff and offer demonstration or even recommend that additional training be scheduled with the education department. If too many tasks are being delegated, this might be a nursing practice issue. All staff need to discuss the appropriateness of delegation on their unit. Sometimes NAP need help to learn how to prioritize. In some cases you discover that you are over-delegating. It is your responsibility to complete documentation of the delegated task. Here are a few tips on appropriate delegation (Mueller and Vogelsmeier, 2013):

- *Assess the knowledge and skills of the delegatee:* Assess the knowledge and skills of the NAP by asking open-ended questions that elicit conversation and details about what he or she knows (e.g., "How do you usually apply the cuff when you measure a blood pressure?" or "Tell me how you prepare the tubing before you give an enema.")
- *Match tasks to the delegatee's skills:* Know which tasks and skills are in the scope of practice and job description for the team members to whom you delegate in your agency. Determine if personnel have learned critical thinking skills such as knowing when a patient is in harm or the difference between normal clinical findings and changes to report.
- *Communicate clearly:* Always provide clear directions by describing a task, the desired outcome, and the time period within which the NAP needs to complete the task. Never give instructions through another staff member. Make the person feel as though he or she is part of the team. Begin requests for help with please and end with thank you. For example, "I'd like you to please help me by getting Mr. Floyd up to ambulate before lunch. Be sure to check his blood pressure before he stands and write your finding on the graphic sheet. OK? Thanks."
- *Listen attentively:* Listen to the NAP's response after you provide directions. Does he or she feel comfortable in asking questions or requesting clarification? If you encourage a response, listen to what the person has to say. Be especially attentive if the staff member has a deadline to meet for another nurse. Help sort out priorities.
- *Provide feedback:* Always give the NAP feedback regarding performance, regardless of outcome. Let them know of a job well done. A "thank you" increases the likelihood of the NAP helping in the future. If an outcome is undesirable, find a private place to discuss what occurred, any miscommunication, and how to achieve a better outcome in the future.

Knowledge Building

As a professional nurse, recognize the importance of pursuing knowledge to remain competent. As an accountable nurse, you are responsible for lifelong learning and maintaining competency (Krautscheid, 2014). You need to maintain and continually improve your knowledge and skills. Lifelong learning allows you to continuously provide safe, effective, quality care. A leader recognizes that there is always something new to learn. Opportunities for learning occur with each patient interaction, each encounter with a professional colleague, and each meeting or class session in which health care professionals meet to discuss clinical care issues. People always have different experiences and knowledge to share. Ongoing development of skills in delegation, communication, and teamwork helps maintain and build competency (Gravlin and Bittner, 2010). In-service programs, workshops, professional conferences, professional reading, and collegiate courses offer innovative and current information on the rapidly changing world of health care. To be a safe and competent nurse you need to actively pursue learning opportunities, both formal and informal, and to share knowledge with the professional colleagues you encounter.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You are a staff nurse on a 32-bed cardiac step-down unit. You are assigned as the preceptor for Tony, RN, a new graduate nurse, who just started his nursing career on your floor.

1. You and Tony just received morning shift report on your patients. You are assigned the following patients. Which patient do you and Tony need to see first? Explain your answer.
   1. Mr. Dodson, a 52-year-old patient who was admitted yesterday with a diagnosis of angina pectoris. He is scheduled for a cardiac stress test at 0900.
   2. Mrs. Wallace, a 60-year-old patient who was transferred out of intensive care at 0630 today. She had uncomplicated coronary artery bypass surgery yesterday.
   3. Mr. Workman, a 45-year-old patient who experienced a myocardial infarction 2 days ago. He is complaining of chest pain rated as 6 on a scale of 0 to 10.
   4. Mrs. Harris, a 76-year-old patient who had a permanent pacemaker inserted yesterday. She is complaining of incision pain rated as a 5 on a scale of 0 to 10.
2. As you work with Tony on your unit, you notice that he has trouble with time-management skills when providing patient care. Which

strategies will you suggest to Tony to help him improve organization of his delivery of patient care?

3. Sonya, a nursing assistive personnel (NAP), is paired to work with you and Tony. You overhear Tony giving Sonya directions for what she needs to do. Tony says, "Sonya, assist Mrs. Harris in room 418 with her afternoon walk. Take her pulse before and after she walks and record it in her chart. I'll check with you when you're finished to see how she did." On the basis of what you know about delegation, did Tony give appropriate or inappropriate directions to Sonya? Provide rationale for your answer.

▊ REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. At 1200 the registered nurse (RN) says to the nursing assistive personnel (NAP), "You did a good job walking Mrs. Taylor by 0930. I saw that you recorded her pulse before and after the walk. I saw that Mrs. Taylor walked in the hallway barefoot. For safety, the next time you walk a patient, you need to make sure that the patient wears slippers or shoes. Please walk Mrs. Taylor again by 1500." Which characteristics of positive feedback did the RN use when talking to the nursing assistant? (Select all that apply.)
   1. Feedback is given immediately.
   2. Feedback focuses on one issue.
   3. Feedback offers concrete details.
   4. Feedback identifies ways to improve.
   5. Feedback focuses on changeable things.
   6. Feedback is specific about what is done incorrectly only.

2. As a nurse, you are assigned to four patients. Which patient do you need to see first?
   1. The patient who had abdominal surgery 2 days ago who is requesting pain medication
   2. A patient admitted yesterday with atrial fibrillation with decreased level of consciousness
   3. A patient with a wound drain who needs teaching before discharge in the early afternoon
   4. A patient going to surgery for a mastectomy in 3 hours who has a question about the surgery

3. A nurse asks a nursing assistive personnel (NAP) to help the patient in room 418 walk to the bathroom right now. The nurse tells the NAP that the patient needs the assistance of one person and the use of a walker. The nurse also tells the NAP that the patient's oxygen can be removed while he goes to the bathroom but to make sure that it is put back on at 2 L. The nurse also instructs the NAP to make sure the side rails are up and the bed alarm is reset after the patient gets back in bed. Which of the following components of the "Five Rights of Delegation" were used by the nurse? (Select all that apply.)
   1. Right task
   2. Right circumstances
   3. Right person
   4. Right direction/communication
   5. Right supervision/evaluation

4. A patient asks a nurse what the patient-centered care model for the hospital means. What is the nurse's best answer?
   1. "This model ensures that all patients have private rooms when they are admitted to the hospital."
   2. "In this model you and the health care team are full partners in decisions related to your health care."
   3. "This model focuses on making the patient experience a good one by providing amenities such as restaurant-style food service."
   4. "Patients and families sign a document providing them full access to their medical charts."

5. While administering medications, a nurse realizes that a prescribed dose of a medication was not given. The nurse acts by completing an incident report and notifying the patient's health care provider. The nurse is exercising:
   1. Authority.
   2. Responsibility.
   3. Accountability.
   4. Decision making.

6. The staff on the nursing unit are discussing implementing interprofessional rounding. Which of the following statements correctly describe interprofessional rounding? (Select all that apply.)
   1. Allows team members to share information about patients to improve care
   2. Provides an opportunity for early patient discharge planning
   3. Improves communication among health care team members
   4. Allows each of the health care team members to identify separate patient goals
   5. Allows each health care provider an opportunity to delegate a task.

7. After a nurse receives a change-of-shift report on his assigned patients, he prioritizes the tasks that need to be completed. This is an example of a nurse displaying which practice?
   1. Organizational skills
   2. Use of resources
   3. Time management
   4. Evaluation

8. A nurse is teaching a patient about wound care that will need to be done daily at home after the patient is discharged. This is which priority nursing need for this patient?
   1. Low priority
   2. High priority
   3. Intermediate priority
   4. Nonemergency priority

9. A registered nurse (RN) is providing care to a patient who had abdominal surgery 2 days ago. Which task is appropriate to delegate to the nursing assistant?
   1. Helping the patient ambulate in the hall
   2. Changing surgical wound dressing
   3. Irrigating the nasogastric tube
   4. Providing brochures to the patient on health diet

10. Which task is appropriate for a registered nurse (RN) to delegate to a nursing assistant?
    1. Explaining to the patient the preoperative preparation before the surgery in the morning
    2. Administering the ordered antibiotic to the patient before surgery
    3. Obtaining the patient's signature on the surgical informed consent
    4. Helping the patient to the bathroom before leaving for the operating room

11. Which of the following are components of interprofessional collaboration? (Select all that apply.)
    1. Interprofessional education does not impact the collaboration among interprofessional team members.
    2. Nurses are often viewed as the team leader because of their coordination of patient care.

3. Effective interprofessional collaboration requires mutual respect and trust from all team members.
4. Open communication improves the collaboration among the interprofessional team members.
5. The goal of interprofessional collaboration is to improve the quality of patient care.

12. A registered nurse performs the following four steps in delegating a task to a nursing assistant. Place the steps in the order of appropriate delegation.
    1. Do you have any questions about walking Mr. Malone?
    2. Before you take him for his walk to the end of the hallway and back, please take and record his pulse rate.
    3. In the next 30 minutes please assist Mr. Malone in room 418 with her afternoon walk.
    4. I will make sure that I check with you in about 40 minutes to see how the patient did.

13. Which example demonstrates a nurse performing the skill of evaluation?
    1. The nurse explains the side effects of the new blood pressure medication ordered for the patient.
    2. The nurse asks a patient to rate pain on a scale of 0 to 10 before administering the pain medication.
    3. After completing the teaching, the nurse observes a patient draw up and administer an insulin injection.
    4. The nurse changes a patient's leg ulcer dressing using aseptic technique.

14. The nurse manager from the surgical unit was awarded the nursing leadership award for practice of transformational leadership. Which of the following are characteristics or traits of transformational leadership displayed by award winner? (Select all that apply.)
    1. The nurse manager regularly rounds on staff to gather input on unit decisions.
    2. The nurse manager sends thank-you notes to staff in recognition of a job well done.
    3. The nurse manager sends memos to staff about decisions that the manager has made regarding unit policies.
    4. The nurse manager has an "innovation idea box" to which staff are encouraged to submit ideas for unit improvements.
    5. The nurse develops a philosophy of care for the staff.

15. A nurse assesses patients and uses assessment findings to identify patient problems and develop an individualized plan of care. The nurse is displaying:
    1. Organizational skills.
    2. Use of resources.
    3. Priority setting.
    4. Clinical decision making.

Answers: 1. 2, 3, 4, 5; **2.** 2, 3; **3.** 1, 2, 3, 4; **4.** 2; **5.** 3; **6.** 1, 2, 3; **7.** 3; **8.** 3; **9.** 1; **10.** 4; **11.** 2, 3, 4, 5; **12.** 3, 2, 4, 1; **13.** 3; **14.** 1, 2, 4; **15.** 4.

Ethics and Values

Ethics is the study of conduct and character. It is concerned with determining what is good or valuable for individuals, groups, and society at large. Acts that are ethical reflect a commitment to standards that individuals, professions, and societies strive to meet. When decisions must be made about health care, understandable disagreement can occur among health care providers, families, patients, friends, and people in the community. The right thing to do can be hard to determine when ethics, values, and perceptions about health care collide. This chapter describes concepts that will help you embrace the role of ethics in your professional life and promote resolution when an ethical dilemma develops.

BASIC TERMS IN HEALTH ETHICS

Your understanding of the terms common in ethical discourse will help you participate thoughtfully in discussions with others and may even help you shape your own thoughts about ethical issues.

Autonomy

Autonomy refers to freedom from external control. In health care the concept applies to provider respect for the autonomy of patients. It can also apply to institutional respect for the autonomy of providers. A commitment to respect the autonomy of others is a fundamental principle of ethical practice.

Respect for patient autonomy refers to the commitment to include patients in decisions about all aspects of care. It is a key feature of patient-centered care. In respecting patient autonomy, you

acknowledge and protect a patient's independence. Respect for autonomy is a relatively new concept and reflects a movement away from paternalistic patient care in which the physician made all decisions. The movement was in part a reaction to the Tuskegee Syphilis Study in which many African-American men were infected with the bacteria without their knowledge. When the story surfaced in the news media in 1972, the outcry resulted in reinforcement of informed consent, especially for research (Reverby, 2013).

Involving patients in decisions about their care is now standard practice. Providers are obligated to inform patients about risks and benefits of treatment plans and then to ensure that they understand and agree with their plan. In many cases (e.g., surgery and diagnostic procedures), the consent of a patient must be documented by the patient's signature. Out of respect for patient autonomy, you will support patients who raise questions about procedures by ensuring that they get the answers they request. As a nurse you will respect patient autonomy in all of your patient care by taking time to explain nursing procedures such as obtaining a blood pressure or administering medications.

Respect for provider autonomy refers to provider relationships to institutions. What happens when a provider is asked to perform duties that conflict with a religious or personal belief? Institutions have developed policies that accommodate respect for providers by finding a way to reassign duties when this conflict occurs. However, the reassignment is conducted so the patient is protected from abandonment and only when patient care is not compromised. What happens when an individual provider takes issue with policies or practices of an institution

and is concerned that a practice is unsafe? Institutional whistle blower protections prohibit reprisal against an employee who makes a legitimate report about clinical safety issues. These protections represent expressions of respect for provider autonomy.

Beneficence

Beneficence refers to taking positive actions to help others. The principle of beneficence is fundamental to the practice of nursing and medicine. The agreement to act with beneficence implies that the best interests of the patient remain more important than self-interest. It implies that nurses practice primarily as a service to others, even in the details of daily work.

Nonmaleficence

Maleficence refers to harm or hurt. **Nonmaleficence** refers to the avoidance of harm or hurt. In health care ethical practice involves not only the will to do good but the equal commitment to do no harm. A health care professional tries to balance the risks and benefits of care while striving at the same time to do the least harm possible. A bone marrow transplant procedure may offer a chance at cure; but the process involves periods of suffering, and it may not be possible to guarantee a positive outcome. Decisions about the best course of action can be difficult and uncertain precisely because nurses agree to avoid harm at the same time as they commit to promoting benefit.

Justice

Justice refers to fairness. The term is most often used in discussions about access to health care resources, including the just distribution of scarce resources. Discussions about health insurance, hospital locations and services, and even organ transplants generally refer to issues of justice. The term itself is open to interpretation about how best to ensure justice. Does the principle of just distribution mean that health care resources should be available to as many people as possible? Or is it more important to remain concerned about equality by ensuring that all people receive resources equally? Especially as health care costs continue to rise, the issue of justice remains a critical part of the discussion about health care reform and access to care.

The term *just culture* refers to the promotion of open discussion without fear of recrimination whenever mistakes, especially those involving adverse events, occur or nearly occur. Blame is withheld at least at first so system issues and other elements can be investigated for their contributions to the error. By fostering open discussion about errors, members of the health care team become more richly informed participants, able to design new systems that prevent harm.

Fidelity

Fidelity refers to the agreement to keep promises. As a nurse you keep promises by following through on your actions and interventions. If you assess a patient for pain and offer a plan to manage the pain, the standard of fidelity encourages you to monitor the patient's response to the plan. Professional practice includes a willingness to revise the plan as necessary to try to keep the promise to reduce pain. Fidelity also refers to the unwillingness to abandon patients regardless of the circumstances, even when personal beliefs differ as they may when dealing with drug dealers, members of the gay community, women who received an abortion, or prisoners.

PROFESSIONAL NURSING CODE OF ETHICS

A **code of ethics** is a set of guiding principles that all members of a profession accept. It is a collective statement about the group's expectations and standards of behavior. The American Nurses Association (ANA) established the first code of nursing ethics decades ago. The ANA reviews and revises the code periodically; but principles of responsibility, accountability, advocacy, and confidentiality remain constant (ANA, 2015).

Advocacy

Advocacy refers to the support of a particular cause. As a nurse you advocate for the health, safety, and rights of patients, including their right to privacy and their right to refuse treatment. Your special relationship with patients provides you with knowledge that is specific to your role as a registered nurse and as such with the opportunity to make a unique contribution to understanding a patient's point of view.

Responsibility

The word **responsibility** refers to a willingness to respect one's professional obligations and to follow through. An example is following an agency's policies and procedures. As a nurse you are responsible for your actions and the actions of those to whom you delegate tasks. You agree to take responsibility to remain competent to practice so you can follow through on your responsibilities reliably.

Accountability

Accountability refers to the ability to answer for one's actions. You ensure that your professional actions are explainable to your patients and your employer. Health care institutions also exercise accountability by monitoring individual and institutional compliance with national standards established by agencies such as The Joint Commission (TJC). TJC establishes national patient safety guidelines to ensure patient and workplace safety through consistent, effective nursing practices (TJC, 2015). The ANA promotes ethical decision making by setting standards for collaborative practice through multidisciplinary discourse (ANA, 2015).

Confidentiality

Federal legislation known as the Health Insurance Portability and Accountability Act of 1996 (HIPAA) mandates **confidentiality** about and protection of patients' personal health information. The legislation defines the rights and privileges of patients for protection of privacy. It establishes fines for violations (USDHHS, 2013). In practice you cannot share information about a patient's medical condition or personal information to anyone not involved in the care of the patient. See Chapter 26 for details on HIPAA regulations governing communication of patient information contained in medical records, both hardcopy and electronic.

Social Networking

The online presence of social networks presents ethical challenges for nurses. On one hand social networks can be a supportive source of information about patient care or professional nursing activities. Social media can provide you emotional support when you encounter hardships at work with colleagues or patients. On the other hand, the risk to patient privacy is great. Even if you post an image of a patient without any obvious identifiers, the nature of shared media reposting can result in the image surfacing in a place where just the context of the image provides clues for friends or family to identify the patient.

Becoming friends in online chat rooms, on Facebook, or on other public sites interferes with your ability to maintain a therapeutic relationship. Friendship with a patient always comes with the risk of clouding your ability to remain objective in your clinical

perceptions. The public nature of online relationships poses the additional risk that other patients may see and learn more than they should know about you and other patients. They may not trust you to remain impartial (i.e., available equally to each patient in your assignment).

Workplace policies will help to answer questions you have about when and where it is appropriate to engage in social media regarding workplace stories or issues. The ANA and the National Council of State Boards of Nursing (NCSBN) have crafted a joint White Paper on Social Media for guidance. As the joint statement puts it, "Effective nurse-patient relationships are built on trust. Patients need to be confident that their most personal information and their basic dignity will be protected by the nurse" (ANA/NCSBN, 2011).

VALUES

Nursing is a work of intimacy. Nursing practice requires you to be in contact with patients physically, emotionally, psychologically, and spiritually. In most other intimate relationships you choose to enter the relationship precisely because you anticipate that your values will be shared with the other person. But as a nurse you agree to provide care to your patients solely on the basis of their need for your services. The ethical principles of beneficence and fidelity shape the practice of health care and distinguish it from other common human relationships such as friendship, marriage, and employer-employee. But by its very nature relationships in health care sometimes can occur in the presence of conflicting values.

A **value** is a personal belief about the worth of a given idea, attitude, custom, or object that sets standards that influence behavior. Inevitably you will work with patients and colleagues whose values differ from yours. To negotiate differences of value, it is important to be clear about your own values: what you value, why, and how you respect your own values even as you try to respect those of others whose values differ from yours (see Chapter 9). The values that an individual holds reflect cultural and social influences, and these values vary among people and develop over time. For example, in some cultures decisions about health care flow from group or family-based discussion rather than independent decisions by one person. Such a practice may challenge your commitment to respect patient autonomy. Your effort to resolve differing opinions and maintain your cultural competence becomes the hallmark of your commitment to ethical practice.

Values Clarification

Ethical dilemmas almost always occur in the presence of conflicting values. To resolve ethical dilemmas one needs to distinguish among value, fact, and opinion. Sometimes people have such strong values that they consider them to be facts, not just opinion. Sometimes people are so passionate about their values that they become judgmental in a way that intensifies conflict. Clarifying values—your own, your patients', your co-workers'—is an important and effective part of ethical discourse. In the process of values clarification, you learn to tolerate differences in a way that often (although not always) becomes the key to the resolution of ethical dilemmas.

Examine the cultural values exercise in Box 22-1. The values in the exercise are in neutral terms so you can appreciate how differing values need not indicate "right" or "wrong." For example, for some people it is important to remain silent and stoic in the presence of great pain, and for others it is important to talk about it to understand and control it. Identifying values as something separate from facts can help you find tolerance for others, even when differences among you seem worlds apart.

BOX 22-1 Cultural Values Exercise

The column on the right contains statements describing an opinion; the column on the left contains statements describing the opposite opinion. Neither statement is right, nor is it wrong. These statements reflect opinion, not necessarily fact. If people from a variety of cultures were given this questionnaire, some would strongly agree with the beliefs on the right, and others with the opinions on the left. Read each statement and reflect on your own values and opinions. Circle 1 if you strongly agree with the statement on the left and 2 if you moderately agree. Circle 4 if you strongly agree with the statement on the right and 3 if you moderately agree.

Statement	Rank	Statement
Preparing for the future is an important activity and reflects maturity.	1 2 3 4	Life has a predestined course. The individual should follow that course.
Vague answers are dishonest and confusing.	1 2 3 4	Vague answers are sometimes preferred because they avoid embarrassment and confrontation.
Punctuality and efficiency are characteristics of a person who is both intelligent and concerned.	1 2 3 4	Punctuality is not as important as maintaining a relaxed atmosphere, enjoying the moment, and being with family and friends.
When in severe pain, it is important to remain strong and not to complain too much.	1 2 3 4	When in severe pain, it is better to talk about the discomfort and express frustration.
It is self-centered and unwise to accept a gift from someone you do not know well.	1 2 3 4	It is an insult to refuse a gift when it is offered.
Addressing someone by his or her first name shows friendliness.	1 2 3 4	Addressing someone by his or her first name is disrespectful.
Direct questions are usually the best way to gain information.	1 2 3 4	Direct questioning is rude and could cause embarrassment.
Direct eye contact shows interest.	1 2 3 4	Direct eye contact is intrusive.
Ultimately the independence of the individual must come before the needs of the family.	1 2 3 4	The needs of the individual are always less important than the needs of the family.

Modified from Renwick GW, Rhinesmith SH: *An exercise in cultural analysis for managers,* Chicago, 1995, Intercultural Press.

ETHICS AND PHILOSOPHY

Historically health care ethics constituted a search for fixed standards that would determine correct actions. Over time ethics has grown into a field of study that is more flexible and is filled with differences of opinion and deeply meaningful efforts to understand human interaction. The following review introduces you to a variety of philosophical approaches to ethics that you may encounter during ethical discussions in health care settings.

Deontology

Deontology proposes a system of ethics that is perhaps most familiar to health care practitioners. Its foundations come from the work of an eighteenth-century philosopher, Immanuel Kant (1724-1804). **Deontology** defines actions as right or wrong on the basis of their "right-making characteristics" such as fidelity to promises, truthfulness, and justice (Beauchamp and Childress, 2012). It specifically does not look at consequences of actions to determine right or wrong. Instead, deontology examines a situation for the existence of essential right or wrong. For example, if you try to make a decision about the ethics of a controversial medical procedure, deontology guides you to focus on how the procedure ensures fidelity to the patient, truthfulness, justice, and beneficence. You focus less on the consequences (ethically speaking). If the medical procedure in the example is just, respects autonomy, and provides good, it will be right, and it will be ethical according to this philosophy. If it provides good, but only to a limited number of people, it could be deemed unjust and therefore unethical.

Deontology depends on a mutual understanding of justice, autonomy, and goodness. But it still leaves room for confusion to surface. The principle of respect for autonomy can be complicated when dealing with children. For example, pediatricians recommend vaccinations against measles. But parents may refuse the recommendation, thinking that they are protecting the child from perceived harm. Whose autonomy should receive the respect—the parents'? What about the child's need to be protected from measles? What about the community's need to be protected from an epidemic? When is it acceptable to step in for a parent when seeking to speak for the child's best interest? A commitment to respect the "rightness" of autonomy is a guiding principle in deontology, but adherence to the principle alone does not always provide clear answers for complicated situations.

Utilitarianism

A utilitarian system of ethics proposes that the value of something is determined by its usefulness. This philosophy is also known as **consequentialism** because its main emphasis is on the outcome or consequence of action. A third term associated with this philosophy is **teleology**, from the Greek word telos, meaning "end," or the study of ends or final causes. John Stuart Mill (1806-1873), a British philosopher, first proposed its philosophical foundations. The greatest good for the greatest number of people is the guiding principle for determining right action in this system. As with deontology, **utilitarianism** relies on the application of a certain principle (i.e., measures of "good" and "greatest") (Beauchamp and Childress, 2012). The difference between utilitarianism and deontology is the focus on outcomes. Utilitarianism measures the effect that an act will have; deontology looks to the presence of principles regardless of outcome.

People have conflicting definitions of "greatest good." For example, research suggests that education about safe sex practices reduces the spread of human immunodeficiency virus (HIV). Reducing the incidence of HIV is good for a great number of people. For some, education about sex is best provided within a family setting rather than in school because it promotes family values. For others, using the same "greatest good" logic, sex education in public schools would be the best solution because it would educate the greatest number of people in an efficient and standard way. As with deontology, utilitarianism provides guidance, but it does not guarantee agreement.

Feminist Ethics

On the basis of their concerns about the unanswered questions that come with application of deontology and utilitarianism, scholars who focused on differences between genders, especially women's points of view, developed a critique of conventional ethical philosophies. Called **feminist ethics**, it looks to the nature of relationships to guide participants in making difficult decisions, especially relationships in which power is unequal or in which a point of view has become ignored or invisible (Beauchamp and Childress, 2012). Writers with a feminist perspective tend to concentrate more on practical solutions than on theory. For example, when deciding whether to perform a possibly futile procedure on a dying patient, feminist ethics might guide us to look at the patient's relationships with family and friends as a way to determine the ethically right thing to do. How would the patient's ability to engage in relationships be affected? If the patient is a parent, how would the patient's relationship to the children be affected by the intervention? These questions might surface less often if the discussion is framed solely by conventional ethical principles.

Critics of feminist ethics worry about the lack of appeal to traditional ethical principles. Without guidance from principles such as autonomy and beneficence, they argue, solutions to ethical questions will depend too much on subjective judgment.

Ethics of Care

The ethics of care and feminist ethics are closely related. Both promote a philosophy that focuses on understanding relationships, especially personal narratives.

An early proponent of the ethics of care, Nel Noddings, used the term *the one-caring* to identify the individual who provides care and *the cared-for* to refer to the patient. In adopting this language Noddings hoped to emphasize the role of feelings. **Ethics of care** also strives to address issues beyond individual relationships by raising ethical concerns about the structures within which individual caring occurs—structures such as hospitals or universities (Noddings, 2013).

Casuistry

Casuistry, or case-based reasoning, turns away from conventional principles of ethics as a way to determine best actions and focuses instead on an "intimate understanding of particular situations" (Beauchamp and Childress, 2012). This approach to ethical discourse depends on finding consensus more than an appeal to philosophical principle. Building consensus is an act of discovery in which collective wisdom guides a group to the best possible decision. As a strategy for solving dilemmas, consensus building promotes respect and agreement rather than a particular philosophy or moral system itself.

NURSING POINT OF VIEW

All patients in health care systems interact with nurses at some point, and they interact in ways that are unique to nursing. Nurses generally engage with patients over longer periods of time than other disciplines. They are involved in intimate physical acts such as bathing, feeding, and special procedures. As a result, patients and families may feel more comfortable in revealing information not always shared with physicians or other health care providers. Details about family life, information about coping styles, personal preferences, and details about fears and insecurities are likely to come out during the course of nursing interventions. Your ability to shape your care on the basis of this special knowledge provides an indispensable contribution to the overall care of your patient.

The care of any patient involves the collaboration of many disciplines. Managers and administrators from many different professional backgrounds contribute to ethical discourse with their knowledge of systems, distribution of resources, financial possibilities and limitations (Figure 22-1).

FIGURE 22-1 Nurses collaborate with other professionals in making ethical decisions.

Processing an Ethical Dilemma

Ethical dilemmas cause distress and controversy for both patients and professional caregivers. To minimize distress, participants strive to process ethical issues carefully and deliberately. The process should promote the free expression of feelings and opinions. However, you do not resolve an ethical dilemma by considering only what people want and feel (Zoloth, 2010).

Resolving an ethical dilemma is similar to the nursing process in its methodical approach to a clinical issue. But it differs from the nursing process in that it requires negotiation of differences of opinion and clarity about situations that are confusing and not easily solved by appealing to the usual ethical principles. Finding clarity and consensus can occur when the following elements remain essential to the process: the presumption of good will on the part of all participants, strict adherence to confidentiality, patient-centered decision making, and the welcome participation of families and primary caregivers (Zoloth, 2010).

The process begins with determining if an ethical dilemma exists. If the question is perplexing and the answer has relevance for several areas of human concern, an ethical dilemma exists. You then gather all pertinent information about the case, including review of the medical record for recent clinical evaluations. Examining your personal values at this point can help to differentiate between fact and opinion, an important part of the process. Once information is gathered, getting consensus on a statement about the dilemma will facilitate discussion. Next, listing all possible courses of action will guide the discussion toward a possible solution and help to identify areas of dissent and consensus. As a group you consider and evaluate alternatives with respect for all differences of opinion. Most of the time people in an ethical conflict come to a resolution and implement a plan. Evaluation of the plan follows (Box 22-2).

If the process involves a family conference or changes in the treatment plan, you document all relevant information in the medical record. Some institutions use a special ethics consultation form to structure documentation. However, if the ethical concern does not directly affect patient care, you may document the discussion in

---

> **BOX 22-2   Key Steps in the Resolution of an Ethical Dilemma**
>
> **Step 1:** Ask the question, Is this an ethical dilemma?
> **Step 2:** Gather information relevant to the case. Patient, family, institutional, and social perspectives are important sources of relevant information.
> **Step 3:** Clarify values. Distinguish among fact, opinion, and values.
> **Step 4:** Verbalize the problem. A clear, simple statement of the dilemma is not always easy, but it helps to ensure effectiveness in the final plan and facilitates discussion.
> **Step 5:** Identify possible courses of action.
> **Step 6:** Negotiate a plan. Negotiation requires a confidence in one's own point of view and a deep respect for the opinions of others.
> **Step 7:** Evaluate the plan over time.

meeting minutes or in a memorandum to those involved in the discussion.

You have been taking care of a patient with a terminal illness for the last 3 weeks. The patient has just revealed to you that she is ready to explore Do Not Resuscitate (DNR) status. However, she has not been willing or able to express these sentiments to the attending physician. The physician has been taking care of the patient for the last 6 weeks. You ask the physician if he would conduct a patient care conference to talk about DNR, but he declines. You are challenged with how to proceed.

Step 1. Ask the question, Is this an ethical dilemma?

The question is perplexing. Your situation meets the criteria for an ethical dilemma. The disagreement does not revolve around whether the patient is in a terminally ill state; thus further clinical information will not change the basic question. Should the patient have an opportunity to discuss DNR orders at this time? You and the physician disagree on an assessment of the patient's readiness to confront difficult issues related to dying. If she is not ready, raising the issues could cause anguish and fear in the patient and her family. But she has expressed interest in discussing the topic. If she is ready and the team avoids discussion, she could suffer unnecessarily physically and emotionally. If she is very close to death, the lack of a DNR order necessitates the application of cardiopulmonary resuscitation (CPR) in a futile situation.

Step 2. Gather as much information as possible that is relevant to the case. Resolution of dilemmas can come from unlikely sources. Helpful information may include test results, the clinical state of the patient, and current literature about the diagnosis or condition of the patient. The patient's religious, cultural, and family situations are also essential to the assessment.

Since the dilemma exists because two professionals, you and the physician, disagree about the patient's state of mind, it is helpful to reassess the patient. An independent assessment could help resolve differences of opinion. Family members or significant others in the patient's life often hold important clues to a patient's state of mind.

Step 3. Examine and determine your values about the issues. Part of the goal is to accurately identify your own opinion, and an equally critical goal is to form respect for others' opinions.

Reflect on your values. You think that this patient wants a DNR order in place. But does this opinion accurately represent the

patient's wishes or possibly your own idea about what is best for her? In addition, you understand that the attending physician has not had time to know this patient well. You continue to believe that the patient is capable of a discussion, in spite of her statements to the physician. In fact, you believe that she will benefit from a discussion, regardless of the final decision. Perhaps the combination of an unfamiliar caretaker and declining physical health has silenced her, even though her fears and concerns persist.

Step 4. Verbalize the problem. By agreeing to a statement of the problem, the group is able to conduct a focused discussion.

Is a DNR order a right or wrong thing for this patient? And is she ready to discuss the options?

Step 5. Consider possible courses of action. Which options are possible in this situation?

You could turn to your supervisor for advice. You could initiate a discussion with the physician, independent of the patient. You might consult with the ethics council in your workplace. Your goal is to find the best place to resolve the dilemma, and discourse is the most common avenue to resolution. Questions you might bring up to discuss with others: Is it in the patient's best interest to facilitate a DNR order? How can one determine what the patient really does want? What happens when, in good faith, professionals disagree about the patient's assessment? The answers to these questions can be elusive because they depend on an understanding of patient feelings and values that are not necessarily obvious.

Step 6. Negotiate the outcome. Negotiations can happen in a variety of settings: at the bedside, in an office, in a conference room. Sometimes a formal ethics meeting provides a useful resource. Wherever negotiations occur, the nurse has an obligation to articulate a personal point of view and at the same time to show respect for the points of views of others at the table.

If an ethics committee meeting occurs, the discussion usually involves participants from other disciplines and should include the patient and patient family. A facilitator or chairperson ensures that the group examines all points of view and identifies all relevant issues. In the best circumstances participants discover a course of action that meets criteria for consensus or acceptance by all. However, occasionally they leave the discussion disappointed or even opposed to the decision. But in a successful discussion all members will have agreed on an action.

The principles involved during an ethics committee discussion include beneficence and nonmaleficence: Which plan provides the most good for this patient, a DNR order or no order? A separate question addresses the patient's point of view and a respect for her autonomy: Would a discussion with the patient promote well-being or anguish? The commitment to respect a patient's autonomy reveals that a troublesome question remains: Does the patient want something different from what she is expressing?

With several members of the health care team present, the discussion proceeds. You present your point of view. You continue to sense that the patient is ready to discuss DNR orders. But you also respect the attending physician and his perception that the patient is reluctant to talk freely about it. In the end the team proposes the following: a formal meeting with the patient in which you, the attending physician, and a respected family member are present. You support this proposal because you believe that it maximizes comfort from the patient's network of friends and family. In

addition, you recognize that in a trusting environment the patient is most likely to express herself freely. You suggest that, rather than asking if the patient wants a DNR order, perhaps the team could wait for her to initiate the discussion. In this way the team would be sure of her consent and willingness to address the difficult questions about dying.

Step 7. Evaluate the action.

At the meeting the patient brings up the DNR order. She expresses relief at the chance to explore her options and feelings. The physician clarifies pain-management issues that she poses. She wants to discuss a DNR order but requests a visit from her priest before making a final decision. At the end of the meeting you ask the patient if her expectations were met, and she says, "Yes, I am so glad you gave me the chance to talk about this. I feel I am ready to die."

Institutional Resources

An ethics committee devoted to the teaching and processing of ethical issues and dilemmas is required in most hospitals. A committee involves individuals from different disciplines and backgrounds who support health care institutions with three major functions: providing clinical ethics consultation, developing and/or revising policies pertaining to clinical ethics and hospital policy (e.g., advance directives, withholding and withdrawing life-sustaining treatments, informed consent, organ procurement), and facilitating education about topical issues in clinical ethics (University of Washington, 2013). Any person involved in seeking ethical advice, including nurses, physicians, health care providers, patients, and family members, can request access to an ethics committee.

You may also process ethical issues in settings other than a committee. Nurses provide insight about ethical problems at family conferences, staff meetings, or even in one-on-one meetings.

When ethical problems are not processed well, moral distress can result. Moral distress occurs when people feel misled or are not aware of their options and do not know when or how to speak up about their concerns. As a member of a health care community, regardless of your work setting, you can reduce the risk for moral distress by promoting discourse even when disagreements or confusion are profound. Ethics committees offer a valuable resource for nurturing discourse and strengthening relationships (Box 22-3).

QSEN   QSEN: BUILDING COMPETENCY IN PATIENT-CENTERED CARE You have been assigned to care for a 27-year-old patient. He is obese and is newly diagnosed with hypertension and diabetes. You learn that he does not have health insurance. He works full time with a steady income, but he thought he was "too young and too healthy to need health insurance." He is about to be discharged to home. Without insurance, he will not be able to afford clinic visits or the new medications that have been prescribed. How will a focus on patient-centered care help you better meet your ethical and professional obligations?

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

ISSUES IN HEALTH CARE ETHICS

Ethical issues change as society and technologies change, but common denominators remain: the basic process used to address the issues and your responsibility to deal with them. The following section describes examples of current issues in which ethical concerns arise.

BOX 22-3   EVIDENCE-BASED PRACTICE

Moral Distress

PICO Question: Which ethical actions diminish distress and promote compassionate care for nurses experiencing moral distress when caring for dying patients?

Evidence Summary

Moral distress describes the anguish experienced when a person feels unable to act according to closely held core values. Evidence indicates that underlying problems of poor communication, inadequate collaboration, and perceived powerlessness contribute to recurrent moral distress (Ulrich et al., 2010). Reliable tools to measure moral distress, tested for reliability and validity, continue to evolve as researchers focus on the experience of moral distress, especially in critical care units (Hamric et al., 2012). In guided interviews with intensive care unit (ICU) providers, researchers demonstrated how "feeling powerless, difficult family dynamics, and recognition of suffering predicted the development of moral distress" (McAndrew and Leske, 2015).

Application to Nursing Practice

Since moral distress is a shared experience, collaborative efforts to alleviate it are most successful. Research suggests that the following interventions can reduce risk for moral distress:
- Interdisciplinary ethics education, in which nurses and physicians learn together about ethical discourse (Ulrich et al., 2010; McAndrew and Leske, 2015)
- Development of workplace support groups for nurses and physicians
- Increasing opportunities for collegial practice such as routine multidisciplinary rounds
- Engaging in constructive and multidisciplinary conversation, which is key (McAndrew and Leske, 2015)

Quality of Life

Quality of life represents something deeply personal. Health care researchers use quality-of-life measures to define scientifically the value and benefits of medical interventions. Increasingly scientists incorporate not just observed measurement but patient self-reports about quality of life and other outcomes, referred to as Patient Reported Outcomes (Basch, 2014). Quality-of-life measures may take into account the age of a patient, the patient's ability to live independently, his or her ability to contribute to society in a gainful way, and other nuanced measures of quality. Still a definition remains deeply individual and difficult to predict. Nussbaum (2011) proposes that quality of life is not just a measurable entity but a shared responsibility that we owe to one another as members of a community. As Nussbaum (2011) describes it, the good life "begins with a commitment to the equal dignity of all people, whatever their class, religion, caste, race, or gender. It is committed to the attainment, for all, of lives that are worthy of that equal dignity." The question of quality of life is central to discussions about quality of care, outcome measures, care at the end of life, futile care, cancer therapy, and health care provider–assisted suicide.

Disabilities

Approximately 56.7 million people (18.7% in the civilian noninstitutionalized population) had a disability in 2010 (Brault, 2012). This includes people who have a disability in the communicative (e.g., blind, deaf), physical (e.g., use of assist device, chronic disease or acute injury affecting mobility), or mental (e.g., learning disability, dementia)

domains. The population of disabled people in the United States and elsewhere has reshaped the discussion about quality of life. The national movement to respect the abilities of all, regardless of their functional status, has inspired a reconsideration of the definition of quality of life. Many school districts no longer separate physically or mentally challenged children but rather integrate them into mainstream classrooms. Public places such as restaurants and buses are accessible to people who use wheelchairs. Antidiscrimination laws enhance the economic security of people with physical, mental, or emotional challenges. These changes result in the greater integration of disabled people into general society.

Philosophically the conversation has shifted from one about a focus on what is wrong when a person has a disability to a conversation about how best to nurture capabilities of all humans regardless their circumstances. Sometimes referred to as a *capabilities approach*, it "begins with a commitment to the equal dignity of all people, whatever their class, religion, caste, race, or gender, and it is committed to the attainment, for all, of lives that are worthy of that equal dignity" (Nussbaum, 2011).

Care at the End of Life

Predictions about health outcomes are not always accurate. Even when they are, opinions about the value or worth of the outcome differ. For example, patients at risk for breast cancer occasionally request a mastectomy before any symptoms of breast disease have appeared, fearful of a family history and thinking that it will prevent future suffering. Physicians may be understandably reluctant to provide this intervention on the basis of knowledge of risk factors and their commitment to "do no harm." On the other hand, a physician might recommend that a patient undergo a liver transplantation for end-stage liver disease, even though the likelihood of a cure is uncertain. The patient may hold the opinion that the transplant is pointless (i.e., unlikely to produce benefit that justifies the suffering that he or she anticipates). Agreement on what is best is often elusive.

Difficult emotional and spiritual challenges resulting in moral distress can characterize the management of care at the end of life. The term *futile* refers to something that is hopeless or serves no useful purpose. In health care discussions the term refers to interventions unlikely to produce benefit for a patient. The concept is slippery when applied to clinical situations.

If a patient is dying of a condition with little or no hope of recovery, almost any intervention beyond symptom management and comfort measures is seen as futile. In this situation an agreement to label an intervention as futile can help providers, families, and patients turn to palliative care measures as a more constructive approach to the situation (see Chapter 37).

Health Care Reform

The Affordable Care Act (ACA), implemented January 2012, facilitated access to care for millions of formerly uninsured in the United States. Access to care is essentially an ethical issue of justice. A Rand corporation survey estimates that at least 9.3 million more adults in the United States now have health coverage as compared to coverage before ACA implementation (Carman and Eibner, 2014). The legislation also incorporates a promotion of wellness by proposing changes in payment for services and by rewarding practices that reduce harm and promote quality outcomes.

Adjustment to the ACA remains ongoing. Some states did not implement it in full (i.e., declined to accept expansion of Medicaid coverage for low-income residents). Many residents who did enroll are first-time users of health insurance and are still learning how to access it. In a poll conducted 6 months after ACA implementation, a quarter

Access to Affordable Health Care

Since the implementation of the Affordable Care Act, more residents in the United States have access to care than ever before. But according to the National Healthcare Disparities Report (NHDR), people of color, ethnic minorities, and low-income residents are "disproportionately represented among those with access problems." Reports from the National Healthcare Quality Report and NHDR reveal that lack of health insurance is the most significant contributing factor to poor quality of care. According to the authors of the report, "Uninsured people were less likely to get recommended care for disease prevention such as cancer screening, dental care, counseling about diet and exercise, and flu vaccination. They also were less likely to get recommended care for disease management such as diabetes care management" (AHRQ, 2013).

Implications for Patient-Centered Care
- Issues of justice and the just distribution of resources help to inform the discussion about access to care and its effect on health care outcomes.
- Health outcomes often correlate directly to health care access.
- Know and respect patient's cultural practices regarding health promotion and health care needs (Chapter 9).
- Identify culturally appropriate resources for patients and families in their community

of respondents incorrectly believed that they had enrolled in a single government plan (Hamel, 2014).

How people access health care in the United States will continue to evolve. Staying knowledgeable about affordable care in your community as a way to ensure healthy outcomes is an important part of your role as advocate for your patients and will reflect your ethical commitment to justice (Box 22-4).

• • •

The courage and intelligence to act as both an advocate for patients and a professional member of the health care community come from a committed effort to learn and understand ethical principles. As a professional nurse you provide a unique point of view regarding patients, the systems that support patients, and the institutions that make up the health care system. You have a duty and a privilege to articulate that point of view. Learning the language of ethical discourse is a part of the skill necessary to exercise this privilege. Review and consideration of various ethical principles help you form personal points of view, a necessary skill in the negotiation of difficult ethical situations.

KEY POINTS

- Ethics is the study of conduct and character. It is concerned with determining what is good or valuable for individuals and society at large.
- The ANA code of ethics provides a foundation for professional nursing.
- Professional nursing promotes accountability, responsibility, advocacy, and confidentiality.
- Principles of ethics in health care include autonomy, beneficence, nonmaleficence, justice, and fidelity.
- The process of values clarification helps you explore values and feelings and decide how to act on personal beliefs and respect values of others, even if they differ from yours.

- Ethical problems arise in the presence of differences in values, changing professional roles, technological advances, and social issues that influence quality of life.
- A process for resolving ethical dilemmas that respects differences of opinions and all participants equally helps health care providers resolve conflict about right actions.
- A nurse's point of view offers a unique voice in the resolution of ethical dilemmas.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You are caring for a 17-year-old female patient with sickle cell disease who has been admitted for treatment of sickle cell crisis. Sickle cell disease is a genetic abnormality that affects hemoglobin in the red blood cells. In a sickle cell crisis weakened red blood cells clump together and impede blood flow, causing extreme pain. To prevent stroke and manage the pain of the crisis, your patient needs aggressive fluid and comfort management. At the change-of-shift report, you learn that, even though she is receiving pain medication around the clock, she continues to report acute pain at a level of 10 on a scale of 0 to 10. She complains about almost everything: her roommate, the food, even the intravenous line that delivers the fluids and pain medications. Her home is far from the hospital, and her family and friends are not able to visit.

During shift report the nurse from the past shift describes the patient as manipulative. On the basis of her concern about a risk for addiction, she has declined to increase the dose of pain medication.

1. Describe this case in terms of the ethical principles that it raises. Refer to the nursing code of ethics to compose your response.
2. How could a values clarification exercise promote an ethical response to this case?
3. In trying to better understand sickle cell disease, you join a chat room online where people with sickle cell disease discuss their problems. Hoping to protect patient privacy, you use only your first name and the patient's first name. You mention the name of the hospital where you work. On the basis of your reading of the ANA White Paper on Social Media, describe benefits and risks of participating in social media in this situation.

ⓔ *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The patient for whom you are caring needs a liver transplant to survive. This patient has been out of work for several months and doesn't have health insurance or enough cash. Even though several ethical principles are at work in this case, list the principles from highest to lowest priority.
   1. Accountability: You as the nurse are accountable for the well-being of this patient.
   2. Respect for autonomy: This patient's autonomy will be violated if he does not receive the liver transplant.
   3. Ethics of care: The caring thing that a nurse could provide this patient is resources for a liver transplant.
   4. Justice: The greatest question in this situation is how to determine the just distribution of resources.
2. **Fill in the Blank.** The point of the ethical practice is an agreement to reassure the public that in all ways the health care team not only

works to heal patients but agrees to do this in the least painful and harmful way possible. This principle is commonly called the principle of _____?

3. A child's immunization may cause discomfort during administration, but the benefits of protection from disease, both for the individual and society, outweigh the temporary discomforts. Which principle is involved in this situation?
   1. Fidelity
   2. Beneficence
   3. Nonmaleficence
   4. Respect for autonomy

4. When designing a plan for pain management for a postoperative patient, the nurse assesses that the patient's priority is to be as free of pain as possible. The nurse and patient work together to identify a plan to manage the pain. The nurse continually reviews the plan with the patient to ensure that the patient's priority is met. Which principle is used to encourage the nurse to monitor the patient's response to the pain?
   1. Fidelity
   2. Beneficence
   3. Nonmaleficence
   4. Respect for autonomy

5. A patient is admitted to a medical unit. The patient is fearful of hospitals. The nurse carefully assesses the patient to determine the exact fears and then establishes interventions designed to reduce these fears. In this setting how is the nurse practicing patient advocacy?
   1. Seeking out the nursing supervisor to talk with the patient
   2. Documenting patient fears in the medical record in a timely manner
   3. Working to change the hospital environment
   4. Assessing the patient's point of view and preparing to articulate it

6. The application of utilitarianism does not always resolve an ethical dilemma. Which of the following statements best explains why?
   1. Utilitarianism refers to usefulness and therefore eliminates the need to talk about spiritual values.
   2. In a diverse community it can be difficult to find agreement on a definition of usefulness, the focus of utilitarianism.
   3. Even when agreement about a definition of usefulness exists in a community, laws prohibit an application of utilitarianism.
   4. Difficult ethical decisions cannot be resolved by talking about the usefulness of a procedure.

7. The *ethics of care* suggests that ethical dilemmas can best be solved by attention to relationships. How does this differ from other ethical practices? (Select all that apply.)
   1. Ethics of care pays attention to the environment in which caring occurs.
   2. Ethics of care pays attention to the stories of the people involved in the ethical issue.
   3. Ethics of care is used only in nursing practice.
   4. Ethics of care focuses only on the code of ethics for nurses.
   5. Ethics of care focuses only on understanding relationships.

8. In most ethical dilemmas in health care, the solution to the dilemma requires negotiation among members of the health care team. Why is the nurse's point of view valuable?
   1. Nurses understand the principle of autonomy to guide respect for a patient's self-worth.
   2. Nurses have a scope of practice that encourages their presence during ethical discussions.
   3. Nurses develop a relationship with the patient that is unique among all professional health care providers.

4. The nurse's code of ethics recommends that a nurse be present at any ethical discussion about patient care.

9. Ethical dilemmas often arise over a conflict of opinion. Reliance on a predictable series of steps can help people in conflict find common ground. All of the following actions can help resolve conflict. What is the best order of these actions in order to promote the resolution of an ethical dilemma?
   1. List the actions that could be taken to resolve the dilemma.
   2. Agree on a statement of the problem or dilemma that you are trying to resolve.
   3. Agree on a plan to evaluate the action over time.
   4. Gather all relevant information regarding the clinical, social, and spiritual aspects of the dilemma.
   5. Take time to clarify values and distinguish between facts and opinions—your own and those of others involved.
   6. Negotiate a plan.

10. The ANA code of nursing ethics articulates that the nurse "promotes, advocates for, and strives to protect the health, safety, and rights of the patient." This includes the protection of patient privacy. On the basis of this principle, if you participate in a public online social network such as Facebook, could you post images of a patient's x-ray film if you obscured or deleted all patient identifiers?
    1. Yes, because patient privacy would not be violated since patient identifiers were removed
    2. Yes, because respect for autonomy implies that you have the autonomy to decide what constitutes privacy
    3. No, because, even though patient identifiers are removed, someone could identify the patient on the basis of other comments that you make online about his or her condition and your place of work
    4. No, because the principle of justice requires you to allocate resources fairly

11. What are the correct steps to resolve an ethical dilemma on a clinical unit? Place the steps in correct order.
    1. Clarify values.
    2. Ask the question, Is this an ethical dilemma?
    3. Verbalize the problem.
    4. Gather information.
    5. Identify course of action.
    6. Evaluate the plan.
    7. Negotiate a plan

12. Resolution of an ethical dilemma involves discussion with the patient, the patient's family, and participants from all health care disciplines. Which of the following best describes the role of the nurse in the resolution of ethical dilemmas?
    1. To articulate the nurse's unique point of view, including knowledge based on clinical and psychosocial observations.
    2. To study the literature on current research about the possible clinical interventions available for the patient in question.
    3. To hold a point of view but realize that respect for the authority of administrators and physicians takes precedence over personal opinion.
    4. To allow the patient and the physician to resolve the dilemma on the basis of ethical principles without regard to personally held values or opinions.

13. It can be difficult to agree on a common definition of the word *quality* when it comes to quality of life. Why? (Select all that apply.)
    1. Average income varies in different regions of the country.
    2. Community values influence definitions of quality, and they are subject to change over time.

3. Individual experiences influence perceptions of quality in different ways, making consensus difficult.
4. The value of elements such as cognitive skills, ability to perform meaningful work, and relationship to family is difficult to quantify using objective measures.
5. Statistical analysis is difficult to apply when the outcome cannot be quantified.
6. Whether or not a person has a job is an objective measure, but it does not play a role in understanding quality of life.

14. Which of the following properly applies an ethical principle to justify access to health care? (Select all that apply.)
    1. Access to health care reflects the commitment of society to principles of beneficence and justice.
    2. If low income compromises access to care, respect for autonomy is compromised.
    3. Access to health care is a privilege in the United States, not a right.
    4. Poor access to affordable health care causes harm that is ethically troubling because nonmaleficence is a basic principle of health care ethics.
    5. Providers are exempt from fidelity to people with drug addiction because addiction reflects a lack of personal accountability.
    6. If a new drug is discovered that cures a disease but at great cost per patient, the principle of justice suggests that the drug should be made available to those who can afford it.

15. Match the examples with the professional nursing code of ethics:
    1. You see an open medical record on the computer and close it so no one else can read the record without proper access.
    2. You administer a once-a-day cardiac medication at the wrong time, but nobody sees it. However, you contact the primary care provider and your head nurse and follow agency procedure.
    3. A patient at the end of life wants to go home to die, but the family wants every care possible. The nurse contacts the primary care provider about the patient's request.
    4. You tell your patient that you will return in 30 minutes to give him his next pain medication.

    a. Advocacy
    b. Responsibility
    c. Accountability
    d. Confidentiality

Answers: 1. 4, 2, 3, 1; **2.** Nonmaleficence; **3.** 2; **4.** 1; **5.** 4; **6.** 2; **7.** 1, 2, 5; **8.** 3; **9.** 4, 5, 2, 1, 6, 3; **10.** 3; **11.** 2, 4, 1, 3, 5, 7, 6; **12.** 1; **13.** 2, 3, 4, 5; **14.** 1, 2, 4; **15.** 1d, 2c, 3a, 4b.

Legal Implications in Nursing Practice

OBJECTIVES

- Describe the legal obligations and role of the nurse regarding federal and state laws that affect health care.
- Explain the legal concepts of standard of care and informed consent.
- List sources of standards of care for nurses.
- Describe the nurse's role regarding a "do not resuscitate" (DNR) order.
- Analyze legal aspects of nurse-patient, nurse–health care provider, nurse-nurse, and nurse-employer relationships.
- List the elements needed to establish negligence.
- Analyze nursing actions most often associated in a breach of nursing practice.

Safe and competent nursing practice requires clinical reasoning and an understanding of the legal framework of health care, the specific state's Nurse Practice Act, and the scope and standards of nursing care. Frequently nurses practice under several sources and jurisdictions of health care law simultaneously. Understanding the legal implications of nursing practice demands clinical judgment skills to protect patient's rights and the nurse from liability. Society expects safe health care delivery, especially from nurses who typically are perceived as being part of the most ethical and trusted profession. As patient care practice innovations and new health care technologies emerge, the principles of negligence and malpractice liability are being applied to challenging new situations. Thus you need to practice nursing armed with the skills that are the outcomes of informed critical thinking.

LEGAL LIMITS OF NURSING

As a professional nurse you need to understand the legal limits of nursing and the professional standards of care that affect nursing

practice. Knowledge of these responsibilities allows you to be a patient advocate and protect patients from harm. If you have specific questions, consult your own attorney or the attorney for your agency.

Sources of Law

The legal guidelines that nurses follow originally were derived from constitutional law, statutory law, regulatory law, and common law. Elected legislative bodies such as state legislatures and the U.S. Congress create **statutory law.** An example of state statutes are the Nurse Practice Acts found in all 50 states (see Chapter 1). **Nurse Practice Acts** describe and define the legal boundaries of nursing practice within each state. The Nurse Practice Act of each state defines the scope of nursing practice and expanded nursing roles, sets education requirements for nurses, and distinguishes between nursing and medical practice. **Regulatory law**, or **administrative law**, reflects decisions made by administrative bodies such as State Boards of Nursing when rules and regulations are passed. An example of a regulatory law is the requirement to report incompetent or unethical nursing conduct to the State

Board of Nursing. **Common law** results from judicial decisions made by courts when individual legal cases are decided. An example of a common law includes informed consent, a patient's right to refuse treatment, negligence, and malpractice.

Statutory law is either civil or criminal. **Civil laws** protect the rights of individuals and provide for fair and equitable treatment when civil wrongs or violations occur (Guido, 2014). The consequences of civil law violations are fines or specific performance of good works such as public service. Nursing negligence or malpractice is an example of a civil law violation. **Criminal laws** protect society as a whole and provide punishment for crimes, which are defined by municipal, state, and federal legislation (Garner, 2014). Criminal laws are separated into misdemeanors or felonies. A **misdemeanor** is a crime that causes injury but does not inflict serious harm (Shilling, 2011). For example, parking in a no-parking zone is a misdemeanor violation of traffic laws. A misdemeanor usually has a penalty of a monetary fine, forfeiture, or brief imprisonment. A **felony** is a serious offense that results in significant harm to another person or society in general. Felony crimes carry penalties of monetary restitution, imprisonment for greater than 1 year, or death (Guido, 2014). Examples of Nurse Practice Act violations that often carry criminal penalties include misuse of a controlled substance or practicing without a license.

Standards of Care

Standards of care are the legal requirements for nursing practice that describe minimum acceptable nursing care. Standards reflect the knowledge and skill ordinarily possessed and used by nurses actively practicing in the profession (Guido, 2014) (see Chapter 1). The American Nurses Association (ANA) (2010) develops standards for nursing practice, policy statements, and similar resolutions. These standards outline the scope, function, and role of the nurse in practice. Nursing standards of care are described in the Nurse Practice Act of every state, in the federal and state laws regulating hospitals and other health care agencies, by professional and specialty nursing organizations, and by the policies and procedures established by the health care agency where nurses work (Guido, 2014). In a malpractice lawsuit a nurse's actual conduct is compared to nursing standards of care to determine whether the nurse acted as any reasonably prudent nurse would act under the same or similar circumstances (Philo et al., 2015). For example, if a patient receives a burn from a warm compress application, negligence is determined by reviewing if the nurse followed the correct procedure for applying the compress. A breach of the nursing standard of care is one element that must be established in a claim of nursing negligence or malpractice (Westrick, 2014).

Nurse Practice Acts define the scope of nursing practice, distinguishing between nursing and medical practice and establishing education and licensure requirements for nurses. The rules and regulations enacted by a State Board of Nursing or a Nursing Commission define the practice of nursing more specifically. For example, State Boards of Nursing develop rules regarding intravenous therapy. Another example involves the use of nursing assistive personnel (NAP) (e.g., nurse assistants). Some State Boards of Nursing or Commissions define responsibilities of the registered nurse (RN) specifically and develop position statements and guidelines to help licensed nurses delegate safely to NAP (NCSBN, 2005). All nurses are responsible for knowing the provisions of the Nurse Practice Act of the state in which they work and the rules and regulations enacted by the State Board of Nursing and other regulatory administrative bodies.

The Joint Commission (TJC) (2014) requires accredited hospitals to have written nursing policies and procedures. These internal standards of care are specific to the agency and need to be accessible on all nursing units. For example, a policy/procedure outlining the steps to follow when changing a dressing or administering medication provides specific information about how nurses are to perform these tasks. Some hospitals currently are using commercially published procedural textbooks and online references to represent the general policies and procedures of the agency. You need to know the policies, procedures, and protocols of your employing agency so you use the same standard of care as the other nurses in your agency. Agency policies and procedures need to conform to state and federal laws and community standards and cannot conflict with legal guidelines that define acceptable standards of care (Guido, 2014).

In a lawsuit for malpractice or negligence, a nursing expert may testify to the jury about the standards of nursing care as applied to the facts of the case (Box 23-1). The nurse may be asked to give evidence in a deposition; statements made by the nurse will be analyzed by the nursing expert *before* a trial (Guido, 2014; Westrick, 2014). Nurse experts base their opinions on existing standards of practice established by Nurse Practice Acts, federal and state hospital licensing laws, TJC standards, professional organizations, institutional policies and procedures, job descriptions, and current nursing evidence-based literature (Guido, 2014). Usually nurses are responsible for meeting the same standards as other nurses practicing in similar settings. Specialized nurses such as certified nurse anesthetists, operating room (OR) nurses, intensive care nurses, nurse practitioners, or certified nurse-midwives have specially defined standards of care and skills. Ignorance of the law or of standards of care is not a defense against malpractice (Guido, 2014). Nurses are required to know valid, reliable, and credible evidence that is applicable to their practice and the settings in which they work, including current standards of care and the policies and procedures of their employing agency (ANA, 2014; Melnyk and Fineout-Overholt, 2014). The jury uses the standards of care to determine whether the nurse acted appropriately.

One of the first and most important cases to discuss a nurse's liability was Darling v Charleston Community Memorial Hospital (1965). It involved an 18-year-old man with a fractured leg. The emergency department physician applied a cast with insufficient padding. The man's toes became swollen and discolored, and he developed decreased sensation. He complained to the nursing staff many times. Although the nurses recognized the symptoms as signs of impaired circulation, they failed to tell their supervisor that the physician did not respond to their calls or the patient's needs. Gangrene developed, and the man's leg was amputated. Although the physician was held liable for incorrectly applying the cast, the nursing staff was also held liable for failing to adhere to the standards of care for monitoring and reporting the patient's symptoms. Even though the nurses attempted to contact the physician, the jury and subsequent judges held that, when the physician fails to respond, the nurse must continue to use the agency chain of command (e.g., charge nurse, nursing supervisor, department director or chief medical officer) to make sure that the patient receives appropriate care. Almost every state uses this 1965 Illinois Supreme Court case as legal precedent.

FEDERAL STATUTORY ISSUES IN NURSING PRACTICE

Patient Protection and Affordable Care Act

The Patient Protection and Affordable Care Act (PPACA or ACA, 2010), is characterized by four themes embedded in nursing practice: (1) consumer rights and protections; (2) affordable health care coverage; (3) increased access to care; and (4) stronger Medicare to improve care for those most vulnerable in our society.

PPACA created a new Patient's Bill of Rights that prohibited patients from being denied health care coverage because of prior existing

BOX 23-1   Anatomy of a Lawsuit

Pleadings Phase

Petition: Elements of the claim. The plaintiff outlines what the defendant nurse did wrong and, as a result of that alleged negligence, how the plaintiff was injured.

Answer: The nurse admits or denies each allegation in the petition. The plaintiff must prove anything that the nurse does not admit.

Discovery: The process of discovering all the facts of the case involves using interrogatories, full access to the medical records in question, and the depositions. The patient and the health care staff are asked questions by counsel for the defense. They answer under oath, and their testimony is recorded and kept for reference.

  Interrogatories: Written questions requiring answers under oath. Typically opposing counsel requests a list of possible witnesses, insurance experts, and which health care providers the plaintiff saw before and after the event.

  Requests for productions: Opposing parties request relevant documents, pictures, or related materials such as medical records for treatment before and after the event.

  Depositions: Questions are posed to opposing parties, witnesses, and experts under oath to obtain all relevant, nonprivileged information about the case. Experts establish the elements of the case and the applicable standard of care.

Medical records: The defendant obtains all of the plaintiff's relevant medical records for treatment before and after the event. Everything written by the nurses and the health care provider in the medical record is open to examination by both the plaintiff and the defendants.

Witnesses' deposition: Questions are posed to the witnesses under oath to obtain all relevant, nonprivileged information about the case.

Parties' depositions: The plaintiff and defendants (health care provider, nurse, and hospital personnel) are almost always deposed.

Other witnesses: Factual witnesses, both neutral and biased, are deposed to obtain information about their version of the case. They may include family members on the plaintiff's side and other medical personnel (e.g., nurses) on the defendant's side.

Experts: The plaintiff selects experts to establish the essential legal elements of the case against the defendant. The defendant selects experts to establish the appropriateness of the nursing case. Nursing experts are asked to testify to the reasonableness or inappropriate actions of the health care staff once the patient's condition began to change. The expert is asked to compare the actions of the nursing staff to the standard of care.

Trial: The trial usually occurs at least 1 to 3 years after the filing of the petition.

Proof of Negligence

- The nurse owed a duty of care to the patient.
- The nurse did not carry out the duty or breached it (failed to use that degree of skill and learning ordinarily used under the same or similar circumstances by members of the profession).
- The patient was physically injured.
- The patient's injury resulted in compensable damages that can be qualified as medical bills, lost wages, and pain and suffering.
- The patient's injury was caused by the nurse's failure to carry out that duty.

PPACA is also intended to reduce overall care costs to the consumer by (1) providing tax credits; (2) increasing insurance company accountability for premiums and rate increases; and (3) increasing the number of choices patients have to select an insurer that best meets their needs. In addition, PPACA increased access to health care. Patients now receive recommended preventive services such as screenings for cancer, blood pressure, and diabetes without having to pay copays or deductibles. As of 2014 at least 54 million Americans with private health insurance have received care under this provision of the law. Many have benefited from PPACA; anyone under 26 years of age may now continue to receive coverage under his or her parents' insurance plan. More than 3.1 million adults are now receiving health care under this clause. In addition, because of increased access to health care exchanges and insurers, as of 2014 many adults who had preexisting conditions are now also eligible for care (USDHHS, 2015).

PPACA improves Medicare coverage for vulnerable populations by improving access to care and prescriptions, decreasing costs of medications, extending the life of the Medicare Trust Fund until 2024, and addressing fraud and abuse in billing practices.

Americans with Disabilities Act

The Americans With Disabilities Act (ADA) of 1990 and as amended in 2008 is a civil rights statute that protects the rights of people with physical or mental disabilities (Dupler et al., 2012). The ADA prohibits discrimination and ensures equal opportunities for people with disabilities in employment, state and local government services, public accommodations, commercial facilities, and transportation. As defined by the statute and the U.S. Supreme Court, a disability is a mental or physical condition that substantially limits a major life activity, including seeing, hearing, speaking, walking, breathing, performing manual tasks, learning, caring for oneself, and/or working. Under the ADA employers are required to construe the definition of a person's disability to the maximum intent allowed under the ADA. For example, as expanded under the ADA, an employer must consider the needs of a person with diabetes mellitus as a potential disability and reasonably accommodate that person's needs. A person with a disability makes the choice whether to tell others of his or her disability. By exception, several cases have held that a health care provider must disclose if he or she has human immunodeficiency virus (HIV). Despite these rulings and as enforced by the Office of Equal Employment Opportunity, the ADA protects health care workers in the workplace with disabilities such as HIV infection. Likewise, health care workers cannot discriminate against HIV-positive patients (Guido, 2014).

Emergency Medical Treatment and Active Labor Act

As a result of patients being transferred from private to public hospitals without appropriate screening and stabilization (referred to as patient dumping), Congress enacted the Emergency Medical Treatment and Active Labor Act (EMTALA) in 1986. This act provides that, when a patient comes to the emergency department or the hospital, an appropriate medical screening occurs within the capacity of the hospital. If an emergency condition exists, staff must evaluate the patient and may not discharge or transfer him or her until the patient's condition stabilizes. Exceptions to this provision include if a patient requests transfer or discharge in writing after receiving information about the benefits and risks or if a health care provider certifies that the benefits of transfer outweigh the risks.

Mental Health Parity Act as Enacted Under PPACA

The Mental Health Parity Act of 1996 (MHPA) required insurance companies to offer the same level of coverage for mental health care that they provide for medical and surgical care. The MHPA was

conditions, limits on the amount of care for those conditions, and/or an accidental mistake in paperwork when a patient got sick (PPACA, 2010). Starting in 2014 more than 17.6 million children with preexisting conditions became eligible for health care; and more than 105 million Americans no longer have lifetime limits to receive care when they are ill.

replaced by the Paul Wellstone and Pete Domenici Mental Health Parity and Addiction Equity Act of 2008 (MHPAEA). The MHPAEA requires health insurance companies to provide equal coverage for mental health and substance abuse treatment. PPACA extended these requirements to small group and individual health insurance plans. It also requires Americans to obtain health insurance that includes these mental health benefits (Federal Register, 2013). PPACA requires parity (the state or condition of being equal) in provision of 10 specific services, including mental health, behavioral health, and substance use services. Insurers may not discriminate or deny coverage to patients with mental illness because of preexisting conditions; and patients may remain on their parent's health insurance until they are 26 years old. Insurers who are not required to comply with all provisions or who may be "grandfathered" into the law may exclude some treatments, especially expensive mental health treatments, from plans that provide lower-level coverage. And because PPACA does not clearly define mental illness other than to require that a "minimum level of mental health services must be covered by all insurance plans," some believe that many patients with mental illness will not be able to afford or will not be provided needed treatment.

Currently admission of a patient to a mental health unit occurs involuntarily or on a voluntary basis. Involuntary admission usually occurs when a patient is determined to be a danger either to himself or herself or others by a mental health professional (MHP). Subsequently the MHP, a court-appointed guardian ad litem, or a family member or other interested party files a petition with the court within 96 hours of the patient's admission to the hospital. A judge may determine that the patient remains a danger to himself or herself or others, in which case the judge grants the involuntary detention, and the patient can be hospitalized for 21 more days for psychiatric treatment. From a legal perspective this may be viewed as depriving the patient of his or her constitutional rights; thus nurses must clearly document the patient's behaviors to support the court's actions and decisions (Guido, 2014; Westrick, 2014).

Potentially suicidal patients are admitted to mental health units. If the patient's history and medical records indicate suicidal tendencies, the patient must be kept under supervision. Lawsuits result from patients' attempts at suicide within a hospital. The allegations in the lawsuits are that the health care provider failed to provide adequate supervision and appropriately implement agency policies and procedures to safeguard a patient while residing in this setting. Documentation of suicide precautions is essential (e.g., safety sitter).

Advance Directives

Advance directives include living wills, health care proxies, and durable powers of attorney for health care (Blais and Hayes, 2011). They are based on values of informed consent, patient autonomy over end-of-life decisions, truth telling, and control over the dying process. The Patient Self-Determination Act (PSDA) enacted in 1991 requires health care institutions to provide written information to patients concerning their rights under state law to make decisions, including the right to refuse treatment and formulate advance directives. Under PSDA a patient's record needs to document whether or not the patient has signed an advance directive. For living wills or durable powers of attorney for health care to be enforced, a patient must be declared legally incompetent or lack the capacity to make decisions regarding his or her own health care treatment. When legal competency needs clarification, a judge makes that determination. The health care provider and family usually make the determination of decisional capacity. Decisional capacity is the ability to make choices for oneself as they relate to medical care. Be familiar with the policies of your institution that comply with the PSDA. Likewise check the state laws to see if a

state honors an advance directive that originates in another state (Guido, 2014; Westrick, 2014).

Living Wills. **Living wills** represent written documents that direct treatment in accordance with a patient's wishes in the event of a terminal illness or condition. With this document a patient is able to declare which medical procedures he or she wants or does not want when terminally ill or in a persistent vegetative state. Living wills are often difficult to interpret and not clinically specific in unforeseen circumstances. Thus you are required to know how your state interprets living wills and under which circumstances a nurse implements them (Guido, 2014).

Health Care Proxies or Durable Power of Attorney for Health Care. A health care proxy or **durable power of attorney for health care (DPAHC)** is a legal document that designates a person or people of one's choosing to make health care decisions when a patient is no longer able to make decisions on his or her own behalf. This agent makes health care treatment decisions on the basis of the patient's wishes (Blais and Hayes, 2011; Westrick, 2014).

In addition to federal statutes, the ethical doctrine of autonomy ensures the patient the right to refuse medical treatment. Courts upheld the right to refuse medical treatment in the Bouvia v Superior Court case (1986). They have also upheld the right of a legally competent patient to refuse medical treatment for religious reasons. Some groups may refuse or accept medical treatment on the basis of religious beliefs. The U.S. Supreme Court stated in the Cruzan v Director of Missouri Department of Health case (1990) that "we assume that the U.S. Constitution would grant a constitutionally protected competent person the right to refuse lifesaving hydration and nutrition." In cases involving a patient's right to refuse or withdraw medical treatment, the courts balance the patient's interest with the interest of the state in protecting life, preserving medical ethics, preventing suicide, and protecting innocent third parties. Children are generally innocent third parties. Although the courts will not force adults to undergo treatment refused for religious reasons, they will grant an order allowing hospitals and health care providers to treat children of abusive or negligent parents or groups who have denied consent for treatment of their minor children for religious reasons. This is based on the legal doctrine of *parens patriae* in which the state or government makes decisions on behalf of those who are unable to make decisions for themselves.

In addition to patient refusals of treatment, a nurse frequently encounters a "do not resuscitate" (DNR) or "no code" DNR order. In 1986, New York state was the first to develop legislation based on the recommendations of the New York State Task Force on Life and the Law. These recommendations went into effect in 1988, which allowed an adult with capacity, in conjunction with his or her physician, to authorize a DNR order (Golden, 1988). Documentation that the health care provider has consulted with the patient and/or family is required before attaching a DNR order to the patient's medical record (Guido, 2014). The health care provider needs to review DNR orders routinely in case the patient's condition demands a change. If a patient does not have a DNR order, health care providers need to make every effort to revive him or her. Some states offer DNR Comfort Care and DNR Comfort Care Arrest protocols. Protocols in these instances list specific actions that health care providers will take when providing cardiopulmonary resuscitation (CPR).

CPR is an emergency treatment provided without patient consent. Health care providers perform CPR when needed unless there is a DNR order in the patient's chart. The statutes assume that all patients will be resuscitated unless there is a written DNR order in the medical record. Legally competent adult patients consent to a DNR order

verbally or in writing after receiving the appropriate information by the health care provider. Be familiar with the DNR protocols of your state.

Uniform Anatomical Gift Act

An individual who is at least 18 years of age has the right to make an organ donation (defined as a "donation of all or part of a human body to take effect upon or after death"). Donors need to make the gift in writing with their signature. In many states adults sign the back of their driver's license, indicating consent to organ donation.

In most states Required Request laws mandate that, at the time of admission to a hospital, a qualified health care provider has to ask each patient over age 18 whether he or she is an organ or tissue donor. If the answer is affirmative, the health care provider obtains a copy of the document. If the answer is negative, the health care provider discusses the option to make or refuse an organ donation and places such documentation in the patient's medical record. In most states there is a law requiring that at the time of death a qualified health care provider ask a patient's family members to consider organ or tissue donation (National Organ Transplant Act, 1984). Individuals are approached in the following order: (1) spouse, (2) adult son or daughter, (3) parent, (4) adult brother or sister, (5) grandparent, and (6) guardian. The person in the highest class makes the donation unless they are aware of conflicting indications by the decedent (Uniform Anatomical Gift Act, 1987). The health care provider who certifies death is not involved in the removal or transplantation of organs (see Chapter 37).

The National Organ Transplant Act (1984) prohibits the purchase or sale of organs. The act provides civil and criminal immunity to the hospital and health care provider who perform in accordance with the act. The act also protects the donor's estate from liability for injury or damage that results from the use of the gift. Organ transplantation is extremely expensive. Patients in end-stage renal disease are eligible for Medicare coverage for a kidney transplant. Sometimes private insurance pays for other transplants. The United Network for Organ Sharing (UNOS) has a contract with the federal government and sets policies and guidelines for the procurement of organs. Patients who require organ transplantation are on a waiting list for an organ in their geographical area that gives priority to patients who demonstrate the greatest need. Be familiar with the policies and procedures of your agency regarding organ donation.

Health Insurance Portability and Accountability Act

The Health Insurance Portability and Accountability Act (HIPAA, 1996) provides rights to patients and protects employees. It protects individual employees from losing their health insurance when changing jobs by providing portability. It allows individual employees to change jobs without losing coverage as a result of preexisting coverage exclusion as long as they have had 12 months of continuous group health insurance coverage (Mortensen et al., 2014).

In the privacy section of the HIPAA there are standards regarding accountability in the health care setting. These rules create patient right to consent to the use and disclosure of their protected health information, to inspect and copy one's medical record, and to amend mistaken or incomplete information. It limits who is able to access a patient's record. It establishes the basis for privacy and confidentiality concerns, viewed as two basic rights within the U.S. health care setting. **Privacy** is the right of patients to keep personal information from being disclosed. **Confidentiality** protects private patient information once it is disclosed in health care settings. Patient confidentiality is a sacred trust. Nurses help organizations protect patients' rights to confidentiality. Although HIPAA does not require extreme measures such as soundproof rooms in hospitals, it does mean that nurses and all health care providers need to avoid discussing patients in public hallways and provide reasonable levels of privacy when communicating with and about patients in any manner. Message boards used in patients' hospital rooms to post daily nursing care information can no longer contain information revealing a patient's medical condition.

Health care information privacy is also protected by standards set by the Health Care Financing Administration (HCFA) for hospitals and health care providers who participate in Medicare and Medicaid (Guido, 2014). These standards require that hospitals and health care providers give notice to patients of their rights to decisions about their care, grievances regarding their care management, personal freedom and safety, confidentiality, access to their own medical records, and freedom from restraints that are not clinically necessary. In addition, many state laws allow patients to access their medical records. Exceptions apply to psychotherapy notes or when a health care provider has determined that access would result in harm to the patient or another party (Privacy Rights Clearinghouse, 2014).

Health Information Technology Act

The Health Information Technology for Economic and Clinical Health Act (HITECH Act, 2009) was passed in conjunction with HIPPA in response to new technology and social media. In particular, HITECH expands the principles extended under the HIPAA, especially when a security breach of personal health information (PHI) occurs. Under the HITECH Act nurses must ensure that patient PHI is not inadvertently conveyed on social media and in particular that protected data are not disclosed other than as permitted by the patient (Box 23-2). Civil and criminal sanctions may be brought against both the nurse and the organization should either or both violate either the HIPPA or the HITECH Act.

Restraints

A physical restraint is any manual method, physical or mechanical device, or material or equipment that immobilizes or reduces the ability of a patient to move freely (CMS, 2008). The Omnibus Reconciliation Act (1987) includes chemical restraint as a form of

BOX 23-2   EVIDENCE-BASED PRACTICE

Social Media and Legal Liability

PICO Question: Can social media be used by nurses without creating legal liability?

Evidence Summary

Social media is used today to reach millions of patients, colleagues, and peers. It is a useful tool for promoting collaboration, disseminating and sharing information, and providing education. It is essential that nurses be responsible and accountable for understanding the use, implications, and guidelines associated with the use of social media (Scruth et al., 2015). The NCSBN (2011) and the International Nurse Regulators Collaborative (INRC) identified nurses' behaviors for appropriate use of social media.

Application to Nursing Practice

- Understand the risks and benefits of using social media
- Maintain professional boundaries
- Present a professional image in all social media interactions
- Maintain privacy and confidentiality
- Understand the implications of identifying yourself as a nurse
- Know state laws governing use of social media

restraint. The use of restraints has been associated with serious complications and even death. You need to know when and how to use and safely apply restraints. The Centers for Medicare and Medicaid Services (CMS) (2008), ANA (2001), and TJC (2014) set standards to reduce the use of all types of restraints in health care settings (i.e., that all patients have the right to be free from seclusion and physical or chemical restraints, except to ensure the patient's safety in emergency situations). They also describe the procedures to follow to restrain a patient, including who orders the restraints, when to write the order, and how often to renew the written order. Restraints can be used (1) only to ensure the physical safety of the patient or other patients, (2) when less restrictive interventions are not successful, and (3) only on the written order of a health care provider (TJC, 2014). The regulations also describe documentation of restraint use and follow-up assessments. Litigation from improper restraint use is a common nursing legal issue (Guido, 2014). Knowing when and how to use restraints correctly is key (Chapter 27). Liability for improper or unlawful restraint lies with the nurse and the health care agency.

STATE STATUTORY ISSUES IN NURSING PRACTICE

Licensure

A State Board of Nursing or Nursing Commission licenses all RNs in the state in which they practice. The requirements for licensure vary among states. All states use the National Council Licensure Examinations (NCLEX®) for RNs and licensed practical nurse examinations. Licensure permits people to offer special skills to the public, and it also provides legal guidelines for protection of the public.

The State Board of Nursing suspends or revokes a license if a nurse's conduct violates the Nurse Practice Act, which is a state law. For example, nurses who perform illegal acts such as selling or taking controlled substances often lose their license. Because a license is a property right, the State Board of Nursing must provide notice and follow due process before revoking or suspending a license. Due process means that the state is required to notify nurses of the charges brought against them. Nurses need to have an opportunity to defend themselves in a hearing. Hearings for suspension or revocation of a license do not occur in court. Usually a panel of professionals conducts the hearing. Nurses can choose to be represented by an attorney. They are allowed opportunities to provide evidence in support of their opinion regarding the charges, and they may call witnesses to testify on their behalf. Most states provide administrative and judicial review of these cases after nurses have exhausted all other forms of appeal. Actions and decisions by State Boards of Nursing are published and accessible by health care agencies and the general public.

Good Samaritan Laws

All states have **Good Samaritan laws** to encourage health care professionals to assist in emergencies (Westrick, 2014). These laws limit liability and offer legal immunity if a nurse helps at the scene of an accident. For example, if you stop at the scene of an automobile accident and give appropriate emergency care such as applying pressure to stop hemorrhage, you are acting within accepted standards, even though proper equipment is not available. If the patient subsequently develops complications as a result of your actions, you are immune from liability as long as you acted without gross negligence (Good Samaritan Act, 1997). Although Good Samaritan laws provide immunity to a nurse who does what is reasonable to save a person's life, if you perform a procedure exceeding your scope of practice and for which you have no training, you are liable for injury that may result

from that act. You should only provide care that is consistent with your level of expertise. In addition, once you have committed to providing emergency care to a patient, you must stay with that patient until you can safely transfer his or her care to someone who can provide needed care such as emergency medical technicians (EMTs) or emergency department staff. If you leave the patient without properly transferring or handing him or her off to a capable person, you may be liable for patient abandonment and responsible for any injury suffered after you leave him or her (Westrick, 2014).

Public Health Laws

Nurses, especially those employed in community health settings, need to understand public health laws. State legislatures enact statutes under health codes, which describe the requirements for reporting communicable diseases, school immunizations, and other conditions intended to promote health and reduce health risks in communities. The Centers for Disease Control and Prevention (CDC) (http://www.CDC.gov) and the Occupational Health and Safety Act (OHSA) (http://www.osha.gov) provide guidelines on a national level for safe and healthy communities and work environments. Public health laws protect populations, advocate for the rights of people, regulate health care and health care financing, and ensure professional accountability for care provided. Community and public health nurses have the legal responsibility to enforce laws enacted to protect public health (see Chapter 3). These laws include reporting suspected abuse and neglect such as child abuse, elder abuse, or domestic violence; reporting communicable diseases; ensuring that patients in the community have received required immunizations; and reporting other health-related issues to protect public health. In most states nurses are mandatory reporters of suspected abuse or neglect of patients. Any health care professional who does not report suspected child abuse or neglect may be liable for civil or criminal legal action. Some State Boards of Nursing are now requiring mandatory continuing education on child abuse and neglect for license renewal or before obtaining a new nursing license.

The Uniform Determination of Death Act

Many legal issues surround the event of death, including a basic definition of the actual point at which a person is legally dead. There are two standards for the determination of death. The cardiopulmonary standard requires irreversible cessation of circulatory and respiratory functions. The whole-brain standard requires irreversible cessation of all functions of the entire brain, including the brainstem. The reason for the development of different definitions is to facilitate recovery of organs for transplantation. Even though the patient is legally "brain dead," the patient's organs are sometimes healthy for donation to other patients. Most states have statutes similar to the Uniform Determination of Death Act (1980). It states that health care providers can use either the cardiopulmonary or the whole-brain definition to determine death. Be aware of legal definitions of death in your state because you need to document all events that occur when the patient is in your care. Nurses have a specific legal obligation to treat the deceased person's remains with dignity (see Chapter 37). Wrongful handling of a deceased person's remains causes emotional harm to the surviving family.

Autopsy

An autopsy or postmortem examination is sometimes requested by the patient or patient's family (Autopsy Consent, 1998). In addition, an autopsy is requested as a part of agency policy; or it is sometimes required under the laws of your state. Some statutes specify that, when there are reasonable grounds to believe that a patient died as a result

of violence, homicide, suicide, accident, or death in an unusual or suspicious manner, you need to notify the medical examiner (Autopsy Consent, 1998). When a patient's death is not subject to a medical examiner review, consent must be obtained. The priority for giving consent is (1) the patient, in writing before death; (2) durable power of attorney; (3) surviving spouse; and (4) surviving child, parent, or sibling in the order named. You also notify the medical examiner if a patient's death is unforeseen and sudden and a heath care provider has not seen the patient in over 36 hours.

Death with Dignity or Physician-Assisted Suicide

Providing end-of-life care in today's world is challenging for health care professionals because people are living longer (see Chapter 37). The Oregon Death With Dignity Act (1994) was the first statute that legislatively defined "death with dignity," more commonly called *physician-assisted suicide*. The statute stated that a competent individual with a terminal disease could make an oral and written request for medication to end his or her life in a humane and dignified manner. A terminal disease is defined as an "incurable and irreversible disease that has been medically confirmed and will, within reasonable medical judgment, produce death within 6 months."

The ANA (2013) believes that nurses' participation in assisted suicide violates the code of ethics for nurses. The American Association of Colleges of Nursing (AACN) supports the International Council of Nurses' mandate to ensure an individual's peaceful end of life (Guido, 2014). The positions of these two national organizations are not considered contradictory and require nurses to approach a patient's end of life with openness to listening to the patient's expressions of fear and to attempt to control the patient's pain during his or her last months of life. You need to know your state's laws and ensure your practice falls within the laws' requirements.

CIVIL AND COMMON LAW ISSUES IN NURSING PRACTICE

Torts

Nursing practice is also regulated by common law or judicial case law of torts. **Torts** are civil wrongful acts or omissions made against a person or property. They are classified as intentional, quasi-intentional, or unintentional. **Intentional torts** are deliberate acts that violate another's rights such as assault, battery, and false imprisonment. **Quasi-intentional torts** are acts in which intent is lacking but volitional action and direct causation occur such as in invasion of privacy and defamation of character. The third classification of tort is the **unintentional tort**, which includes negligence or malpractice.

Intentional Torts

Assault. **Assault** is an intentional threat toward another person that places the person in reasonable fear of harmful, imminent, or unwelcome contact (Shilling, 2011). No actual contact is required for an assault to occur. For example, it is an assault for a nurse to threaten to give a patient an injection or to threaten to restrain a patient for an x-ray film procedure when the patient has refused consent. Likewise, it is an assault for a patient to threaten a nurse (Guido, 2014).

Battery. **Battery** is any intentional offensive touching without consent or lawful justification (Shilling, 2011). The contact can be harmful to the patient and cause an injury, or it merely can be offensive to the patient's personal dignity. In the example of a nurse threatening to give a patient an injection without the patient's consent, if the nurse actually gives the injection, it is battery. Battery also results if the health care provider performs a procedure that goes beyond the scope of a

patient's consent. For example, if a patient gives consent for an appendectomy and the surgeon performs a tonsillectomy, battery has occurred. The key component is the patient's consent.

In some situations consent is implied. For example, if a patient gets into a wheelchair or transfers to a stretcher after receiving advice that it is time to be taken for an x-ray film procedure, the patient has given implied consent to the procedure. If a patient learns that he or she will have an x-ray film of the head instead of the foot and the patient refuses to have the x-ray film taken, the consent has been revoked or withdrawn.

False Imprisonment. The tort of **false imprisonment** occurs with unjustified restraint of a person without a legal reason. This occurs when nurses restrain a patient in a confined area to keep the person from freedom. False imprisonment requires that the patient be aware of the confinement. An unconscious patient has not been falsely imprisoned (Guido, 2014).

Quasi-Intentional Torts

Invasion of Privacy. The tort of **invasion of privacy** protects a patient's right to be free from unwanted intrusion into his or her private affairs. HIPAA and HITECH Act privacy standards have raised awareness of the need for health care professionals to provide confidentiality and privacy. Typically invasion of privacy is the release of a patient's medical information to an unauthorized person such as a member of the press, the patient's employer, or the patient's family or online. The information that is in a patient's medical record is a confidential communication that may be shared with health care providers for the purpose of medical treatment only.

Do not disclose a patient's confidential medical information without his or her consent. A patient must authorize the release of information and designate to whom the health care information may be released. For example, respect the wish not to inform a patient's family of an illness. Similarly, do not assume that a patient's spouse or family members know all of the patient's history, particularly with respect to private issues such as mental illness, medications, pregnancy, termination of pregnancy, birth control, or sexually transmitted infections.

An individual's right to privacy sometimes conflicts with the public's right to know. In one case a television crew filmed a married couple who were participating in a hospital program. The couple had previously told no one but their immediate family that they were involved in the in vitro fertilization program and had received assurance that there would be no publicity or public exposure. After the newscast they received phone calls and embarrassing questions. The couple filed a lawsuit. The court held that the husband and wife stated a claim for invasion of privacy and that, even though the in vitro fertilization program was of public interest, the identity of the plaintiffs was a private matter (YG v Jewish Hospital, 1990).

Many states, through their respective public health departments, require that hospitals report certain infectious or communicable diseases. Sometimes the patient is a public figure whose physical condition is newsworthy (Guido, 2014). There are also cases in which information about a scientific discovery or a major medical breakthrough is newsworthy, as with the first heart transplant case or the first artificial heart recipient. If an event falls into any of these categories, never speak to the media; guide information through the public relations department of the institution to ensure that invasion of privacy does not occur. It is not the nurse's responsibility to decide independently the legality of disclosing information.

Defamation of Character. **Defamation of character** is the publication of false statements that result in damage to a person's reputation. **Slander** occurs when one speaks falsely about another. For example, if

a nurse tells people erroneously that a patient has gonorrhea and the disclosure affects the patient's business, the nurse is liable for slander. Libel is the written defamation of character (e.g., charting false entries in a medical record) (Philo et al., 2015).

Unintentional Torts

Negligence. Negligence is conduct that falls below the generally accepted standard of care of a reasonably prudent person (Karno, 2011). The law establishes the standard of care to protect others against an unreasonably great risk of harm (Westrick, 2014). Negligent acts such as hanging the wrong intravenous solution for a patient often result in disciplinary action by the State Board of Nursing and a lawsuit for negligence against both the nurse and his or her employer.

Malpractice. Malpractice is one type of negligence and often referred to as professional negligence. When nursing care falls below a standard of care, nursing malpractice results. Certain criteria are necessary to establish nursing malpractice: (1) the nurse (defendant) owed a duty of care to the patient (plaintiff), (2) the nurse did not carry out or breached that duty, (3) the patient was injured, and (4) the nurse's failure to carry out the duty caused the injury. Even though nurses do not intend to injure patients, some patients file claims of malpractice if nurses give care that does not meet the appropriate standards. Malpractice sometimes involves failing to check a patient's identification correctly before administering blood and then giving the blood to the wrong patient. It also involves administering a medication to a patient even though the medical record contains documentation that the patient has an allergy to that medication. In general, courts define nursing malpractice as the failure to use that degree of skill or learning ordinarily used under the same or similar circumstances by members of the nursing profession (Box 23-3) (Keenan et al., 2013).

The best way for nurses to avoid malpractice is to follow standards of care, give competent care, and communicate with other health care providers. You also avoid malpractice by developing a caring rapport with the patient and documenting assessments, interventions, and evaluations fully. Nurses need to know the current nursing literature in their areas of practice. Know and follow the policies and procedures of the agency where you work. Be sensitive to common sources of patient injury such as falls and medication errors. Finally,

---

BOX 23-3 Common Sources of Negligence

Be aware of the common negligent acts that have resulted in lawsuits against hospitals and nurses.

- Failure to assess and/or monitor, including making a nursing diagnosis
  - Failure to observe, assess, correctly diagnose or treat in a timely manner
  - Failure to use, calibrate, or replace equipment required to safely care for the patient
  - Failure to document care and evaluation of care provided to the patient in a timely manner
- Failure to notify the health care provider of significant changes in a patient's status
- Failure to respond to or correctly implement new and existing orders
- Failure to follow the six rights of medication administration
- Failure to convey discharge instructions to the patient, his or her family, or providers who are assuming responsibility for the patient
- Failure to ensure patient safety, especially patients who have a history of falling, are sedated or confused, are frail, are mentally impaired, get up in the night, or are uncooperative
- Failure to follow policies and procedures
- Failure to properly delegate and supervise

---

communicate with the patient, explain all tests and treatments, document that you provided specific explanations to him or her, and listen to his or her concerns about treatments. You are accountable for timely reporting of any significant changes in the patient's condition to the health care provider and documenting these changes in the medical record (see Chapter 26). Timely and truthful documentation is important to provide the communication necessary among health care team members. Be certain that documentation is legible and signed (Westrick, 2014).

A number of courts have stated that, when a health care provider negligently alters or loses medical records relevant to a malpractice claim, the health care provider needs to demonstrate why these events occurred. An agency has a duty to maintain nursing records. Statutes and accreditation regulations establish these duties. Nursing notes contain substantial evidence needed to understand the care received by a patient. If records are lost or incomplete, there is a presumption that the care was negligent and therefore the cause of the patient's injuries. In addition, incomplete or illegible records make a health care provider less credible or believable. Especially when using electronic medical records, it is important to determine changes in patient conditions documented by prior nursing staff and document timely responses to those changes. In addition, it is essential to provide and document patient decision making—the patient is the primary decision maker, regardless of setting, when care is provided.

Consent

A patient's signed consent form is necessary for admission to a health care agency, invasive procedures such as intravenous central line insertion, surgery, some treatment programs such as chemotherapy, and participation in research studies (Guido, 2014). A patient signs a general consent form for treatment when admitted to a health care agency or other health care facility. A patient or the patient's representative needs to sign separate special consent or treatment forms before the performance of a specialized procedure. State laws designate individuals who are legally able to give consent to medical treatment (Medical Patient Rights Act, 1994). Nurses need to know the law in their states and be familiar with the policies and procedures of their employing agency regarding consent (Box 23-4). Special consideration is used when a patient is deaf or illiterate or speaks a foreign language. An official interpreter must be present to explain the terms of consent. A family member or acquaintance who speaks a patient's language should not interpret health information. Make every effort to help the patient make an informed choice.

When a competent patient refuses care or treatment, it is important to recognize that this act is legally his or her right. You inform the health care provider of the patient's refusal to receive care and document this in the medical record.

Informed Consent. Informed consent is a patient's agreement to have a medical procedure after receiving full disclosure of risks, benefits, alternatives, and consequences of refusal (Westrick, 2014). Informed consent requires a health care provider to disclose information in terms a patient is able to understand to make an informed choice (Guido, 2014). Failure to obtain consent in situations other than emergencies can result in a claim of battery.

Informed consent is part of the health care provider–patient relationship. It must be obtained and witnessed when the patient is not under the influence of medication such as opioids. Because nurses do not perform surgery or direct medical procedures, in most situations obtaining patients' informed consent does not fall within the nurse's responsibility. The person responsible for performing the procedure is responsible for obtaining the informed consent.

Those who may consent to medical treatment are governed by state law but generally include the following:

I. Adults
  A. Any competent individual 18 years of age or older for himself or herself
  B. Any parent for his or her unemancipated minor
  C. Any guardian for his or her ward
  D. Any adult for the treatment of his or her minor brother or sister (if an emergency and parents are not present)
  E. Any grandparent for a minor grandchild (in an emergency and if parents are not present)
II. Minors
  A. Ordinarily minors may not consent to medical treatment without a parent. However, emancipated minors may consent to medical treatment without a parent. Emancipated minors include:
     1. Minors who are designated emancipated by a court order
     2. Minors who are married, divorced, or widowed
     3. Minors who are in active military service
  B. Unemancipated minors may consent to medical treatment if they have specific medical conditions
     1. Pregnancy and pregnancy-related conditions (Various states differ in characterizing a pregnant minor as either emancipated or unemancipated. Know your state rules in this matter.)
     2. A minor parent for his or her custodial child
     3. Sexually transmitted infection (STI) information and treatment
     4. Substance abuse treatment
     5. Outpatient and/or temporary sheltered mental health treatment
  C. The issue of emancipated or unemancipated minors does not relieve the health care provider's duty to attempt to obtain meaningful informed consent (Guido, 2014).

Key elements of informed consent include the following: (1) the patient receives an explanation of the procedure or treatment; (2) the patient receives the names and qualifications of people performing and assisting in the procedure; (3) the patient receives a description of the serious harm, including death, that may occur as a result of the procedure and anticipated pain and/or discomfort; (4) the patient receives an explanation of alternative therapies to the proposed procedure/treatment and the risks of doing nothing; (5) the patient knows that he or she has the right to refuse the procedure/treatment without discontinuing other supportive care; (6) the patient knows that he or she may refuse the procedure/treatment even after the procedure has begun (Westrick, 2014).

The nurse's signature as a witness to the consent means that the patient voluntarily gave consent, the patient's signature is authentic, and the patient appears to be competent to give consent (Guido, 2014). When nurses provide consent forms for patients to sign, they must ask the patients if they understand the procedure for which they are giving consent. If patients deny understanding or you suspect that they do not understand, notify the health care provider or nursing supervisor. Health care providers must inform a patient refusing surgery or other medical treatment about any harmful consequences of refusal. If the patient continues to refuse the treatment, the nurse should again ensure that documentation of the rejection is written, signed, and witnessed. It is important to note that nursing students cannot and should not be responsible for or asked to witness consent forms because of the legal nature of the document.

Parents are usually the legal guardians of pediatric patients; therefore they typically are the people who sign consent forms for treatment. Occasionally a parent or guardian refuses treatment for a child. In these cases the court sometimes intervenes on the child's behalf. Courts generally consider the child's ultimate safety and well-being as the most important factors.

In some instances obtaining informed consent is difficult. For example, if a patient is unconscious, you must obtain consent from a person legally authorized to give it on the patient's behalf. Sometimes a patient has legally designated surrogate decision makers through special power of attorney documents or court guardianship procedures. In emergencies, if it is impossible to obtain consent from the patient or an authorized person, a health care provider may perform a procedure required to benefit the patient or save a life without liability for failure to obtain consent. In such cases the law assumes that the patient would wish to be treated.

Patients with mental illnesses must also give consent. They retain the right to refuse treatment until a court has determined legally that they are incompetent to decide for themselves.

Termination of Pregnancy or Abortion Issues

In 1973 in the case of Roe v Wade, the U.S. Supreme Court ruled that there is a fundamental right to privacy, which includes a woman's decision to terminate a pregnancy. The court ruled that during the first trimester a woman could end her pregnancy without state regulation because the risk of natural mortality from abortion is less than with normal childbirth. During the second trimester the state has an interest in protecting maternal health, and it enforces regulations regarding the person terminating the pregnancy and the facility where it is done. By the third trimester, when the fetus becomes viable, the interest of the state is to protect the fetus; therefore it prohibits termination except when necessary to save the mother.

In Webster v Reproductive Health Services (1989) the court substantially narrowed Roe v Wade. Some states require viability tests before conducting abortions if the fetus is over 28 weeks' gestational age; others consider 26 weeks' gestational age or less when terminating a pregnancy. Some states also require a minor's parental consent or a judicial decision that the minor is mature and can self-consent. Others do not require parental consent; thus again it is critical to know the law in your state related to termination of pregnancy before working in this area of practice.

Nursing Students

Nursing students are liable if their actions exceed their scope of practice and cause harm to patients. If a student harms a patient as a direct result of his or her actions or lack of action, the student, instructor, hospital, or health care agency and the university or educational institution generally share the liability for the incorrect action. Nursing students should never be assigned to perform tasks for which they are unprepared, and instructors should supervise them carefully as they learn new skills. Although nursing students are not employees of the hospital, the agency has a responsibility to monitor their acts. They are expected to perform as professional nurses would in providing safe patient care. Faculty members are usually responsible for instructing and observing students, but in some situations staff nurses serving as preceptors share these responsibilities. Every nursing school should provide clear definitions of preceptor and faculty responsibility. It is equally important that nursing preceptors be aware of state laws applicable to nursing students, faculty, and the educational institution when supervising students.

When students work as nursing assistants or nurse's aides when not attending classes, they should not perform tasks that do not appear in

a job description for a nurse's aide or assistant. For example, even if a student has learned to administer intramuscular medications in class, the student now working as a nurse's aide may not perform this task. If a staff nurse overseeing the nursing assistant or aide knowingly assigns work without regard for the person's ability to safely conduct the task defined in the job description, the staff nurse is also liable. If someone requests that a student employed in the agency as a nurse's aide performs tasks that he or she is not prepared to complete safely, the student employee needs to bring this information to the supervisor's attention so the task can be assigned to an appropriate health care professional.

Malpractice Insurance

Malpractice or professional liability insurance is a contract between a nurse and an insurance company. This insurance provides both malpractice and professional defense coverage for individual nurses. Malpractice insurance provides for a defense when a nurse is in a lawsuit. The insurance company pays for costs, attorney's fees and settlement, and other related fees generated in the representation of the nurse. Nurses employed by health care agencies generally are covered by insurance provided by the agency; however, it is important to remember that the lawyer is representing your employer and not you. The insurance provided by the employing agency only covers nurses while they are working within the scope of their employment.

Nurses are also investigated by the State Board of Nursing or Nursing Commission to determine whether the alleged breach in care violated the Nurse Practice Act. This investigation typically is separate from the malpractice action and not covered under the employer's insurance coverage. Without individual insurance coverage, the nurse will be required to personally pay all costs and attorney fees incurred by him or her in the defense against these claims. Typically these costs exceed more than $10,000; therefore nurses should ensure that they have the means or personal liability to defend any action against their license to ensure their ongoing employment as a nurse.

Abandonment and Assignment Issues

Abandonment of a patient occurs when a nurse refuses to provide care for a patient after having established a patient-nurse relationship. Before having established that relationship, a nurse may refuse an assignment when (1) the nurse lacks the knowledge or skill to provide competent care; (2) care exceeding the Nurse Practice Act is expected; (3) health of the nurse or her unborn child is directly threatened by the type of assignment; (4) orientation to the unit has not been completed and safety is at risk; (5) the nurse clearly states and documents a conscientious objection on the basis of moral, ethical, or religious grounds; or (6) the nurse's clinical judgment is impaired as a result of fatigue, resulting in a safety risk for the patient (Westrick, 2014).

When refusing an assignment, it is important to give your immediate supervisor specific reasons for the refusal and determine if other alternatives such as reassignment are available. Be sure that you document in your personal notes specifics of the incident, to whom you reported it, and actions you took to ensure that patients were safe and that you did not abandon your patients (Westrick, 2014).

Short Staffing. During nursing shortages or staff downsizing periods, the issue of inadequate staffing occurs. The Community Health Accreditation Program (CHAP) and other state and federal standards require agencies to have guidelines for determining the number (staffing ratios) of nurses required to give care to a specific number of patients. Legal issues occur when there are not enough nurses available to provide competent care or when nurses work excessive overtime. One such example is in a class-action suit, Spires v Hospital Corporation of America, filed on April 10, 2006. The wife claimed there was poor patient care related to insufficient RN staffing and that the poor nurse-staffing levels led to the resultant death of her husband. This suit emphasized the potential seriousness of short staffing and the importance of nurses' asserting employee rights.

In an attempt to address the short-staffing problem, many states now require that nursing committees in acute care settings determine safe staffing on the basis of the needs of patients admitted to their facilities. In California fixed nurse-patient ratios are required in acute care settings. The safe staffing ratio debate is occurring throughout the country and demands close attention by all nurses (ANA, 2014).

The ANA in conjunction with professional nursing organizations has supported federal legislation titled the Registered Nurse Safe Staffing Act (ANA, 2014). This act supports recent evidence linking ratios of RN staffing to improved patient mortality and better patient outcomes. Under this act Medicare-certified facilities nationally would be required to establish staffing committees comprised of 55% direct-care nurses who would determine adequacy of staffing on the basis of patients admitted to specific units that provide predetermined types of care. Under this act, nurses become an integral part of ensuring that patients receive care from nurses qualified to meet their needs and that care is provided in a safe environment.

Floating. Nurses are sometimes required to "float" from the area in which they normally practice to other nursing units on the basis of census load and patient acuities. Nurses who float must inform the supervisor of any lack of experience in caring for the type of patients on the nursing unit. They should request and receive an orientation to the unit. Supervisors are liable if they give a staff nurse an assignment that he or she cannot handle safely. Before accepting employment, learn the policies of the agency regarding floating and understand what is expected (Guido, 2014).

Health Care Providers' Orders. The health care provider (physician or advanced practice nurse) is responsible for directing medical treatment. Nurses follow health care providers' orders unless they believe that the orders are in error, violate agency policy, or are harmful to the patient. Therefore you need to assess all orders; if you find one to be erroneous or harmful, further clarification from the health care provider is necessary. If the health care provider confirms an order and you still believe that it is inappropriate, use the agency chain of command to inform your direct supervisor. The supervising nurse should help resolve the questionable order. A medical consultant sometimes helps clarify its appropriateness or inappropriateness. A nurse carrying out an inaccurate or inappropriate order is legally responsible for any harm the patient suffers.

In a malpractice lawsuit against a health care provider and a hospital, one of the most frequently litigated issues is whether the nurse kept the health care provider informed of the patient's condition. To inform a health care provider properly, you perform a competent nursing assessment of the patient to determine the signs and symptoms that are significant related to the attending health care provider's tasks of diagnosis and treatment. Be certain to document that you notified the health care provider and his or her response, your follow-up, and the patient's response.

Make sure that all the health care provider orders are in writing, dated and timed appropriately, and transcribed correctly. Verbal or telephone orders are not recommended because they leave the possibilities for error. If a verbal or telephone order is necessary during an emergency, it is signed by the health care provider as soon as possible, usually within 24 hours (TJC, 2016).

RISK MANAGEMENT AND QUALITY ASSURANCE

The rationale for risk-management and quality improvement programs is the development of an organizational system of ensuring appropriate, quality health care by identifying potential hazards and eliminating them before harm occurs (Guido, 2014). **Risk management** involves several components, including identifying possible risks, analyzing them, acting to reduce the risks, and evaluating the steps taken to reduce them (Miller, 2011). TJC (2016) requires the use of quality improvement and risk-management procedures.

Both quality improvement and risk management require thorough documentation. One tool used in risk management is the **occurrence report** or incident report. Occurrence reporting provides a database for further investigation in an attempt to determine deviations from standards of care, to identify corrective measures needed to prevent recurrence, and to alert risk management to a potential claim situation. Examples of an occurrence include patient or visitor falls or injury; failure to follow health care provider orders; a significant complaint by patient, family, health care provider, or other hospital department; an error in technique or procedure; and a malfunctioning device or product. Agencies generally have specific guidelines to direct health care providers in how to complete the occurrence report. The report is confidential and separate from the medical record; however, it is often discoverable during a legal proceeding. As a nurse you are responsible for providing information in the medical record about the occurrence. Never document in the patient's medical record that you completed an occurrence report.

Risk management also requires complete documentation. A nurse's documentation is often the evidence of care received by a patient and establishes support that the nurse acted reasonably and safely. When a lawsuit is filed, very often the nurses' notes are the first thing an attorney reviews. The nurse's assessments and the reporting of significant changes in the assessments are very important factors in defending a lawsuit. Therefore it is critical for you to document the health care provider contacted, the information communicated to the health care provider, and the health care provider's response.

QSEN   **QSEN: BUILDING COMPETENCY IN QUALITY IMPROVEMENT**   You are a member of your unit's task force focusing on quality improvement and reduction in sentinel events. The chairperson explains to the task force that quality improvement relates to data collection, evaluation, and improvement in outcomes. One of the nurses asks, "How can we reduce the number of occurrence reports being filed on the unit related to patient falls?" How would you respond?

ⓔ *Answers to QSEN Activities can be found on the Evolve website.*

One area of potential risk is associated with the use of electronic monitoring devices. No monitor is reliable at all times; therefore do not depend on them completely. Continual assessment of a patient is necessary to help document the accuracy of electronic monitoring. There are also electrical hazards to the nurse and the patient. Biomedical engineers check equipment to ensure that it is in proper working order and that a patient will not receive an electrical shock. Document when calibration of equipment occurs.

Nurses on the units are risk managers. For example, surgeons rely on OR nurses to compare the consent form with the indicated and prepped surgical site for accuracy. Because of errors with patients undergoing the wrong surgery or having surgery performed on the wrong site, TJC's Universal Protocol includes guidelines for preventing such mishaps (TJC, 2016) and now require mandatory time-outs before beginning the surgery. Implement this protocol whenever an invasive surgical procedure is to be performed, regardless of the location (hospital, ambulatory surgical center [ASC], or health care provider office). The three principles of the protocol are: (1) preoperative verification that relevant documents and studies are available before the start of the procedure and that these documents are consistent with the patient's expectations; (2) marking the operative site with indelible ink to mark left and right distinction, multiple structures (e.g., fingers), and levels of the spine; and (3) a *time-out* just before starting the procedure for final verification of the correct patient, procedure, site, and any implants.

Patient safety and improved care are the goals of quality improvement and risk management. TJC (2016) and groups such as the Institute of Medicine have a focus on patient safety as major goals. **Never events** are preventable errors, which may include falls, urinary tract infections from improper use of catheters, and pressure ulcers (AHRQ, 2015). The federal government and health care insurance companies have developed policies to withhold reimbursement for preventable medical errors (AHRQ, 2015). Know your agency policies and procedures to help develop a system and culture of patient safety.

Professional Involvement

Become involved in professional organizations and committees that define the standards of care for nursing practice. If current laws, rules and regulations, or policies under which nurses practice are not evidence based, advocate to ensure that the scope of nursing practice is defined accurately. Be willing to represent nursing and the patient's perspective in the community as well. The voice of nursing is powerful and effective when the organizing focus is the protection and welfare of the public entrusted to nurses' care (Blais and Hayes, 2011).

■ KEY POINTS

- RNs and licensed practical nurses are licensed by the state in which they practice; licensing is based on educational requirements, the passing of an examination, and other criteria.
- The civil law system is concerned with the protection of a person's private rights, and the criminal law system deals with the rights of individuals and society as defined by legislative statutes.
- A nurse is liable for malpractice if the nurse (defendant) owed a duty to the patient (plaintiff), the nurse did not carry out that duty, the patient was injured, and the nurse's failure to carry out the duty caused the patient's injury.
- All patients are entitled to confidential health care and freedom from unauthorized release of information.
- Under the law, practicing nurses must follow standards of care, the guidelines of professional organizations, and the written policies and procedures of the employing agency.
- Nurses who witness consents are responsible for confirming that patients have given informed consent for any surgery or other medical procedure voluntarily before the procedure is performed.
- Nurses are responsible for performing all procedures correctly and exercising professional judgment as they carry out health care providers' orders.
- Nurses follow health care providers' orders unless they believe the order to be in error, that it violates agency policy, or that it can harm patients.
- Staffing standards determine the ratio of nurses to patients; if the nurse has to care for more patients than is reasonable, he or she needs to make a formal protest to the nursing administration.
- Legal issues involving death include documenting all events surrounding the death and treating a deceased person with dignity.

- All nurses need to know the laws that apply to their area of practice.
- Depending on state laws, nurses are required to report possible criminal activities such as child abuse and certain communicable diseases.
- Nurses are patient advocates and ensure quality of care through risk management and lobbying for safe nursing practice standards.
- Nurses file incident/occurrence reports for all errors even when someone is not injured.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You are working the first shift on the hematology-oncology unit and receive report on your assigned team of three patients. You have a nursing assistive personnel (NAP) assigned to help you with routine care. You make quick rounds on your patients to ensure that there are no immediate needs before you begin checking medications. Patient No. 1 is scheduled for surgery later in the morning for a biopsy and needs the surgical consent signed. Patient No. 2 is receiving blood products for a human immunodeficiency virus (HIV) complication and needs frequent vital sign monitoring. You find patient No. 3, an 83-year-old confused man, lying on the floor. He states that he needed to go to the restroom and no one was there to help.

1. The nurse prepares the surgical consent form for patient No. 1. Which key points does he or she need to ensure that the patient received before witnessing informed consent?
2. The son of patient No. 2 calls to talk to the nurse caring for his father. The son asks questions about the reason for the blood administration. Which guidelines does the nurse follow in responding to the son's questions about the father's condition? Which federal statutes are involved in this scenario?
3. One week after discharge from the hospital, the hospital received a written complaint from the family of patient No. 3 about the incident related to the fall and the intent to take legal action.
   a. What must patient No. 3 establish to prove negligence against the nurse?
   b. Describe situations in which restraints may be applied legally to prevent falls.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse is caring for a patient who recently had coronary bypass surgery and now is on the postoperative unit. Which are legal sources of standards of care that the nurse uses to deliver safe health care? (Select all that apply.)
   1. Information provided by the head nurse
   2. Policies and procedures of the employing hospital
   3. State Nurse Practice Act
   4. Regulations identified in The Joint Commission manual
   5. The American Nurses Association standards of nursing practice
2. A nurse is sued for negligence due to failure to monitor a patient appropriately after a procedure. Which of the following statements are correct about this lawsuit? (Select all that apply.)
   1. The nurse does not need any representation.
   2. The patient must prove injury, damage, or loss occurred.
   3. The person filing the lawsuit has to show a compensable damage, such as lost wages, occurred.

4. The patient must prove that a breach in the prevailing standard of care caused an injury.
5. The burden of proof is always the responsibility of the nurse.
3. A nurse stops to help in an emergency at the scene of an accident. The injured party files a suit, and the nurse's employing institution insurance does not cover the nurse. What would probably cover the nurse in this situation?
   1. The nurse's automobile insurance
   2. The nurse's homeowner's insurance
   3. The Good Samaritan law, which grants immunity from suit if there is no gross negligence
   4. The Patient Care Partnership, which may grant immunity from suit if the injured party consents
4. A nurse is planning care for a patient going to surgery. Who is responsible for informing the patient about the surgery along with possible risks, complications, and benefits?
   1. Family member
   2. Surgeon
   3. Nurse
   4. Nurse manager
5. A woman has severe life-threatening injuries and is hemorrhaging following a car accident. The health care provider ordered 2 units of packed red blood cells to treat the woman's anemia. The woman's husband refuses to allow the nurse to give his wife the blood for religious reasons. What is the nurse's responsibility?
   1. Obtain a court order to give the blood
   2. Coerce the husband into giving the blood
   3. Call security and have the husband removed from the hospital
   4. More information is needed about the wife's preference and if the husband has her medical power of attorney
6. A nurse notes that an advance directive is on a patient's medical record. Which statement represents the best description of an advance directive guideline that the nurse will follow?
   1. A living will allows an appointed person to make health care decisions when the patient is in an incapacitated state.
   2. A living will is invoked only when the patient has a terminal condition or is in a persistent vegetative state.
   3. The patient cannot make changes in the advance directive once admitted to the hospital.
   4. A durable power of attorney for health care is invoked only when the patient has a terminal condition or is in a persistent vegetative state.
7. A nurse notes that the health care unit keeps a listing of the patient names at the front desk in easy view for health care providers to more efficiently locate the patient. The nurse talks with the nurse manager because this action is a violation of which act?
   1. Patient Protection and Affordable Care Act (PPACA)
   2. Patient Self-Determination Act (PSDA)
   3. Health Insurance Portability and Accountability Act (HIPAA)
   4. Emergency Medical Treatment and Active Labor Act
8. Which of the following actions, if performed by a registered nurse, would result in both criminal and administrative law sanctions against the nurse? (Select all that apply.)
   1. Taking or selling controlled substances
   2. Refusing to provide health care information to a patient's child
   3. Reporting suspected abuse and neglect of children
   4. Applying physical restraints without a written physician's order
   5. Completing an occurrence report on the unit
9. The nurse received a hand-off report at the change of shift in the conference room from the night shift nurse. The nursing student assigned to the nurse asks to review the medical records of the

patients assigned to them. The nurse begins assessing the assigned patients and lists the nursing care information for each patient on each individual patient's message board in the patient rooms. The nurse also lists the patients' medical diagnoses on the message board. Later in the day the nurse discusses the plan of care for a patient who is dying with the patient's family. Which of these actions describes a violation of the Health Insurance Portability and Accountability Act (HIPAA)?
   1. Discussing patient conditions in the nursing report room at the change of shift
   2. Allowing nursing students to review patient charts before caring for patients to whom they are assigned
   3. Posting medical information about the patient on a message board in the patient's room
   4. Releasing patient information regarding terminal illness to family when the patient has given permission for information to be shared

10. A patient has a fractured femur that is placed in skeletal traction with a fresh plaster cast applied. The patient experiences decreased sensation and a cold feeling in the toes of the affected leg. The nurse observes that the patient's toes have become pale and cold but forgets to document this because one of the nurse's other patients experienced cardiac arrest at the same time. Two days later the patient in skeletal traction has an elevated temperature, and he is prepared for surgery to amputate the leg below the knee. Which of the following statements regarding a breach of duty apply to this situation? (Select all that apply.)
   1. Failure to document a change in assessment data
   2. Failure to provide discharge instructions
   3. Failure to follow the six rights of medication administration
   4. Failure to use proper medical equipment ordered for patient monitoring
   5. Failure to notify a health care provider about a change in the patient's condition

11. A homeless man enters the emergency department seeking health care. The health care provider indicates that the patient needs to be transferred to the City Hospital for care. This action is most likely a violation of which of the following laws?
   1. Health Insurance Portability and Accountability Act (HIPAA)
   2. Americans with Disabilities Act (ADA)
   3. Patient Self-Determination Act (PSDA)
   4. Emergency Medical Treatment and Active Labor Act (EMTALA) without triage completed

12. You are the night shift nurse caring for a newly admitted patient who appears to be confused. The family asks to see the patient's medical record. What is the priority nursing action?
   1. Give the family the record
   2. Discuss the issues that concern the family with them
   3. Call the nursing supervisor
   4. Determine from the medical record if the family has been granted permission by the patient to access his or her medical information

13. A home health nurse notices significant bruising on a 2-year-old patient's head, arms, abdomen, and legs. The patient's mother describes the patient's frequent falls. What is the best nursing action for the home health nurse to take?
   1. Document her findings and treat the patient
   2. Instruct the mother on safe handling of a 2-year-old child
   3. Contact a child abuse hotline
   4. Discuss this story with a colleague

14. Which of the following statements indicate that the new nursing graduate understands ways to remain involved professionally? (Select all that apply.)
   1. "I am thinking about joining the health committee at my church."
